**Session A1 DCMP: Charge Order and the Pseudogap in the Underdoped Cuprates** Ballroom I - Tom Devereaux, Stanford University

**8:00AM A1.00001 Towards a complete Fermi surface in underdoped high  $T_c$  superconductors<sup>1</sup>**

NEIL HARRISON, nharrison@lanl.gov — The discovery of magnetic quantum oscillations in underdoped high  $T_c$  superconductors raised many questions, and initiated a quest to understand the origin of the Fermi surface the like of which had not been seen since the very first discovery of quantum oscillations in elemental bismuth. While studies of the Fermi surface of materials are today mostly assisted by computer codes for calculating the electronic band structure, this was not the case in the underdoped high  $T_c$  materials. The Fermi surface was shown to be reconstructed into small pockets, yet there was no hint of a viable order parameter. Crucial clues to understanding the origin of the Fermi surface were provided by the small value of the observed Fermi surface cross-section, the negative Hall coefficient and the small electronic heat capacity at high magnetic fields. We also know that the magnetic fields were likely to be too weak to destroy the pseudogap and that vortex pinning effects could be seen to persist to high magnetic fields at low temperatures. I will show that the Fermi surface that appears to fit best with the experimental observations is a small electron pocket formed by connecting the nodal 'Fermi arcs' seen in photoemission experiments, corresponding to a density-wave state with two different orthogonal ordering vectors. The existence of such order has subsequently been detected by x-ray scattering experiments, thereby strengthening the case for charge ordering being responsible for reconstructing the Fermi surface. I will discuss new efforts to understand the relationship between the charge ordering and the pseudogap state, discussing the fate of the quasiparticles in the antinodal region and the dimensionality of the Fermi surface. **8:36AM A1.00002 Three-dimensional charge density wave order in YBCO at high magnetic field**

WEI-SHENG LEE, Stanford Institute of Materials and Energy Sciences, SLAC National Accelerator Lab. and Stanford University — Charge density wave (CDW) correlations have been shown to universally exist in cuprate superconductors. However, their nature at high magnetic fields, *e.g.* inferred from nuclear magnetic resonance, Hall coefficient, and sound velocity measurements, is distinct from that measured by x-ray scattering at zero and low fields. In this talk, I will discuss our recent experiment which combines a pulsed magnet with an x-ray free electron laser to characterize the CDW in  $\text{YBa}_2\text{Cu}_3\text{O}_{6.67}$  via x-ray scattering in fields up to 28 Tesla. While the zero-field CDW order, which develops below  $\sim 150$  K, is essentially two dimensional, a three-dimensionally ordered CDW emerges at magnetic fields beyond 15 Tesla and at temperatures below the zero-field superconducting transition temperature. While the two CDW arrange differently along the c-axis, they share the same incommensurate periodicity in the  $\text{CuO}_2$  plane. Our observations imply that the two forms of CDW and high-temperature superconductivity are intimately linked.

**9:12AM A1.00003 Fractionalized Fermi liquids and the pseudogap<sup>1</sup>**

SUBIR SACHDEV, Harvard Univ — Fractionalized Fermi liquids (FL\*) are metals with Fermi surfaces of electron-like quasiparticles; however the volume enclosed by the Fermi surface is not equal to the Luttinger value determined by the density of all electrons. There are general non-perturbative arguments that any such state with a non-Luttinger volume must also have emergent gauge excitations which have vanishing energy on manifolds of non-trivial topology. In doped antiferromagnets with hole density  $p$ , the Luttinger volume of a closed Fermi surface of holes is  $1 + p$  in the state without antiferromagnetic order. Simple FL\* models of doped antiferromagnets will be described with ground states which preserve all symmetries, and have hole pockets of total volume  $p$ . Such models provide natural explanations for a number of recent observations on the pseudogap phase of the hole-doped cuprate superconductors. Confinement transitions of such FL\* phases to conventional phases will also be described.

<sup>1</sup>Supported by NSF Grant DMR-1360789

**9:48AM A1.00004 Charge order in cuprates: from hole to electron doping.**

ANDREA DAMASCELLI, University of British Columbia, Quantum Matter institute — Charge ordering has resurged as a prominent phenomenon in the physics of high- $T_c$  cuprates. In this talk I will review our recent results from  $\text{Bi2201}$  [1,2] and YBCO hole-doped cuprates [3,4], as well as electron doped NCCO [5]. With the early discovery of stripe-like order in La-based cuprates, this establishes charge ordering instabilities to be omnipresent in all cuprate families. I will discuss the connection between charge ordering and pseudogap phenomenology [2,5], similarities and asymmetries between hole and electron doping [2,5], and the native local symmetry of charge modulations [3,4].

**10:24AM A1.00005 Short ranged orders in numerical data and STM data, their mechanism and roles.**

EUN-AH KIM, Cornell Univ — With the recent experimental break through establishing the short-ranged spin and charge order as universal phenomena in under-doped cuprates, both the origin and the role of these local ordering tendencies take the center stage of cuprates research. In this talk, I will present analysis of short-ranged charge order observed in both our numerical data on multi-band spin-Fermi on model and scanning tunneling spectroscopy data. I will discuss the implications of the results in the context of the origin and the role of charge order.

**Monday, March 14, 2016 8:00AM - 11:00AM –**

**Session A2 DCMP DAMOP: Frontiers in the Theory of Non-Equilibrium Physics: From Nanosystems to Cold Atoms** Ballroom II - Marcos Rigol, Pennsylvania State University

**8:00AM A2.00001 Out-of-equilibrium phenomena and Transport in Cold Atoms<sup>1</sup>**, THIERRY GIAMARCHI, DQMP, University of Geneva — Transport of particle or charge current between two reservoirs is one of the most studied phenomenon in the context of condensed matter. Despite its apparent simplicity this phenomenon is in fact a case of an out of equilibrium situation requiring in principle new theoretical tools and concepts for its solution. One way to sweep the difficulty under the rug has been usually to tackle this problem in the linear response, where one can come back to the comfortable case of equilibrium. There are however many cases when the linear response is not enough and when a full solution of the non-equilibrium problem is needed. This is in particular the case for quantum point contacts or junctions where the full current-voltage characteristics gives direct information on the physics of the problem. In the recent years, in complement to condensed matter experimental realizations, due to the full control on the parameters of the problem and the fact that they realize isolated quantum systems cold atoms have proven a fantastic laboratory to produce out of equilibrium situations. This ranges from the case of quenches, to more recently via experiments of the ETHZ group to the case of real transport between reservoirs. This experimental activity has in turn thus stimulated strongly theoretical developments in this field. I will discuss in this talk some of the recent advances and realizations both at the experimental and of course the theoretical level. I will in particular focus on a recent study [1] which was able to realize a tunable, ballistic quantum point contact between two fermi reservoirs with a tunable interaction allowing to reach unitarity and to provide a theoretical description of the out-of equilibrium corresponding problem. In such a system the current has been shown to originate from multiple Andreev reflections which leads to a very non-linear current-chemical potential characteristics. The geometry of the contact can be changed showing a competition between superfluidity and thermally activated transport which leads to a conductance minimum and poses several theoretical questions for its theoretical description. [1] "Connecting strongly correlated superfluids by a quantum point contact", D. Husemann, S. Uchino, S. Krinner, M. Lebrat, T. Giamarchi, T. Esslinger and J.-P. Brantut, arXiv:1508.00578 (2015).

**8:36AM A2.00002 'Consistent bosonization-debosonization': A resolution of the non-equilibrium transport puzzle blazes a new path forward**, NAYANA SHAH, University of Cincinnati — In this talk, we will critically reexamine the bosonization-debosonization procedure for systems including certain types of localized features (although more general scenarios are possible). By focusing on the case of a tunneling junction out of equilibrium, I will show that the conventional approach gives results that are not consistent with the exact solution of the problem even at the qualitative level and highlight the inconsistencies that can adversely affect the results of all types of calculations. I will subsequently report on a 'Consistent bosonization-debosonization procedure that we have developed to resolve the aforementioned non-equilibrium transport puzzle and argue that this framework should be widely applicable [1]. I will touch upon its application for the two-lead Kondo problem [2] that besides being a key theoretical prototype of a strongly correlated system is also of immediate experimental relevance in many ways (see also related talk by Bolech). [1] Nayana Shah, C. J. Bolech, arXiv:1508.03078, [2] C. J. Bolech, Nayana Shah, arXiv:1508.03079

**9:12AM A2.00003 Non-equilibrium Aspects of Quantum Integrable Systems<sup>1</sup>**, NATAN ANDREI, Rutgers University — The study of non-equilibrium dynamics of interacting many body systems is currently one of the main challenges of modern condensed matter physics, driven by the spectacular progress in the ability to create experimental systems - trapped cold atomic gases are a prime example - that can be isolated from their environment and be highly controlled. Many old and new questions can be addressed: thermalization of isolated systems, nonequilibrium steady states, the interplay between non equilibrium currents and strong correlations, quantum phase transitions in time, universality among others. In this talk I will describe nonequilibrium quench dynamics in integrable quantum systems. I'll discuss the time evolution of the Lieb-Liniger system, a gas of interacting bosons moving on the continuous infinite line and interacting via a short range potential. Considering a finite number of bosons on the line we find that for any value of repulsive coupling the system asymptotes towards a strongly repulsive gas for any initial state, while for an attractive coupling, the system forms a maximal bound state that dominates at longer times. In the thermodynamic limit -with the number of bosons and the system size sent to infinity at a constant density and the long time limit taken subsequently- I'll show that the density and density-density correlation functions for strong but finite positive coupling are described by GGE for translationally invariant initial states with short range correlations. As examples I'll discuss quenches from a Mott insulator initial state or a Newton's Cradle. Then I will show that if the initial state is strongly non translational invariant, e.g. a domain wall configuration, the system does not equilibrate but evolves into a nonequilibrium steady state (NESS). A related NESS arises when the quench consists of coupling a quantum dot to two leads held at different chemical potential, leading in the long time limit to a steady state current. Time permitting I will also discuss the quench dynamics of the XXZ Heisenberg chain.

**9:48AM A2.00004 Universal behavior after a quantum quench in interacting field theories<sup>1</sup>**, ADITI MITRA, New York University — The dynamics of an isolated quantum system represented by a field theory with  $O(N)$  symmetry, and in  $d \geq 2$  spatial dimensions, is investigated after a quantum quench from a disordered initial state to the critical point. A perturbative renormalization-group approach involving an expansion around  $d=4$  is employed to study the time-evolution, and is supplemented by an exact solution of the Hartree-Fock equations in the large- $N$  limit. The results show that the dynamics is characterized by a prethermal regime controlled by elastic dephasing where excitations propagate ballistically, and a light cone emerges in correlation functions in real space. The memory of the initial state, together with the absence of time-scales at the critical point, gives rise to universal power-law aging which is characterized by a new non-equilibrium short-time exponent. The dynamics of the entanglement following a quench is also explored, and reveals that while the time evolution of the entanglement entropy itself is not much different between a free bosonic theory and an interacting bosonic theory, the low-energy entanglement spectrum on the other hand shows clear signature of the non-equilibrium short-time exponent related to aging. This work was done in collaboration with Y. Lemonik (NYU), M. Tavora (NYU), A. Chiocchetta (SISSA), A. Maraga (SISSA), and A. Gambassi (SISSA).

**10:24AM A2.00005 Exploring the nonequilibrium dynamics of ultracold quantum gases by using numerical tools<sup>1</sup>**, FABIAN HEIDRICH-MEISNER, LMU Munich, Germany — Numerical tools such as exact diagonalization or the density matrix renormalization group method have been vital for the study of the nonequilibrium dynamics of strongly correlated many-body systems. Moreover, they provided unique insight for the interpretation of quantum gas experiments, whenever a direct comparison with theory is possible. By considering the example of the experiment by Ronzheimer et al. [1], in which both an interaction quench and the release of bosons from a trap into an empty optical lattice (sudden expansion) was realized, I discuss several nonequilibrium effects of strongly interacting quantum gases. These include the thermalization of a closed quantum system and its connection to the eigenstate thermalization hypothesis [2], nonequilibrium mass transport [1], dynamical fermionization [3], and transient phenomena such as quantum distillation or dynamical quasicondensation [4]. I highlight the role of integrability in giving rise to ballistic transport in strongly interacting 1D systems [1] and in determining the asymptotic state after a quantum quench [5]. The talk concludes with a perspective on open questions concerning 2D systems and the numerical simulation of their nonequilibrium dynamics [6].

Session A3 DCMP GMAG: Recent Progress on 'Order by Disorder' Phenomena Ballroom III - Israel Klich, University of Virginia

### 8:00AM A3.00001 Order From disorder in Frustrated Spin Systems<sup>1</sup>

PIERS COLEMAN, Rutgers Univ — This talk will review the phenomenon of "Order from disorder": the mechanism by which fluctuations remove a degeneracy within a frustrated spin system. An important consequence of order-from-disorder, is the ability of frustrated Heisenberg spin systems to overcome the Mermin-Wagner theorem, developing new forms of discrete order, even when the spins themselves remain disordered with a finite correlation length. The most well-known example, is the two-dimensional frustrated  $J_1 - J_2$  Heisenberg model, which undergoes a finite temperature Ising phase transition into a stripy or "nematic" state, even though the spins do not order until absolute zero[1,2]. Nematic ordering of this kind is believed to occur in the iron-based superconductors, such as  $BaFe_2As_2$ . More recently, it has been possible to theoretically study the triangular-honeycomb versions of the  $J_1 - J_2$  model, called a windmill model[3-4], in which order-from disorder drives the development of six-state clock order. Remarkably, in this case, order-from-disorder leads to an intermediate power-law spin phase, despite the underlying Heisenberg spins.

### 8:36AM A3.00002 Love triangles, quantum fluctuations and spin jam

SEUNG-HUN LEE, University of Virginia — When magnetic moments are interacting with each other in a situation resembling that of complex love triangles, called frustration, a large set of states that are energetically equivalent emerge. This leads to exotic spin states such as spin liquid and spin ice. Recently, we presented evidence for the existence of a topological glassy state, that we call spin jam, induced by quantum fluctuations.[1,2] The case in point is  $SrCr_9pGa_{12-9p}O_{19}$  (SCGO(p)), a highly frustrated magnet, in which the magnetic Cr ions form a quasi-two-dimensional triangular system of bi-pyramids. This system has been an archetype in search for exotic spin states. Understanding the nature of the state has been a great intellectual challenge. Our new experimental data and theoretical spin jam model provide for the first time a coherent understanding of the phenomenon. Furthermore, the findings strongly support the possible existence of purely topological glassy states. Reference: [1] *Spin jam induced by quantum fluctuations in a frustrated magnet*, J. Yang et al., Proc. Natl. Acad. Sci. of U.S.A. Vol. 127, 11519-11523 (2015). [2] *Glassiness and exotic entropy scaling induced by quantum fluctuations in a disorder-free frustrated magnet*, I. Klich, S.-H. Lee, K. Iida, Nature Communications 5, 3497 (2014).

### 9:12AM A3.00003 The many faces of order-by-disorder in rare-earth pyrochlore magnets

MICHEL J P GINGRAS, University of Waterloo — Order-by-disorder (ObD) is a concept of central importance in the field of frustrated magnetism. Saddled with large accidental degeneracies, a subset of states, those that support the largest quantum and/or thermal fluctuations, may be selected to form true long-range order. More formally, one often begins describing a system in terms of some order parameter  $m$  with the low-energy description framed in terms of an effective action  $\Gamma_0(m)$ . In each ObD scenario, one starts from an artificial limit where there is an accidental degeneracy; that is the effective action at this point,  $\Gamma_0(m)$ , has an accidental symmetry. One may then view ObD phenomena as cases where the corrections to  $\Gamma_0(m)$  arise through some form of fluctuation corrections, may they be thermal, quantum or virtual, towards an enlarged higher energy Hilbert space. In the rare-earth pyrochlore oxides, of formula  $R_2M_2O_7$ , the trivalent magnetic rare-earth ions  $R^{3+}$  (e.g  $R = Gd, Er, Yb$ ;  $M = Ti, Sn$  is non-magnetic) reside on a three-dimensional pyrochlore lattice of corner-sharing tetrahedra. This architecture is prone to a high degree of magnetic frustration, with the  $R_2M_2O_7$  pyrochlore materials having been found over the past twenty years to display a gamut of exotic phenomena. In this talk, I will discuss three such phenomena: (i) the intermediate partially-ordered multiple- $k$  state between 0.7K and 1K in the  $Gd_2Ti_2O_7$  Heisenberg antiferromagnet <sup>1</sup>, (ii) the ordered  $\psi_2$  state selection in the  $XY$   $Er_2Ti_2O_7$  antiferromagnet <sup>2</sup> and (iii) the puzzling high sample sensitivity of the  $Yb_2Ti_2O_7$  "quantum spin ice" candidate <sup>3</sup>. I will argue that in all three cases, some form of fluctuation corrections to their simplest  $\Gamma_0(m)$  description play a significant role in the state selection and experimentally observed behaviors.

<sup>2</sup> arXiv:1510.04292

<sup>3</sup> arXiv:1505.05499

### 9:48AM A3.00004 Order by Disorder in the XY Pyrochlore Antiferromagnet $\text{Er}_2\text{Ti}_2\text{O}_7$ <sup>1</sup>, BRUCE D.

GAULIN, McMaster University — Crystal field effects associated with  $\text{Er}^{3+}$  magnetic moments in  $\text{Er}_2\text{Ti}_2\text{O}_7$  give rise to local XY anisotropy and effective quantum  $S=1/2$  spins which are antiferromagnetically coupled on this materials cubic pyrochlore lattice [1].  $\text{Er}_2\text{Ti}_2\text{O}_7$  orders into a non-collinear antiferromagnetic  $\Psi_2$  state below  $\sim 1.2$  K, in zero magnetic field, but the mechanism for its ground state selection has been a puzzle for more than a decade. We have carried out inelastic neutron scattering measurements on single crystal samples of  $\text{Er}_2\text{Ti}_2\text{O}_7$  at low temperatures and in the presence of a strong [110] magnetic field, allowing us to determine the underlying spin Hamiltonian for this quantum antiferromagnet [2, 3]. These results point to ground state selection via an order-by-quantum-disorder mechanism [3], and a concomitant order-by-disorder gap of  $\sim 0.05$  meV has also been observed [4], associated with the pseudo-Goldstone modes in the low field ordered state. In addition, we have explored the sensitivity of the ground state selection to magnetic dilution by preparing and studying single crystals of  $\text{Er}_{2-x}\text{Y}_x\text{Ti}_2\text{O}_7$  [5]. These studies are particularly topical in light of two theoretical predictions [6,7] that the  $\Psi_2$  ordered state may be unstable to formation of the related  $\Psi_3$  phase at low temperatures, in the presence of quenched disorder. ### 10:24AM A3.00005 Quantum order-by-disorder and excitations in anisotropic kagome-lattice antiferromagnets<sup>1</sup>, ALEXANDER CHERNYSHEV, University of California, Irvine — Our recent works have advanced theoretical understanding of

the quantum effects in kagome-lattice antiferromagnets and have provided insights into the quantum order-by-disorder mechanism, important for a broad class of frustrated spin systems. In particular, we have challenged a general expectation that the quantum and thermal order-by-disorder mechanisms always select the same ground state. We have shown that the non-linear terms in the quantum hamiltonian of the anisotropic kagome-lattice antiferromagnets can yield a rare example of the ground state that is different from the one favored by thermal fluctuations. We have also demonstrated that the order selection is generated by topologically non-trivial tunneling processes, yielding a new energy scale in the system.

Related to the ground-state selection mechanism are the non-linear effects in the spectra of the kagome-lattice systems. Further progress has been made in understanding spectral properties of realistic kagome-lattice antiferromagnets such as Fe-jarosite, for which we have demonstrated a remarkable wipe-out effect for a significant portion of the spectrum. This phenomenon is related to an existence of the so-called "flat mode," a ubiquitous feature of the kagome-lattice and other highly-frustrated antiferromagnets, and is due to a resonant-like decay processes involving two of such modes.

### Session A4 DPOLY GSOFIT GSNP: Polymer Dynamics: An Honor Session for Sir Sam Edwards

Ballroom IV - Gary Grest, Sandia National Laboratories

### 8:00AM A4.00001 : Polymer Dynamics from Edwards to Today , MASAO DOI, Nagoya University —

### 8:36AM A4.00002 Polymer dynamics, the Edwards tube model and neutron scattering. , JULIA

HIGGINS, Department of Chemical Engineering, Imperial College, London — Sam Edwards' papers with Masao Doi describing polymer dynamics and rheology based on the tube model were published just as high resolution quasi-elastic neutron scattering experiments achieved the resolution capable of observing directly some of the effects of the tube. The talk will summarize these experiments as well as later work on polymer inter-diffusion across interfaces observed by neutron reflection, where again the tube model is used to interpret the data.

### 9:12AM A4.00003 Recent advances with generalized entropy theory of glass-formation in polymers<sup>1</sup>, KARL FREED, University of Chicago — The generalized entropy theory (GET) of glass-formation in polymers is a combination of the

lattice cluster theory (LCT) for the configurational entropy density with the Adam-Gibbs (AG) theory for the structural relaxation time. A greatly simplified form of the GET (whose expression for the free energy is roughly double that of Flory-Huggins theory) accurately reproduces the four characteristic temperatures of glass-formation (the onset, crossover, glass transition, and Kauzmann temperatures) of the full GET to within 4K for a series of models of polymers composed of semi-flexible chains having the structure of poly(n-alpha olefins). The theory is now simple enough to be used in courses in polymer physics. Although the successes of the GET provide a strong validation of the final form of the AG theory provided the configurational entropy is used, the physical basis of the AG theory has remained an enigma. Hence, we have developed a new, more general, statistical mechanical derivation of AG theory that explains the previously perplexing observations that the string-like elementary excitations have the mass and temperature dependence of systems undergoing equilibrium self-assembly.

### 9:48AM A4.00004 The Ordinary-Extraordinary Transition in Dynamics of Solutions of Charged Macromolecules , MURUGAPPAN MUTHUKUMAR, University of Massachusetts — Dynamic light scattering measurements on

dilute salt-free polyelectrolyte solutions have shown over the past three decades that there are two distinctive diffusive modes: fast and slow. The diffusion coefficient deduced from the fast mode has been found to be essentially independent of molar mass and polymer concentration and it is merely a factor of four smaller than that of small electrolyte ion such as sodium or potassium ion. The diffusion coefficient deduced from the slow mode is much smaller suggestive of clumps of many chains although these chains are similarly charged. Upon addition of sufficient amount of small molecular salts, the fast and slow modes merge together and the deduced diffusion coefficient is within the expected value for uncharged polymers. We will present a theory for these observed behaviors based on the coupling between the polyelectrolyte chains and their counterions.

**10:24AM A4.00005 Nanotribology of charged polymer brushes<sup>1</sup>**, JACOB KLEIN, Weizmann Institute of Science — Polymers at surfaces, whose modern understanding may be traced back to early work by Sam Edwards<sup>1</sup>, have become a paradigm for modification of surface properties, both as steric stabilizers and as remarkable boundary lubricants<sup>2</sup>. Charged polymer brushes are of particular interest, with both technological implications and especially biological relevance where most macromolecules are charged. In the context of biolubrication, relevant in areas from dry eye syndrome to osteoarthritis, charged polymer surface phases and their complexes with other macromolecules may play a central role. The hydration lubrication paradigm, where tenaciously-held yet fluid hydration shells surrounding ions or zwitterions serve as highly-efficient friction-reducing elements, has been invoked to understand the excellent lubrication provided both by ionized<sup>3</sup> and by zwitterionic<sup>4</sup> brushes. In this talk we describe recent advances in our understanding of the nanotribology of such charged brush systems. We consider interactions between charged end-grafted polymers, and how one may disentangle the steric from the electrostatic surface forces<sup>5</sup>. We examine the limits of lubrication by ionized brushes, both synthetic and of biological origins, and how highly-hydrated zwitterionic chains may provide extremely effective boundary lubrication<sup>6</sup>. Finally we describe how the lubrication of articular cartilage in the major joints, a tribosystem presenting some of the greatest challenges and opportunities, may be understood in terms of a supramolecular synergy between charged surface-attached polymers and zwitterionic groups<sup>7</sup>. 1. **Monday, March 14, 2016 8:00AM - 11:00AM —**  
**Session A5 GMAG DCMP FIAP: Magnetic Resonance and Spin-Dependent Optical Phenomena in Semiconductors** 301 - Masashi Shiraishi, U. Kyoto

**8:00AM A5.00001 Optimizing Frequency-Modulated CW EDMR in silicon**, LIHUANG ZHU, KIPP VAN SCHOOTEN, CHANDRASEKHAR RAMANATHAN, Dartmouth College — Electrically detected magnetic resonance (EDMR) is a powerful method of probing dopant and defect spin states in semiconductor devices. Moreover, at the single dopant level, these spin states are heavily investigated as potential qubit systems, though facile electronic access to single dopants is exceedingly difficult. We therefore characterize detection sensitivities of frequency-modulated CW-EDMR of phosphorus donors in silicon Si:P using a home-built 2.5 GHz system (~80 mT) at 5 K. An arbitrary waveform generator controls the frequency modulation, allowing us to optimize the signal to noise ratio (SNR) of both the dangling bond and phosphorus donor signals against multiple experimental parameters, such as modulation amplitude and modulation frequency. The optimal range of frequency modulation parameters is constrained by the relaxation time of the phosphorous electron at 5 K, resulting in the same sensitivity limit as field modulated CW-EDMR, but offers some technical advantages; e.g. reducing the relative contribution of magnetic field induced currents and eliminating the need for field modulation coils. We further characterize the EDMR SNR in Si:P as a function of optical excitation energy by using a narrow line laser, tunable across donor exciton and band gap states.

**8:12AM A5.00002 Electron Spin Resonance in a 2D Fermi Liquid with Spin-Orbit Coupling**, SAURABH MAITI, MUHAMMAD IMRAN, DMITRII MASLOV, University of Florida — Electron spin resonance (ESR) is usually interpreted as a single-particle phenomenon protected from the effect of many-body correlations. We show that this is not the case in a two-dimensional Fermi liquid (FL) with spin-orbit coupling (SOC). Depending on whether the magnetic field is below or above some critical value, ESR in such a system probes up to three collective chiral-spin modes, augmented by the presence of the field, or the Larmor mode, augmented both by SOC and FL renormalizations. We argue that ESR can be used as a probe not only for SOC but also for many-body physics.

**8:24AM A5.00003 Electric dipolar spin resonance in systems with a valley dependent  $g$ -factor**, MARKO RANCIC, GUIDO BURKARD, Department of Physics, University of Konstanz, D-78457 Konstanz, Germany — We theoretically investigate the electric dipole spin resonance (EDSR) in a single Si/SiGe quantum dot in the presence of a magnetic field gradient, e.g., produced by a micromagnet. The control of electron spin states can be achieved by applying an oscillatory electric field, which induces periodic oscillations in real space of the electron spin inside the quantum dot. This motion inside a magnetic field gradient produces an effective periodic in-plane magnetic field, and allows for driven spin rotations near resonance. The magnetic field gradient induces a valley dependent  $g$ -factor and a valley dependent Rabi frequency. Our first goal is to quantitatively and qualitatively describe valley dependent  $g$ -factors and a valley dependent Rabi frequencies using a microscopic model. A valley dependent  $g$ -factor combined with inter-valley scattering gives rise to a novel electron spin decoherence mechanism. The second goal of our study is to describe the drop of coherence in the presence of inter-valley scattering, and furthermore, to discuss the interplay between valley and spin relaxation. All relevant decoherence mechanisms are quantitatively evaluated by solving a Lindblad master equation.

**8:36AM A5.00004 Electrically and optically detected spin echo of hopping carriers in organic semiconductors<sup>1</sup>**, VAGHARSH MKHITARYAN, VIATCHESLAV DOBROVITSKI, Ames Laboratory, Iowa State University, Ames, Iowa 50011 — We develop a theory for electrically and optically detected primary (2-pulse) and stimulated (3-pulse) spin echo produced by the polaron pairs coupled to the nuclear spins in organic semiconductors. The theory employs fully quantum description of the nuclear and polaron spins, and explains how the structure of the echo signal (electron spin echo envelope modulation, ESEEM) depends on the statistics and rate of the polaron hopping. For the primary spin echo the envelope modulation is strong for slow hopping; both modulation amplitude and dephasing time  $T_2$  decrease with increasing hopping rate. As the hopping rate increases further,  $T_2$  starts to increase again due to motional narrowing, while the primary echo signal becomes exponential without modulation. The stimulated spin echo signal also shows strong envelope modulation for slow polaron hopping. For faster hopping the stimulated echo (unlike the primary echo) shows a modulation which does not disappear for fast hopping, and has the frequency of the nuclear Larmor precession. Besides describing the recent spin echo measurements in  $\pi$ -conjugated polymers [1], our work provides a way to directly determine the polaron hopping dynamics from the spin echo experiments. [1] H. Malissa et al, *Science* 345, 1487 (2014).

**8:48AM A5.00005 Tuning magnetic exchange interactions in crystalline thin films of substituted Cobalt Phthalocyanine<sup>1</sup>**, NAVEEN RAWAT, LANE MANNING, KIM-NGAN HUA, RANDALL HEADRICK, Univ of Vermont, MICHAEL BISHOP, STEPHEN MCGILL, National High Magnetic Field Lab, florida, RORY WATERMAN, MADALINA FURIS, Univ of Vermont — Magnetic exchange interactions in diluted organometallic crystalline thin film alloys of Phthalocyanines (Pcs) made of a organo-soluble derivatives of Cobalt Pc and metal-free (H<sub>2</sub>Pc) molecule and is investigated. To this end, we synthesized a organosoluble CoPc and successfully employed a novel solution-based pen-writing deposition technique to fabricate long range ordered thin films of mixtures of different ratios ranging from 1:1 to 10:1 H<sub>2</sub>Pc:CoPc. Our previous magnetic circular dichroism (MCD) results on the parent CoPc crystalline thin films identified different electronic states mediating exchange interactions and indirect exchange interaction competing with superexchange interaction. This understanding of spin-dependent exchange interaction between delocalized  $\pi$ -electrons with unpaired d spins along with the excitonic delocalization character enabled the further tuning of these interactions by essentially varying the spatial distance between the spins. Furthermore, high magnetic field ( $B < 25$  T) MCD and magneto-photoluminescence show evidence of spin-polarized band-edge excitons in the same materials.

**9:00AM A5.00006 Measurement of hyperfine fields and the  $\Delta g$ -effect in  $\pi$ -conjugated polymer-based OLEDs using multi-frequency electrically detected magnetic resonance**, GAJADHAR JOSHI, HANS MALISSA, RICHARD MILLER, LILLIE OGDEN, DOUGLAS BAIRD, SHIRIN JAMALI, MARZIEH KAVAND, KAPIL AMBAL, Univ of Utah, JOHAN VAN TOL, NHMFL FSU, JOHN LUPTON, Universitaet Regensburg, CHRISTOPH BOEHME, Univ of Utah — Magneto-opto-electronic properties of organic semiconductors, such as organic magnetoresistance or magneto-electroluminescence, are strongly influenced by the interplay of proton induced hyperfine fields to which charge carrier spins are coupled [Nguyen et al., Nat. Mater. 9, 345-352 (2010), Mcamey et al. Phys. Rev. Lett. 104, 017601 (2010)]. In addition, the weak but non-negligible and highly inhomogeneously distributed spin-orbit effects caused by the material's structural disorder can affect spin-dependent processes. In order to quantitatively access and discriminate between these mechanisms, we investigate the inhomogeneous broadening of polaron spin-resonances using electrically detected magnetic resonance (EDMR) spectroscopy at various magnetic fields between 3mT and 12T. While random local hyperfine fields cause an external magnetic field-independent line broadening, spin-orbit contributions give rise to a distribution of the charge carrier g-factors. This  $\Delta g$  effect leads to a resonance line-width contribution that is proportional to the external magnetic field. We observe an EDMR line that is largely field-independent in the low-magnetic field, but shows substantial broadening of line shape at higher fields.

**9:12AM A5.00007 Magnetoresistance detected spin collectivity in organic light emitting diodes**, HANS MALISSA, DAVID P WATERS, GAJADHAR JOSHI, MARZIEH KAVAND, MARK E LINES, Department of Physics and Astronomy, University of Utah, PAUL L BURN, Centre for Organic Photonics & Electronics, School of Chemistry & Molecular Biosciences, The University of Queensland, JOHN M LUPTON, Department of Physics and Astronomy, University of Utah and Institut fuer Experimentelle und Angewandte Physik, Universitaet Regensburg, CHRISTOPH BOEHME, Department of Physics and Astronomy, University of Utah — Organic magnetoresistance (OMAR) typically refers to the significant change in the conductivity of thin layers of organic semiconductors at low static magnetic fields ( $< 10$  mT). When radio frequency (rf) radiation is applied to an organic semiconductor under bipolar injection, and in the presence of small magnetic fields  $B$ , magnetic resonance can occur, which is observed as a change of the OMAR effect [Baker et al., Nat. Commun. 3, 898 (2012)]. When  $B$  and the resonant driving field are stronger than local hyperfine fields, an ultrastrong coupling regime emerges, which is marked by collective spin effects analogous to the optical Dicke effect [Roundy and Raikh, Phys. Rev. B 88, 125206 (2013)]. Experimentally, this collective behavior of spins can be probed in the steady state OMAR of organic light-emitting diodes (OLEDs) at room temperature by observation of a sign reversal of the OMAR change under rf irradiation. Furthermore, in the presence of strong driving fields, an ac Zeeman effect can be observed through OMAR [Waters et al., Nat. Phys. 11, 910 (2015)], a unique window to observe room temperature macroscopic spin quantum coherence.

**9:24AM A5.00008 Microwave frequency modulation for improving polarization transfer in DNP experiments<sup>1</sup>**, MALLORY GUY, CHANDRASEKHAR RAMANATHAN, Department of Physics and Astronomy, Dartmouth College — Dynamic nuclear polarization (DNP) is a driven process that transfers the inherently high electron polarization to surrounding nuclear spins via microwave irradiation at or near the electron Larmor frequency. In a typical DNP experiment, the amplitude and frequency of the applied microwaves are constant. However, by adding time dependence in the form of frequency modulation, the electron excitation bandwidth is increased, thereby increasing the number of electron spins active in the polarization transfer process and improving overall efficiency. Both triangular and sinusoidal modulation show a 3 fold improvement over monochromatic irradiation. In the present study, we compare the nuclear spin polarization after DNP experiments with no modulation of the applied microwaves, triangular and sinusoidal modulation, and modulation schemes derived from the sample's ESR spectrum. We characterize the polarization as a function of the modulation amplitude and frequency and compare the optimal results from each modulation scheme. Working at a field of 3.34 T and at a temperature of 4 K, we show that by using a modulation scheme tailored to the electronic environment of the sample, polarization transfer is improved over other modulation schemes. Small-scale simulations of the spin system are developed to gain further insight into the dynamics of this driven open system. This understanding could enable the design of modulation schemes to achieve even higher polarization transfer efficiencies.

**9:36AM A5.00009 Resonant and Time-Resolved Spin Noise Spectroscopy**, XINLIN SONG, BRENNAN PURSLEY, VANESSA SIH, University of Michigan — Spin noise spectroscopy is a technique which can probe the system while it remains in equilibrium. It was first demonstrated in atomic gases and then in solid state systems. Most existing spin noise measurement setups digitize the spin fluctuation signal and then analyze the power spectrum. Recently, pulsed lasers have been used to expand the bandwidth of accessible dynamics and allow direct time-domain correlation measurements. Here we develop and test a model for ultrafast pulsed laser spin noise measurements as well as a scheme to measure spin lifetimes longer than the laser repetition period. For the resonant spin noise technique, analog electronics are used to capture correlations from the extended pulse train, and the signal at a fixed time delay is measured as a function of applied magnetic field. [1]

**9:48AM A5.00010 Modification of electron spin properties in a GaAs epilayer by an in-plane electric field<sup>1</sup>**, MICHAEL MACMAHON, VANESSA SIH, Department of Physics, University of Michigan, Ann Arbor, MI 48109 — The interaction of electron spins with accelerating electric fields in bulk gallium arsenide results in many effects that are relevant to proposed spin-based devices. For example, in-plane electric fields have been shown to change the g-factor<sup>2</sup>, generate spin polarization<sup>3</sup>, and decrease the spin lifetime<sup>4</sup>. Most such studies have used only very low electric fields, typically less than 100 V/cm. We investigate the dependence of spin lifetime on electric field at high electric fields and separate the contribution due to heating.

**10:00AM A5.00011 3T and nonlocal 4T Hanle measurements of spin accumulation in the persistent photoconductor  $\text{Al}_{0.3}\text{Ga}_{0.7}\text{As:Si}^1$** , JOON-IL KIM, K. KOUNTOURIOTIS, T. LIU, S. VON MOLNAR, P. XIONG, Florida State University, J. LU, X.Z. YU, J.H. ZHAO, Institute of Semiconductors, Chinese Academy of Sciences — 3-terminal (3T) and nonlocal 4-terminal (4T) Hanle measurements have been performed on a spin injection/detection device with patterned Fe electrodes and  $\text{Al}_{0.3}\text{Ga}_{0.7}\text{As:Si}$ , a persistent photoconductor, as the channel. The persistent photoconductivity facilitates *in situ* incremental photo-doping of the AlGaAs channel, which enables direct comparisons of the 3T and 4T Hanle results on the same device over a broad range of carrier densities across the insulator-metal transition. Although their magnitudes differ by about an order of magnitude, the 3T and 4T Hanle signals exhibit broad similarities in their dependencies on the injection current and carrier density, as well as the resulting spin lifetimes. Specifically, at each bias current, the magnitudes of both the 3T and 4T Hanle signals are observed to decrease exponentially with increasing carrier density of the AlGaAs deep into the metallic state. The spin lifetimes extracted from the 3T and 4T Hanle curves, both via the FWHM of the Lorentzian fit and the 1D spin drift-diffusion model analysis, show similar values and evolution with the carrier density.

**10:12AM A5.00012 Wurtzite Spin-Lasers**, GAOFENG XU, SUNY Buffalo, PAULO E. FARIA JUNIOR, GUILHERME M. SIPAHI, University of Sao Paulo, Brazil, IGOR ZUTIC, SUNY Buffalo — Lasers in which spin-polarized carriers are injected provide paths to different practical room temperature spintronic devices, not limited to magnetoresistive effects [1]. While theoretical studies of such spin-lasers have focused on zinc-blende semiconductors as their active regions, the first electrically injected carriers at room temperature were recently demonstrated in GaN-based wurtzite semiconductors [2], recognized also for the key role as highly-efficient light emitting diodes [3]. By focusing on a wurtzite quantum well-based spin-laser, we use accurate electronic structure calculations to develop a microscopic description for its lasing properties. We discuss important differences between wurtzite and zinc-blende spin-lasers. [1] P. E. Faria Junior, G. Xu, J. Lee, N. C. Gerhardt, G. M. Sipahi, and I. Zutic, Phys. Rev. B 92, 075311 (2015). Phys. 87, 1139 (2015).

**10:24AM A5.00013 Manipulation of spin transfer torque using light<sup>1</sup>**, MASSIMO RONTANI, KARSTEN VENDELBJERG, CNR-NANO Research Center S3, Modena, Italy, LU SHAM, Dept of Physics, University of California San Diego — We show that the spin transfer torque induced by a spin-polarized current on a nanomagnet as the current flows through a semiconductor-nanomagnet-semiconductor junction is externally controlled by shining the junction off-resonantly with a strong laser beam. The excitonic coherence driven by the laser dresses the virtual electron-hole pairs coupling conduction and valence bands and inducing an evanescent state in the proximity of the nanomagnet. The Fano-like quantum interference between this localized state and the continuum spectrum is different in the two spin channels and hence it dramatically alters the spin transport, leading to the coherent control of the spin transfer torque.

**10:36AM A5.00014 Microscopic description of a spin laser<sup>1</sup>**, PAULO E. FARIA JUNIOR, University of Sao Paulo, GAOFENG XU, SUNY Buffalo, JEONGSU LEE, University of Regensburg, NILS C. GERHARDT, Ruhr-University Bochum, GUILHERME M. SIPAHI, University of Sao Paulo / SUNY Buffalo, IGOR ZUTIC, SUNY Buffalo — Spin lasers provide interesting possibilities for spintronic applications at room temperature[1]. They have the same elements of a conventional laser, but the injected carriers are spin polarized which allows the output light polarization to have either positive or negative helicity. These devices are commonly implemented as VCSELs, which have the advantage of tuning the photon energy by the cavity design. We investigate a spin VCSEL with a AlGaAs/GaAs quantum well active region using band structure calculations and spin-dependent optical gain. In addition to the desirable properties for steady-state operation and cavity designs, we also show that by applying a uniaxial strain, large values of birefringence  $> 200$  GHz can be achieved[2]. Combined with spin injected carriers, the birefringence in the device allows polarization dynamics much faster than photon intensity dynamics[3]. Our theoretical prediction for high-frequency birefringence was experimentally demonstrated in similar spin VCSELs[4]. [1] I. Zutic and P. E. Faria Junior, Nat. Nanotech. 9, 750 (2014). [2] P. E. **10:48AM A5.00015 Modulating Spin Relaxation with Light and a Novel Spintronic Room Temperature Infrared Photodetector<sup>1</sup>**, MD IFTEKHAR HOSSAIN, Dept of ECE,VCU, Richmond, VA,23284, SAUMIL BANDYOPADHYAY, EECE Dept., MIT, Cambridge, MA 02139, JAYASIMHA ATULASIMHA, Dept of MNE,VCU, Richmond, VA,23228, SUPRIYO BANDYOPADHYAY, Dept of ECE,VCU, Richmond, VA,23284 — We report modulating the spin relaxation rate in an InSb nanowire with infrared (IR) light. The nanowire is fashioned into a spin valve with cobalt and nickel contacts using electrochemical self-assembly. The spin relaxation length is long in the dark since ~96% of the electrons occupy the lowest conduction subband at room temperature, which results in near elimination of the D'yakonov-Perel' (DP) spin relaxation. Under IR illumination, electrons are excited to higher subbands by IR photons, resulting in the revival of the DP relaxation and a threefold shortening of the spin relaxation length [1]. This changes the resistance of the spin valve and therefore has applications in a novel spintronic IR photodetector that can ideally work at room temperature with infinite light-to-dark contrast ratio, infinite detectivity and zero dark current if all other spin relaxation mechanisms are eliminated and spins can be injected into the nanowire and detected with 100% efficiency. This work is supported by the NSF under grant CMMI-1301013. [1] M. I. Hossain, et al., Nanotechnology, 26, 281001(2015)

### 8:00AM A6.00001 Magnetic ordering in lanthanide-molybdenum oxide nanostructure arrays ,

JOSEPH HAGMANN, SON LE, National Institute of Standards and Technology, LYNN SCHNEEMEYER, PATTI OLSEN, Montclair State University, TIGLET BESARA, THEO SIEGRIST, Florida State University, DAVID SEILER, CURT RICHTER, National Institute of Standards and Technology — Reduced ternary molybdenum oxides, or bronzes, offer an attractive materials platform to study a wide variety of remarkable physical phenomena in a system with highly varied structural chemistry. Interesting electronic behaviors, such as superconductivity, charge density waves, and magnetism, in these materials arise from the strong hybridization of the 4d states of high-valent Mo with O p orbitals. We investigate a series of molybdenum bronze materials with Lanthanide-Mo<sub>16</sub>O<sub>44</sub> composition that can be described as a three-dimensional array of metallic Mo<sub>8</sub>O<sub>32</sub> nanostructures computationally predicted to contain a single charge with spin separated by insulating MoO<sub>4</sub> tetrahedra. This study reveals novel magnetic ordering in Lanthanide-Mo<sub>16</sub>O<sub>44</sub> systems arising, not from the inclusion of magnetic elements, but rather from an exchange interaction between cubic Mo<sub>8</sub>O<sub>32</sub> units. Here, we report the magnetometry and transport behaviors of a series of Lanthanide-Mo<sub>16</sub>O<sub>44</sub> materials, emphasizing an observed low-temperature phase transition signifying the onset of antiferromagnetic ordering between the arrayed nanostructures, and relate these behaviors to their experimentally-characterized structures to reveal the intriguing physics of these correlated electronic systems.

### 8:12AM A6.00002 Thermogravimetric and Magnetic Studies of the Oxidation and Reduction

Reaction of SmCoO<sub>3</sub> to Nanostructured Sm<sub>2</sub>O<sub>3</sub> and Co , BRIAN KELLY, Department of Physics and Astronomy, University of Delaware, RONALD CICHOCKI, Department of Chemistry and Biochemistry, University of Delaware, GERALD POIRIER, Advanced Materials Characterization Laboratory, University of Delaware, KARL UNRUH, Department of Physics and Astronomy, University of Delaware — The SmCoO<sub>3</sub> to nanostructured Sm<sub>2</sub>O<sub>3</sub> and Co oxidation and reduction reaction has been studied by thermogravimetric analysis (TGA) measurements in forming gas (FG) and inert N<sub>2</sub> atmospheres, x-ray diffraction (XRD) and vibrating sample magnetometry (VSM). The TGA measurements showed two clearly resolvable reduction processes when heating in FG, from the initial SmCoO<sub>3</sub> phase through an intermediate nanostructured mixture of Sm<sub>2</sub>O<sub>3</sub> and CoO when heated to 330C for several minutes, and then the conversion of CoO to metallic Co when heated above 500C. These phases were confirmed by XRD and VSM. Similar measurements in N<sub>2</sub> yielded little mass change below 900C and coupled reduction processes at higher temperatures. Isoconversional measurements of the CoO to Co reduction reaction in FG yielded activation energies above 2eV/atom in the nanostructured system. This value is several times larger than those reported in the literature or obtained by similar measurements of bulk mixtures of Sm<sub>2</sub>O<sub>3</sub> and CoO, suggesting the nanostructuring was the source of the large increase in activation energy.

### 8:24AM A6.00003 Roles of Surface and Interface Spins in Exchange Coupled Nanostructures<sup>1</sup>

, MANH-HUONG PHAN, Department of Physics, University of South Florida, Tampa, FL 33620, USA — Exchange bias (EB) in magnetic nanostructures has remained a topic of global interest because of its potential use in spin valves, MRAM circuits, magnetic tunnel junctions, and spintronic devices. The exploration of EB on the nanoscale provides a novel approach to overcoming the superparamagnetic limit and increasing the thermoremanence of magnetic nanoparticles, a critical bottleneck for magnetic data storage applications. Recent advances in chemical synthesis have given us a unique opportunity to explore the EB in a variety of nanoparticle systems ranging from core/shell nanoparticles of Fe/ $\gamma$ -Fe<sub>2</sub>O<sub>3</sub>, Co/CoO, and FeO/Fe<sub>3</sub>O<sub>4</sub> to hollow nanoparticles of  $\gamma$ -Fe<sub>2</sub>O<sub>3</sub> and hybrid composite nanoparticles of Au/Fe<sub>3</sub>O<sub>4</sub>. Our studies have addressed the following fundamental and important questions: (i) Can one decouple collective contributions of the interface and surface spins to the EB in a core/shell nanoparticle system? (ii) Can the dynamic and static response of the core and shell be identified separately? (iii) Can one tune “minor loop” to “exchange bias” effects in magnetic hollow nanoparticles by varying the number of surface spins? (iv) Can one decouple collective contributions of the inner and outer surface spins to the EB in a hollow nanoparticle system? (v) Can EB be induced in a magnetic nanoparticle by forming its interface with a non-magnetic metal? Such knowledge is essential to tailor EB in magnetic nanostructures for spintronics applications. In this talk, we will discuss the aforementioned findings in terms of our experimental and atomistic Monte Carlo studies.

### 9:00AM A6.00004 Synthesis and magnetic properties of highly crystalline Fe<sub>3</sub>O<sub>4</sub> nanorods , R

DAS, K STOJAK REPA, V KALAPPATTIL, Univ. of South Florida, J ALONSO, Univ. of South Florida, BCMaterials, MH PHAN, H SRIKANTH, Univ. of South Florida — Anisotropic one-dimensional magnetic nanostructures have drawn considerable attention due to their high surface to volume ratio, which drastically influences physical and chemical properties. In the past decade, most attention has been paid to the synthesis of Fe<sub>3</sub>O<sub>4</sub> nanoparticles (NPs), mainly focusing on a spherical morphology. In this work, we report the first systematic study of the magnetic properties of highly crystalline Fe<sub>3</sub>O<sub>4</sub> nanorods (NRs), which were synthesized by the hydrothermal method. XRD and TEM confirm the formation of highly crystalline Fe<sub>3</sub>O<sub>4</sub> NRs with narrow size distribution. For high aspect ratio NRs (656nm), room temperature saturation magnetization is close to that of bulk Fe<sub>3</sub>O<sub>4</sub> (~90emu/g) and much larger than that of spherical NPs of the same volume (60-70emu/g). DC magnetization vs. temperature data display a sharp change in the magnetization at 120K, which is attributed to the Verwey transition, whose presence affirms the excellent crystallinity of Fe<sub>3</sub>O<sub>4</sub> NRs. Owing to their high effective anisotropy and saturation magnetization, the Fe<sub>3</sub>O<sub>4</sub> NRs show enhanced heating efficiency relative to their spherical NP counterparts when tested in a standard hyperthermia set-up.

### 9:12AM A6.00005 Ferroic ordering and charge-spin-lattice order coupling in Gd doped Fe<sub>3</sub>O<sub>4</sub> nanoparticles ,

SUVRA LAHA, EHAB ABDELHAMID, MAHESHIKA PALIHAWADANA ARACHCHIGE, Wayne State University, AMBESH DIXIT, Indian Institute of Technology Jodhpur, GAVIN LAWES, Wayne State University, VAMAN NAIK, University of Michigan Dearborn, RATNA NAIK, Wayne State University — Rare earth doped spinels have been extensively studied for their potential applications in magneto-optical recording and as MRI contrast agents. In the present study, we have investigated the effect of gadolinium doping (1-5 at.%) on the magnetic and dielectric properties of Fe<sub>3</sub>O<sub>4</sub> nanoparticles synthesized by the chemical co-precipitation method. The structure and morphology of the as-synthesized gadolinium doped Fe<sub>3</sub>O<sub>4</sub> (Gd-Fe<sub>3</sub>O<sub>4</sub>) nanoparticles were characterized by XRD, SEM and TEM, and the magnetic properties were measured by a Quantum Design physical property measurement system. We find that the penetration of excess Gd<sup>3+</sup> ions into Fe<sub>3</sub>O<sub>4</sub> spinel matrix significantly influences the average crystallite size and saturation magnetization in Gd-Fe<sub>3</sub>O<sub>4</sub>. The average crystallite size, estimated from XRD using Scherrer equation, increases with increasing Gd doping percentage and the saturation magnetization drops monotonically with excess Gd<sup>3+</sup> ions. Interestingly, Gd-Fe<sub>3</sub>O<sub>4</sub> develops enhanced ferroelectric ordering at low temperatures. The details of the temperature dependent dielectric, ferroelectric and magnetocapacitance measurements to understand the onset of charge-spin-lattice coupling in Gd-Fe<sub>3</sub>O<sub>4</sub> system will be presented.

### 9:24AM A6.00006 A comparison of methods for the determination of the magnetocrystalline anisotropy constant in an Fe<sub>3</sub>O<sub>4</sub>-based ferrofluid ,

RONALD TACKETT, MEGAN ALLYN, Kettering University, VIJAYENDRA GARG, ADERBAL DE OLIVEIRA, University of Brasilia, PREM VAISHNAVA, Kettering University — The dynamics of the relaxation behavior of superparamagnetic nanoparticles is governed by many factors such as the anisotropy constant, composition, size and nature of coating of the nanoparticles particles. We report values of the anisotropy constant (K) for magnetite nanoparticle (size ~12 nm) coated with dextran and suspended in water by dc and ac magnetization measurements, Mossbauer spectroscopy and the temperature dependent specific absorption rate (SAR) measurement. The magnetite nanoparticles were synthesized by co-precipitation and characterized by X-ray diffraction (XRD) and Transmission electron microscopy (TEM). The K values from dc magnetic susceptibility, Mossbauer spectroscopy, ac magnetic susceptibility, and that obtained by temperature dependent SAR measurements are all within the range of the accepted values in the literature. Merits and demerits of the four methods of determining K values will be discussed. We will also report on the temperature dependence of the anisotropy constant and the NEel relaxation constant.

**9:36AM A6.00007 Effect of magnetic anisotropy and particle size distribution on temperature dependent magnetic hyperthermia in  $\text{Fe}_3\text{O}_4$  ferrofluids**, MAHESHIKA PALIHAWADANA ARACHCHIGE, Wayne State University, HUMESHKAR NEMALA, Illinois Wesleyan University, VAMAN NAIK, University of Michigan Dearborn, RATNA NAIK, Wayne State University — Magnetic hyperthermia (MHT) has a great potential as a non-invasive cancer therapy technique. Specific absorption rate (SAR) which measures the efficiency of heat generation, mainly depends on magnetic properties of nanoparticles such as saturation magnetization ( $M_s$ ) and magnetic anisotropy (K) which depend on the size and shape. Therefore, MHT applications of magnetic nanoparticles often require a controllable synthesis to achieve desirable magnetic properties. We have synthesized  $\text{Fe}_3\text{O}_4$  nanoparticles using two different methods, co-precipitation (CP) and hydrothermal (HT) techniques to produce similar XRD crystallite size of 12 nm, and subsequently coated with dextran to prepare ferrofluids for MHT. However, TEM measurements show average particle sizes of 13.8 3.6 nm and 14.6 3.6 nm for HT and CP samples, implying the existence of an amorphous surface layer for both. The MHT data show the two samples have very different SAR values of 110 W/g (CP) and 40W/g (HT) at room temperature, although they have similar  $M_s$  of 70 4 emu/g regardless of their different TEM sizes. We fitted the temperature dependent SAR using linear response theory to explain the observed results. CP sample shows a larger magnetic core with a narrow size distribution and a higher K value compared to that of HT sample.

**9:48AM A6.00008 The investigation of smart magnetic nanoparticles for use in the hyperthermia treatment of cancer**, MEGAN ALLYN, Kettering University, PARASHU KHAREL, South Dakota State University, PREM VAISHNAVA, RONALD TACKETT, Kettering University — The magnetic fluid hyperthermia (MFH) treatment of cancer has emerged as a possible low-side-effect alternative to traditional chemotherapy- and radiation-based therapy. As the nanoparticles absorb energy from a low amplitude RF magnetic field they heat up; however, currently used hyperthermia systems require external temperature monitoring as the nanoparticles can easily heat to temperature greater than the desired window between 42C and 46C. To combat this, we are investigating smart magnetic nanoparticles whose Curie temperatures fall within the desired range. In order to do this, we have doped non-magnetic cations onto the structure of the AFM  $\text{LaMnO}_3$ . We report synthesis of  $\text{La}_{1-x}\text{M}_x\text{MnO}_3$  (M = Ba, Ca, Sr; x = 0.10 0.25) nanoparticles via sol-gel method for use in temperature-controlled MFH. These nanoparticles were characterized via powder x-ray diffraction and found to have the expected R-3c perovskite structure. For elemental analysis, energy dispersive spectroscopy was performed using scanning electron microscopy. The temperature dependence of the magnetization was investigated using vibrating sample magnetometry (VSM) to determine the Curie temperature of the ensembles. The results of the change in temperature vs time and SAR values will be presented.

**10:00AM A6.00009 Magnetically Stimulated Release of a Model Drug From a Magnetic Drug Carrier**, TOM RILEY, BEN EVANS, None — The use of particles in the micro and nanometer ranges has become increasingly important as therapeutic tools in medicine. In particular, magnetically-active particles may allow for magnetically-controlled release of drugs at targeted locations. The drugs can be delivered directly to cancerous tumors at desired concentrations. While hydrogel-based microspheres have been commonly proposed for such purposes, there is also a need for a lipophilic magnetic microsphere for delivery of poorly-soluble pharmaceuticals. We have created a well-dispersed suspension of iron oxide nanoparticles in a silicone matrix, and have used the material to manufacture microspheres in sizes ranging from 100nm to 50 microns. Our spheres are stable in aqueous suspensions, yet their silicone matrix is uniquely suited for the transport and delivery of hydrophobic pharmaceuticals. A high concentration of magnetic nanoparticles (50% wt.) enables magnetic localization, magnetic heating (hyperthermia), and magnetic stimulation to trigger drug release. Using fluorescein as a model drug, we use UV-visible spectroscopy to show a slow native release rate of the hydrophobic fluorescein from the spheres. We use these measurements to quantify the loading capacity of the microspheres, and we show results of magnetically-stimulated drug release using a DM100 field applicator (nanoScale Biomagnetics).

**10:12AM A6.00010 Electric field control of the magnetic order parameter of magnetic pillars embedded in a ferroelectric matrix**, MICHAEL FITZSIMMONS, Oak Ridge National Lab, Q WANG, Argonne National Lab, A CHEN, T LOOKMAN, Q.X. JIA, Los Alamos National Lab, D.A. GILBERT, J.A. BORCHERS, NIST, B HOLLADAY, S SINHA, UCSD — Using polarized beam small angle neutron scattering (SANS) we quantitatively measured the influence of an electric field on correlation of magnetism in a ferroelectric/ferrimagnetic nanocomposite. The nanocomposite consists of ~12 nm wide pillars of  $\text{CoFe}_2\text{O}_4$  (dark regions, inset figure left), a room temperature ferrimagnet, embedded in a ferroelectric,  $\text{BaTiO}_3$ , matrix (light regions, inset figure right). We used a model-free method to extract the correlations of the magnetic structure from the SANS data (figure below). We found a 700 kV/cm electric field induced a change of magnetization of ~2% (scattering geometry, inset figure left). We explain our results using a simple representation for free energy that attributes coupling between electric polarization and magnetic order parameters to strain.

**10:24AM A6.00011 Characterization and Magnetic Properties of Nano-ferrite  $\text{ZnFe}_2\text{-xLa}_x\text{O}_4$  prepared by Co-precipitation method**, ALY ABOU-ALY, Physics department, Faculty of Science, Alexandria University, Alexandria, Egypt, DOAA BAKEER, Physics department, Faculty of Science, Damanhur University, Damanhur, Egypt, NAYERA MOHAMMED, RAMADAN AWAD, MARWA HASEBBO, Physics department, Faculty of Science, Alexandria University, Alexandria, Egypt — Nano size spinel ferrite with nominal compositions  $\text{ZnFe}_{2-x}\text{La}_x\text{O}_4$ ,  $0.0 \leq x \leq 0.3$  were prepared using stoichiometric amounts of  $\text{ZnCl}_2$ ,  $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$  and  $\text{LaCl}_3 \cdot 7\text{H}_2\text{O}$  by Co-precipitation method. The structures, optical and magnetic properties of the prepared samples were investigated, and compared with similar compositions prepared by different methods. The X-ray powder diffraction analysis shows single-phase cubic spinel structure up to  $x = 0.2$ . The lattice parameter "a" significantly increases with increasing x, which confirms the substitution of La at Fe sites. The crystallite size, estimated by different methods, has been found in the range of 7-14 nm. This crystallite size is found to be less than that prepared by sol gel combustion method. The FTIR spectra indicate the presence of absorption bands in the range of 390- 561 $\text{cm}^{-1}$ . The magnetic hysteresis was studied using vibrating sample magnetometer (VSM). The saturation magnetization, coercivity and remnents magnetization have nonsystematic change as the La-substitution increases. This is because the magnetic properties of Nano- ferrites are strongly dependent on the cation distribution among tetrahedral and octahedral sites in the cubic spinel structure.

**10:36AM A6.00012 Magnetite nano-islands on Graphene<sup>1</sup>**, NATHANIEL ANDERSON, QIANG ZHANG, Ames Laboratory and Iowa State University, RICHARD ROSENBERG, Advance Photon Source, Argonne National Laboratory, DAVID VAKNIN, Ames Laboratory and Iowa State University — X-ray magnetic circular dichroism (XMCD) of ex-situ iron nano-islands grown on graphene reveals that iron oxidation spontaneously leads to the formation of magnetite nano-particles - i.e. the formation of the inverse spinel  $\text{Fe}_3\text{O}_4$ . Fe islands have been grown with two different heights (20 and 75 MLs) on epitaxial graphene and we have determined their magnetic behavior both as function of temperature and applied external field. Our XAS and XMCD at an applied magnetic field of  $B = 5$  T show that the thin film (20 MLs) is totally converted to magnetite whereas the thicker film (75 MLs) exhibits magnetite properties but also those of pure metal iron. For both samples, temperature dependence of the XMCD shows clear transitions at ~120 K consistent with the Verwey transition of bulk magnetite. XMCD at low temperatures shows a weak hysteresis and provide the average spin  $\langle S_z \rangle$  and angular-momentum  $\langle L_z \rangle$  moments, the dipolar  $\langle T_z \rangle$  term, and the total moment  $\langle M_z \rangle$ . In addition, manipulation and comparison of the XMCD data from both samples allows us to extract information about the pure iron nano-islands from the thicker sample.

**8:00AM A7.00001 Identifying the relation between trapping force of Laser Tweezers and Size of Microsphere particles<sup>1</sup>**, ALEXANDRA DIABRE, Seton Hall University — Optical trapping technique is the method in which micron and sub-micron particles can be studied. In this technique the laser pressure radiation creates the essential force to trap particles. This force depends on several parameters including the particles' indices of refraction, the specification of the beads surrounding environment and the characteristics of the implemented laser. On this work we present the outcome of the experiment we designed to analyze the trapping force. In this experiment we used micro sized beads with different indices of refraction, changed the viscosity of the surrounding environment of the beads and adjusted the power of the laser implemented. By analyzing the motion of the beads in several trials, the trapping force was estimated and its dependency to the parameters mentioned above was identified. Finally the outcomes of our experiment were compared with the theoretical reported results.

<sup>1</sup>This work was conducted under the supervision by Dr. Mitra Feizabadi

**8:12AM A7.00002 Scanning Tunneling Microscopy of Charge Density Wave states in TbTe<sub>3</sub>**, AARON KRAFT, LING FU, BISHNU SHARMA, Clark University, IAN FISHER, Stanford University, MICHAEL BOYER, Clark University — Charge density wave (CDW) states are broken symmetry states which involve a periodic lattice distortion and an opening of a band gap. While these states are prevalent in condensed matter systems, often coexisting with other states such as superconductivity, much is still not understood about the microscopic properties of CDWs or their onset through T<sub>CDW</sub>. For these reasons we use scanning tunneling microscopy (STM) to study CDW states in TbTe<sub>3</sub> where T<sub>CDW</sub> ~335 K. We will present temperature dependent STM data through T<sub>CDW</sub> as well as our efforts in modeling the combined effects of crystal lattice structure, CDW states, and wave-vector mixing to understand the periodicities detected in our topographic images.

**8:24AM A7.00003 Thermal Properties of Nd-Doped PrOs<sub>4</sub>Sb<sub>12</sub> Extracted From Measurement of Specific Heat<sup>1</sup>**, TAYLOR MCCULLOUGH-HUNTER, Physics Department, California State University, Fresno, SHOJI HISHIDA, PEI-CHUN HO, Department of Physics, California State University, Fresno, BRIAN MAPLE, Department of Physics, University of California, San Diego, TATSUYA YANAGISAWA, Department of Physics, Hokkaido University, Japan — PrOs<sub>4</sub>Sb<sub>12</sub> has attracted interest due to its unconventional heavy fermion superconductivity, interest that has increased once the Nd-doped compound was shown at certain concentrations of Nd to simultaneously display ferromagnetism and superconducting properties at low temperatures. In order to better understand the more exotic low temperature behavior exhibited by this system, it is necessary to characterize its normal-state properties. Therefore, the molar specific heat of Pr<sub>1-x</sub>Nd<sub>x</sub>Os<sub>4</sub>Sb<sub>12</sub> is measured using finite heat pulse relaxation calorimetry. A curve-fit of the temperature-dependent molar specific heat allows an estimation of the Debye and Einstein temperatures, as well as the electronic specific heat coefficient. These properties are examined across x to determine the behavior of the system with respect to Nd-concentration. The results from the measurements will be discussed during the presentation.

**8:36AM A7.00004 Pressure Dependence of the Magnetic Response of the S = 1 Polymeric Chain [Ni(HF<sub>2</sub>)(3-Clpy)<sub>4</sub>]BF<sub>4</sub>.<sup>1</sup>**, JAYNISE PEREZ, Univ of Puerto Rico - Mayaguez, MARCUS PEPRAH, PEDRO QUINTERO, MARK MEISEL, Dept. of Physics and NHMFL, Univ. of Florida, JAMIE MANSON, Dept. of Chemistry, Eastern Washington Univ. — [Ni(HF<sub>2</sub>)(3-Clpy)<sub>4</sub>]BF<sub>4</sub> (py = pyridine) is an S = 1 antiferromagnetic polymeric chain with a single-ion anisotropy (zero-field splitting) of D/kB = 4.3 K and an intrachain exchange interaction value of J/kB = 4.86 K at ambient pressure [1]. The ratio of these parameters (D/J = 0.88) places this system close to a quantum critical point at D/J ≈ 1, which falls between the Haldane and the Large-D phases. The temperature dependence of the low-field (1 kG) magnetic susceptibility was measured as a function of pressure, up to 1.49 GPa, using a homemade piston-clamp cell [2]. The data indicate the antiferromagnetic component is suppressed with increasing pressure. [1] J.L. Manson et al., Inorg. Chem. 51 (2012) 7520. [2] M.K. **8:48AM A7.00005 High pressure differential conductance measurements of (Pb,Sn)Se**, TIFFANY PAUL, DERRICK VANGENNEP, DANIEL JACKSON, AMLAN BISWAS, JAMES HAMLIN, Department of Physics, University of Florida, Gainesville, FL 32608 — Topological transitions have been recognized as a new type of quantum phase transition. Recently, a number of papers have reported scanning tunneling microscope (STM) measurements of the Landau level spectra of topologically non-trivial materials. Such measurements can offer substantial insight into the nature of the transition between topologically distinct phases. Although applied pressure represents an attractive means to drive a topological quantum phase transition, STM measurements can not be performed under high pressure conditions. In this talk, I will discuss our recent attempts to observe Landau level spectra in compressed (Pb,Sn)Se using differential conductance measurements. **9:00AM A7.00006 Phase Transitions in Nanostructured Mn<sub>0.18</sub>TaS<sub>2</sub><sup>1</sup>**, LUCAS BEVING, MATHEW FLEMING, PAYTON BURKEN, PAUL SHAND, TIMOTHY KIDD, LAURA STRAUSS, University of Northern Iowa — Phase transitions in a sample of Mn-intercalated TaS<sub>2</sub> were investigated. The concentration of manganese relative to tantalum was determined to be 18%. The phase transitions of the sample were explored using a variety of techniques: Curie-Weiss, Critical Scaling, Arrott-Noakes, and Kouvel-Fisher. All but the first method include the use of critical exponents defined using the spontaneous magnetization and susceptibility in zero applied field. The sample was found to undergo a transition from paramagnetism to an ordered state below 100 K. Two of the aforementioned methods were converted to computational methods. These same methods for determining the transition temperature and critical exponents may also indicate the existence of a second transition very close to the first. These results have been extracted using the theory of scaling.

**9:12AM A7.00007 Lattice thermal conductance of quantum wires with disorder**, ERIK VYHMEISTER, Andrews University, SELMAN HERSHFELD, University of Florida — We model the lattice thermal conductance in long quantum wires connected to two large heat baths at different temperatures in the harmonic approximation. The thermal conductance is computed with the Landauer formula for phonons, where it is related to the sum over all transmission probabilities for phonons through the wire. The net transmission probability is computed using a recursive Green function technique, which allows one to study long wires efficiently. We consider several different kinds of disorder to reduce the lattice thermal conductivity: periodic rectangular holes of varying sizes and shapes, periodic triangular holes, and narrow bands, averaged over randomness to account for variance in manufacturing. Depending on the model, the thermal conductance was reduced by 80 percent or more from the perfectly ordered wire case. Funded by NSF grant DMR-1461019.

**9:24AM A7.00008 3-D matrix template-assisted growth of oriented oxide nanowire arrays using glancing angle pulsed laser deposition**, N WRIGHT, Univ of Connecticut - Storrs, D MATEO-FELICIANO, A OSTOSKI, P MUKHERJEE, S WITANACHCHI, Univ of South Florida — Nanosphere lithography is a combination of different methods to nanofabrication. In this work nanosphere lithography is used to study the growth of Zinc Oxide Nano-columns (ZnO NCs) on different diameter Silica Nanosphere (SNS) self-assembled templates. ZnO NCs are promising building blocks for many existing and emerging optical, electrical, and piezoelectric devices, specifically, the seeded growth of other oxide materials. Recently, reports have shown a ferroelectric phase of zinc stannate ( $\text{ZnSnO}_3$ ) and while lead zirconium titanate oxide (PZT) has been the main material of interest in ferroelectric and piezoelectric applications, the toxicity of lead has been of great concern. The possibility of developing lead free piezoelectric materials is of great interest in the ferroelectric community. Langmuir-Blodgett method was used to construct a self-assembled monolayer of SNSs on silicon substrates. Oriented ZnO NCs were grown on top of the spheres using the glancing angle pulsed laser deposition technique. Columns were formed in a spatially ordered closed-packed hexagonal configuration. Growth of ZnO NCs was studied as function of ambient Oxygen pressure with SNS size ranging from 250-1000 nm. Cross-sectional Scanning Electron Microscopy and X-ray diffraction (XRD) were used to study the template structure. Relative aspect ratios were studied and showed tunability of column dimensions with sphere size. XRD revealed ZnO NC arrays were c-axis oriented with hexagonal wurtzite structure.

**9:36AM A7.00009 Observation of Interlayer Excitons in Monolayer  $\text{MoSe}_2$ - $\text{WSe}_2$  Heterostructure on BN Substrate<sup>1</sup>**, ALICE HUANG, Rutgers University, ESSANCE RAY, KYLE SEYLER, PASQUAL RIVERA, ERIC WONG, PAUL NYUGEN, GENEVIEVE CLARK, XIAODONG XU, University of Washington, GROUP OF XIAODONG XU TEAM — Interlayer excitons have previously been observed in monolayer MX2 heterostructures exhibiting type II band alignment. Specifically, interlayer excitons in  $\text{MoSe}_2$ - $\text{WSe}_2$  heterostructures have been thoroughly characterized with photoluminescence (PL) and photoluminescence excitation spectroscopy (PLE). However, electrical control of the interlayer exciton exhibits PL intensity dependence that is inconsistent with the dipole and electric field model - possibly owing to carrier charge effects - and requires further elucidation. The addition of BN substrate, which has been shown to (1) smooth the surface and (2) reduce carrier charge inhomogeneity of graphene devices, presents itself as a potential solution. In this preliminary study, we fabricated an  $\text{MoSe}_2$ - $\text{WSe}_2$  heterostructure on BN substrate. Photoluminescence (PL) measurements on the device confirm the presence of interlayer excitons at approximately 1.40 eV, consistent with  $\text{MoSe}_2$ - $\text{WSe}_2$  heterostructures. Furthermore, the PL characterization reveals unreported spectral features for both the interlayer and intralayer excitons.

**9:48AM A7.00010 Magneto-Optical Study of Lithographically Patterned Ferromagnetic Multilayer  $(\text{Co/Pt})_8$  Micro-Channels<sup>1</sup>**, ALEXIS BOWERS, Lock Haven Univ, NITIN SAMARTH, SUSAN KEMPINGER, ROBERT FRALEIGH, Pennsylvania State University — Controlled domain movement in magnetic structures has become promising for applications in magnetic memory systems and data processing. This study examines magnetic domain nucleation and propagation within a series of lithographically patterned Co/Pt micro-channels with perpendicular magnetic anisotropy (PMA). Magnetic domains are nucleated and then manipulated using out-of-plane sweep protocols and studied in situ using magneto-optical Kerr effect (MOKE) imaging. Co/Pt multilayers were fabricated with optical lithography and sputter deposition. Effects of channel width and annealing are presented. Annealing the Co/Pt after fabrication as a function of time and temperature resulted in increasing the coercivity of the unpatterned film, decreasing the coercivity of the micro-channels, and reducing the average domain size in both. Atomic force microscopy (AFM) characterization of the micro-channels showed non-uniform deposition near feature edges. MOKE imaging demonstrated that the feature edges had a much lower coercivity (70G) than the middle of the channel/pad (150G) or the unpatterned film (250G). We found that an oscillating field protocol to re-initialize soft domains near feature edges proved to be more effective than a traditional field sweep to initialize a domain wall in the channel. Once a domain wall was formed, we explored a combination of constant and pulsed field protocols to manipulate the domain wall.

**10:00AM A7.00011 Nuclear Magnetic Resonance Study of 3D Dirac Semimetal,  $\text{Na}_3\text{Bi}$ <sup>1</sup>**, AMELIA ESTRY, National High Magnetic Field Laboratory, NICK CURRO, KENT SHIRER, MATTHEW LAWSON, JOHN CROCKER, BLAINE BUSH, PETER KLAVINS, CHING (JIM) LIN, TANAT KISSIKOV, Department of Physics, University of California, Davis, ADAM DIOGUARDI, Los Alamos National Laboratory, ROBERT CAVA, Department of Chemistry, Princeton University — Dirac semimetals (DS) are a hot topic of research in topological materials because their unique properties indicate a potential in electronic applications. The electron band structure of ordinary semimetals differ from insulators and conductors as the top of the valence band and bottom of the conduction band have a small overlap. In DS, this overlap occurs only at discrete points, known as Dirac points. At the Dirac points, the relationship of energy to momentum (dispersion relation) is linear, allowing electrons near the Dirac points to behave as massless particles. Of particular interest are the three-dimensional Dirac semimetals, where this interesting band structure is present along all three dimensions. We attempt to probe the local conditions of a three-dimensional DS,  $\text{Na}_3\text{Bi}$ , using nuclear magnetic resonance (NMR) to perturb the spin states of the nuclei. Studying each of the nuclei sites of  $\text{Na}_3\text{Bi}$  using NMR can provide insight into the interactions among the nuclei and between the nuclei and the surrounding electrons.  $\text{Na}_3\text{Bi}$  has a complex NMR spectrum which requires further study to understand.

**10:12AM A7.00012 A MATLAB GUI to study Ising model phase transition**, CURTISLEE THORNTON, TRINANJAN DATTA, Georgia Regents University — We have created a MATLAB based graphical user interface (GUI) that simulates the single spin flip Metropolis Monte Carlo algorithm. The GUI has the capability to study temperature and external magnetic field dependence of magnetization, susceptibility, and equilibration behavior of the nearest-neighbor square lattice Ising model. Since the Ising model is a canonical system to study phase transition, the GUI can be used both for teaching and research purposes. The presence of a Monte Carlo code in a GUI format allows easy visualization of the simulation in real time and provides an attractive way to teach the concept of thermal phase transition and critical phenomena. We will also discuss the GUI implementation to study phase transition in a classical spin ice model on the pyrochlore lattice.

**10:24AM A7.00013 Spin wave Feynman diagram vertex computation package**, ALEXANDER PRICE, Georgia Regents University, PHILIP JAVERNICK, University of North Carolina at Chapel Hill, TRINANJAN DATTA, Georgia Regents University — Spin wave theory is a well-established theoretical technique that can correctly predict the physical behavior of ordered magnetic states. However, computing the effects of an interacting spin wave theory incorporating magnons involve a laborious by hand derivation of Feynman diagram vertices. The process is tedious and time consuming. Hence, to improve productivity and have another means to check the analytical calculations, we have devised a Feynman Diagram Vertex Computation package. In this talk, we will describe our research groups effort to implement a Mathematica based symbolic Feynman diagram vertex computation package that computes spin wave vertices. Utilizing the non-commutative algebra package NCAAlgebra as an add-on to Mathematica, symbolic expressions for the Feynman diagram vertices of a Heisenberg quantum antiferromagnet are obtained. Our existing code reproduces the well-known expressions of a nearest neighbor square lattice Heisenberg model. We also discuss the case of a triangular lattice Heisenberg model where non collinear terms contribute to the vertex interactions.

**10:36AM A7.00014 A critical comparison of electrical methods for measuring spin-orbit torques<sup>1</sup>**, XUANZI ZHANG, YU-MING HUNG, LAURA REHM, ANDREW D. KENT, New York University — Direct (DC) and alternating current (AC) transport measurements of spin-orbit torques (SOTs) in heavy metal-ferromagnet heterostructure with perpendicular magnetic anisotropy have been proposed and demonstrated [1,2]. A DC method measures the change of perpendicular magnetization component while an AC method probes the first and second harmonic magnetization oscillation in responses to an AC current ( $\sim 1$  kHz). Here we conduct both types of measurements on  $\beta$ -Ta/CoFeB/MgO in the form of patterned Hall bars (20  $\mu$ m linewidth) and compare the results. Experiments results are qualitatively in agreement with a macro spin model including Slonzewski-like and a field-like SOTs. However, the effective field from the ac method is larger than that obtained from the DC method. We discuss the possible origins of the discrepancy and its implications for quantitatively determining SOTs. [1] L. Liu, C. Pai, Y. Li, H. Tseng, D. Ralph, and R Buhrman, Science 336, 1126 (2012). **10:48AM A7.00015 Analysis of Methods to Excite Head-Tail Motion Within the Cornell Electron Storage Ring**, NAOMI GENDLER, Reed College, MIKE BILLING, JIM SHANKS, Cornell University — The main accelerator complex at Cornell consists of two rings around which electrons and positrons move: the synchrotron, where the particles are accelerated to 5 GeV, and the Storage Ring, where the particles circulate at a fixed energy, guided by quadrupole and dipole magnets, with a steady energy due to a sinusoidal voltage source. Keeping the beam stable in the Storage Ring is crucial for its lifetime. A long-lasting, invariable beam means more accurate experiments, as well as brighter, more focused X-rays for use in the Cornell High Energy Synchrotron Source (CHESS). The stability of the electron and positron beams in the Cornell Electron Storage Ring (CESR) is important for the development of accelerators and for usage of the beam in X-ray science and accelerator physics. Bunch oscillations tend to enlarge the beam's cross section, making it less stable. We believe that one such oscillation is "head-tail motion," where the bunch rocks back and forth on a pivot located at the central particle. In this project, we write a simulation of the bunch that induces head-tail motion with a vertical driver. We also excite this motion physically in the storage ring, and observe a definite head-tail signal. In the experiment, we saw a definite persistence of the drive-damp signal within a small band around the head-tail frequency, indicating that the head-tail frequency is a natural vertical mode of the bunch that was being excited. The signal seen in the experiment matched the signal seen in the simulation to within an order of magnitude.

**Monday, March 14, 2016 8:00AM - 11:00AM —**

**Session A11 DMP: Pairing Interaction and Gap Symmetry in Fe-based Superconductors** 307 -

Rafael Fernandes, University of Minnesota

**8:00AM A11.00001 Glide-Plane Symmetry and Superconducting Gap Structure of Iron-Based Superconductors<sup>1</sup>**, THOMAS MAIER, Oak Ridge National Lab — This talk will provide a review [1] of the implications of the glide plane symmetry of a single Fe-pnictide/chalcogen plane on the structure of the superconducting gap. It will be shown that  $\eta$ -pairing with non-zero total momentum occurs inevitably in this system, but that its contribution to the superconducting condensate has the usual even parity symmetry and time reversal symmetry is preserved. I will demonstrate that for a single plane the gap function, which appears in physical quantities, is identical to that found in 1 Fe per unit cell pseudo-crystal momentum calculations and discuss the effects of the symmetry breaking out-of-plane hopping integrals in three dimensions. [1] Y. Wang, T. Berlijn, P. J. Hirschfeld, D. J. Scalapino, T. A. Maier, Phys. Rev. Lett. 114, 107002 (2015).

<sup>1</sup>A portion of this research was conducted at the Center for Nanophase Materials Sciences, which is a DOE Office of Science User Facility.

**8:36AM A11.00002 Robust measurement of superconducting gap sign changes via quasiparticle interference: an application to 111 compounds<sup>1</sup>**, ILYA EREMIN, DUSTIN ALTENFELD, Institut für Theoretische Physik III, Ruhr-Universität Bochum, D-44801 Bochum, Germany, PETER HIRSCHFELD, Department of Physics, University of Florida, Gainesville, Florida 32611, USA, IGOR MAZIN, Code 6393, Naval Research Laboratory, Washington, DC 20375, USA — While quasiparticle interference (QPI) measurements based on scanning tunneling spectroscopy are often proposed as definitive tests of gap structure, the analysis typically relies on details of the model employed. Here using the simplified two-band model system we propose, that the temperature dependence of momentum-integrated QPI data can be used to identify gap sign changes in a qualitative way, and present an illustration for  $s_{\pm}$  and  $s_{++}$  states in a system with typical Fe-pnictide Fermi surface. Using ARPES derived band structures within 10 orbital model Hamiltonian we analyze the QPI spectra in LiFeAs and Co-doped NaFeAs compounds and show that the sign-changing gap can be clearly identified using non-magnetic impurity scattering.

**8:48AM A11.00003 Features of Superconducting Gaps Revealed by STM/STS in Iron Based Superconductors With and Without Hole Pockets<sup>1</sup>**, HAI-HU WEN, Nanjing University, HAI-HU WEN TEAM — The pairing mechanism and gap structure in iron based superconductors (IBS) remains unresolved. We have conducted extensive STM/STS study on the Na(Fe<sub>1-x</sub>T<sub>x</sub>)As (T=Co, Cu, Mn)[1], Ba<sub>1-x</sub>K<sub>x</sub>Fe<sub>2</sub>As<sub>2</sub>[2], KFe<sub>2</sub>As<sub>2</sub>[3], and Li<sub>1-x</sub>Fe<sub>x</sub>OHFeSe[4] single crystals. We found the clear evidence of the in-gap quasi-particle states induced by the non-magnetic Cu impurities in Na(Fe<sub>0.97-x</sub>Co<sub>0.03</sub>Cu<sub>x</sub>)As, giving strong evidence of the  $S^{\pm}$  pairing. Furthermore, we show the presence of the bosonic mode with the energy identical to that of the neutron resonance and a simple linear relation  $\Omega/k_B T_c \approx 4.3$ , being explained a consequence of the Spairing. The STS spectrum in Li<sub>1-x</sub>Fe<sub>x</sub>OHFeSe clearly indicates the presence of double superconducting gaps with  $\Delta_1 \approx 14.3$  meV and  $\Delta_2 \approx 8.6$  meV. Further analysis based on QPI allows us to assign the larger (smaller) gap to the outer (inner) hybridized electron pockets[4]. The huge value  $2\Delta_1/k_B T_c = 8.7$  discovered here undoubtedly proves the strong coupling mechanism. [1] H. Yang et al., Nature Communications 4, 2947 (2013). [2] Z. Y. **9:00AM A11.00004 Specific Heat in High Magnetic Fields of  $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$** , CAMILLA M. MOIR, FSU/NHMFL, JOSE A. GALVIS, NHMFL, PHILLIP WALMSLEY, Stanford, JAMES G. ANALYTIS, UC Berkeley, JIUN-HAW CHU, IAN R. FISHER, Stanford, ARKADY SHEKHTER, NHMFL, GREG S. BOEBINGER, FSU/NHMFL, SCOTT C. RIGGS, NHMFL — We measure the magnetic field dependence of the specific heat in  $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$  with  $x$  ranging from  $x=0.31$  to  $x=0.6$  in fields up to 34.5T. We report three important observations:  $\sqrt{H}$  behavior indicating a nodal superconducting gap with a linear energy dispersion, saturation of the heat capacity at the magnetic field that corresponds to the resistive onset [1], and a calculated quasiparticle mass using the increase in the electronic specific heat coefficient when entering the normal state,  $\Delta\gamma = \gamma(34.5\text{T}) - \gamma(0\text{T})$ , as a measure of the normal state specific heat. [1] James G. Analytis, H-H. Kuo, Ross D. McDonald, Mark Wartenbe, P. M. C. Rourke, N. E. Hussey & I. R. Fisher. *Nature Phys.* 10, 194–197 (2014)

**9:12AM A11.00005 Direct evidence for a pressure induced nodal superconducting gap in the  $\text{Ba}_{0.65}\text{Rb}_{0.35}\text{Fe}_2\text{As}_2$  superconductor**, ZURAB GUGUCHIA, Laboratory for Muon Spin Spectroscopy, Paul Scherrer Institute, Switzerland, ALEX AMATO, PSI, JIAN KANG, University of Minnesota, USA, HUBERTUS LUETKENS, PABITRA K. BISWAS, PSI, GIACOMO PRANDO, IFW Dresden, Germany, FABIAN V. ROHR, Universität Zurich, Switzerland, ZBIGNIEW BUKOWSKI, Institute of Low Temperature and Structure Research, Poland, ALEXANDER SHENGELAYA, Tbilisi State University, Georgia, HUGO KELLER, Universität Zurich, Switzerland, ELVEZIO MORENZONI, PSI, RAFAEL M. FERNANDES, University of Minnesota, USA, RUSTEM KHASANOV, PSI — In contrast to other unconventional superconductors, in the Fe-based superconductors (Fe-HTSs) both  $d$ -wave and extended  $s$ -wave pairing symmetries are close in energy. Probing the proximity between these different superconducting (SC) states and identifying experimental parameters that can tune them is of central interest. We report high-pressure muon spin rotation experiments on the temperature-dependent magnetic penetration depth in the optimally doped nodeless  $s$ -wave Fe-HTS  $\text{Ba}_{0.65}\text{Rb}_{0.35}\text{Fe}_2\text{As}_2$ . Upon pressure, a strong decrease of the penetration depth is observed, while the SC transition temperature remains nearly constant. More importantly, the low-temperature behavior of the inverse squared magnetic penetration depth, which is a direct measure of the superfluid density, changes qualitatively from an exponential saturation at zero pressure to a linear-in- $T$  behavior at higher pressures, indicating that hydrostatic pressure promotes the appearance of nodes in the SC gap.

**9:24AM A11.00006 Thermoelectric signatures of time-reversal symmetry breaking states in multiband superconductors**, MIKHAIL SILAEV, JULIEN GARAUD, EGOR BABAIEV, KTH, The Royal Institute of Technology — We demonstrate that superconductors which break time-reversal symmetry can exhibit thermoelectric properties, which are entirely different from the Ginzburg mechanism. As an example, we show that in the  $s+i$  superconducting state there is a reversible contribution to thermally induced supercurrent, whose direction is not invariant under time-reversal operation. Moreover in contrast to Ginzburg mechanism it has a singular behavior near the time-reversal symmetry breaking phase transition. A local hot spot in such superconductors is surrounded by a multipolar magnetic field, sensitive to the presence of domain walls and crystalline anisotropy of superconducting states. A non-stationary heating process produces an electric field and a charge imbalance in different bands. These effect can be measured and used to distinguish  $s+i$  and  $s+id$  superconducting states in the candidate materials such as  $\text{Ba}_{1-x}\text{K}_x\text{Fe}_2\text{As}_2$ .

**9:36AM A11.00007 Raman resonance due to magnetic fluctuations in iron-based superconductors**, JIASHEN CAI, ALBERTO HINOJOSA, ANDREY CHUBUKOV, University of Minnesota — We perform theoretical analysis of polarization-sensitive Raman spectroscopy on  $\text{NaFe}_{1-x}\text{Co}_x\text{As}$  and  $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$ , focusing on two features seen in the  $B_{1g}$  symmetry channel (in one Fe unit cell notation): the strong temperature dependence of the static, uniform Raman response in the normal state and the existence of a collective mode in the superconducting state. We show that both features can be explained by the coupling of fermions to pairs of magnetic fluctuations via the Aslamazov-Larkin process. We argue that the singular temperature dependence in the normal state comes from the Aslamazov-Larkin vertex, while the resonance is due to the interaction between two propagating spin fluctuations in an  $s^{+-}$  superconductor.

**9:48AM A11.00008 Electron pairing in the presence of incipient bands in iron-based superconductors<sup>1</sup>**, ANDY LINSCHIED, XIAO CHEN, SAURABH MAITI, PETER HIRSCHFELD, University of Florida — Recent experiments on certain Fe-based superconductors (SC) have hinted at a role for paired electrons in incipient bands that are close to, but do not cross the Fermi level. Within a simple multiband weak-coupling BCS approximation, we categorize the problem into two cases: case(I) where SC arises from the incipient band pairing alone, and case(II) where it is induced on an incipient band by pairing due to Fermi-surface based interactions. Negative conclusions regarding the importance of incipient bands are largely based on case(I). However, we show explicitly that models under case(II) can explain the mild suppression of  $T_c$ , as well as robust large gaps on an incipient band. We also model the interplay between phonon and spin fluctuation (SF) driven SC and describe the bootstrap of electron-phonon SC by SF coupling the incipient and the regular bands. We argue that pairing on incipient bands may be important in several Fe-based materials, including  $\text{LiFeAs}$ ,  $\text{FeSe}$  intercalates and  $\text{FeSe}$  monolayers on  $\text{SrTiO}_3$ , and indeed may contribute to high  $T_c$  in some cases. In addition, we address the question whether this conclusion holds if the SF interaction is derived explicitly in the incipient band scenario and retardation effects are included on the level of the Eliashberg equations.

**10:00AM A11.00009 Smearing of the Lifshitz transition by superconductivity<sup>1</sup>**, ALEXEI KOSHELEV, KONSTANTIN MATVEEV, Materials Science Division, Argonne National Laboratory — We consider a multiband metal with deep primary bands and a shallow secondary one [1]. In the normal state the system undergoes Lifshitz transition when the bottom of the shallow band crosses the Fermi level. In the superconducting state Cooper pairing in the shallow band is induced by the deep ones. As a result, the density of electrons in the shallow band remains finite even when the bottom of the band is above the Fermi level. We study the density of states in the system and find qualitatively different behaviors on the two sides of the Lifshitz transition. On one side of the transition the density of states diverges at the energy equal to the induced gap, whereas on the other side it vanishes. We argue that this physical picture describes the recently measured gap structure in shallow bands of iron pnictides and selenides. [1] A. E. Koshelev and K. A. Matveev *Phys. Rev. B* **90**, 140505(R) (2014)

**10:12AM A11.00010 Microscopic theory of superconductivity near a Lifshitz transition<sup>1</sup>**, VIVEK MISHRA, THOMAS MAIER, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, TN-37831, USA., DOUG SCALAPINO, Department of Physics, University of California, Santa Barbara, CA-93106, USA. — Observation of robust superconductivity in some of the iron based superconductors in the vicinity of a Lifshitz point has attracted many theoretical and experimental studies. The majority of these studies have been phenomenological. Here we discuss a microscopic treatment of the pairing mechanism for a bilayer Hubbard model, which goes through a Lifshitz transition. We study pairing driven by spin-fluctuations by solving the strong coupling Eliashberg equations and make a systematic comparison of the results with non-perturbative dynamical cluster quantum Monte Carlo calculations. Our findings are quite general and we will discuss their application to some of the iron based superconductors.

**10:24AM A11.00011 Topological Phase Transitions in Line-nodal Superconductors<sup>1</sup>**, GIL YOUNG CHO, SANGEUN HAN, EUN-GOOK MOON, KAIST — Fathoming interplay between symmetry and topology of many-electron wave-functions deepens our understanding in quantum nature of many particle systems. Topology often protects zero-energy excitation, and in a certain class, symmetry is intrinsically tied to the topological protection. Namely, unless symmetry is broken, topological nature is intact. We study one specific case of such class, symmetry-protected line-nodal superconductors in three spatial dimensions (3d). Mismatch between phase spaces of order parameter fluctuation and line-nodal fermion excitation induces an exotic universality class in a drastic contrast to one of the conventional  $\phi^4$  theory in 3d. *Hyper-scaling violation* and *relativistic dynamic scaling* with unusually large quantum critical region are main characteristics, and their implication in experiments is discussed. For example, continuous phase transition out of line-nodal superconductors has a *linear* phase boundary in a temperature-tuning parameter phase-diagram.

**10:36AM A11.00012 Orbital-selective pairing: a  $\tau 3$  B<sub>1g</sub> pairing candidate state for the alkaline iron selenides.**, RONG YU, Renmin University of China, EMILIAN M NICA, QIMIAO SI, Rice University — The iron-based unconventional superconductors are inherently multi-orbital systems and show remarkable variation in the Fermi-surfaces and pairing symmetries. In the alkaline iron selenides cases, ARPES experiments indicate fully gapped superconducting states, which suggests s-wave pairing, while neutron-scattering studies show resonances in the spin-spectrum with wave vectors across the electron Fermi pockets, suggesting d-wave pairing. We propose a novel superconducting state composed of a direct product of an s-wave form factor and a rotational symmetry-breaking orbital matrix in the  $d_{xz}/yz$  sectors [1]. It belongs to the B<sub>1g</sub> representation of the D<sub>4h</sub> point group, allowing for the overall change in sign between the pairing field at the electron pockets close to the 1-Fe BZ edge. While it supports a spin resonance, it also produces a fully gapped quasiparticle spectrum, making it a candidate pairing state for the alkaline iron selenide compounds. Our results also show how such a state can become energetically competitive in the regime of quasi-degeneracy between the s and d-wave pairing states. In a broader context, this pairing provides an alternative to the *s+id* to reconstruct the degenerate pairing states, while preserving the time-reversal symmetry. We discuss possible analogs in other multi-band strong-coupling superconductors such as the heavy fermions. [1] "Emergent superconducting state from quasi-degenerate s- and d-wave pairing channels in iron-based superconductors," E. M. Nica, R. Yu, and Q. Si, arXiv:1505.04170v1 (2015).

**10:48AM A11.00013 Searching for the Genes of Unconventional High Temperature Superconductors**, JIANGPING HU, Purdue University & Institute of Physics, CAS — In the past, both cuprates and iron-based superconductors were discovered accidentally. Lacking of successful predictions on new high T<sub>c</sub> materials is one of major obstacles to reach a consensus on the high T<sub>c</sub> mechanism. In this talk, we discuss two emergent principles, which are called as the correspondence principle and the selective magnetic pairing rule, to unify the understanding of both cuprates and iron-based superconductors. These two principles provide a unified explanation why the d-wave pairing symmetry and the s-wave pairing symmetry are robust respectively in cuprates and iron-based superconductors. In the meanwhile, the above two principles explain the rareness of unconventional high T<sub>c</sub> superconductivity, identify necessary electronic environments required for high T<sub>c</sub> superconductivity and finally serve as direct guiding rules to search new high T<sub>c</sub> materials. We predict that the third family of unconventional high T<sub>c</sub> superconductors exist in the compounds which carry two dimensional hexagonal lattices formed by cation-anion trigonal bipyramidal complexes with a *d<sub>xy</sub> filling configuration on the cation ions. Their superconducting states are expected to be dominated by the d<sub>xy</sub> + id pairing symmetry and their maximum T<sub>c</sub> should be higher than those of iron-based superconductors. Verifying the prediction can convincingly establish the high T<sub>c</sub>*

**Session A12 DLS: Advances in Real-Time Measurement of Structural Transformations** 308 - Roseanne Sension, University of Michigan

**8:00AM A12.00001 Tabletop Extreme Ultraviolet Spectroscopy of Element-Specific Organometallic Photophysics**, JOSH VURA-WEIS, University of Illinois at Urbana-Champaign — High-harmonic extreme ultraviolet (XUV) spectroscopy has the potential to provide the elemental, oxidation-state, and spin-state specificity of core-level spectroscopy with the convenience and ultrafast time resolution of tabletop laser sources. We will show that M-edge spectroscopy of first-row transition metal complexes (3p→3d excitation) is a sensitive probe of the electronic structure of organometallic complexes in solution. Furthermore, this technique can be used to determine the relaxation dynamics of these molecules in the first few femtoseconds to nanoseconds after photoexcitation.

**8:36AM A12.00002 Advancing the molecular movie: Femtosecond X-ray scattering of an electrocyclic chemical reaction<sup>1</sup>**, MICHAEL MINITTI, SLAC National Accelerator Laboratory — Since it began operation in 2009, SLAC's Linac Coherent Light Source (LCLS) has allowed scientists to make new types of X-ray measurements that were once thought unattainable by delivering one trillion X-ray photons in incredibly short bursts of less than a few femtoseconds. It was promised that this astonishing quantity of photons, delivered in such a small slice of time, could capture the motions of atoms in chemical reactions. Now we have used this capability to make a "molecular movie" of a molecule undergoing a chemical reaction from start to finish, with frames just a few femtoseconds long. We assembled the movie by taking individual X-ray snapshots of the molecules that show the positions of their atoms at each moment in time. Comparing these results to computer simulations of the reaction, we determined the routes the individual molecules followed as it's structure rearranged. This is the first step in developing robust methods for visualizing molecular motions in chemistry, biology, and materials science at the atomic scale. Please enjoy the movie!

**9:12AM A12.00003 Structure and Dynamics with Ultrafast Electron Microscopes**, BRADLEY SIWICK, McGill University, Department of Physics, Center for the Physics of Materials — In this talk I will describe how combining ultrafast lasers and electron microscopes in novel ways makes it possible to directly 'watch' the time-evolving structure of condensed matter, both at the level of atomic-scale structural rearrangements in the unit cell and at the level of a material's nano- microstructure. First, I will briefly describe my group's efforts to develop ultrafast electron diffraction using radio- frequency compressed electron pulses in the 100keV range, a system that rivals the capabilities of xray free electron lasers for diffraction experiments. I will give several examples of the new kinds of information that can be gleaned from such experiments. In vanadium dioxide we have mapped the detailed reorganization of the unit cell during the much debated insulator-metal transition. In particular, we have been able to identify and separate lattice structural changes from valence charge density redistribution in the material on the ultrafast timescale. In doing so we uncovered a previously unreported optically accessible phase/state of vanadium dioxide that has monoclinic crystallography like the insulator, but electronic structure and properties that are more like the rutile metal. We have also combined these dynamic structural measurements with broadband ultrafast spectroscopy to make detailed connections between structure and properties for the photoinduced insulator to metal transition. Second, I will show how dynamic transmission electron microscopy (DTEM) can be used to make direct, real space images of nano-microstructural evolution during laser-induced crystallization of amorphous semiconductors at unprecedented spatio-temporal resolution. This is a remarkably complex process that involves several distinct modes of crystal growth and the development of intricate microstructural patterns on the nanosecond to ten microsecond timescales all of which can be imaged directly with DTEM.

**9:48AM A12.00004 Understanding subcellular function on the nanometer scale in real time: Single-molecule imaging in living bacteria** , JULIE BITEEN, Univ of Michigan - Ann Arbor — It has long been recognized that microorganisms play a central role in our lives. By beating the diffraction limit that restricts traditional light microscopy, single-molecule fluorescence imaging is a precise, noninvasive way to sensitively probe position and dynamics, even in living cells. We are pioneering this super-resolution imaging method for unraveling important biological processes in live bacteria, and I will discuss how we infer function from subcellular dynamics (Tuson and Biteen, *Analytical Chemistry* 2015). In particular, we have understood the mechanism of membrane-bound transcription regulation in the pathogenic *Vibrio cholerae*, revealed an intimate and dynamic coupling between DNA mismatch recognition and DNA replication, and measured starch utilization in an important member of the human gut microbiome.

**10:24AM A12.00005 Orbital-specific mapping of chemical dynamics with ultrafast x-rays** , PHILIPPE WERNET, Helmholtz-Zentrum Berlin — Charge and spin density changes at the metal sites of transition-metal complexes and in metalloproteins determine reactivity and selectivity. To understand their function and to optimize complexes for photocatalytic applications the changes of charge and spin densities need to be mapped and ultimately controlled. I will discuss how time-resolved soft x-ray spectroscopy enables a fundamental understanding of local atomic and intermolecular interactions and their dynamics on atomic length and time scales of Ångströms and femtoseconds. The approach consists in using time-resolved, atom- and orbital-specific x-ray spectroscopy and quantum chemical theory to map the frontier-orbital interactions and their evolution in real time of ultrafast chemical transformations. We recently used femtosecond resonant inelastic x-ray scattering (RIXS, the x-ray analog of resonant Raman scattering) at the x-ray free-electron laser LINAC Coherent Light Source (LCLS, Stanford, USA) to probe the reaction dynamics of a transition-metal complex in solution on the femtosecond time scale. Spin crossover and ligation are found to define the excited-state dynamics. It is demonstrated how correlating orbital symmetry and orbital interactions with spin multiplicity allows for determining the reactivity of short-lived reaction intermediates. I will discuss how this complementary approaches that probe structural dynamics and how it can be extended to map the local chemical interactions and their dynamical evolution in metalloproteins.

**Monday, March 14, 2016 8:00AM - 11:00AM –**  
**Session A13 GQI: Quantum Characterization, Verification and Validation** 309 - Charles Tahan, Laboratory for Physical Sciences

**8:00AM A13.00001 Estimating the coherence of noise** , JOEL WALLMAN, Univ of Waterloo — To harness the advantages of quantum information processing, quantum systems have to be controlled to within some maximum threshold error. Certifying whether the error is below the threshold is possible by performing full quantum process tomography, however, quantum process tomography is inefficient in the number of qubits and is sensitive to state-preparation and measurement errors (SPAM). Randomized benchmarking has been developed as an efficient method for estimating the average infidelity of noise to the identity. However, the worst-case error, as quantified by the diamond distance from the identity, can be more relevant to determining whether an experimental implementation is at the threshold for fault-tolerant quantum computation. The best possible bound on the worst-case error (without further assumptions on the noise) scales as the square root of the infidelity and can be orders of magnitude greater than the reported average error. We define a new quantification of the coherence of a general noise channel, the unitarity, and show that it can be estimated using an efficient protocol that is robust to SPAM. Furthermore, we also show how the unitarity can be used with the infidelity obtained from randomized benchmarking to obtain improved estimates of the diamond distance and to efficiently determine whether experimental noise is close to stochastic Pauli noise.

**8:36AM A13.00002 Gate-set tomography and beyond** , ROBIN BLUME-KOHOUT, Sandia National Laboratories — Four years ago, there was no reliable way to characterize and debug quantum gates. Process tomography required perfectly pre-calibrated gates, while randomized benchmarking only yielded an overall error rate. Gate-set tomography (GST) emerged around 2012-13 in several variants (most notably at IBM; see PRA 87, 062119) to address this need, providing complete and calibration-free characterization of gates. At Sandia, we have pushed the capabilities of GST well beyond these initial goals. In this talk, I'll demonstrate our open web interface, show how we characterize gates with accuracy at the Heisenberg limit, discuss how we put error bars on the results, and present experimental GST estimates with  $1e-5$  error bars. I'll also present preliminary results of GST on 2-qubit gates, including a brief survey of the tricks we use to make it possible. I'll conclude with an analysis of GST's limitations (e.g., it scales poorly), and the techniques under development for characterizing and debugging larger (3+ qubit) systems.

**9:12AM A13.00003 Toward a new culture in verified quantum operations** , STEVE FLAMMIA, University of Sydney — Measuring error rates of quantum operations has become an indispensable component in any aspiring platform for quantum computation. As the quality of controlled quantum operations increases, the demands on the accuracy and precision with which we measure these error rates also grows. However, well-meaning scientists that report these error measures are faced with a sea of non-standardized methodologies and are often asked during publication for only coarse information about how their estimates were obtained. Moreover, there are serious incentives to use methodologies and measures that will continually produce numbers that improve with time to show progress. These problems will only get exacerbated as our typical error rates go from 1 in 100 to 1 in 1000 or less. This talk will survey existing challenges presented by the current paradigm and offer some suggestions for solutions that can help us move toward fair and standardized methods for error metrology in quantum computing experiments, and towards a culture that values full disclosure of methodologies and higher standards for data analysis.

**9:48AM A13.00004 Applying QCVV protocols to real physical systems.**<sup>1</sup> , EASWAR MAGESAN, IBM TJ Watson Research Center — As experimental systems move closer to realizing small-scale quantum computers with high fidelity operations, errors become harder to detect and diagnose. Verification and validation protocols are becoming increasingly important for detecting and understanding the precise nature of these errors. I will outline various methods and protocols currently used to deal with errors in experimental systems. I will also discuss recent advances in implementing high fidelity operations which will help to understand some of the tools that are still needed on the road to realizing larger scale quantum systems.

<sup>1</sup>Work partially supported by ARO under contract W911NF-14-1-0124

**10:24AM A13.00005 Applying benchmarking protocols to encoded qubits with non-Markovian errors** , SETH MERKEL, HRL Laboratories, LLC. — An essential goal for any quantum information processing platform is to develop the tools necessary to validate high-fidelity quantum gates. This effort has produced a suite of benchmarking and tomographic protocols that have been applied to a wide variety of physical implementations. All these protocols, however, were designed with strict error assumptions that can and will be violated by physical errors, especially as we push to lower and lower error rates. In this talk we look at randomized benchmarking with encoded states (from which leakage errors may occur) in the presence of non-Markovian noise and under the influence of sequence-length dependent filtering errors. These circumstances may apply to a variety of physical systems, but are particularly pertinent for  $1/f$  charge noise and hyperfine leakage noise in electrically controlled quantum dot qubits. We demonstrate how these errors affect the outcome of randomized benchmarking, including the signatures of said errors and the confidence with which we can report an average gate fidelity.

**Session A14 FHP: Peer Review: History and Issues** 310 - Robert Crease, Stony Brook University

**8:00AM A14.00001 Plagiarism and Trust in Peer Review** , MARIO BIAGIOLI, University of California, Davis — No abstract available.

**8:36AM A14.00002 The Curious Origins of the Scientific Referee** , ALEX CSISZAR, Department of the History of Science, Harvard University — Where did the figure of the scientific referee come from, and why? Beginning in the 1820s, in the midst of reform movements in English science and in English politics, a number of British scientific societies established formal systems for reading and reporting on manuscripts by special readers, who soon became known as referees. In this personage came to be juxtaposed elements of the legal expert, the trustworthy gentleman, the state bureaucrat, and even the anonymous literary reviewer. But when the scientific referee appeared on the scene of British science, it was not certain who he was, or what he was supposed to be for. The initial impetus for the Royal Society of London's referee system had been as much about generating publicity as making anonymous judgments. But gradually the referee report became shrouded in secrecy, and the referee was increasingly viewed as an agent for conferring rewards on authors in exchange for contributions to knowledge. The conception of the referee as primarily a gatekeeper of knowledge became dominant only later in the century, as scientific practitioners came to perceive the existence of a special set of texts called the scientific literature that could be marked off from other periodicals and which required protecting. The notion that some form of peer review – as it came to be known during the Cold War – was a *sine qua non* of legitimate scientific journals was an even later development.

**9:12AM A14.00003 In Referees We Trust? Controversies over Grant Peer Review in the Late Twentieth Century** , MELINDA BALDWIN, Harvard University — While many accounts of external refereeing assume that it has been a consistent part of science since the seventeenth century, the practice developed far more slowly and haphazardly than many observers realize, and it was not until after the Second World War that "peer review" became considered an essential part of scientific publishing or grant-making. This talk will explore refereeing procedures at American grant-giving organizations in the twentieth century, focusing especially on the National Science Foundation and the National Institutes of Health. The creators of the NSF and the NIH put refereeing systems in place at their foundation. However, the form and function of these systems differed from modern "peer review" in several important ways. At the NSF the initial purpose of the referee process was to advise the NSF program directors, not to dictate funding decisions. At the NIH, small "study sections" devoted to particular subjects made recommendations to the NIH leadership, which rendered final judgments. However, beginning in the 1960s a series of controversies about NIH and NSF grants placed refereeing procedures at these organizations under more intense scrutiny. These debates culminated in six days of Special Oversight Hearings into the NSF's peer review process in the summer of 1975. Following the hearings, both the NSF and NIH reformed their review processes to place more emphasis on referees' opinions about grant proposals, making peer review increasingly responsible for decision-making. These controversies illustrate that refereeing continued to undergo significant changes in form and purpose throughout the twentieth century, and further suggest that both the scientific community and the public placed increased emphasis on the role of the referee during the late twentieth century.

**9:48AM A14.00004 Where is the trust in the peer review dynamic?** , DANIEL UCKO<sup>1</sup>, Stony Brook University/American Physical Society APS — The motto of the Royal Society is "nullius in verba", which translates roughly as "take nobody's word for it", and this motto is furthermore emblematic of the conduct of science. We want facts and not opinions, verified results and not conjecture. From the time that we first started communicating scientific results, it has been recognized that scientific claims must be verified by someone who is not the maker of those claims, and who furthermore has no stake in the matter, in other words, a claim needs to be evaluated objectively. Peer review as a method of evaluation can be thought of as akin to an experiment, where the review process tests the hypothesis of a submitted paper. Peer review is however also a social process with human actors: authors, referees, and editors. As a process, peer review depends on trust, but in what way does that manifest? There are many agents in peer review: in addition to the human actors, there is also the institution that is the journal, as well as the publisher (e.g. APS) that stands behind the journal. People can also have trust in the very concept of peer review. If we accept as a proposition that publications are witnesses to science in the same way that people who attend scientific demonstrations are witnesses of an experiment, then how much do we trust this witness? A few further questions arise:

- If referees (and sometimes authors) are anonymous, what does this do to the mechanisms of trust?
- Is trust only possible between human agents, or can you trust a process or a journal in a similar way to trusting a certain car brand?
- Is an absence of trust the same as distrust?
- Is trust rational, or cognitive, or is it a practice?

In this paper I will attempt to locate the trust and ask how trust is earned, and, conversely, how it can be lost, using peer review as example.

<sup>1</sup>I have a joint affiliation with Stony Brook University and APS and would like both listed, in that order, in the abstract

**Session A15 DCMP DMP: Graphene: Quantum Hall Effect** 314 - Paul Campbell, Naval Research Laboratory

**8:00AM A15.00001 Valley Hall Effect in the presence of strain fluctuation in graphene systems<sup>1</sup>** , WENYU SHAN, DI XIAO, Carnegie Mellon University — We develop a theory of valley Hall transport in graphene on hexagonal boron nitride substrate, where the strain-induced random gauge potential becomes the dominant source of disorder. We find a large value (if not quantized) of valley Hall conductivity in the band transport regime, for a wide class of strain-fluctuation modes. Such exotic property is a consequence of a generic enhanced coordinate shift under vector disorder scattering for Dirac systems. When applied to monolayer or bilayer graphene, our theory reproduces the large valley Hall angle and finite-temperature behaviors of valley Hall conductivity observed in experiments. Our theory provides an alternative interpretation of experimental results for nonlocal transport in graphene, instead of previous understanding based on the equilibrium current in ground state.

**8:12AM A15.00002 Observation of fractional Bloch band quantum Hall states in graphene/h-BN superlattices**, LEI WANG, Physics, Cornell University, YUANDA GAO, Mechanical Engineering, Columbia University, BO WEN, Physics, Columbia University, JAMES HONE, Mechanical Engineering, Columbia University, CORY DEAN, Physics, Columbia University — The Hofstadter energy spectrum provides a uniquely tunable system to study emergent topological order in the regime of strong interactions. Previous experiments, however, have been limited to low Bloch band fillings where only the Landau level index plays a role. Here we report measurements of high mobility graphene superlattices where the complete unit cell of the Hofstadter spectrum is accessible. We observe coexistence of conventional fractional quantum Hall effect (QHE) states together with the integer QHE states associated with the fractal Hofstadter spectrum. At large magnetic field, we observe signatures of another series of states, which appears at fractional Bloch filling index. These fractional Bloch band QHE states are not anticipated by existing theoretical pictures and point towards a distinct type of many-body state.

**8:24AM A15.00003 Spin and valley resolved Landau level crossing in tri-layer ABA stacked graphene.**, BISWAJIT DATTA, Tata Institute of Fundamental Research, Mumbai, India, VISHAKHA GUPTA, Birla Institute of Technology & Science, Pilani, Goa campus, Tata Institute of Fundamental Research, Mumbai, India, ABHINANDAN BORAH, Tata Institute of Fundamental Research, Mumbai, India, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, MANDAR DESHMUKH, Tata Institute of Fundamental Research, Mumbai, India — We present quantum Hall measurements on a high quality encapsulated tri-layer graphene device. Low temperature field effect mobility of this device is around  $500,000 \text{ cm}^2/\text{Vs}$  and we see SdH oscillations at a magnetic field as low as 0.3 T. Quantum Hall measurements confirm that the chosen tri layer graphene is Bernal (ABA) stacked. Due to the presence of both mass-less monolayer like Dirac fermions and massive bi-layer like Dirac fermions in Bernal stacked tri-layer graphene, there are Landau level crossings between monolayer and bi-layer bands in quantum Hall regime. Although most of the Landau Level crossings are predominantly present on the electron sides, we also observe signatures of the crossings on the hole side. This behaviour is consistent with the asymmetry of electron and hole in ABA tri-layer graphene. We observe a series of crossings of the spin and valley resolved Landau Levels.

**8:36AM A15.00004 Landau Level Crossings in Dual-Gated Bilayer Graphene at Large Displacement Fields**, CHENG PAN, YONG WU, BIN CHENG, SHI CHE, CHUN NING LAU, MARC BOCKRATH, University of California, Riverside — Previous work shows that Landau levels in bilayer graphene with the same orbital index  $N$  but different spin and valley degrees of freedom can form superpositions at a finite electric field[1-2]. Using the technique of one dimensional edge contacts[3] we fabricate dual-gated boron-nitride-encapsulated bilayer graphene device with a graphite local gate, which enables us to apply large electric fields and observe Landau level crossings between levels with neighboring orbital indices. We will discuss our latest results. [1] R. T. Weitz et al., Science 330, 812-816 (2010). [2] K. Lee et al., Science 345, 58-61 (2014). [3] L. Wang et al., Science 342, 614-617 (2013)

**8:48AM A15.00005 Quantum Hall Effect in Bernal-stacked tetralayer graphene**, YANMENG SHI, SHI CHE, TIMOTHY ESPIRITU, ZIQI PI, Department of Physics and Astronomy, University of California Riverside, Riverside, CA 91765, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, 1-1 Namiki, Tsukuba, Japan, CHUN NING LAU, Department of Physics and Astronomy, University of California Riverside, Riverside, CA 91765 — Bernal-stacked few layer graphene is of particular interest due to its unique tunable band structure. Here we study the electric transport of Bernal-stack tetralayer graphene that are encapsulated by boron nitride sheets. The device shows a clear Landau fan with multiple Landau level crossing features. We will present the dependence of its quantum Hall properties on electric and magnetic fields, and compare with theoretical calculations.

**9:00AM A15.00006 Quantum Hall resistance standard in graphene devices under relaxed experimental conditions**, F. SCHOPFER, R. RIBEIRO-PALAU, F. LAFONT, J. BRUN-PICARD, LNE, D. KAZAZIS, Laboratoire de Photonique et de Nanostructures, CNRS, A. MICHON, Centre de Recherche sur l'Hétéroépitaxie et ses Applications, CNRS, F. CHEYNIS, Aix Marseille Université, CNRS, CINAM, O. COUTURAUD, C. CONSEJO, B. JOUAULT, Laboratoire Charles Coulomb, CNRS, Montpellier Université, W. POIRIER, LNE — Large-area and high-quality graphene devices synthesized by CVD on SiC are used to develop reliable electrical resistance standards, based on the quantum Hall effect (QHE), with state-of-the-art accuracy of  $1 \times 10^{-9}$  and under an extended range of experimental conditions of magnetic field (down to 3.5 T), temperature (up to 10 K) or current (up to 0.5 mA). These conditions are much relaxed as compared to what is required by GaAs/AlGaAs standards and will enable to broaden the use of the primary quantum electrical standards to the benefit of Science and Industry for electrical measurements. Furthermore, by comparison of these graphene devices with GaAs/AlGaAs standards, we demonstrate the universality of the QHE within an ultimate uncertainty of  $8.2 \times 10^{-11}$ . This suggests the exact relation of the quantized Hall resistance with the Planck constant and the electron charge, which is crucial for the new SI to be based on fixing such fundamental constants. These results show that graphene realizes its promises and demonstrates its superiority over other materials for a demanding application. Nature Nanotech. 10, 965-971, 2015, Nature Commun. 6, 6806, 2015

**9:12AM A15.00007 Scaling behavior of the quantum Hall plateau-plateau transition in graphene p-n-p junctions**, WEI-HUA WANG, IAMS, Academia Sinica, CHENG-HUA LIU, National Taiwan University, PO-HSIANG WANG, Academia Sinica, TAK-PONG WOO, CHUN-WEI CHEN, CHI-TE LIANG, National Taiwan University — We present the observation of scaling behavior in graphene p-n-p junctions achieved by controlled metallic diffusion. Generally, metal deposition on graphene surface introduces substantial carrier scattering, which undermines the high mobility of intrinsic graphene. However, we discover a weakly functionalized regime of the deposited contact with small carrier scattering, while p-type doping of graphene is realized due to the metal oxide formation. Consequently, the resulted graphene channel are composed of p-type doped and an intrinsic regions. The high-quality graphene p-n-p junctions is evidenced by a pronounced quantum Hall effect and Shubnikov-de Haas oscillations. Remarkably, we observed a well-defined QH plateau-plateau transition of zeroth Landau level, yielding a scaling exponent of  $\kappa = 0.21 \pm 0.01$ . Moreover, the graphene p-n-p junctions exhibit weak localization behavior, and the coherence length was found to be correlated to carrier scattering in the graphene devices.

**9:24AM A15.00008 Landau Level Mixing in the  $\nu = 0$  Quantum Hall State of Graphene<sup>1</sup>**, BRADEN FESHAMI, HERBERT FERTIG, Department of Physics, Indiana University — The  $\nu = 0$  quantum Hall state in graphene has been the focus of many studies over the last several years. Recent experimental developments have allowed for the possibility of tuning the strength of the Zeeman interaction by tilting a graphene sample in the presence of an external magnetic field. Many of the theoretical frameworks for these systems involve projecting into the zeroth Landau level (LL) and specifying effective interaction parameters to simplify the calculation. We explore the effects of keeping a larger number of LLs, allowing for the possibility of Landau level mixing, within a self-consistent Hartree-Fock theory of the system. We include a SU(4) symmetric, Coulombic-like, interaction, and introduce microscopic on-site and nearest-neighbor interactions. Phase diagrams are constructed over a range of these two microscopic interaction strengths for different magnetic field strengths and Zeeman couplings.

**9:36AM A15.00009 Unconventional Quantum Hall Edge-Bulk Correlation in Gated Graphene Devices**, YONG-TAO CUI, Stanford University, BO WEN, Columbia University, ERIC MA, GEORGI DIANKOV, Stanford University, ZHENG HAN, Columbia University, FRANCOIS AMET, Stanford University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, DAVID GOLDBABER-GORDON, Stanford University, CORY DEAN, Columbia University, ZHI-XUN SHEN, Stanford University — The quantum Hall effect in a two dimensional electron system (2DES) has been understood as chiral edge states circulating a highly insulating bulk when the bulk Landau levels are completely filled. We combine edge-sensitive charge transport with scanning Microwave Impedance Microscopy that probes the bulk transition through Landau levels, to directly examine such edge-state picture in gated graphene devices. Surprisingly, comparison of these measurements reveals that quantized transport typically occurs below complete filling of bulk Landau levels, different from the conventional picture in semiconductor-based 2DESs. We suggest that gate-induced charge accumulation near edges leads to a complex edge state configuration in which counter-propagating edge states could exist at the same edge. The backscattering between these states, together with an incompressible strip separating the bulk and the edge region, can explain the observed deviations.

**9:48AM A15.00010 Collective Bulk and Edge Modes through the Quantum Phase Transition in Graphene at  $\nu = 0$** <sup>1</sup>, GANPATHY MURTHY, University of Kentucky, EFRAT SHIMSHONI, Bar-Ilan University, Israel, HERBERT FERTIG, Indiana University, Bloomington — Undoped graphene in a strong, tilted magnetic field exhibits a radical change in conduction upon changing the tilt-angle, which can be attributed to a quantum phase transition[1] from a canted antiferromagnetic (CAF) to a ferromagnetic (FM) bulk state at filling factor  $\nu = 0$ . This behavior signifies a change in the nature of the collective ground state and excitations across the transition. Using the time-dependent Hartree-Fock approximation, we study the collective neutral (particle-hole) excitations in the two phases, both in the bulk and on the edge of the system[2]. The CAF has gapless neutral modes in the bulk, whereas the FM state supports only gapped modes in its bulk. At the edge, however, only the FM state supports gapless charge-carrying states. Linear response functions are computed to elucidate their sensitivity to the various modes. The response functions demonstrate that the two phases can be distinguished by the evolution of a local charge pulse at the edge[3]. 1. M. Kharitonov, Phys. Rev. B **85**, 155439 (2012). 2. G. Murthy, E. Shimshoni, and H. A. Fertig, Phys. Rev. B **90**, 241410(R) (2014). 3. G. Murthy, E. Shimshoni, and H. A. Fertig, arxiv:1510.04255 (2015).

**10:00AM A15.00011 Observation of helical edge states and fractional quantum Hall effect in a graphene electron-hole bilayer**, JASON YUANHONG LUO, JAVIER SANCHEZ-YAMAGISHI, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute of Materials Science, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology — 1D electronic systems are common theoretical building blocks for constructing quantum circuits, motivating a search for new experimental systems where 1D edge states of different quantum numbers can be coupled to each other by design. Twisted bilayer graphene allows for the stacking of two separate 1D quantum hall edge states, thus providing a natural sandbox for studying different types of edge state interactions. Via doping to form an electron-hole bilayer at moderate magnetic fields, we can induce edge modes of opposite chiralities and spin polarizations on different layers, thereby creating helical edge states reminiscent of a two-dimensional quantum spin Hall system. We report magnetotransport measurements of high-quality twisted bilayer graphene, showing how non-local measurements allow us to elucidate the nature and robustness of the helical edge states, as well as hints of fractional edge state interactions that are observable at higher magnetic fields.

**10:12AM A15.00012 Emergence of Helical Edge Conduction in Graphene in the  $\nu = 0$  Quantum Hall State**<sup>1</sup>, HERBERT FERTIG, Indiana University, PAVEL TIKHONOV, EFRAT SHIMSHONI, Bar-Ilan University, GANPATHY MURTHY, University of Kentucky — The conductance of graphene subject to a strong, tilted magnetic field exhibits a dramatic change with tilt-angle, interpreted as an evidence for the transition from a canted antiferromagnetic (CAF) to a ferromagnetic (FM)  $\nu = 0$  quantum Hall state. We develop a theory for the electric transport in this system based on the spin-charge connection, whereby the evolution in the nature of collective spin excitations throughout this quantum phase transition is reflected in the charge-carrying modes. To this end we study quantum fluctuations of the spin-valley configuration in a system with an edge, and derive an effective theory describing collective charge edge excitations coupled to neutral bulk excitations. Focusing particularly on the FM phase, naively expected to exhibit perfect conductance due to the emergence helical edge modes, we analyze the mechanism whereby the coupling to bulk excitations assists in generating back-scattering. Finally, we calculate the conductance as a function of temperature and the Zeeman energy the parameter that tunes the transition between the two phases.

**10:24AM A15.00013 Edge State Structure of the  $\nu = 0$  quantum Hall State in monolayer Graphene**, ANGELIKA KNOTHE, Universite Paris-Sud 11 and University of Freiburg, THIERRY JOLICOEUR, Universite Paris-Sud 11 — Single-layer graphene at neutrality under a magnetic field is a many-body insulator whose phase structure is under intense scrutiny. When tilting the applied magnetic field, there is a phase transition towards a conducting state. A plausible description is to start from a SU(4) spin-valley symmetric quantum Hall ferromagnet and add some lattice-scale anisotropies in valley space. In the manifold of ground states captured by this approach, it has been proposed that graphene undergoes a transition between a canted antiferromagnetic state and a ferromagnetic state. While this picture is clear in the bulk of the system, it remains to understand the effect of this phase change on the current-carrying edge states that are formed at the physical boundaries of a real sample. We use an extended Hartree-Fock approach to describe a finite-size system with a simple model for the edge and extract the one-body spectrum. We then describe the current-carrying edge textures.

**10:36AM A15.00014 Andreev reflection in edge states of time reversal invariant Landau levels**, K. G. S. H. GUNAWARDANA, Ames Laboratory, Iowa State University, BRUNO UCHOA, University of Oklahoma — We describe the conductance of a normal-superconducting junction in systems with Landau levels that preserve time-reversal symmetry. Those Landau levels have been observed in strained honeycomb lattices. The current is carried along the edges in both the normal and superconducting regions. When the Landau levels in the normal region are half filled, the Andreev reflection is maximal and the conductance plateaus have a peak as a function of the filling factor. The height of those peaks is quantized at  $4e^2/h$ . The interface of the junction has Andreev edge states, which form a coherent superposition of electrons and holes that can carry a net valley current. We identify unique experimental signatures for superconductivity in time-reversal-invariant Landau levels.

**10:48AM A15.00015 Andreev conversion of quantum Hall edge state in graphene**, GIL-HO LEE, SEAN HART, DI WEI, KATIE HUANG, Harvard University, DMITRI EFETOV, MIT, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS, AMIR YACOBY, PHILIP KIM, Harvard University — Understanding the interplay between superconductivity (SC) and quantum Hall effect (QHE) has been a long-sought theoretical and experimental problem. SC contacts to QHE systems enable us to study interesting physics, such as Cooper pair injection into ballistic 2D channels, Andreev edge states, and emergent excitations of non-Abelian anyons. We developed an in-situ etching technique for highly transparent superconducting contact (NbN) to hBN encapsulated graphene channels. The high critical field of NbN electrodes ( $H_{c2} > 30$  T) and the high quality of our graphene devices allows us to experimentally access a wide range of magnetic field where SC and QHE coexist. In order to probe the Andreev conversion of QH edge states, we measure the chemical potential of normal electrodes located on the upstream and the downstream QH edge states relative to a narrow grounded superconducting electrode. We observed that the chemical potential in downstream has sign opposite to the one measured in upstream suggesting Andreev conversion of incident electrons to outgoing holes across the narrow superconducting contact. We systematically investigated this phenomena as a function of temperature, magnetic field, bias voltage and the width and length of the superconducting electrode.

**8:00AM A16.00001 On-Chip High-Responsivity Graphene–Boron Nitride Photodetector Integrated with Si Waveguide**, YUANDA GAO, Columbia University, REN-JYE SHUIE, DIRK ENGLUND, Massachusetts Institute of Technology, JAMES HONE, Columbia University — Graphene and other two-dimensional (2D) materials have emerged as promising materials for broadband and high-speed photodetection [1] and optical modulation [2]. These optoelectronic capabilities can augment complementary metal–oxide– semiconductor (CMOS) devices for high-speed and low-power optical interconnects. Here, we demonstrate an on-chip ultrafast photodetector based on a two-dimensional heterostructure consisting of high-quality graphene encapsulated in hexagonal boron nitride. Coupled to the optical mode of a silicon waveguide, this 2D heterostructure-based photodetector exhibits a maximum responsivity of 0.36 A/W and high-speed operation with a 3 dB cutoff at 42 GHz [3]. From photocurrent measurements as a function of the top-gate and source-drain voltages, we conclude that the photoresponse is consistent with hot electron mediated effects. 1. Gan, X. et al. Chip-integrated ultrafast graphene photodetector with high responsivity. *Nat. Photonics* 7, 883–887 (2013). 2. Gao, Y. et al. High-Responsivity Graphene–Boron Nitride Photodetector and Autocorrelator in a Silicon Photonic Integrated Circuit. *Nano Lett.* Article ASPA

**8:12AM A16.00002 Buckled Graphene-like Materials in Ultrafast and Superstrong Optical Fields**, HAMED KOOCHAKI KELARDEH, VADYM APALKOV, MARK STOCKMAN, Georgia State University — We discuss the theoretical investigation of buckled Dirac materials (silicene and germanene) interacting with ultrashort and ultrastrong optical pulses. Highly intensive few-cycle fields strongly modify the electronic and optical properties of these two dimensional materials. The strong nonlinearity of the system for the fields applied ( $V/\text{\AA}$ ), will cause the violation of the charge (C) and parity (P) and time reversal symmetries. Such symmetry violations are related to the electron transfer between the sublattices produced by the normal field component and result in nonreciprocity, optical rectification and the appearance of a cross current. We also note a direct resemblance between silicene and field-effect transistors (FET). In FETs, the (perpendicular) gate field changes the carrier concentration and thereby, controls its conductance. Analogously, in silicene, the normal field component of the pulse, transfers carriers between two sublattices, and consequently modulates the response function of silicene to the in-plane field. **Reference:** H. K. Kelardeh, V. Apalkov, and M. I. Stockman, *Ultrafast field control of symmetry, reciprocity, and reversibility in buckled graphene-like materials*, *Phys. Rev. B* **92** (4), 045413 (2015).

**8:24AM A16.00003 Optical Detection of Local Electric Field Dynamics in Solutions by Waveguide-integrated Graphene Device**, JASON HORNG, HALLEH BALCH, UC Berkeley, FENG WANG TEAM — The spatio-temporal dynamics of local electric fields in ionic solutions plays a central role in various chemical and biological processes ranging from batteries technologies to neuron signaling. A non-invasive, precise detection scheme for measuring local electric fields dynamics has long been sought for. Here, we report a sensitive, high-speed, high spatial resolution optical imaging method for local electric fields based on the unique optoelectronic properties of graphene. With enhancement from a waveguide involving critical coupling concept, we show that our graphene optical sensor provides an ideal platform for studying dynamics of local electric field fluctuations in different nonequilibrium solutions.

**8:36AM A16.00004 Passive optical switches based on endohedral fullerenes**, YONGCHANG DONG, Clemson Univ, DEEPIKA SAINI COLLABORATION, LUIS A. ECHEGOYEN COLLABORATION, RAMAKRISHNA PODILA COLLABORATION — Although there have been many attempts to find better nanomaterial-based optical limiters & switches in recent years, currently there are only a few effective options for high-energy lasers. Reverse saturable absorption in fullerenes has been widely used to realize excellent passive optical limiters for the visible region up to 650 nm. The electronic structure of fullerenes can be modified by the encapsulation of endohedral clusters to achieve exotic quantum states of matter such as superconductivity. Building on this concept, in this talk, we show that three tri-metallic nitride endohedral fullerenes could alter the HOMO-LUMO gap and allow passive optical switching with a low limiting threshold ( $0.3 \text{ J/cm}^2$ ) and a wider operation window up to 1064 nm (average pulse energy  $>0.5 \text{ mJ}$  in ns regime).

**8:48AM A16.00005 Kirigami Graphene Transistors for Biological Sensing**, MICHAEL REYNOLDS, Cornell University, MORGAN BROWN, Oregon State University, KATHRYN MCGILL, PATRICIA DAVIDSON, JAN LAMMERDING, Cornell University, ETHAN MINOT, Oregon State University, JESSE GOLDBERG, PAUL MCEUEN, Cornell University — As flexible, locally amplifying probes, graphene transistors have potential applications in biological sensing, particularly for read-out of extracellular potentials. We present here electrolyte-gating measurements of stretchable graphene transistors aimed at exploring this application. The graphene is etched into patterns inspired by the Japanese paper art of kirigami to permit in-plane stretching<sup>1</sup>. Using a technique developed in our group for manipulating these devices in solution, we can maneuver and stretch devices in an electrolyte solution while monitoring their electrical response. These devices show proximity-dependent gating to voltages on an additional small metal probe near the device, and we quantify the nature and sensitivity of this response. The flexibility of these devices makes them promising as wearable electronics for cells, and we present early results on interactions between graphene devices and cardiomyocyte cells.

**9:00AM A16.00006 Nanopores in suspended WS<sub>2</sub> membranes for DNA sequencing**, GOPINATH DANDA, Department of Electrical and Systems Engineering, University of Pennsylvania, PAUL MASIH DAS, YUNG-CHIEN CHOU, JEROME MLACK, CARL NAYLOR, Department of Physics and Astronomy, University of Pennsylvania, NESTOR PEREA-LOPEZ, ZHONG LIN, Department of Physics, The Pennsylvania State University, LAURA BETH FULTON, Department of Mechanical Engineering, University of Pittsburgh, MAURICIO TERRONES, Department of Physics, The Pennsylvania State University, A. T. CHARLIE JOHNSON, MARIJA DRNDIC, Department of Physics and Astronomy, University of Pennsylvania — Recent advances in solid-state nanopore sensor systems for DNA detection and analysis have been supported by using increasingly thinner materials to the point of utilizing atomically thin two-dimensional materials such as graphene and MoS<sub>2</sub>. However, these materials still have issues with pore wettability and signal-to-noise ratios displayed in DNA translocation measurements. Recently, the fabrication and operation of nanopores in MoS<sub>2</sub> have been demonstrated, but the wetting properties and signal-to-noise ratios of transition metal dichalcogenides are yet to be understood and further improved. Here we fabricate suspended WS<sub>2</sub> nanopore devices with sub-10 nm pore diameters using a novel nanomaterial transfer method and TEM nanosculpting to study and better understand nanopore wetting properties and performance in DNA translocation measurements.

**9:12AM A16.00007 Electronic nanobiosensors based on two-dimensional materials<sup>1</sup>**, JINGLEI PING, Univ of Pennsylvania — Atomically-thick two-dimensional (2D) nanomaterials have tremendous potential to be applied as transduction elements in biosensors and bioelectronics. We developed scalable methods for synthesis and large-area transfer of two-dimensional nanomaterials, particularly graphene and metal dichalcogenides (so called “MX<sub>2</sub>” materials). We also developed versatile fabrication methods for large arrays of field-effect transistors (FETs) and micro-electrodes with these nanomaterials based on either conventional photolithography or innovative approaches that minimize contamination of the 2D layer. By functionalizing the FETs with a computationally redesigned water-soluble mu-opioid receptor, we created selective and sensitive biosensors suitable for detection of the drug target naltrexone and the neuropeptide enkephalin at pg/mL concentrations. We also constructed DNA-functionalized biosensors and nano-particle decorated biosensors by applying related bio-nano integration techniques. Our methodology paves the way for multiplexed nanosensor arrays with all-electronic readout suitable for inexpensive point-of-care diagnostics, drug-development and biomedical research. With graphene field-effect transistors, we investigated the graphene/solution interface and developed a quantitative model for the effect of ionic screening on the graphene carrier density based on theories of the electric double layer. Finally, we have developed a technique for measuring low-level Faradaic charge-transfer current (fA) across the graphene/solution interface via real-time charge monitoring of graphene microelectrodes in ionic solution. This technique enables the development of flexible and transparent pH sensors that are promising for *in vivo* applications.

**9:48AM A16.00008 Enhancing the performance of Graphene NEMS<sup>1</sup>**, MARSHA PARMAR, Indian Inst of Science — In recent past Nanoelectromechanical systems (NEMS) have got several sensing based applications such as force, spin, charge and mass sensors. These devices due to their smaller size, operate in very high frequency regime (MHz - GHz) and have very high quality factors (10<sup>2</sup> -10<sup>5</sup>). Nevertheless these devices are limited by their comparatively smaller linear operational range. Electromechanical devices based on 2D materials are extremely sensitive to strain. We studied the effect of strain on the performance of single layer Graphene NEMS. Our results reveal that the strain in Graphene NEMS can be tuned to increase the linear operational range. We report a 25 dB increase in dynamic range by tuning the strain from 10<sup>-3</sup> at room temperature to 10<sup>-2</sup> at 200K. This increase in dynamic range is also accompanied by partial cancellation of elastic and electrostatic nonlinearities. The resulting mass resolution estimated from the experimental data is 100 yg.....<sup>1</sup> which is one order of magnitude better than previously reported values. Reference: 1. Parmar, M. M., Gangavarapu, P. R. Y. & Naik, A. K. Dynamic range tuning of graphene nanoresonators. *Applied Physics Letters* **107**, 113108 (2015).

**10:00AM A16.00009 Biosensors based on DNA-Functionalized Graphene**, RAMYA VISHNUBHOTLA, JINGLEI PING, AMEY VRUDHULA, A.T. CHARLIE JOHNSON, Univ of Pennsylvania — Since its discovery, graphene has been used for sensing applications due to its outstanding electrical properties and biocompatibility. Here, we demonstrate the capabilities of field effect transistors (FETs) based on CVD-grown graphene functionalized with commercially obtained DNA oligomers and aptamers for detection of various biomolecular targets (e.g., complementary DNA and small molecule drug targets). Graphene FETs were created with a scalable photolithography process that produces arrays consisting of 50-100 FETs with a layout suitable for multiplexed detection of four molecular targets. FETs were characterized via AFM to confirm the presence of the aptamer. From the measured electrical characteristics, it was determined that binding of molecular targets by the DNA chemical recognition element led to a reproducible, concentration-dependent shift in the Dirac voltage. This biosensor class is potentially suitable for applications in drug detection. This work is funded by NIH through the Center for AIDS Research at the University of Pennsylvania.

**10:12AM A16.00010 Direct observation of PMMA removal from graphene surface**, XIAOHAN WANG, HARRY CHOU, LI TAO, ANDREW DICK, ANDREI DOLOCAN, DEJI AKINWANDE, C. GRANT WILLSON, Univ of Texas, Austin — PMMA is often used as a carrier layer for transfer of CVD graphene from copper to other substrates. After transfer, the PMMA is removed by chemical or thermal treatment. However, regardless of the method used, polymer residues are left on the graphene surface, which degrade the performance of graphene-based devices. Here, we present a systematic study of PMMA removal after graphene transfer. Raman and FET measurements were applied to monitor the polymer dissolution in an acetone bath. Isotope labeling and in-situ TOF-SIMS, XPS, Raman and AFM all show chemical changes in surface residues upon vacuum annealing. These data along with strategies to clean the graphene surface will be presented.

**10:24AM A16.00011 Carbon nanotube as a local drag sensor**, AUSTIN CHENG, Harvard University, JEAN-DAMIEN PILLET, Columbia University, PHILIP KIM, Harvard University — We report a Columb drag measurement in a carbon nanotube (CNT) and graphene hybrid device. In this device, the CNT and graphene serve as a 1D and 2D electronic system respectively and are separated by a thin hexagonal boron nitride (h-BN). By flowing a drive current in one conductor, due to electron-electron interactions, a drag voltage is developed in the other conductor. In the case where a current is applied to graphene, the CNT can act as a local drag sensor that probes the microscopic effects of electronic interactions hidden in graphene. We demonstrate this drag sensor capability by applying a magnetic field in graphene and show the transition from compressible states to incompressible states.

**10:36AM A16.00012 Amino Acids Interaction with Boron Nitride Nanomaterials**, KEVIN WATERS, RAVINDRA PANDEY, Michigan Technological University, SHASHI KARNA, US Army Research Laboratory — Stability and electronic properties of bioconjugated BN nanostructures are investigated. The biomolecules considered are amino acids ranging from monomers to peptides, and the low- dimensional BN nanostructures are monolayer and tubular configurations. Specifically, we examine the role of an aqueous background in stabilizing such bioconjugated nanostructures by employing the continuum solvent model. It is expected that the calculated results will provide guidance for selective sensing of biomolecules by the next generation nanomaterials.

**10:48AM A16.00013 Biomolecular interactions of emerging two-dimensional materials with aromatic amino acids**, SAI SUNIL KUMAR MALLINENI<sup>1</sup>, MEHMET KARAKAYA<sup>2</sup>, RAMAKRISHNA PODILA<sup>3</sup>, APPARAO RAO<sup>4</sup>, None — The present work experimentally investigates the interaction of aromatic amino acids, viz., tyrosine, tryptophan, and phenylalanine with novel two-dimensional (2D) materials including graphene (G), graphene oxide (GO), and boron nitride (BN). Photoluminescence, micro-Raman spectroscopy and cyclic voltammetry were employed to investigate the nature of interactions and possible charge transfer between 2D materials and amino acids. Consistent with previous theoretical studies<sup>[1,2]</sup>, graphene and BN were observed to interact with amino acids through  $\pi$ - $\pi$  interactions. Furthermore, we found that GO exhibits strong interactions with tryptophan and tyrosine as compared to graphene and BN, which we attribute to the formation of H-bonds between tryptophan and GO as shown theoretically in Ref. 2. On the other hand, phenylalanine did not exhibit much difference in interactions with G, GO, and BN.(1) The Journal of Chemical Physics 130, 124911 (2009) (2) J. Phys. Chem. Lett. 2013, 4, 3710–3718

**Monday, March 14, 2016 8:00AM - 10:48AM –**

**Session A17 DMP: Graphene: Growth and Synthesis** 316 - Joshua Robinson, Pennsylvania State University

**8:00AM A17.00001 Materials Science and Engineering with Two-dimensional Atomic Layers**

, PULICKEL M. AJAYAN, Rice University — There has been tremendous interest in recent years to study two-dimensional atomic layers which form building blocks of many bulk layered materials and devices. This talk will focus on the materials science aspects of 2D atomic layer, in particular the emerging structures based on transition metal chalcogenides. Several aspects that include synthesis, characterization and device fabrication will be explored with the objective of achieving all 2D functional structures for future technologies. The concept of nanoscale engineering and the goal of creating new artificially stacked van der Waals solids will be discussed through a number of examples. The challenges involved in scalable synthesis, doping, defect engineering, surface modifications of monolayers and the controlled creation of stacked structures and in-plane junctions from multiple compositions will be discussed. Some of anticipated applications of these materials will also be discussed.

**8:36AM A17.00002 Large area single crystalline graphene growth on copper foil**, JAEHYUCK JUNG,

HOANG DANH PHAN, LEE CHANGGU, Sungkyunkwan Univ, GRAPHENE ENGINEERING LAB TEAM — Graphene synthesis methods using chemical vapor deposition (CVD) have been developed dramatically in these years but still it is challenging to make large size single crystal grains which have similar properties with pristine graphene. Here we report a pita-pocket method of growing large area single crystalline graphene on copper foil. We made holes on top of the closed copper pocket to provide stable gas flow inside of pocket, and copper domains with (111) crystal orientation, which gives an advantage for hexagonal graphene crystal growth, were formed continuously during synthesis. Liquid crystal analysis and electron backscatter diffraction (EBSD) were used to observe the copper crystallographic orientation. Also we compared with a traditional pocket method and an opened flat copper foil method. Graphene from the other methods had poly-crystallinity with different orientation in contrast to graphene from the hole-pocket method.

**8:48AM A17.00003 Strain-Engineering the Gauge Potential of Dirac fermions in PECVD-grown Graphene**, CHEN-CHIH HSU, MARCUS TEAGUE, JAIQING WANG, NAI-CHANG YEH, Dept. of Physics, Caltech — Non-trivial strain can induce pseudo-magnetic fields in graphene so that the electronic properties of Dirac fermions can be tuned by controlling the strain on graphene. Here we employ nearly strain-free single-domain PECVD-graphene<sup>1</sup> to induce controlled strain by placing graphene on nanostructured substrates. Strain-induced gauge potentials and pseudo-magnetic fields can be manifested by the local tunneling conductance peaks at quantized energies.<sup>2,3</sup> Additionally, pseudo-magnetic field-induced local spontaneous time-reversal symmetry breaking can be revealed by spatially alternating presence and absence of the zero mode in the tunneling conductance spectra.<sup>2,3</sup> We also employ molecular dynamics simulations to determine the spatial distribution of the pseudo-magnetic field for a given nanostructure. We find that a tetrahedron-like nanostructure can be an effective valley splitter to separate the trajectories of Dirac fermions of opposite pseudo-spins. Proper design and arrangement of several valley filters can function as a valley propagator to guide valley-polarized currents. We plan to verify the valley Hall effect associated with a valley splitter and to assess the feasibility of realistic valleytronic applications. 1. D.A. Boyd et al. Nat. Comm. 6, 6620 (2015). 2. **9:00AM A17.00004 ABSTRACT WITHDRAWN –**

**9:12AM A17.00005 SPALEED Studies of the Growth of Zero to Mono-layer Graphene on SiC(0001)<sup>1</sup>**, M. HUPALO, Ames Laboratory, M. T. HERSHBERGER, Iowa State University and Ames Laboratory, H. HATTAB, Ames Laboratory, D. C. MCDUGALL, Iowa State University and Ames Laboratory, M. HORN VON HOEGEN, University of Duisburg-Essen, M. C. TRINGIDES, Iowa State University and Ames Laboratory — The growth of graphene on SiC was studied in detail with SPA LEED to understand the transition from zero to monolayer graphene with increasing temperature starting at 1200C. Both the changing diffraction spots with annealing and their line shapes are studied in detail until a fully completed monolayer is obtained with only 6x6 spots remaining. In particular we focus on two strong features not investigated previously: (i) superstructures spots at  $\pi/13$  locations present between the specular and the graphene spots. These spots are possibly related to different coincidence lattices before graphene locks into its final 6x6 orientation. (ii) The presence of a very broad background intensity covering ~60% of the BZ both around the specular and graphene spots whose origin is still unknown. Detailed studies of the dependence of this background component on energy and comparison between the graphene and specular spots suggest that the origin is not due to the standard variation with electron energy, i.e. a  $g(s)$  curve caused by the topography. Throughout the literature this broad background has been seen in graphene grown in different types of substrates. We comment on possible reasons for the origin of the background.

<sup>1</sup>Ames Laboratory is operated by the US-DOE under Contract No. DE-AC02-07CH11358.

**9:24AM A17.00006 Growth of Graphene on Cu Single Crystal Substrates**, TYLER MOWLL, ENG

WEN ONG, University at Albany-SUNY, PARUL TYAGI, Global Foundries, ZACHARY ROBINSON, College at Brockport-SUNY, CARL VENTRICE, SUNY Polytechnic Institute — A common technique for synthesizing single-layer graphene films is CVD on Cu foil substrates. However, the presence of crystalline defects in the CVD graphene films results in a reduction in the transport properties. In order to achieve a better understanding of the influence of the surface termination of the Cu substrate on the crystallization of graphene during the CVD process, a systematic study of graphene growth on Cu(100), Cu(110), and Cu(111) crystals has been performed. The graphene synthesis is done in a UHV chamber that has been modified to perform graphene growth at pressures as high as 100 mTorr. The precursor gas used is ethylene. This growth procedure allows for the preparation of the clean Cu surfaces in UHV, growth under typical CVD conditions, and characterization of the graphene in UHV, without exposing the sample to atmospheric contaminants. Our results indicate that the surface termination of the Cu substrate has a strong influence on the decomposition rate of the ethylene and the rotational alignment of the graphene grains as they nucleate on each surface. For Cu(111), single-domain graphene growth can be achieved for ethylene pressures of 5 mTorr or less. For both Cu(100) and Cu(110), a minimum of two graphene domains is always observed.

**9:36AM A17.00007 Strain sensing through the optical properties of graphene: Comparing indentation of epitaxial- and CVD-grown graphene**, ERIN L. WOOD, YANFEI YANG, NIST, Gaithersburg, MD, USA, WILL GANNETT, NIST, Boulder, CO, USA, GORDON A. SHAW, RANDOLPH E. ELMQUIST, NIST, Gaithersburg, MD, USA, MARK W. KELLER, NIST, Boulder, CO, USA, ANGELA R. HIGHT WALKER, NIST, Gaithersburg, MD, USA — The unprecedented mechanical and electrical properties of graphene have garnered great interest, yet critical understanding of deformation processes is needed before robust devices are realized. Raman spectroscopy is an information rich, non-destructive probe of mechanical, structural, and electrical properties of graphene through analysis of the prominent bands; D, G, and G'. Previous reports on strained graphene have been largely limited to graphene transferred to flexible substrates and have produced divergent results regarding shifting and splitting in the G band. To systematically evaluate strain, we compare as-grown graphene on either Cu or SiC to the blank substrates which are well understood. Strain was applied by micro- or nano-indentation and Raman mapping was collected of the deformed area providing validation of the applied strain. Confocal Raman microscopy is diffraction limited, however, and localized strain cannot be spatially resolved at the nanoscale. To overcome this, an AFM probe was co-located within the Raman laser focus to obtain sub-diffraction spatial resolution. This also increases the sensitivity to the surface, allowing for observation of the D peak within a micron of nano-indents, which was unseen in confocal Raman spectroscopy.

**9:48AM A17.00008 Oxygen-Activated Growth and Bandgap Tunability of Large Single-Crystal Bilayer Graphene** , YUFENG HAO, JAMES HONE, columbia univerisity, RODNEY RUOFF, UNIST, LUIGI COLOMBO, Texas Instruments, THE HONE GROUP TEAM — Distinct from zero-bandgap single-layer graphene, Bernal-stacked bilayer graphene (BLG) is a semiconductor whose bandgap can be tuned by a transverse electric field, making it a unique material for a number of electronic and photonic devices. In this presentation, we will focus on the most recent progress in the identification of new growth mechanisms towards large-area single-layer BLG on Copper: multiple control experiments and first-principles calculations are used to support the proposed mechanisms. We emphasize that trace amount of impurities on metal surface are critical to initiate graphene growth and affect the growth kinetics. Furthermore, contrary to the traditional viewpoint that graphene growth is always surface-limited process, our new observations strongly suggest that metal bulk plays a role to feed carbon species for graphene growth. State-of-the-art structural characterizations and electrical transport measurements of the CVD graphene layers will be presented as well.

**10:00AM A17.00009 In-Situ Measurements of Graphene Mechanics During Annealing** , AARON HUI, ROBERTO DE ALBA, ABHILASH SEBASTIAN, JEEVAK PARPIA, Cornell University — Graphene shows great potential as a material for a new generation of mechanical nanodevices. However, current methodologies used for fabricating graphene structures involve polymer resists for transfer and patterning, which degrades mechanical performance. To improve surface quality, high current or high temperature annealing of graphene is commonly employed. Previous studies of graphene mechanics have focused on performance after annealing or temperature-dependent behavior from 4K-300K. Here we present real-time, in-situ measurements of graphene mechanical resonance during high temperature annealing from 300K-600K. Upon heating, reversible changes in mechanical frequency are indicative of graphene thermal contraction. Discontinuous and irreversible changes are also seen, corresponding to graphene slipping and mass desorption. Both reversible and irreversible changes in quality factor are also observed. Characterizing the effects of annealing on the structural properties of graphene will enable more precise engineering for particular applications, such as mass sensing.

**10:12AM A17.00010 Effective structural properties in polycrystalline graphene** , ZUBAER HOSSAIN, University of Delaware — This talk will discuss effective structural properties in polycrystalline graphene under the presence of atomic scale heterogeneity. Polycrystallinity is ubiquitous in solids, but theories describing their effective behavior remain limited, particularly when heterogeneity is present in the form of nonuniform deformation or composition. Over the decades, exploration of the effective transport and strength properties of heterogeneous systems has been carried out mostly with random distribution of grains or regular periodic structures under various approximations, in translating the underlying physics into a single representative volume element. Although heterogeneity can play a critical role in modulating the basic behavior of low-dimensional materials, it is difficult to capture the local characteristics accurately by these approximations. Taking polycrystalline graphene as an example material, we study the effective structural properties (such as Young's Modulus, Poisson's ratio and Toughness) by using a combination of density functional theory and molecular dynamic simulations. We identify the key mechanisms that govern their effective behavior and exploit the understanding to engineer the behavior by doping with a carefully selected choice of chemical elements.

**10:24AM A17.00011 Pump-induced far-infrared reflection in quasi-intrinsic graphene** , MARTIN MITTENDORFF, RYAN J. SUESS, THOMAS E. MURPHY, University of Maryland, College Park, MD 20742, USA, HARALD SCHNEIDER, MANFRED HELM, STEPHAN WINNERL, Helmholtz-Zentrum Dresden-Rossendorf, D-01314 Dresden, Germany — We present an experimental far-infrared pump-probe study on multilayer epitaxial graphene that is complemented by a straightforward theoretical model. To gain deeper insights into the pump-induced change in the complex conductivity in the far-infrared, pump-probe measurements recording both transmission and reflection were performed. These measurements reveal a pump-induced increase of the transmission at low pump fluence, and a decreased transmission at high pump fluence due to a strong pump-induced reflection. Modelling the temperature dependent conductivity for interband and intraband processes in combination with an energy balance equation reproduces the observed results.

**10:36AM A17.00012 Atomic intercalation – a practical method to determine the nanoscale adhesion energy of graphene on HOPG<sup>1</sup>** , JUN WANG, Oak Ridge National Lab, DAN SORESCU, National Energy Technology Laboratory (NETL), U.S. Department of Energy, SEOKMIN JEON, ALEXEI BELIANINOV, SERGEI KALININ, ARTHUR BADDORF, PETRO MAKSYMOVYCH, Oak Ridge National Lab — A detailed analysis of atomic intercalates in graphite provides a direct estimate of the nanoscale elastic adhesion of a graphene sheet atop highly ordered pyrolytic graphite (HOPG). Atomic intercalation is carried out using conventional ion sputtering, creating “blisters” in the top-most layer of the HOPG surface. Scanning tunneling microscopy coupled with image analysis and density functional theory is used to reconstruct the atomic positions and the strain map within the deformed graphene sheet. To estimate the adhesion energy we invoke an analytical model originally devised for macroscopic deformations of graphene. This model yields a value of  $0.221 \pm 0.011 J/m^2$  for the adhesion energy of graphite, which is in surprisingly good agreement with reported experimental and theoretical values. This implies that mechanical properties of graphene scale at least to lengths of a few nanometers. The simplicity of our method enables analysis of elastic mechanical properties in many two-dimensional layered materials and provides a unique opportunity to investigate the local variability of mechanical properties on the nanoscale.

## Monday, March 14, 2016 8:00AM - 11:00AM – Session A18 GMAG DMP FIAP: Spin-Hall I 317 - Arne Brataas, Norwegian University

**8:00AM A18.00001 In-plane current induced spin orbit effects in nanometer scale Hall bar of  $\beta$ -W/Ta/CoFeB/MgO/Ta multilayers<sup>1</sup>** , AVYAYA J. NARASIMHAM, State University of New York, Albany, YU-MING HUNG, Department of Physics, New York University, MENG ZHU, SUNY Polytechnic Institute, Albany , ANDREW D. KENT, Department of Physics, New York University, VINCENT P.LABELLA, SUNY Polytechnic Institute, Albany — The giant spin Hall effect (GSHE) is caused by spin orbit interactions in a semiconductor or metal that result in a spin current that is transverse to the charge current. Recent spin Hall effect studies in the beta phase metals Ta and W show that transverse spin currents are strong enough to switch an adjacent magnetic layer. Films with perpendicular magnetic anisotropy (PMA) can exhibit uniform magnetizations and higher thermal stability. Inserting a 1 nm Ta insert-layer between the CoFeB and W induces PMA which is confirmed by vibrating sample magnetometer and anomalous Hall voltage measurements.  $\beta$ -W(5)/Ta(1) channel and the adjacent CoFeB/MgO/Ta layers are patterned into a 100 nm wide Hall bar structures. Effect of in-plane current induced change in coercivity while sweeping in-plane magnetic field are studied. An empirical model to quantitatively understand the switching will be presented.

<sup>1</sup>SRC-NRI-INDEX -Spin Logic

**8:12AM A18.00002 Spin Orbit Torque in TbCo Films with Bulk Perpendicular Magnetic Anisotropy**, KOHEI UEDA, MAXWELL MANN, AIK-JUN TAN, GEOFFREY. S. D. BEACH, MIT — Spin-orbit torque (SOT) has generated considerable interest for manipulating magnetization in spintronic devices with ultra-low dissipation. Recent research has demonstrated that highly efficient magnetization control can be driven by current-induced SOT in ferromagnet/heavy metals bilayers with strong spin orbit coupling. However, most work on SOT has focused on ultra-thin magnetic films with interfacial perpendicular magnetic anisotropy (PMA), whereas future devices will require bulk PMA for sufficient thermal stability. Recently, Zhao et al reported SOT induced magnetization switching in a bulk PMA material; however, the films examined were still rather thin. Here we examine spin orbit torques in TbCo alloy films with bulk PMA, sandwiched between top and bottom Ta layers. By performing conventional harmonic and current-induced switching measurements, we quantified the current-induced effective fields generated by damping-like (DL) and field-like (FL) torques. The DL torque is much larger than FL torque, and corresponds to an effective spin Hall angle consistent with that of Ta. Owing to the relatively small saturation magnetized of these ferrimagnetic materials, the current-induced effective field is comparable to that observed in nm-thick Co films, despite the much larger film thicknesses used here. These results demonstrate ferromagnetic alloys with bulk PMA can be engineered to simultaneously provide thermal stability and efficient SOT switching.

**8:24AM A18.00003 Spin-orbit torque induced reversible coercivity change in Co/Pd multilayer thin films.**, SANDEEP KUMAR, Univ of California - Riverside — In this work we report reversible reduction in coercivity of Co/Pd multilayer thin films under high-density direct current biasing. We carried out in-situ focused magneto optic Kerr effect based hysteresis measurement while the specimen was under DC bias. The experiments show a reversible reduction in coercivity during the application of direct current. We propose this reduction occurs due to the spin-orbit torques (Rashba) generated at high current densities. Using an in-situ transmission electron microscope biasing experiment, we also showed the presence of dissymmetric lattice structure of Co/Pd multilayers. Our results suggest that the Rashba torque is the dominant spin-orbit torque since coercivity change is a bulk phenomenon as compared to spin Hall effect.

**8:36AM A18.00004 Novel current driven domain wall dynamics in synthetic antiferromagnets<sup>1</sup>**, SEE-HUN YANG, IBM Almaden Research Center — It was reported [1,2] that the domain walls in nanowires can be moved efficiently by electrical currents by a new type of torque, chiral spin torque (CST), the combination of spin Hall effect and Dzyaloshinskii-Moriya interaction. Recently we demonstrated that ns-long current pulses can move domain walls at extraordinarily high speeds (up to  $\sim 750$  m s<sup>-1</sup>) in synthetic antiferromagnetic (SAF) nanowires that have almost zero net magnetization [3], which is much more efficient compared with similar nanowires in which the sub-layers are coupled ferromagnetically (SF). This high speed is found to be due to a new type of powerful torque, exchange coupling torque (ECT) that is directly proportional to the strength of the antiferromagnetic exchange coupling between the two sub-layers, showing that the ECT is effective only in SAF not in SF. Moreover, it is found that the dependence of the wall velocity on the magnetic field applied along the nanowire is non-monotonic. Most recently we predict a Walker-breakdown-like domain wall precession in SAF nanowires in the presence of in-plane field based on the model we develop, and this extraordinary precession has been observed [4]. In this talk I will discuss this in details by showing a unique characteristics of SAF sublayers' DW boost-and-drag mechanism along with CST and ECT. <sup>1</sup> Novel current driven domain wall dynamics in synthetic antiferromagnets

**9:12AM A18.00005 Spin-Hall Switching of In-plane Exchange Biased Heterostructures**, MAXWELL MANN, GEOFFREY BEACH, Massachusetts Inst of Tech-MIT — The spin Hall effect (SHE) in heavy-metal/ferromagnet bilayers generates a pure transverse spin current from in-plane charge current, allowing for efficient switching of spintronic devices with perpendicular magnetic anisotropy [1,2,3,4]. Here, we demonstrate that an AFM deposited adjacent to the FM establishes a large in-plane exchange bias field, allowing operation at zero HIP. We sputtered Pt(3nm)/Co(0.9nm)/Ni80Co20O(tAF) stacks at room-temperature in an in-plane magnetic field of 3 kOe. The current-induced effective field was estimated in Hall cross devices by measuring the variation of the out-of-plane switching field as a function of JIP and HIP. The spin torque efficiency, dHSL/dJIP, is measured versus HIP for a sample with tAF=30 nm, and for a control in which NiCoO is replaced by TaOx. In the latter, dHSL/dJIP varied linearly with HIP. In the former, dHSL/dJIP varied nonlinearly with HIP and exhibited an offset indicating nonzero spin torque efficiency with zero HIP. The magnitude of HEB was 600 Oe in-plane. **9:24AM A18.00006 Few-nanosecond pulse switching with low write error for in-plane nanomagnets using the spin-Hall effect**, SRIHARSHA ARADHYA, GRAHAM ROWLANDS, SHENGJIE SHI, JUNSEOK OH, D. C. RALPH, ROBERT BUHRMAN, Cornell University — Magnetic random access memory (MRAM) using spin transfer torques (STT) holds great promise for replacing existing best-in-class memory technologies in several application domains. Research on conventional two-terminal STT-MRAM thus far has revealed the existence of limitations that constrain switching reliability and speed for both in-plane and perpendicularly magnetized devices. Recently, spin torque arising from the giant spin-Hall effect in Ta, W and Pt has been shown to be an efficient mechanism to switch magnetic bits in a three-terminal geometry [1-3]. Here we report highly reliable, nanosecond timescale pulse switching of three-terminal devices with in-plane magnetized magnetic tunnel junctions. We obtain write error rates (WER) down to  $\sim 10^{-5}$  using pulses as short as 2 ns, in contrast to conventional in-plane STT-MRAM devices where write speeds were limited to a few tens of nanoseconds for comparable WER. Utilizing micro-magnetic simulations, we discuss the differences from conventional MRAM that allow for this unanticipated and significant performance improvement. Finally, we highlight the path towards practical application enabled by the ability to separately optimize the read and write pathways in three-terminal devices. [1] L. Liu et al., Science, 336, 2012; [2] C-F. Pai et al., APL, 101, 2012; [3] M-H. Nguyen et al., APL, 106, 2015.

**9:36AM A18.00007 Magnetization dynamics in LSMO/Pt nanowires in the presence of spin orbit torques**, HANKYU LEE, IGOR BARSUKOV, CHRISTOPHER SAFRANSKI, ALEJANDRO JARA, YU-JIN CHEN, University of California, Irvine, ADRIAN SWARTZ, BONGJU KIM, GLAM, Stanford Univ., HAROLD HWANG, GLAM, Stanford Univ., SLAC Nat. Accel. Lab., ILYA KRIVOROTOV, University of California, Irvine — La<sub>0.7</sub>Sr<sub>0.3</sub>MnO<sub>3</sub> (LSMO) possesses attractive magnetic properties for nanowire spin torque oscillators (STOs) driven by spin orbit torques: low magnetic damping, low saturation magnetization and high spin polarization. In this context, good understanding of magnetization dynamics in LSMO/Pt bilayer nanowires is important. Here, we report measurements of the spectral properties of spin-wave modes in LSMO/Pt nanowires magnetized along the two principal in-plane axes. In electrically-detected ferromagnetic resonance (FMR) we observe excitation of multiple spin wave modes, including non-aligned modes when the nanowire is magnetized perpendicular to its axis. Spectral linewidth of the FMR resonances gives quantitative information on the Gilbert damping parameter of the nanowire. In comparison to extended LSMO/Pt films, the magnetic damping in the nanowire is reduced due to the suppression of two-magnon scattering. We will present data on the effect of high bias current density applied to the wire on the frequency and linewidth of the observed spin wave resonances.

**9:48AM A18.00008 Study of spin orbit torque switching in ferrimagnetic  $Gd_x(Fe_{90}Co_{10})_{100-x}$  alloy<sup>1</sup>**, NIKLAS ROSCHEWSKY, Department of Physics, University of California, Berkeley, TOMOYA MATSUMURA, TAKESHI KATO, Department of Electrical Engineering and Computer Science, Nagoya University Furo-cho, Chikusa-ku, SATOSHI IWATA, Advanced Measurement Technology Center, Nagoya University Furo-cho, Chikusa-ku, SURAJ CHEEMA, JAMES CLARKSON, Department of Materials Science and Engineering, University of California, Berkeley, SAYEED SALAHUDDIN, Department of Electrical Engineering and Computer Sciences, University of California, Berkeley — Magnetization switching in ferromagnetic metals (FM) with spin-orbit torques (SOT) is a well established technique. The SOT originates from spin accumulation at the interface of the FM generated by the spin Hall effect in an adjacent heavy metal. Here we report measurements of SOT in the alloy  $Gd_x(Fe_{90}Co_{10})_{100-x}$ , where the transition metal sub-lattice and the rare earth sub-lattice couple antiferromagnetically. By varying the composition  $x$  of the alloy we can tune the total magnetization. Anomalous Hall effect measurements are conducted to study the effect of SOT on the  $Gd_x(Fe_{90}Co_{10})_{100-x}$  magnetization.

<sup>1</sup>This work was supported by Department of Energy Basic Energy Sciences Award no DE -SC0012371

**10:00AM A18.00009 Nanowire spin Hall oscillators: width dependence**, ANDREW SMITH, Univ of California - Irvine, TOBIAS SCHNEIDER, Helmholtz-Zentrum Dresden - Rossendorf, Institute of Ion Beam Physics and Materials Research, Bautzner Landstrae 400, 01328 Dresden, German, LIU YANG, ILYA KRIVOROTOV, Univ of California - Irvine — We present experimental studies of auto-oscillatory magnetization dynamics in nanowire spin Hall oscillators (SHOs) as a function of the wire width ranging from 0.17  $\mu$ m to 2  $\mu$ m. These SHOs consist of long Pt(7 nm)/Py(5 nm)/AlOx(2 nm) wires on a sapphire substrate. Direct current generating anti-damping spin torque is applied to a section of the wire between two leads separated by a 2  $\mu$ m gap, which defines the SHO active region.<sup>1</sup> All devices show onset of auto-oscillations at similar critical current densities. For the 0.17  $\mu$ m and 0.34  $\mu$ m wide nanowire SHOs, auto-oscillatory modes arising from the bulk and edge eigenmodes of the nanowire are clearly seen in the emission spectra. For SHO devices based on wider wires, the bulk auto-oscillatory modes dominate the emission spectrum due to the larger wire volume occupied by the bulk modes. Our work demonstrates robust operation of nanowire-based SHOs over a wide range of nanowire widths and presents an example of a spin torque oscillator with the active area extended into the  $m^2$  domain. [1] Zheng Duan et al, Nature Communications 5, 5616 (2014)

**10:12AM A18.00010 Non-adiabatic spin-transfer torque independent of the spin relaxation rate**, KYOUNG-WHAN KIM, NIST - Natl Inst of Stds & Tech, KYUNG-JIN LEE, Korea University, HYUN-WOO LEE, POSTECH, MARK STILES, NIST - Natl Inst of Stds & Tech — Non-adiabatic spin-transfer torques play an important role in magnetization dynamics. For example, they determine current-induced magnetic domain wall velocity. A well-known mechanism for non-adiabatic spin-transfer torques arises from spin relaxation and is directly proportional to the spin relaxation rate. Here we report mechanism that is independent of the spin relaxation rate. This mechanism is related to the recently reported intrinsic damping-like spin-orbit torque, which is proportional to an electric field but is independent of the conductivity, and hence the scattering rate. Likewise, the mechanism we report is independent of the scattering rate. It originates from the effective spin-orbit coupling that arises in systems with magnetic textures as we previously reported for related processes. In this work, we demonstrate the existence of such a spin-transfer torque, which is a contribution to the non-adiabatic spin-transfer torque and is independent of scattering rates. We also demonstrate that the magnitude of this torque can be much larger than other mechanisms for non-adiabatic spin-transfer torques, and may be the dominant contribution in some systems.

**10:24AM A18.00011 Optical detection of spin Hall effect in metals**, OLAF VAN T ERVE, AUBREY HANBICKI, CONNIE LI, BEREND JONKER, Naval Research Lab — Spin Hall effects in metals have been successfully measured using electrical methods such as nonlocal spin valve transport, ferromagnetic resonance or spin torque transfer experiments. These methods require complex processing techniques and measuring setups. Here we present room temperature measurements of the spin Hall effect in non-magnetic metals such as Pt and  $\beta$ -W using a standard bench top magneto-optic Kerr effect (MOKE) system. With this system, one can readily determine the angular dependence of the induced polarization on the bias current direction. When a bias current is applied, the spin Hall effect causes electrons of opposite spin to be scattered in opposite directions, resulting in a spin accumulation at the surface of the film. The MOKE signal tracks the applied square wave bias current with an amplitude and phase directly related to the spin Hall angle. Using this technique, we show that the spin-Hall angle of  $\beta$ -W is opposite in sign and significantly larger than that of Pt. In addition, we use this technique to detect spin diffusion from  $\beta$ -W into Al thin films, as well as spin diffusion from the topological surface states of  $Bi_2Se_3$  into Al. We will also show direct modulation of the reflected light up to 100 kHz, using Bi doped Cu samples. This work was supported by internal programs at NRL.

**10:36AM A18.00012 Spin Hall magnetoresistance in ultra thin Pt/LSMO.**, NA LEI, Beihang University, YU BAI, ZHAO DING, JIAN SHAO, WENGANG WEI, LIFENG YIN, YIZHENG WU, JIAN SHEN, Fudan University — Spin Hall magnetoresistance (SMR) in a non-/ferro-magnetic (NM/FM) bilayer is an angular dependence of resistance of the NM layer on the magnetization of FM layer [1]. It provides an easy approach to the spin Hall effect in a simple bilayer system, however similar effects mixed in the system and might complicated the data analysis and interpretation. Here we present a case of ultra thin Pt/LSMO, in which LSMO (below 7 unit cells) layer is an insulating magnetic oxide with Curie temperature of 120K. Below 120K, our results clearly show the coexistence of the anisotropic magnetoresistance (AMR) and SMR effects. However, far away above Curie temperature, where the LSMO is paramagnetic, the magnetoresistance doesn't disappear but even increase, which is distinct from the case of Pt/YIG [2]. Here it is neither SMR nor AMR, and an additional mechanism is required. Anomalous Hall effect was also performed, which is consistent with SMR measurement. We propose some physical pictures which could attribute to this magnetoresistance in paramagnetic state. Reference: [1] H. Nakayama, M. Althammer, Y.-T. Chen, K. Uchida, et al., Phys. Rev. Lett. 110(20), 206601 (2013). [2] K. Uchida, Z. Qiu, T. Kikkawa, R. Iguchi, E. Saitoh, Appl. Phys. Lett. 106, 052405 (2015).

**10:48AM A18.00013 Spin Transport in Ferromagnetic and Antiferromagnetic Insulators<sup>1</sup>**, SHAN-SHAN SU, GEN YIN, YIZHOU LIU, Department of Electrical and Computer Engineering, University of California, Riverside, JIADONG ZANG, Department of Physics, University of New Hampshire, YAFIS BARLAS, Department of Physics and Astronomy, University of California, Riverside, ROGER LAKE, Department of Electrical and Computer Engineering, University of California, Riverside — Recently, experiments of spin pumping have been done for system with antiferromagnetic oxides (AFMOs) as a spacer between YIG and Pt [1-3]. Observation of spin transport through the AFMO and the enhancement of spin pumping signal in the system due to the insertion of AFMO have been reported [1,2]. In this research, we model the spin transport in Pt/YIG/Pt and Pt/YIG/AFMO/Pt heterostructures using the Landau-Lifshitz-Gilbert equations coupled with the non-equilibrium Green's function equations. We show that a pure spin current generated at the first Rashba SOC electrode is carried by magnon through YIG, which can be converted back to spin pumping signal at the second electrode. The spin dynamical details at the heterostructure can determine the transport efficiency. The effect of different magnetization orientations and finite temperatures will be addressed. [1]C. Hahn et al., EPL 108, 57005 (2014) [2]H. Wang et al., Phys. Rev. Lett. 113, 097202 (2014) [3]H. Wang et al., Phys. Rev. B 91, 220419 (2015)

**Session A19 GMAG DMP: Manganites and Cobaltites** 318 - Junjie Zhang, Argonne National Laboratory

**8:00AM A19.00001 Investigating short-range magnetism in strongly correlated materials via magnetic pair distribution function analysis and *ab initio* theory**, BENJAMIN FRANDSEN, Columbia University, KATHARINE PAGE, Oak Ridge National Laboratory, MICHELA BRUNELLI, European Synchrotron Radiation Facility, JULIE STAUNTON, University of Warwick, SIMON BILLINGE, Columbia University — Short-range magnetic correlations are known to exist in a variety of strongly correlated electron systems, but our understanding of the role they play is challenged by the difficulty of experimentally probing such correlations. Magnetic pair distribution function (mPDF) analysis is a newly developed neutron total scattering method that can reveal short-range magnetic correlations directly in real space, and may therefore help ameliorate this difficulty. We present temperature-dependent mPDF measurements of the short-range magnetic correlations in the paramagnetic phase of antiferromagnetic MnO, an archetypal strongly correlated transition-metal oxide. We observe significant correlations on a  $\sim 1$  nm length scale that differ substantially from the low-temperature long-range-ordered spin arrangement. With no free parameters, *ab initio* calculations using the self-interaction-corrected local spin density approximation of density functional theory quantitatively reproduce the magnetic correlations to a high degree of accuracy. These results yield valuable insight into the magnetic exchange in MnO and showcase the utility of the mPDF technique for studying magnetic properties of strongly correlated electron systems.

**8:12AM A19.00002 Magnetic Order in the Mixed-Spin Triangular Lattice Antiferromagnet  $\text{Na}_x\text{MnO}_2$** , ROBIN CHISNELL, DAN PARSHALL, NIST Center for Neutron Research, XIN LI, Harvard, AMBER LARSON, University of Maryland, TAKEHITO SUZUKI, JOSEPH CHECKELSKY, MIT, EFRAIN RODRIGUEZ, University of Maryland, JEFFREY LYNN, NIST Center for Neutron Research —  $\text{Na}_x\text{TMO}_2$  (TM = transition metal) materials consist of alternating layers of Na and TM ions with the TM ions arranged on a geometrically frustrated triangular lattice. Na can be easily and reversibly removed from these materials, making them of interest for application in rechargeable batteries and allowing for exploration of their rich phase diagrams as a function of Na concentration. Na ordering is an important factor in ground state selection, and is driven by electrostatic interactions in many  $\text{Na}_x\text{TMO}_2$  systems. The TM = Mn series differs in that Na ordering is driven by a cooperative Jahn-Teller effect, due to the coexistence of Jahn-Teller active  $\text{Mn}^{3+}$  and inactive  $\text{Mn}^{4+}$  ions. This effect also results in an ordered arrangement of the  $\text{Mn}^{3+}$  and  $\text{Mn}^{4+}$  ions, and thus of spin-2 and spin-3/2 moments. For  $x = 5/8$ , we have recently shown the coexistence of charge and magnetic stripe orderings [1]. Here, we present the results of neutron diffraction measurements performed on single crystal samples of  $\text{Na}_x\text{MnO}_2$  and discuss the details of the magnetic structure in the magnetically ordered phase.

**8:24AM A19.00003 Spin polarized scanning tunneling microscopy of bilayer manganite  $\text{La}_{2-2x}\text{Sr}_{1+2x}\text{Mn}_2\text{O}_7$  single crystals.**<sup>1</sup>, XINZHOU TAN, ALEX DE LOZANNE, JIANSI ZHOU, JOHN GOODENOUGH, Univ of Texas, Austin — We employ spin-polarized scanning tunneling microscopy to investigate the (001) surface of bilayer manganite  $\text{La}_{2-2x}\text{Sr}_{1+2x}\text{Mn}_2\text{O}_7$  single crystals with  $x = 0.32$  at various temperature and different magnetic fields. A spin reorientation transition (SRT) at this doping level starts around 70K, when the ferromagnetic spins change from out of plane to in plane configuration. Tracing the SRT while applying magnetic field along the c axis we are going to investigate the corresponding magnetic domain wall structure and motion in detail by spin polarized tunneling. Moreover, we are also going to search for the emergence of skyrmions near the same doping level.

**8:36AM A19.00004 ABSTRACT WITHDRAWN —**

**8:48AM A19.00005 Electronic, structural and magnetic properties of  $\text{LaMnO}_3$  phase transition at high temperature**, PABLO RIVERO, Louisiana State University, VINCENT MEUNIER, Rensselaer Polytechnic Institute, WILLIAM SHELTON, Louisiana State University — We have developed a theoretical approach for investigating systems that contain a range of correlation that varies with experimentally controlled parameters. We applied this method to the  $\text{LaMnO}_3$  compound [1,2,3] to accurately describe the antiferromagnetic (AFM) insulating ground-state, the metal-to-insulator transition and the high temperature ferromagnetic (FM) state, where we observe a half-metallic behavior. [1]: T. Saitoh, A. E. Bocquet, T. Mizokawa, H. Namatame, A. Fujimori, M. Abbate, Y. Takeda, and M. Takano, *Phys. Rev. B*, **13942** (1995). [2]: J. S. Zhou, and J. B. Goodenough, *Phys. Rev. B*, **R15002** (1999). [3]: J. Rodríguez-Carvajal, M. Hennion, F. Moussa, A. H. Mouden, L. Pinsard, and A. Revcolevschi, *Phys. Rev. B*, **R3189** (1998).

**9:00AM A19.00006 Spin wave damping in colossal magnetoresistive  $\text{La}_{0.7}\text{Ca}_{0.3}\text{MnO}_3$** , JOEL HELTON, SUSUMU JONES, US Naval Academy, MATTHEW STONE, Oak Ridge National Laboratory, DMITRY SHULYATEV, National University of Science and Technology "MISIS", DANIEL PARSHALL, JEFFREY LYNN, NIST Center for Neutron Research — The hole-doped perovskite  $\text{La}_{0.7}\text{Ca}_{0.3}\text{MnO}_3$  is best known for the colossal magnetoresistance displayed at a combined ferromagnetic and metal-insulator phase transition ( $T_C = 257$  K). Previous studies have reported that the spin wave excitations in the ferromagnetic phase become anomalously damped near the Brillouin zone boundary, though a later work suggested that this was a measurement artifact due to an optical phonon branch. We have used the ARCS time-of-flight neutron spectrometer to investigate the spin wave excitations of  $\text{La}_{0.7}\text{Ca}_{0.3}\text{MnO}_3$  at  $T = 100$  K and find a damping for spin waves at energies exceeding 20 meV that cannot be explained solely by proximity to the phonon branch. With additional measurements using the BT7 triple-axis neutron spectrometer, the spin wave damping is explored as a function of reduced wavevector, excitation energy, and temperature.

**9:12AM A19.00007 Biquadratic and ring exchange interactions in orthorhombic perovskite manganites**, NATALYA FEDOROVA, CLAUDE EDERER, NICOLA SPALDIN, Materials Theory, ETH Zurich, ANDREA SCARAMUCCI, Laboratory for Developments and Methods, Paul Scherrer Institut — We use *ab initio* electronic structure calculations within the GGA+U approximation to density functional theory (DFT) to determine the microscopic exchange interactions in the series of orthorhombic rare-earth manganites ( $\text{o-RMnO}_3$ ). Our motivation is to construct a model Hamiltonian (excluding effects due to spin-orbit coupling), which can provide an accurate description of the magnetism in these materials. First we map the exchange couplings for several representatives of  $\text{o-RMnO}_3$  series onto a Heisenberg Hamiltonian and find a clear deviation from the Heisenberg-like behavior. We demonstrate that this deviation can be explained only by the presence of relatively strong higher order exchange interactions (biquadratic and four-spin ring couplings) and show that they have the strongest effect in compounds, where nearest-neighbor exchange interactions are weakened due to the presence of large  $\text{GdFeO}_3$ -type distortion. Finally we discuss how these higher order terms determine magnetic ground states, influence magnetic excitations and define the multiferroic properties of  $\text{o-RMnO}_3$ .

**9:24AM A19.00008 Role of Entropy and Structural Parameters in the Spin State Transition of  $\text{LaCoO}_3$** , BISMAYAN CHAKRABARTI, TURAN BIROL, KRISTJAN HAULE, Rutgers, The State University of New Jersey — The spin state transition in  $\text{LaCoO}_3$  has eluded description for decades despite concerted theoretical and experimental effort. In this study, we approach this problem using fully charge consistent Density Functional Theory + Dynamical Mean Field Theory (DFT+DMFT). We show, from first principles, that  $\text{LaCoO}_3$  cannot be described by a single, pure spin state at any temperature, but instead shows a gradual change in the population of higher spin multiples as temperature is increased. We explicitly elucidate the critical role of the lattice expansion and oxygen octahedral rotations in the spin state transition. We also show that the spin state transition and the metal-insulator transition in the compound occur at different temperatures. In addition, our results shed light on the importance of electronic entropy, which has so far been ignored in all first principles studies of this material.

### 9:36AM A19.00009 LaCoO<sub>3</sub> (LCO) - Dramatic changes in Magnetic Moment in fields to 500T<sup>1</sup>

, Y. LEE, B. N. HARMON, Ames Laboratory, U.S. DOE and Dept. of Physics and Astronomy, Iowa State University — LCO has attracted great attention over the years (>2000 publications) because of its unusual magnetic properties; although in its ground state at low temperatures it is non-magnetic. A recent experiment<sup>[1]</sup> in pulsed fields to 500T showed a moment of  $\sim 1.3\mu_B$  above 140T, and above  $\sim 270T$  the magnetization rises, reaching  $\sim 3.8\mu_B$  by 500T. We have performed first principles DFT calculations for LCO in high fields. Our earlier calculations<sup>[2]</sup> explained the importance of a small rhombohedral distortion in the ground state that leads to a suppression of the  $1.3\mu_B$  moment for fields below  $\sim 140T$ . By allowing fairly large atomic displacements in high fields, moments of  $\sim 4\mu_B$  are predicted. [1] V. V. Platonov *et al.* Phys. Solid State **54**, 279 (2012) [2] Y. Lee and B. N. Harmon *et al.* J. Appl. Phys. **113**, 17E145 (2013)

### 9:48AM A19.00010 ABSTRACT WITHDRAWN —

10:00AM A19.00011 Interplay between frustration, magnetism and sodium vacancy ordering in Na<sub>0.84</sub>CoO<sub>2</sub>, STANISLAW GALESKI, KURT MATTENBERGER, BERTRAM BATLOGG, Laboratory for Solid State Physics, ETH Zurich, Switzerland — We have performed an extensive survey of low temperature specific heat of Na<sub>0.84</sub>CoO<sub>2</sub>. Heat capacity measurements were performed with an AC steady state method using a membrane nanocalorimeter. Thanks to the 10-30 nanogram sample mass we were able to perform well controlled ultra-fast cooling (500K/s) from high temperatures to temperatures where the sodium ions become immobile. This allowed us to take snapshots of different high temperature sodium configurations, relate them to particular structural transitions and at the same time establish their influence on the low temperature magnetic order. Through correlation with XRD data we demonstrate that the least ordered sodium configuration increases the T<sub>c</sub> of the 22K transition by 2K.

10:12AM A19.00012 Angle-resolved photoemission on the delafossite oxide metal PtCoO<sub>2</sub>, VERONIKA SUNKO, University of St Andrews, PALLAVI KUSHWAHA, Max Planck Institute for Chemical Physics of Solids, P.J.W. MOLL, Laboratory for Solid State Physics, ETH Zurich, Switzerland, L. BAWDEN, J.M. RILEY, University of St Andrews, NABHANILA NANDI, HELGE ROSNER, M.P. SCHMIDT, F. ARNOLD, E. HASSINGER, Max Planck Institute for Chemical Physics of Solids, T.K. KIM, M. HOESCH, Diamond Light Source, A.P. MACKENZIE, Max Planck Institute for Chemical Physics of Solids, P.D.C. KING, University of St Andrews — The delafossite structural series of oxides has recently attracted considerable attention because of the remarkable and varied properties of the compounds in the series. Here we consider the Pt-based 5d delafossite oxide PtCoO<sub>2</sub>, the most conductive oxide known [1]. From angle-resolved photoemission and density-functional theory, we show that the underlying Fermi surface is a single cylinder of nearly hexagonal cross-section, with very weak dispersion along k<sub>z</sub>. Despite being predominantly composed of d-orbital character, the conduction band is remarkably steep, with an average effective mass of only 1.14m<sub>e</sub>. Moreover, the sharp spectral features observed in photoemission remain well-defined with little additional broadening for over 500 meV below E<sub>F</sub>, pointing to suppressed electron-electron scattering. Together, our findings establish PtCoO<sub>2</sub> as a model nearly-free electron system and an ideal testbed for elucidating the ultrahigh conductivity in delafossite oxides. [1] Kushwaha P. *et al.*, Sci. Adv. **1**, 9 (2015)

10:24AM A19.00013 Theory for the Spin State and Spectroscopic Modes of Multiferroic CaBaCo<sub>4</sub>O<sub>7</sub><sup>1</sup>, RANDY FISHMAN, Oak Ridge National Laboratory, SANDOR BORDACS, ISTVAN KEZMARKI, VILMOS KOCIS, Budapest University of Technology and Economics, URMAS NAGEL, TOOMAS ROOM, National Institute of Chemical Physics Department, Y. TOKUNAGA, Y. TAKAHASHI, Y. TAGUCHI, Y. TOKURA, RIKEN Center for Emergent Matter Science — With alternating Kagome and triangular lattices, the type I multiferroic CaBaCo<sub>4</sub>O<sub>7</sub> is highly frustrated. Magnetic frustration produces a non-collinear, ferrimagnetic spin state with a net magnetic moment of about 1 m<sub>B</sub> along the b axis below 60 K. Based on the field dependence of the three observed spectroscopic modes between 0.8 and 2.7 THz and on the field dependence of the magnetization up to 14 T, we construct a microscopic model for this compound. Using the symmetry of the crystal, the model is constructed in terms of eight independent nearest-neighbor exchange interactions as well as both in-plane and easy-axis anisotropies. With three observed Co species (spins 1.45, 1.0, and 1.2), the magnetic unit cell contains 16 spins. Our results indicate that the easy-plane and hexagonal anisotropy in the triangular layers is far larger than the anisotropy in the kagome layers. The observed spin-induced polarization along the c axis is produced by magnetostriction. We also predict other spin-wave modes outside the window of the spectroscopic measurements.

10:36AM A19.00014 Investigation of the magnetic properties in double perovskite R<sub>2</sub>CoMnO<sub>6</sub> single crystals (R=rare earth: La to Lu)<sup>1</sup>, M. K. KIM, J. Y. MOON, H. Y. CHOI, S. H. OH, N. LEE, Y. J. CHOI, Yonsei Univ, LABORATORY FOR INNOVATIVE FUNCTIONAL MATERIALS TEAM — We have successfully synthesized the series of the double-perovskite R<sub>2</sub>CoMnO<sub>6</sub> (R=rare earth: La to Lu) single crystals and have investigated their magnetic properties. The ferromagnetic order of Co<sup>2+</sup>/Mn<sup>4+</sup> spins emerges mainly along the c axis. Upon decreasing the size of rare earth ion, the magnetic transition temperature decreases linearly from 204 K for La<sub>2</sub>CoMnO<sub>6</sub> to 48 K for Lu<sub>2</sub>CoMnO<sub>6</sub>, along with the enhancement of monoclinic distortion. The temperature and magnetic-field dependences of magnetization reveal the various magnetic characteristics such as the metamagnetic transition in R=Eu, the isotropic nature of rare earth moment in R=Gd, and the reversal of magnetic anisotropy in R=Tb and Dy. Our results offer comprehensive information for understanding the roles of mixed-valent magnetic ions and rare earth magnetic moments on the magnetic properties.

<sup>1</sup>R2CoMnO6 single crystals, double-perovskite, magnetic anisotropy, rare earth

10:48AM A19.00015 Enhanced magnetic coercivity and maximum energy product in double-perovskite Y<sub>2</sub>CoMnO<sub>6</sub> single crystals, HWAN YOUNG CHOI, S.H. OH, J.Y. MOON, M.K. KIM, D.G. OH, N. LEE, Y.J. CHOI, Yonsei university — We have investigated the influence of different annealing conditions on the magnetic properties on the single crystals of double-perovskite Y<sub>2</sub>CoMnO<sub>6</sub>. The ferromagnetic moment along the c-axis with the large magnetic coercivity and high squareness ratio was observed. Particularly, in the quenched specimen, the magnetic functionality has been greatly improved compared to that of the as-grown crystal. The magnetic coercivity and maximum energy product have been increased by  $\sim 120\%$  and  $\sim 50\%$ , respectively, by comprising substantial disorders and defects. Our result renders an efficient route to improve the magnetic functionality in mixed-valent magnets.

## 8:00AM A20.00001 Spin superfluidity and long-range transport in thin-film ferromagnets ,

HANS SKARSVÅG, CECILIA HOLMQVIST, ARNE BRATAAS, Norwegian University of Science and Technology (NTNU) — In ferromagnets, magnons may condense into a single quantum state. Analogous to superconductors, this quantum state may support transport without dissipation. Recent works suggest that longitudinal spin transport through a thin-film ferromagnet is an example of spin superfluidity. Although intriguing, this tantalizing concept ignores long-range dipole interactions; here, we demonstrate that such interactions dramatically affect spin transport.<sup>1</sup> In single-film ferromagnets, "spin superfluidity" only exists at length scales (a few hundred nanometers in yttrium iron garnet) somewhat larger than the exchange length. Over longer distances, dipolar interactions destroy spin superfluidity. Nevertheless, we predict the re-emergence of spin superfluidity in tri-layer ferromagnet–normal metal–ferromagnet films that are  $\sim 1\ \mu\text{m}$  in size. Such systems also exhibit other types of long-range spin transport in samples that are several micrometers in size.

## 8:12AM A20.00002 Magnetization dynamics in exchange coupled antiferromagnet spin superfluids<sup>1</sup> ,

YIZHOU LIU, Department of Electrical and Computer Engineering, Univ of California - Riverside, YAFIS BARLAS, Department of Physics and Astronomy, Univ of California - Riverside, GEN YIN, Department of Electrical and Computer Engineering, Univ of California - Riverside, JIADONG ZANG, Department of Physics and Material Science Program, University of New Hampshire, ROGER LAKE, Department of Electrical and Computer Engineering, Univ of California - Riverside — Antiferromagnets (AFMs) are commonly used as the exchange bias layer in magnetic recording and spintronic devices. Recently, several studies on the spin transfer torque and spin pumping in AFMs reveal much more interesting physics in AFMs. Properties of AFMs such as the ultrafast switching within picoseconds and spin superfluidity demonstrate the potential to build AFM based spintronic devices. Here, we study the magnetization dynamics in an exchange coupled AFM systems. Beginning from the Landau-Lifshitz-Gilbert equation, we derive a Josephson-like equation for the exchange coupled system. We investigate the detailed magnetization dynamics by employing spin injection and spin pumping theory. We also propose a geometry that could be used to measure this magnetization dynamics.

<sup>1</sup>This work was supported as part of the Spins and Heat in Nanoscale Electronic Systems (SHINES) an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award SC0012670.

## 8:24AM A20.00003 Superfluidity of magnons in ferromagnetic films ,

CHEN SUN, Texas A&M University, THOMAS NATTERMANN, University of Cologne, VALÉRY POKROVSKY, Texas A&M University, Landau Institute for Theoretical Physics — The magnon Bose-Einstein condensation in Yttrium Iron Garnet films at room temperature was discovered by the Münster experimental group (S.O. Demokritov) in 2006. Since the magnon condensate is coherent the natural question is whether the condensate is superfluid. Though the normal magnon density exceeds the condensate density in about 100 times, the velocity of the superfluid part is by 5-7 decimal orders larger than that of the normal part at the same field gradients. Thus, the spin current is dominated by the condensate, i.e. superfluid. A deeper obstacle is that the phase trapping is inconsistent with the free motion whose phase linearly depends on coordinate. The superfluidity can start only after submission of a finite (threshold) energy to the condensate by an external source. At energy close to threshold, the phase on long intervals of length remains close to the trapped values and changes by  $2\pi$  on a comparatively short intervals (phase solitons). The superfluid velocity remains almost zero between solitons and acquires finite value inside solitons. At large energy the superfluidity of magnons becomes close to a uniform flow.

## 8:36AM A20.00004 Two-Fluid Theory for Spin Superfluidity in Magnetic Insulators ,

BENEDETTA FLEBUS, Univ of Utrecht, SCOTT BENDER, YAROSLAV TSERKOVNÝAK, UCLA, REMBERT DUINE, Univ of Utrecht, UU TEAM, UCLA TEAM — We investigate coupled spin and heat transport in easy-plane magnetic insulators. These materials display a continuous phase transition between normal and condensate states that is controlled by an external magnetic field. Using hydrodynamic equations supplemented by Gross-Pitaevski phenomenology and magnetoelectric circuit theory, we derive a two-fluid model to describe the dynamics of thermal and condensed magnons, and the appropriate boundary conditions in a hybrid normal-metal–magnetic-insulator–normal-metal heterostructure. We discuss how the emergent spin superfluidity can be experimentally probed via a spin Seebeck effect measurement.

## 8:48AM A20.00005 Magneto-optical Phase Transition in a Nanostructured Co/Pd Thin Film<sup>1</sup> ,

CHIDUBEM NWOKOYE, LAWRENCE BENNETT, EDWARD DELLA TORRE, ABID SIDDIQUE, MING ZHANG, MICHAEL WAGNER, Institute for Magnetic Research, Department of Electrical and Computer Engineering, The George Washington University, Washington, DC 20052, USA, FRANK NARDUCCI, Naval Air Systems Command, Avionics, Sensors and E\*Warfare Department, Patuxent River, MD 20670, USA — Interest in the study of magnetism in nanostructures at low temperatures is growing. We report work that extends the magnetics experiments in [1] that studied Bose-Einstein Condensation (BEC) of magnons in confined nanostructures. We report experimental investigation of the magneto-optical properties, influenced by photon-magnon interactions, of a Co/Pd thin film below and above the magnon BEC temperature. Comparison of results from SQUID and MOKE experiments revealed a phase transition temperature in both magnetic and magneto-optical properties of the material that is attributed to the magnon BEC. Recent research in magnonics has provided a realization scheme for developing magnon BEC qubit gates for a quantum computing processor [2]. Future research work will explore this technology and find ways to apply quantum computing to address some computational challenges in communication systems. [1] Bennett L. H. and Della Torre, E. (2014) J. Mod. Phys. 5, 693. [2] Andrianov S. N. and Moiseev, S. A. (2014) Phys. Rev. A 90,042303.

## 9:00AM A20.00006 Bose-Einstein condensation of confined magnons in nanostructures: the first 30 years and some recent experiments ,

LAWRENCE BENNETT, EDWARD DELLA TORRE, CHIDUBEM NWOKOYE, ABID SIDDIQUE, MOHAMMADREZA GHAREMANI, Institute for Magnetic Research, Department of Electrical and Computer Engineering, The George Washington University, Washington, DC 20052, USA — The Bose-Einstein condensation (BEC) theory was proposed in 1924 by Bose and Einstein. They showed that a non-interacting gas of bosons condenses into a coherent BEC in which a macroscopic number of bosons occupy the lowest-energy single particle state below a critical temperature [1]. An extension of this phenomenon to magnons, spin-wave quanta that behave as bosonic quasiparticles, in magnetic nanoparticles has been observed [2,3]. The BEC of magnons has unique characteristics differentiating it from atomic BEC, creating the potential for a whole new variety of interesting behaviors and applications that include high temperature Bose-Einstein condensation and novel nanomagnetic devices. We report the review of the theoretical and experimental work done in the first 30 years and present recent experimental research related to the topic. [1] Bose, S. N. (1924) Zeitschrift für Physik, 26, 178; Einstein, A. and Sitzungsber. K. (1925) Preuss. Akad. Wiss., Phys. Math. Kl. 3. [2] Swartzendruber, L. J., Rugkwamsook, P., Bennett, L. H., and Della Torre, E. (2000) J. Appl. Phys., 87, 5684. [3] Bennett L. H., and Della Torre E. (2014) J. Mod. Phys., 5, 693.

**9:12AM A20.00007 Extinction of phase transition and spin transport on site diluted quantum two-dimensional antiferromagnet in Bose-Einstein condensation<sup>1</sup>**, LEONARDO DOS SANTOS LIMA, Departamento de Física e Matemática, Centro Federal de Educação Tecnológica de Minas Gerais — We study the two-dimensional Heisenberg antiferromagnetic model with ion single anisotropy in the square lattice in the presence of nonmagnetic impurities at  $T = 0$  using the SU(3) Schwinger boson theory. In particular, we discuss the influence of site disorder on the quantum phase transition of this model at  $D_c$  that separates the Néel phase,  $D < D_c$ , which is gapless, from the disordered phase, gapped phase,  $D > D_c$ . We find that the long-range order in  $D < D_c$  for the model without impurities is destroyed for a concentration of nonmagnetic impurities  $x_c \approx 0.15$ . We have studied also the spin transport of this model. In particular we discuss the influence of site disorder on the spin conductivity of the model and the influence of quantum phase transition on it. We find a large influence of the site dilution at the ac conductivity or continuum conductivity, and on the spin stiffness  $D_S$  that generates information about the dc conductivity. The point of extinction of  $D_c$  *withxdoesnotgenerateaninfluenceonthespinconductivity*.

**9:24AM A20.00008 Resonant x-ray magnetic diffraction of  $q = 0$  antiferromagnetic order in  $\text{Cd}_2\text{Os}_2\text{O}_7$  under high pressure**, YEJUN FENG, Argonne National Lab, YISHU WANG, California Institute of Technology, A. PALMER, The University of Chicago, J.-Q. YAN, D. MANDRUS, Univ. Tennessee and Oak Ridge National Lab, J.W. KIM, Argonne National Lab, T. F. ROSENBAUM, California Institute of Technology — The pyrochlore structured  $\text{Cd}_2\text{Os}_2\text{O}_7$  manifests a continuous metal-insulator transition at ambient pressure. Associated with the rise of the insulating phase is the formation of an all-in/all-out type of spin arrangement for Os ions on each tetrahedron unit, resulting in antiferromagnetic order with a  $q=0$  wave vector. The nature of the insulating phase is not understood due to the interplay of different degrees of freedom with almost degenerate energy scales characteristic of 5d transition metal compounds. Here we probe directly the pressure evolution of the antiferromagnetism using resonant x-ray magnetic diffraction techniques. We track the antiferromagnetic state to 18 GPa at 4 K, gradually suppressing the strength of the magnetic order and locating the boundary of an apparent continuous quantum phase transition.

**9:36AM A20.00009 Very large Rashba coupling by a staggered crystal field in the inversion-symmetric  $\text{BaNiS}_2$  semi-metal<sup>1</sup>**, ANDREA GAUZZI, DAVID SANTOS-COTTON, MICHELE CASULA, IMPMC-Sorbonne Universités, GABRIEL LANTZ, LPS-Université Paris Sud, YANNICK KLEIN, IMPMC-Sorbonne Universités, EVANGELOS PAPALAZAROU, MARINO MARSI, LPS-Université Paris Sud — By means of a single-crystal angular resolved photoemission spectroscopy study combined with first principles calculations, we give evidence of a giant Rashba coupling  $\alpha_R \approx 0.25$  eV Å leading to an energy splitting as large as  $\Delta\epsilon \approx 150$  meV in a novel situation of an inversion-symmetric system - the  $\text{BaNiS}_2$  semi-metal - composed of comparatively light elements. This finding is explained by a huge staggered crystal field  $\approx 1.4$  V/Å associated with a peculiar non-symorphic square-pyramidal structure, which produces a local inversion asymmetry at the Ni site. We show that this very effective mechanism of Rashba coupling enables large changes of the electronic structure of solids without using either heavy elements or external fields.

**9:48AM A20.00010 Low-temperature magneto-thermal conductivity of the helimagnet  $\text{Cu}_2\text{OSeO}_3$ <sup>1</sup>**, NARAYAN PRASAI, SUNXIANG HUANG, JOSHUA L. COHN, University of Miami, BENJAMIN TRUMP, GUY G. MARCUS, TYREL M. MCQUEEN, CHIA LING CHEN, Johns Hopkins University — We report measurements of thermal conductivity ( $\kappa$ ) in the range  $0.6 \text{ K} \leq T \leq 200 \text{ K}$  for single crystals of the helimagnetic insulator  $\text{Cu}_2\text{OSeO}_3$ . A maximum in  $\kappa$  near  $T = 8 \text{ K}$  with  $\kappa_{max} \sim 300 \text{ W/mK}$  implies a very high lattice quality for an oxide. The magneto-thermal conductivity at  $T \leq 10 \text{ K}$  and influence of spin-reorientation transitions associated with low- $T$  magnetic phases will be discussed for different orientations of the magnetic field relative to the crystallographic and heat flow directions.

<sup>1</sup>This material is based upon work supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Material Sciences and Engineering, under grants No. DEFG02-12ER46888 (Univ. Miami) and No. DEFG02-08ER46544 (Johns Hopkins Univ.)

**10:00AM A20.00011 Anisotropic RKKY and Dzyaloshinsky-Moriya interactions in a two-dimensional spin-polarized electron gas with Rashba and Dresselhaus spin-orbit coupling**, MOHAMMAD MAHDI VALIZADEH, SASHI SATPATHY, University of Missouri - Columbia — Chiral order in magnetic structures is currently an area of considerable interest and leads to such structures as the skyrmion lattice. The chiral structures originate from the Dzyaloshinsky-Moriya (DM) interactions caused by broken symmetry and the presence of the spin-orbit interaction. We study the indirect exchange interaction between two localized magnetic moments mediated by a spin-polarized 2DEG in the presence of both Rashba and Dresselhaus spin-orbit coupling. We find anisotropic RKKY and DM interactions, e. g., of the form  $J_1(S_{1x}S_{2x} + S_{1y}S_{2y}) + J_2S_{1z}S_{2z}$  in the former case, in the presence of a non-zero spin polarization. The magnitude of the vector and tensor DM interactions are estimated and compared to recent experiments on magnetic thin films.

**10:12AM A20.00012 Minimal Ingredients for Orbital Texture Switches at Dirac Points in Strong Spin-Orbit Coupled Materials**, JUSTIN WAUGH, University of Colorado at Boulder, THOMAS NUMMY, University of Colorado at Boulder, STEPHEN PARHAM, DANIEL DESSAU, University of Colorado at Boulder — Recent angle resolved photoemission spectroscopy measurements on strong spin-orbit coupled materials have shown an in-plane orbital texture switch at their respective Dirac points. This feature has also been demonstrated in a few materials ( $\text{Bi}_2\text{Se}_3$ ,  $\text{Bi}_2\text{Te}_3$ , and BiTeI) through DFT calculations. Here we present a minimal orbital-derived tight binding model to calculate the electron wave-function in a two-dimensional crystal lattice. We show that the orbital components of the wave-function demonstrate an orbital-texture switch in addition to the usual spin switch seen in spin polarized bands. This orbital texture switch is determined by the existence of three main properties: local or global inversion symmetry breaking, strong spin-orbit coupling, and non-local physics (the electrons are on a lattice). Using our model we demonstrate that the orbital texture switch is ubiquitous and to be expected in many real systems. The orbital hybridization of the bands is the key aspect for understanding the unique wave function properties of these materials, and this minimal model helps to establish the quantum perturbations that drive these hybridizations.

**10:24AM A20.00013 A mechanism for orbital angular momentum and giant spin-splitting in solids and nanostructures**, SEHOON OH, HYOUNG JOON CHOI, Department of Physics, IPAP, and Center for Computational Studies of Advanced Electronic Material Properties, Yonsei University, Seoul 03722, Korea — Giant spin-splitting (GSS) of electronic bands, which is several orders of magnitude greater than Rashba model, has been observed in various systems including noble-metal surfaces, thin film of transition-metal dichalcogenides, often accompanied by the orbital angular momentum (OAM). Here, we study structural and orbital conditions for emergence of a GSS by using tight-binding and first-principles calculations. We find that broken mirror symmetry of local atomic structure around an atom can produce non-zero OAM at the atom. This OAM results in a GSS if the atom is a high-atomic number element. We demonstrate these structural and orbital conditions in the cases of simple atomic chains,  $\text{WSe}_2$  monolayer, Au(111) surface, and bulk HgTe. Based on this mechanism of the spin-splitting, we suggest methods to control the GSS, which can be used in applications such as spintronic devices. This work was supported by NRF of KOREA (Grant No. 2011-0018306) and KISTI supercomputing center (Project No. KSC-2015-C3-039).

**Session A21 GMAG DMP: Magnetic Layers** 320 - Mark Meisel, University of Florida

**8:00AM A21.00001 Specific Heat Studies of a 2D  $S = \text{Heisenberg Antiferromagnet}$** , CHRISTOPHER LANDEE, FAN XIAO, Department of Physics, Clark University, SIMON GERBER, MICHEL KENZELMANN, Paul Scherrer Institute, NU XU, ANDERS SANDVIK, Department of Physics, Boston University — We report on the field-dependent specific heat of a highly two-dimensional Heisenberg,  $S = 1/2$  antiferromagnet (2D QHAF),  $[\text{Cu}(\text{pz})_2(2\text{-OHpy})_2](\text{ClO}_4)_2$ , where pz = pyrazine and 2-OHpy = 2-pyridone. The copper atoms and pyrazine molecules form distorted rectangular layers of pyrazine-bridged copper(II) ions with the pyridone molecules normal to the layers, providing exceptional spacing between layers [1]. The zero-field specific heat of this compound (1.8 – 35 K) is compared to the recent QMC simulations of the specific heat for the 2D QHAF. Under applied field, the temperature dependence of the specific heat varies smoothly, but no field-induced ordering is observed. This behavior differs from the field-induced ordering in the 2D QHAF  $\text{Cu}(\text{pz})_2(\text{ClO}_4)_2$  reported previously [2]. [1] V. Selmani, C. P. Landee, M. M. Turnbull, J. L. Wikaira, and F. Xiao. Inorg. Chem. Comm. 13, 1399-1401 (2010), doi: 10.1016/j.inoche.2010.07.045 [2] N. Tsyrlin, F. Xiao, A. P. Schneidewind, H. M. Rönnow, J. Gavilano, C. P. Landee, M. M. **8:12AM A21.00002 Thickness- and magnetic-field-driven suppression of antiferromagnetism in  $\text{V}_5\text{S}_8$  single crystals**, WILL HARDY, Applied Physics Graduate Program, Smalley-Curl Institute, Rice University, JIANGTAN YUAN, Department of Materials Science and NanoEngineering, Rice University, PANPAN ZHOU, Department of Physics and Astronomy, Rice University, JUN LOU, Department of Materials Science and NanoEngineering, Rice University, DOUGLAS NATELSON, Department of Physics and Astronomy, Rice University — The search for novel materials approaching the  $2d$  limit can be expanded beyond the transition metal dichalcogenides (TMDs) to related compounds, widening the range of available physical phenomena and tuning parameters.  $\text{V}_5\text{S}_8$ , a metal with an antiferromagnetic (AFM) ground state below  $\sim 32$  K, displays a prominent spin-flop transition at  $\sim 4.2$  T. Here we study the AFM state in thin CVD-grown single crystals of  $\text{V}_5\text{S}_8$ , focusing on temperatures close to  $T_{\text{Néel}}$ , where the exact transition temperature depends on the crystal thickness. Magnetoresistance (MR) measurements performed just below  $T_{\text{Néel}}$  reveal magnetic hysteresis, likely a result of a first-order magnetic field-driven breakdown of the AFM state. In thin crystals, on the order of 10 nm thick, monotonic MR measurements suggest that antiferromagnetism is suppressed as the thickness nears the  $2d$  limit. This work demonstrates the possibility of growing single crystals of a relatively complicated magnetic system with thicknesses approaching one unit cell, thereby allowing the tuning of magnetic properties by a field-driven phase transition.

**8:24AM A21.00003 Field induced phase transition in layered honeycomb spin system  $\alpha\text{-RuCl}_3$  studied by thermal conductivity**<sup>1</sup>, IAN LEAHY, ALEX BORNSTEIN, University of Colorado, Boulder, CO 80309, KWANG-YONG CHOI, Chung-Ang University, Seoul, South Korea, MINHYEA LEE, University of Colorado, Boulder, CO 80309 —  $\alpha\text{-RuCl}_3$ , a quasi two-dimensional honeycomb lattice is known to be a candidate material to realize the Heisenberg-Kitaev spin model of a highly anisotropic bond-dependent exchange interaction. We investigate in-plane thermal conductivity ( $\kappa$ ) as a function of temperature ( $T$ ) and in-plane applied field ( $H$ ). At  $H = 0$ , the onset of a strong increase in  $\kappa$  marks the spontaneous long range ordering temperature,  $T_c = 6.5\text{K}$ , corresponding to zigzag antiferromagnetic ordering. A broad peak appearing below  $T_c$  in  $\kappa$  was found to be suppressed significantly as  $H$  increases up to  $\approx 7\text{T}$ , implying the system undergoes a field-induced transition from ordered to a new spin-disordered state analogous to the transverse-field Ising model. Further increasing  $H$  above  $7.1\text{T}$ , the large field seems to begin polarizing spins thus increasing the phonon mean free path, resulting in a significant rise in  $\kappa$ . This tendency is clearly shown in the field dependence of  $\kappa$  below  $T_c$ , which has a pronounced minimum at  $H_{\text{min}} = 7.1\text{T}$ . We will discuss our scaling analysis to characterize this field-induced phase transition and compare to the transverse-field Ising spin system.

**8:36AM A21.00004 Fingerprints of the field-induced Berezinskii-Kosterlitz-Thouless transition in quasi-two-dimensional quantum magnets**<sup>1</sup>, ALŽBETA ORENDÁČOVÁ, P.J. Šafárik University, Košice — The two-dimensional (2d) easy-plane (XY) model provides a prototypical description of 2d systems exhibiting topological excitations, which drive the Berezinskii-Kosterlitz-Thouless (BKT) transition that occurs in 2d superfluids, electron plasmas, Josephson junction arrays, ultracold atomic 2d Bose gases, etc. The excitations in the 2d XY model are spin waves and vortices. In the BKT scenario, at low temperatures, all vortices (V) and antivortices (AV) are bound to V-AV pairs, and spin waves dominate in this quasi-long-range-ordered phase with an infinite correlation length,  $\xi$ , and an algebraic decay of correlations. At a critical temperature,  $T_{\text{BKT}}$ , the V-AV pairs start to unbind, driving the transition to a free vortex phase above  $T_{\text{BKT}}$ , characterized by an exponential divergence of  $\xi$  [1]. Vortices remain stable also in quantum 2d anisotropic Heisenberg systems with a very weak XY anisotropy [2]. The BKT scenario appears even in 2d isotropic Heisenberg magnets due to frustration [3] or an external magnetic field [4]. I will focus on quasi-2d spin  $1/2$  Heisenberg antiferromagnets with extremely weak spin anisotropy [5]. These highly anisotropic layered Cu(II) organo-metallic insulators with relatively low saturation fields, about 6 T, enabled a comprehensive study in a wide range of magnetic fields and temperatures. A response of all compounds to the application of a magnetic field mimics 2d behavior with fingerprints of a field-induced Berezinskii-Kosterlitz-Thouless phase transition. [1] J. V. José (Ed.), 40 Years of Berezinskii-Kosterlitz-Thouless Theory, World Scientific, 2013. [2] A. Cuccoli et al., Phys. Rev. Lett. 90 (2003) 167205. [3] B. Jeevanesan et al., Phys. Rev. **9:12AM A21.00005 Magnetic Property Determination of Nickel Niobate ( $\text{NiNb}_2\text{O}_6$ )**, TIMOTHY MUNSIE, MURRAY WILSON, ALANNAH HALLAS, YIPENG CAI, Department of Physics and Astronomy, McMaster University, TRAVIS WILLIAMS, ADAM ACZEL, Oak Ridge National Laboratory, HANNA DABKOWSKA, Brockhouse Institute for Materials Research, JOHN GREEDAN, Department of Chemistry, McMaster University, GRAEME LUKE, Department of Physics and Astronomy, McMaster University — We have synthesized a novel polymorph of the material nickel niobate,  $\text{NiNb}_2\text{O}_6$ , in a previously undetermined space group. We have examined the material using SQUID magnetometry and have observed a magnetic transition at approximately 14 K, and a second magnetic feature below 2 K. We have determined these materials using muon spin rotation and relaxation at TRIUMF National Lab in Vancouver, Canada and using neutron scattering on the HB-3A beamline of the High Flux Isotope Reactor at Oak Ridge National Labs, TN. Using these techniques we were able to determine that the magnetic structure is highly two-dimensional. This talk will discuss the nature of the phase transition and its evolution through low temperatures.

**9:24AM A21.00006 Direct Visualization of Surface Phase of Oxygen Molecules Physisorbed on the Ag(111) Surface: A Two-dimensional Quantum Spin System**, SHUNJI YAMAMOTO, YASUO YOSHIDA, ISSP, The Univ. of Tokyo, HIROSHI IMADA, YOUSOO KIM, SISL, RIKEN, YUKIO HASEGAWA, ISSP, The Univ. of Tokyo — Oxygen molecule ( $O_2$ ) is one of the smallest molecular magnets with an  $S=1$  quantum spin. This makes  $O_2$  attractive as a building block of low-dimensional (LD) quantum spin systems. Recently, the existence of a spin in physisorbed  $O_2$  on Ag(111) was confirmed by the ortho-para conversion of molecular hydrogen. Therefore, there is a strong need for STM-based techniques with single-molecule resolution in order to verify the potential of the  $O_2$ /Ag(111) for LD quantum spin systems. Here we report the real-space observation of oxygen molecules physisorbed on an Ag(111) surface by using low-temperature scanning tunneling microscopy and spectroscopy. A well-ordered  $O_2$  structure was observed, and the lattice was distorted from an isosceles triangular lattice. The distortion can be explained by the competition between the magnetic and elastic instabilities of the  $O_2$  lattice. In differential tunneling conductance spectra, we found no feature of the Kondo resonance at 4.7 K; in contrast, the physisorbed  $O_2$  on Ag(110) showed a clear Kondo resonance at 18 K. Based on these observations, we discuss the realization of an  $S=1$  two-dimensional antiferromagnetic quantum spin system.

**9:36AM A21.00007 Extent of the Z2 topological phase in the quantum dimer model**, MARC SCHULZ, FIONA J BURNELL, Univ of Minn - Minneapolis — The possibility that topological order is realized in the anti-ferromagnetic Heisenberg model on the Kagome lattice has been supported by increasing numerical evidence over the last years. In particular, effective low-energy descriptions in terms of quantum dimers models provide valuable insights. It has been shown that the phase diagram of the quantum dimer model contains a point at which the Hamiltonian is exactly solvable and realizes a Z2 topological phase. We study the extent of this phase around the exactly solvable point. Therefore we consider the low-energy spectrum which we determine by means of high-order perturbation theory.

**9:48AM A21.00008 Effect of hydrogenation on magnetic properties of heavy transition-metal dichalcogenides<sup>1</sup>**, PRIYANKA MANCHANDA, S. -H. LIOU, AXEL ENDERS, D. J. SELLMYER, RALPH SKOMSKI, University of Nebraska, Lincoln — Two-dimensional transition-metal dichalcogenides (2D TMDs) are emerging as a unique class of materials because of their underlying fundamental physics and technological applications in electronics, sensors, energy storage, photonics, and spintronics. The outstanding electronic properties of 2D TMDs can be further tuned by various external means, such as control of external electric field, chemical functionalization, alloying, and strain. The electronic and magnetic properties of chemical functionalized 2D TMDs is of special interest. Experimentally, adsorbed fluorine has been shown very recently to create a small magnetic moment of 0.06 emu/g in  $MoS_2$  nanosheets. Although several studies as well as review articles on the properties of TMDs have been published in the past few years, Mo and W chalcogenides are most widely studied among the “beyond-graphene” 2D TMDs. However, studies of chemical functionalization on TMDs containing heavy TMDs such as Ta and Pt are still infancy. In the present work, we investigate the effect of hydrogenation on the magnetism of  $PtSe_2$  monolayers using density-functional theory. We find that the hydrogen induces a magnetic moment of 0.7  $\mu_B$  per unitcell. This work has been supported by ARO, and DOE-BES.

<sup>1</sup>This work has been supported by ARO, and DOE-BES.

**10:00AM A21.00009 Calculating small interchain exchange parameters in Copper Pyrazine Dinitrate<sup>1</sup>**, IORWERTH THOMAS, STEWART CLARK, TOM LANCASTER, Durham University — The coordination polymer copper pyrazine dinitrate ( $Cu(pyz)(NO_3)_2$ ) is a one-dimensional antiferromagnet that undergoes a magnetic phase transition to a state of long-range three dimensional magnetic order (LRO) below a temperature of 110 mK. The precise nature of the LRO is dependent on the strength of interchain interactions, which are very weak compared to the dominant superexchange interaction along the chain. It is therefore possible that different approaches to ab initio calculations of exchange interaction parameters may be subject to small systematic effects that would lead to erroneous results. In order to investigate whether such a problem arises in this case, we use the GGA+U approach to Density Functional Theory to compare the results obtained by two methods of calculating these parameters: the dimer fragment approach and the periodic method, and relate them to both experiment and previous calculations performed using the hybrid approach.

<sup>1</sup>Supported by the Templeton Foundation as part of the Durham Emergence Project

**10:12AM A21.00010 Time-Dependent Behavior in Arrays of Coupled Heisenberg Spin Chains**, ROBERT KONIK, Brookhaven Natl Lab, ANDREW JAMES, London Centre for Nanoscience, J-S CAUX, Universiteit van Amsterdam — We employ matrix product state methods combined with data from exact solvability to study infinite arrays of coupled XXZ Heisenberg spin chains of finite length under a time dependent perturbation. We present results for both sudden changes (quantum quenches) as well more gradual changes in the interchain coupling. We benchmark our results and methods against perturbation theory as well as available equilibrium results on two dimensional Heisenberg models. We discuss these results in light of recent pump-probe resonant inelastic x-ray scattering experiments on the iridate compound  $Sr_2IrO_4$ .

**10:24AM A21.00011 Excitations in the quantum paramagnetic phase of the quasi-one-dimensional Ising magnet  $CoNb_2O_6$  in a transverse field: Geometric frustration and quantum renormalization effects<sup>1</sup>**, IVELISSE CABRERA, Clarendon Laboratory, University of Oxford/NIST Center for Neutron Research, J. D. THOMPSON, R. COLDEA, D. PRABHAKARAN, Clarendon Laboratory, University of Oxford, R. I. BEWLEY, T. GUIDI, ISIS Facility, Rutherford Appleton Laboratory, J. A. RODRIGUEZ-RIVERA, NIST Center for Neutron Research, C. STOCK, NIST Center for Neutron Research/The University of Edinburgh — We report extensive single-crystal inelastic neutron scattering measurements of the magnetic excitations in the quasi 1D Ising ferromagnet  $CoNb_2O_6$  in the quantum paramagnetic phase to characterize the effects of the finite interchain couplings. In this phase, we observe that excitations have a sharp, resolution-limited line shape at low energies and over most of the dispersion bandwidth, as expected for spin-flip quasiparticles. We map the full bandwidth along the strongly dispersive chain direction and resolve clear modulations of the dispersions in the plane normal to the chains, characteristic of frustrated interchain couplings in an antiferromagnetic isosceles triangular lattice. The dispersions can be well parametrized using a linear spin-wave model that includes interchain couplings and further neighbor exchanges. The observed dispersion bandwidth along the chain direction is smaller than that predicted by a linear spin-wave model using exchange values determined at zero field. We attribute this effect to quantum renormalization of the dispersion beyond the spin-wave approximation in fields slightly above the critical field, where quantum fluctuations are still significant.

<sup>1</sup>We acknowledge support from EPSRC Grant No. EP/H014934/1, the Oxford Clarendon Fund Scholarship and NSERC of Canada.

**10:36AM A21.00012 Quantum Acoustic Magnetic Resonance Imaging and Spectroscopy:** VIOLETA ZAMORANO, V CELLI, B SHIVARAM, University of Virginia — We present a new modality to characterize single molecule and molecular magnets and propose that it can be used as a powerful spectroscopy and imaging tool. Heisenberg type Hamiltonians representing realistic molecules with appropriate crystal field terms are solved and the magnetic field dependence of the resulting quantum spin energy levels enumerated. The results through thermodynamic identities yield the bulk modulus which is shown to be sensitive to the crystal field parameters at low temperatures. Thus high field low temperature measurements of the sound velocity in molecular and single molecule magnets open the road to a completely new method of understanding such systems.

**10:48AM A21.00013 Molecular quantum magnetism with strong spin-orbit coupling in inorganic solid  $\text{Ba}_3\text{Yb}_2\text{Zn}_5\text{O}_{11}$** , SANG-YOUN PARK, SUNGDAE JI, JAE-HOON PARK, MPPC-CPM, Pohang Univ of Sci & Tech, SEUNGHWAN DO, KWANG-YONG CHOI, Dept. of Physics, Chung-Ang University, DONGJIN JANG, BURKHARD SCHMIDT, MANUEL BRANDO, Max Planck Institute for Chemical Physics of Solids, NICHOLAS BUTCH, NIST Center for Neutron Research — The molecular magnet, assembly of finite number of spins which are isolated from environment, is a model system to study the quantum information process such as the qubit or spintronic devices. In past decades, the molecular magnet has been mostly realized in organic material, however, it has difficulty synthesizing materials or controlling their properties, meanwhile tremendous endeavors to search inorganic molecular magnet are continuing. Here, we propose  $\text{Ba}_3\text{Yb}_2\text{Zn}_5\text{O}_{11}$  as a candidate of inorganic molecular magnet. This material consists of an alternating 3D-array of small and large tetrahedron containing antiferromagnetically coupled four pseudospin-1/2 Yb ions, and magnetic properties are described by an isolated tetrahedron without long-range magnetic ordering. Inelastic neutron scattering measurement with external magnetic field reveals that extraordinarily huge Dzyaloshinsky-Moriya (DM) interaction originating from strong spin-orbit coupling in Yb isospin is the key to explain energy level of tetrahedron in addition to Heisenberg exchange interaction and Zeeman effect. Magnetization measurement shows the Landau-Zener transition between avoided crossing levels caused by DM interaction.

**Monday, March 14, 2016 8:00AM - 10:48AM —**

**Session A22 DCOMP: Electrons, Phonons, and Electron-Phonon Scattering I** 321 - David Singh, University of Missouri

**8:00AM A22.00001 Ab initio phonon limited transport**, MATTHIEU VERSTRAETE, Univ de Liege — We revisit the thermoelectric (TE) transport properties of two champion materials, PbTe and SnSe, using fully first principles methods. In both cases the performance of the material is due to subtle combinations of structural effects, scattering, and phase space reduction. In PbTe anharmonic effects are completely opposite to the predicted quasi-harmonic evolution of phonon frequencies and to frequently (and incorrectly) cited extrapolations of experiments. This stabilizes the material at high T, but also tends to enhance its thermal conductivity, in a non linear manner, above 600 Kelvin. This explains why PbTe is in practice limited to room temperature applications. SnSe has recently been shown to be the most efficient TE material in bulk form. This is mainly due to a strongly enhanced carrier concentration and electrical conductivity, after going through a phase transition from 600 to 800 K. We calculate the transport coefficients as well as the defect concentrations *ab initio*, showing excellent agreement with experiment, and elucidating the origin of the double phase transition as well as the new charge carriers. AH Romero, ECU Gross, MJ Verstraete, and O Hellman PRB 91, 214310 (2015) O. Hellman, IA Abrikosov, and SI Simak, PRB 84 180301 (2011)

**8:36AM A22.00002 High throughput solution of Boltzmann transport equation: phonons, thermal conductivity and beyond**, JOSE PLATA, PINKU NATH, DEMET USANMAZ, Duke University, CORMAC TOHER, Duke Univ, MARCO FORNARI, Central Michigan University, MARCO BUONGIORNO NARDELLI, University of North Texas, STEFANO CURTAROLO, Duke University — Quantitatively accurate predictions of the lattice thermal conductivity have important implications for key technologies ranging from thermoelectrics to thermal barrier coatings. Of the many approaches with varying computational costs and accuracy, which have been developed in the last years, the solution of the Boltzmann transport equation (BTE) is the only approach that guarantees accurate predictions of this property. We have implemented this methodology in the AFLOW [1] high throughput materials science framework, which enables us to compute these anharmonic force constants and solve BTE to obtain the lattice thermal conductivity and related properties automatically in a single step. This technique can be combined with less expensive methodologies previously implemented in AFLOW [2] to create an efficient and fast framework to accelerate the discovery of materials with interesting thermal properties. [1] S. Curtarolo et al., Comp. Mat. Sci. 58, 218 (2012). [2] C. Toher, et. al, Phys. Rev. B 90, 174107, 2014

**8:48AM A22.00003 Parallel calculations of vibrational properties in complex materials: negative thermal expansion and elastic inhomogeneity.**<sup>1</sup>, F.D. VILA, J.J. REHR, U. of Washington — Effects of thermal vibrations are essential to obtain a more complete understanding of the properties of complex materials. For example, they are important in the analysis and simulation of x-ray absorption spectra (XAS). In previous work<sup>2</sup> we introduced an *ab initio* approach for a variety of vibrational effects, such as crystallographic and XAS Debye-Waller factors, Debye and Einstein temperatures, and thermal expansion coefficients. This approach uses theoretical dynamical matrices from which the locally-projected vibrational densities of states are obtained using a Lanczos recursion algorithm. In this talk I present recent improvements to our implementation, which permit simulations of more complex materials with up to two orders of magnitude larger simulation cells. The method takes advantage of parallelization in calculations of the dynamical matrix with VASP. To illustrate these capabilities we discuss two problems of considerable interest: negative thermal expansion in  $\text{ZrW}_2\text{O}_8$ ; and local inhomogeneities in the elastic properties of supported metal nanoparticles. Both cases highlight the importance of a local treatment of vibrational properties.

**9:00AM A22.00004 Lattice dynamics and electron-phonon coupling calculations using non-diagonal supercells**<sup>1</sup>, JONATHAN LLOYD-WILLIAMS, University of Cambridge, BARTOMEU MONSERRAT, Rutgers University — Quantities derived from electron-phonon coupling matrix elements require a fine sampling of the vibrational Brillouin zone. Converged results are typically not obtainable using the direct method, in which a perturbation is frozen into the system and the total energy derivatives are calculated using a finite difference approach, because the size of simulation cell needed is prohibitively large. We show that it is possible to determine the response of a periodic system to a perturbation characterized by a wave vector with reduced fractional coordinates  $(m_1/n_1, m_2/n_2, m_3/n_3)$  using a supercell containing a number of primitive cells equal to the least common multiple of  $n_1$ ,  $n_2$ , and  $n_3$ . This is accomplished by utilizing supercell matrices containing nonzero off-diagonal elements. We present the results of electron-phonon coupling calculations using the direct method to sample the vibrational Brillouin zone with grids of unprecedented size for a range of systems, including the canonical example of diamond. We also demonstrate that the use of nondiagonal supercells reduces by over an order of magnitude the computational cost of obtaining converged vibrational densities of states and phonon dispersion curves.

## 9:12AM A22.00005 Ab Initio Electronic Relaxation Times and Transport in Noble Metals<sup>1</sup>

JAMAL I. MUSTAFA, University of California at Berkeley and Lawrence Berkeley National Lab, MARCO BERNARDI, California Institute of Technology, JEFFREY B. NEATON, STEVEN G. LOUIE, University of California at Berkeley and Lawrence Berkeley National Lab — Relaxation times employed to study electron transport in metals are typically assumed to be constants and obtained empirically using the Drude model. Here, we employ ab initio calculations to compute the electron-phonon relaxation times of Cu, Ag, and Au, and find that they vary significantly on the Fermi surface, spanning  $\sim 15$ – $45$  fs. We compute room temperature resistivities in excellent agreement with experiment by combining *GW* bandstructures, Wannier-interpolated band velocities, and ab initio relaxation times. Our calculations are compared to other approximations used for the relaxation times. Additionally, an importance sampling scheme is introduced to speed up the convergence of resistivity and transport calculations by sampling directly points on the Fermi surface.

## 9:24AM A22.00006 First-principles calculation of LO phonon scattering in BaSnO<sub>3</sub><sup>1</sup>

KARTHIK KRISHNASWAMY, BURAK HIMMETOGLU, ANDERSON JANOTTI, CHRIS G. VAN DE WALLE, University of California, Santa Barbara — BaSnO<sub>3</sub> (BSO) has drawn interest owing to the recent discovery of high electron mobility, highest among the perovskite materials. In our theoretical work, we calculate the electron scattering rate due to LO phonon scattering from first-principles density functional calculations. The calculated mobility is much higher than the experimentally observed value, suggesting defect scattering as the primary limiting factor in currently grown BSO samples, and that reducing the defect density can enhance BSOs mobility significantly.

<sup>1</sup>This work was supported by the LEAST Center and by ONR.

## 9:36AM A22.00007 Consequences of ionic and covalent bonding in Ge-Sb-Te phase change materials

SAIKAT MUKHOPADHYAY, Materials Science and Technology Division, Oak Ridge National Laboratory, JIFENG SUN, Department of Physics and Astronomy, University of Missouri, ALASKA SUBEDI, Max Planck Institute for the Structure and Dynamics of Matter, THEO SIEGRIST, Department of Chemical and Biomedical Engineering, FAMU-FSU College of Engineering, Tallahassee, DAVID SINGH, Department of Physics and Astronomy, University of Missouri — Structural transformation of Ge<sub>2</sub>Sb<sub>2</sub>Te<sub>5</sub> has attracted a great deal of research as it involves two states (crystalline and amorphous) that are stable at ambient temperature but with remarkably different physical properties, in particular, very different optical constants. The differences in physical properties in these states have been explained in terms of resonant bonding that has been generalized to the description of covalent systems with high symmetry structures such as benzene and graphite. However, given the local lattice distortions noted from both experimental and theoretical investigations, it is clear that the meaning of “resonant bonding” in GST is very different from that in graphite or benzene and the precise nature of bonding in this phase has not been fully established. In this talk, based on our first-principles calculations, we show that there is a strong competition between ionic and covalent bonding in the cubic phase, and establish a link between the origins of phase change memory properties and giant responses of piezoelectric materials.

## 9:48AM A22.00008 ABSTRACT WITHDRAWN —

## 10:00AM A22.00009 Novel, discontinuous polaron transition in a two-band model<sup>1</sup>

MIRKO M. MOELLER, GEORGE A. SAWATZKY, MONA BERCIU, Univ British Columbia — The coupling of charge carriers (electrons or holes) to phonons leads to the formation of a polaron, a coherent quasi-particle consisting of the charge carrier and the cloud of phonons surrounding it and moving coherently with it. Here we present exact diagonalization and momentum average approximation results for the single polaron properties of a two-band model with phonon modulated hopping, inspired by the perovskite BaBiO<sub>3</sub>. For large coupling we find that the ground state momentum changes *discontinuously* from  $k = \pi$  to  $k = 0$ . Such sharp transitions of the polaron's ground state properties cannot occur in the well-studied models of the Holstein or Fröhlich type in which the carrier-phonon coupling modulates the on-site energies. However, they can occur in models where the carrier-phonon coupling modulates the hopping integrals such as the SSH model for which a similar yet smooth transition of the ground state momentum was recently shown to exist. We compare our findings to the SSH model and point out qualitative differences which we believe to be due to the two band nature of our model versus the single band SSH model.

## 10:12AM A22.00010 Quasiparticle properties of the nonlinear Holstein model at finite doping and temperature.

SHAOZHI LI, Univ of Tennessee, Knoxville, BETH NOWADNICK, Cornell University, STEVEN JOHNSTON, Univ of Tennessee, Knoxville — Models with linear electron-phonon (e-ph) interactions often predict the formation of small polarons with large lattice displacements. This directly violates the approximations made in deriving the linear model, which implies that one should consider higher order terms in the interaction. Previously we have shown that even small positive nonlinear e-ph interactions dramatically suppress charge-density-wave formation and s-wave superconductivity relative to the linear model [EPL. 109, 27007 (2015)]. In this talk, we present a determinant quantum Monte Carlo study of the single-particle properties of quasiparticles and phonons in a two-dimensional Holstein model that includes an additional nonlinear e-ph interaction. We show that a small positive nonlinear e-ph interaction reduces the effective coupling between electrons and phonons and hardens the effective phonon frequency. Conversely, a small negative nonlinear interaction can enhance e-ph coupling resulting in heavier quasiparticles. In addition, we find that an effective linear model fails to simultaneously capture the quantitative effects of the nonlinearity of both the electronic and phononic degrees of freedom, even though it can qualitatively reproduce properties.

## 10:24AM A22.00011 Entanglement of nuclear spins and phonons in ideal solids.

VADIM OGANESYAN, CUNY-CSI, STEVEN MORGAN, GREGORY BOUTIS, CUNY-Brooklyn College — We investigate quantum many-body dynamics of nuclei in solids, in particular as they are affected by dynamical excitations of the underlying matrix, i.e. phonon modulation of dipolar couplings. Our recent work documented consequences of this coupling in calcium fluoride, where small changes in the spectrum of the free induction decay (FID) were measured, roughly consistent with theoretical estimates based on a simplified elastic model. Such theory also predicts temperature dependent enhancement of the diffusion constant of dipolar order, essentially due to growth in the phonon mean-free path.

## 10:36AM A22.00012 Chiral Phonons and Electrical Resistivity of Ferromagnetic Metals at Low Temperatures<sup>1</sup>

EDGARDO SOLANO CARRILLO, ANDREW J. MILLIS, Columbia University — In the presence of a magnetic field (produced for example by the exchange field of a ferromagnet) phonons become chiral, with left and right circularly polarized modes in addition to the longitudinal or zero-helicity mode. The scattering of spin-split electrons by chiral phonons is investigated, with particular attention to the question of whether the scattering can account for the linear resistivity observed in metallic ferromagnets at low temperature. The theory is shown to explain the observed spin relaxation time of Ni.

**8:00AM A23.00001 Plasmonic Nanomaterials for Optical-to-Electrical Energy Conversion**

MATTHEW SHELDON, Texas AM University — High-quality semiconductor solids have been the dominant photovoltaic materials platform for decades. Although several alternative approaches have been proposed, e.g. dye-sensitized cells or polymeric solids, none compete in terms of cost and conversion efficiency, the crucial benchmarks for industrial scale implementation. However, semiconductors suffer from several fundamental limitations relating to the microscopic mechanism of power conversion that preclude them, even theoretically, from achieving conversion efficiency at the Carnot limit of 95%. Indeed, the fundamentally different tasks of semiconductors in photovoltaic devices, both as optical absorbers, and separately, for electron-hole pair separation and collection, often demand opposing trade-offs in materials optimization. Alternatively, recent advances in subwavelength metal optics, e.g. nanophotonics, metamaterials, and plasmonics, provide several new examples where nanostructured metals perform the separate tasks of absorption and charge separation necessary for photovoltaic power conversion. Nanostructured metals are extremely efficient broadband absorbers of radiation, with tailorable optical properties throughout the visible and infrared spectrum. It is traditionally assumed that the lack of a band gap and consequent fast electronic relaxation (fs) and short mean free path (100 nm) hinders efficient carrier collection. However, new phenomena resulting from the remarkable energy concentration and nanoscale collection geometry afforded by plasmonic systems suggest new strategies may be possible that use all metal structures. In this talk, I will describe two ongoing studies in our laboratory that exemplify opportunities for metal-based optical energy conversion: (1) Excitation with circularly polarized illumination can induce strong, persistent electrical drift currents in resonant metal nanostructures via the inverse faraday effect. (2) Plasmonic absorption in metal nanostructures provides an entirely new mechanism for generating electrochemical potential from photons. This behavior is termed a 'plasmoelectric effect' (*Science*, 2014).

**8:36AM A23.00002 Hot carrier metamaterial detectors and energy converters**

LISA KRAYER, JEREMY N MUNDAY, Univ of Maryland-College Park — Metamaterials can be used to manipulate the flow of light in ways not typically available with traditional materials. Beyond their optical properties, metamaterials can be used as the basis for optoelectronic devices through the incorporation of a metal-semiconductor interface. The absorbed radiation in the metal can excite surface plasmons, which nonradiatively decay into hot electrons or holes that can be injected into the base semiconductor and contribute to photocurrent generation. In this talk, we will present our latest work on metamaterial photo-detectors and solar energy converters.

**8:48AM A23.00003 Non-equilibrium hot carrier dynamics in plasmonic nanostructures**

PRINEHA NARANG, RAVISHANKAR SUNDARAMAN, ADAM JERMYN, Caltech, EMILIANO CORTES, STEFAN A. MAIER, Imperial College, London, WILLIAM A. GODDARD, III, Caltech — Decay of surface plasmons to hot carriers is a new direction that has attracted considerable fundamental and application interest, yet a fundamental understanding of ultrafast plasmon decay processes and the underlying microscopic mechanisms remain incomplete. Ultrafast experiments provide insights into the relaxation of non-equilibrium carriers at the tens and hundreds of femtoseconds time scales, but do not yet directly probe shorter times with nanometer spatial resolution. Here we report the first ab initio calculations of non equilibrium transport of plasmonic hot carriers in metals and experimental observation of the injection of these carriers into molecules tethered to the metal surface. Specifically, metallic nanoantennas functionalized with a molecular monolayer allow for the direct probing of electron injection via surface enhanced Raman spectroscopy of the original and reduced molecular species. We combine first principles calculations of electron-electron and electron-phonon scattering rates with Boltzmann transport simulations to predict the ultrafast dynamics and transport of carriers in real materials. We also predict and compare the evolution of electron distributions in ultrafast experiments on noble metal nanoparticles.

**9:00AM A23.00004 Plasmon drag in esheric percolation series of metallic arrays**

XUEYUAN WU, JIANTAO KONG, KRYSZTOF KEMPA, MICHAEL J. BURNS, MICHAEL J. NAUGHTON, Boston College — Perforated thin metallic films, which evolve from hole to island arrays, form an Escheric percolation series. The plasmonic response of such a series has been investigated [1], with critical phenomena observed near the percolation threshold. In this work, we investigate the plasmon drag effect in such structures, and propose a microscopic explanation for the recently discovered plasmoelectric effect [2]. [1] E. M. Akinoglu, T. Sun, J. Gao, M. Giersig, Z.F. Ren, and K. Kempa, "Evidence for critical scaling of plasmonic modes at the percolation threshold in metallic nanostructures", *Appl. Phys. Lett.* **103**, 171106 (2013). doi: 10.1063/1.4826535 [2] M.T. Sheldon, J. v.Groep, A.M. Brown, A. Polman, H.A. Atwater, "Plasmoelectric potentials in metal nanostructures", *Science* **346**, 828-831 (2014). doi: 10.1126/science.1258405

**9:12AM A23.00005 Collective plasmonic oscillations in nanostrips arrays and sine wave gratings. Comparative study**

NATALIA NOGINOVA, Norfolk State Univ, SOHEILA MASHHADI, SARAH WILSON, FRANCES WILLIAMS, Norfolk State University, JARRETT VELLA, AUGUSTINE URBAS, AFRL, Wright-Patterson AFB, MATTHEW LEPAIN, MAXIM DURACH, Georgia Southern University — Excitation of collective plasmonic modes and their effects on optical behavior were experimentally and theoretically studied in 1 D arrays of gold nanostrips in comparison with those in continuous gold films with a sine wave profile and similar periodicity. Two kinds of collective resonance modes are efficiently excited in gold strips, with participation of gold-air and gold-glass interfaces. These modes correspond to maxima in the angular dependence of reflection, as opposed to minima observed at surface plasmon polariton conditions in a continuous sine wave grating. Spectral and polarization dependences are obtained. A theoretical approach based on the novel combined transfer-matrix coupled-wave analysis and coordinate transformation method is shown to well describe experiments.

**9:24AM A23.00006 Semiconductor-free hot carrier devices for energy harvesting and photodetection.**

TAO GONG, JEREMY MUNDAY, University of Maryland, College Park — The maximum efficiency for a single-junction solar cell is around 30% by the Shockley-Queisser (SQ) limit. The energy loss is typically through a thermalization process between the excited high-energy carriers, e.g. hot carriers, and the lattice. Therefore, the collection of the hot carriers before thermalization would allow for reduced power loss. Recently, photodetectors based on metal-semiconductor Schottky junctions have been exploiting hot electron effects to allow sub-bandgap absorption and hence show promise as near IR wavelength detectors. Here we present a simple, semiconductor-free hot carrier device based on transparent conducting oxides (TCO) electrodes. We experimentally demonstrate the hot carrier generation and extraction under monochromatic and broadband light illumination of normal and oblique incidence. Under optimized conditions, a power conversion efficiency >10% is predicted for high-energy photon excitation. The performance of the device shows further improvement by employing nanostructures, which couple the incident light into surface plasmons, leading to absorption enhancement. This semiconductor-free device provides an alternative way of energy harvesting and photodetection.

### **9:36AM A23.00007 High-contrast and fast electrochromic switching enabled by plasmonics**

ALBERT TALIN, Sandia National Labs, TING XU, ERICH WALTER, AMIT AGRAWAL, CHRISTOPHER BOHN, JEYAVEL VELMURUGAN, WENQI ZHU, HENRI LEZEC, NIST — With vibrant colors and simple, room-temperature processing methods, electrochromic polymers have long attracted attention as active materials for flexible, low-power consuming devices such as smart windows and displays. However, despite their many advantages, slow switching speed and complexity of combining several separate polymers to achieve full-color gamut has limited electrochromic materials to niche applications. Here we exploit the enhanced light-matter interaction associated with the deep-subwavelength mode confinement of surface plasmon polaritons propagating in metallic nanoslit arrays coated with ultra-thin electrochromic polymers to build a novel configuration for achieving high-contrast and fast electrochromic switching. The switchable configuration retains the short temporal charge-diffusion characteristics of thin electrochromic films while maintaining the high optical-contrast associated with thicker electrochromic coatings. We further demonstrate that by controlling the pitch of the nanoslit arrays, it is possible to achieve a full-color response with high-contrast and fast switching-speeds while relying on just one electrochromic polymer.

### **9:48AM A23.00008 Alloyed Noble Metal Nanoparticles with Tunable Optical Properties**

GARRETT C. WESSLER, CHEN GONG, Institute for Research in Electronics and Applied Physics, Dept. of Materials Science & Engr., Univ. of Maryland College Park, MARIAIA REBELLO DE SOUSA DIAS, Institute for Research in Electronics and Applied Physics, Univ. of Maryland College Park, JOSHUA A. TAILON, LOURDES G. SALAMANCA-RIBA, Dept. of Materials Science & Engr., Univ. of Maryland College Park, MARINA S. LEITE, Institute for Research in Electronics and Applied Physics, Dept. of Materials Science & Engr., Univ. of Maryland College Park — Noble metal nanoparticles (NPs) have been widely used in sensing, optics, and catalysis applications by taking advantage of surface plasmon resonance (SPR). This response is slightly tuned by varying the size and shape of the NPs; however, a method to obtain truly on-demand plasmonic responses is still lacking due to the intrinsic nature of a metal's dielectric function. Here, we fabricate size and composition controlled metal alloy NP arrays by deposit-and-anneal methods and through-template depositions. We control the composition of the metal NPs by co-sputtering and by alternating electron-beam evaporation of the Ag and Au targets. To characterize the NPs, macroscopic transmission measurements are combined with spectrally dependent near-field scanning optical microscopy to show the local optical properties around the NPs. By varying the atomic fraction of Ag and Au in the alloys, we modulate the optical properties of the NPs for different applications. For example, hot carrier plasmonic devices necessitate high absorption in the visible range, while photovoltaic applications require low absorption by the NPs.

### **10:00AM A23.00009 Plasmonic thickness variation study of gold nanostructures in ultraviolet-visible light regime**

PIJUSH GHOSH, DESALEGN TADESSE DEBU, DAVID FRENCH, STEPHEN BAUMAN, JOSEPH B. HERZOG, Univ of Arkansas-Fayetteville — Noble metal nanostructures exhibit strong surface plasmon resonances in the ultraviolet-visible light range that are not present in bulk metal. In this study, we have observed the plasmonic properties of different sized gold nanodisks and nanorods with varying thickness. The samples were fabricated by electron beam lithography on silicon dioxide substrates. Depending on the thickness of the nanostructures, strong and well-defined surface plasmon resonances were found (wavelength 400nm - 1000nm). For experimental and theoretical results, we have used Dark field spectroscopy and finite element method, respectively. We found that resonance peak was shifted with nanostructure thickness. By using Dark field spectroscopy, the scattered light from individual structures can be analyzed with less background noise and the incident light was at an angle to the substrate.

### **10:12AM A23.00010 Complex Near-Field Plasmonic Response of Au Nanospirals<sup>1</sup>**

JORDAN HACHTEL, RODERICK DAVIDSON, Vanderbilt University, ANDREW LUPINI, BENJAMIN LAWRIE, Oak Ridge National Laboratory, RICHARD HAGLUND, SOKRATES PANTELIDES, Vanderbilt University — Complex metallic nanostructures that support unique near-field surface plasmon modes have shown applications across the fields of photovoltaics, bio-sensing, and even quantum computing. Chiral Au nanospirals not only possess a non-symmetric morphology that results in second-harmonic generation, but possess multiple distinct near-field plasmonic modes that cover a wide range of plasmon frequencies. We use cathodoluminescence (CL) and electron energy loss spectroscopy (EELS) within a scanning transmission electron microscopy (STEM) to study the surface plasmons and map them with nanoscale precision. The two techniques are complementary as EELS measures excitations in the sample, while CL measures the subsequent radiative decays. We STEM-EELS/CL to map and analyze the spatial profile, intensity and polarization response of the intricate near-field plasmon modes in these versatile nanostructures.

### **10:24AM A23.00011 Infrared Resonances in Plasmonic Nanorod and Nanoarc Antennas**

ANDREW LAWSON, University of Maryland, College Park, MD USA, CHASE ELLIS, JOSEPH TISCHLER, U.S. Naval Research Laboratory, Washington, DC USA, ODED RABIN, University of Maryland, College Park, MD USA — Tunability of the frequency and polarization of localized surface plasmon resonances (LSPR) of nanostructures is crucial for their implementation in nanophotonics applications such as photovoltaics, chiroptical spectroscopy, and infrared detection. We report spectroscopic data of plasmonic nanorods and nanoarcs collected by polarized Fourier transform infrared reflectance spectroscopy (FTIR). The effects of the nanostructure material, geometry and substrate material are investigated by patterning gold and aluminum structures with varying length on silicon and glass substrates, as well as on anodic aluminum oxide, a cost effective alternative to standard transparent substrates. By varying such parameters for straight rods and arcs, we find that the measured LSPR frequencies of our nanostructures span the mid-infrared spectral range ( $\lambda=2-12$  microns). However, we find that bending the nanostructures (i.e., forming arcs rather than straight rods) results in additional resonances with unique polarizations not observed in straight nanorods. We find that the nanorods exhibit half-wave antenna behavior which can be modeled using antenna theory with a linearly scaled effective wavelength which accounts for structure dimensions and material.

### **10:36AM A23.00012 Localized and Propagating Surface Plasmons in Aluminum Nanostructures: The Effect of Metal Deposition Method on Resonance Quality and Depolarization<sup>1</sup>**

VLADIMIR LIBERMAN, KENNETH DIEST, COREY STULL, MATTHEW COOK, DONNA LENNON, MORDECHAI ROTHCHILD, MIT Lincoln Laboratory, STEFAN SCHOECH, J. A. Woollam Co., Inc. — The field of plasmonics has provided revolutionary concepts in sensing, nano-optics and energy harvesting. Al plasmonics has recently emerged as an alternative, CMOS-compatible nanofabrication platform for applications in the UV-visible ranges. Previously, we found that high-temperature sputtered Al films showed significantly better plasmonic response than conventional evaporated films. Here, we extend this thin film work to patterned aluminum nanostructures that support both localized and propagating plasmon modes. The nanostructures from sputtered and evaporated aluminum are fabricated side-by-side in a CMOS compatible state-of-the-art facility. The quality of plasmonic resonances is analyzed with Mueller Matrix spectroscopic ellipsometry over a wide range of incidence angles and wavelengths. Full band structure is experimentally obtained and verified with full-field simulations. We find a strong enhancement in the ellipsometric depolarization parameter near the wavelengths of plasmonic resonance. The depolarization parameter is interpreted as a powerful connection between the near and the far field, providing a diagnostic of the quality of plasmonic resonances.

**10:48AM A23.00013 Optical forces in a cluster of cylinders.**<sup>1</sup> , JINYING XU, Fuzhou University — We present a rigorous multiple-scattering method to calculate the optical force exerted on a cylinder placed near a cluster of parallel cylinders. Various kinds of cluster structure with both dielectric and left-hand materials are considered. It is shown that optical forces are sensitive to the position of the test cylinder, the material of the cylinders in the cluster or the structure of the system. The optical force is strong within frequency bands corresponding to surface-plasmon excitations of the cylinders.

**8:00AM A24.00001 Quantum Transport and Emergence of Superradiant States** , AMIN TAYEBI, VLADIMIR ZELEVINSKY, Michigan State University — Quantum transport is investigated in the framework of the Feshbach projection formalism. This approach provides an alternative to popular methods such as the Feynman diagrammatic techniques and the master equation. The suggested method, being practically simpler, is quite general, not perturbative and reveals new physics, including the sharp redistribution of decay widths and the emergence of short-lived “superradiant” states and long-lived “trapped” states for sufficiently strong coupling to the leads. The superradiant states significantly enhance the transport phenomenon. An additional advantage of the formalism is its flexibility, which allows for a straightforward incorporation of disorder and additional degrees of freedom, such as phonons. Numerical results of transport through specific structures is presented. The interplay of superradiance and polaronic self-localization effects is discussed.

**8:12AM A24.00002 Validity criteria for scattering rates obtained with Fermi’s golden rule in semi-classical transport** , KRISTOF MOORS, KU Leuven, imec, BART SORE, imec, KU Leuven, U Antwerpen, WIM MAGNUS, imec, U Antwerpen — Fermi’s golden rule is often invoked to obtain scattering rates due to imperfections for semi-classical transport in different condensed matter systems. As it is an estimate for relatively small perturbations, its validity depends on the system and imperfection properties under consideration. We present a formal way to obtain easy to handle validity criteria, based on general system parameters, e.g. system size and momentum of the electron states, and the statistical properties of the imperfections. The criteria can also be obtained with a simple set of Feynman rules and corresponding diagrams. We show concrete examples of validity criteria for electron transport in metallic nanowires with several elastic scattering mechanisms, e.g. point defect or grain boundary scattering. We observe realistic nanowire examples where the scattering rate appears to be valid but also cases where the criteria are clearly violated. The latter indicates that higher order effects come into play, such as electrons being trapped between grain boundaries or at a rough surface, which cannot be described using Fermi’s golden rule. The presented validity criteria are therefore very useful to check whether or not the transport properties predicted by a semi-classical transport simulation can be trusted.

**8:24AM A24.00003 Parallel Quantum Circuit in a Tunnel Junction**<sup>1</sup> , OMID FAIZY NAMARVAR, GHASEN DRIDI, CHRISTIAN JOACHIM, PicoLab, CEMES-CNRS, GNS THEORY GROUP TEAM — In between 2 metallic nanopads, adding identical and independent electron transfer paths in parallel increases the electronic effective coupling between the 2 nanopads through the quantum circuit defined by those paths. Measuring this increase of effective coupling using the tunnelling current intensity can lead for example for 2 paths in parallel to the now standard  $G = G_1 + G_2 + 2\sqrt{G_1 G_2}$  conductance superposition law (1). This is only valid for the tunnelling regime (2). For large electronic coupling to the nanopads (or at resonance),  $G$  can saturate and even decay as a function of the number of parallel paths added in the quantum circuit (3). We provide here the explanation of this phenomenon: the measurement of the effective Rabi oscillation frequency using the current intensity is constrained by the normalization principle of quantum mechanics. This limits the quantum conductance  $G$  for example to go when there is only one channel per metallic nanopads. This effect has important consequences for the design of Boolean logic gates at the atomic scale using atomic scale or intramolecular circuits.

**8:36AM A24.00004 Multi-channel quantum dragons from rectangular nanotubes with even-odd structure**<sup>1</sup> , GODFRED INKOOOM, MARK NOVOTNY, Mississippi State University — Recently, a large class of nanostructures called quantum dragons have been discovered theoretically [1]. Quantum dragons are nanostructures with correlated disorder but have an electron transmission probability  $T(E)=1$  for all energies  $E$  when connected to idealized leads. Hence for a single channel, the electrical conductance for a two-probe measurement should give the quantum of conductance  $G_o = \frac{2e^2}{h}$ . The time independent Schrödinger equation for the single band tight binding model is solved exactly to obtain  $T(E)$ . We have generalized the matrix method and the mapping methods of [1] in order to study multi-channel quantum dragons for rectangular nanotubes with even-odd structure. The studies may be relevant for experimental rectangular nanotubes, such as MgO, copper phthalocyanine or some types of graphyne. [1] M.A. Novotny, Phys. Rev. B 90 165103 [14 pages] (2014).

**8:48AM A24.00005 Effect of broadening in the weak coupling limit of vibrationally coupled electron transport through molecular junctions and the analogy to quantum dot circuit QED systems** , RAINER HARTLE, Institut für theoretische Physik, Georg-August-Universität Göttingen, MANAS KULKARNI, Department of Physics, New York City College of Technology, City University of New York — We [1] investigate the nonequilibrium population of a vibrational mode in the steady state of a biased molecular junction, using a rate equation approach. We focus on the limit of weak electronic-vibrational coupling and show that, in the resonant transport regime and for sufficiently high bias voltages, the level of vibrational excitation increases with decreasing coupling strength, assuming a finite and non-zero value. An analytic behavior with respect to the electronic-vibrational coupling strength is only observed if the influence of environmental degrees of freedom is explicitly taken into account. We consider the influence of three different types of broadening: hybridization with the electrodes, thermal fluctuations and the coupling to a thermal heat bath. Our results apply to vibrationally coupled electron transport through molecular junctions but also to quantum dots coupled to a microwave cavity, where the photon number can be expected to exhibit a similar behavior. [1] Rainer Hartle, Manas Kulkarni, Phys. Rev. B 91, 245429 (2015)

**9:00AM A24.00006 Landauer's formula with finite-time relaxation: Kramers' crossover in electronic transport**<sup>1</sup>, DANIEL GRUSS, Center for Nanoscale Science and Technology, National Institute of Standards and Technology, KIRILL VELIZHANIN, Theoretical Division, Los Alamos National Laboratory, MICHAEL ZWOLAK, Center for Nanoscale Science and Technology, National Institute of Standards and Technology — Landauer's formula relates the conductance of a region of interest to its transmission probability. It is the standard theoretical tool to examine ballistic transport in nano- and meso-scale junctions and devices. This view of transport as transmission necessitates a simplified view of transmission, one occurring through an essentially fixed structure. Starting from a description of transport that includes relaxation of electrons in the reservoirs, we derive a Landauer-like formula for the steady-state current. We demonstrate that the finite relaxation time gives rise to three regimes of behavior. Weak relaxation within a small region nearby to the junction gives a contact limited current. Strong relaxation also influences the current by localizing electrons, distorting their natural dynamics and reducing the current. In an intermediate regime, the standard Landauer view is recovered. This behavior is analogous to Kramers' turnover in chemical reactions.

**9:12AM A24.00007 ABSTRACT WITHDRAWN —**

**9:24AM A24.00008 Kondo-correlated transport in single molecule ferromagnetic break junction devices with controllable electrode magnetization alignment**, GAVIN SCOTT, TING-CHEN HU, Bell Labs - Murray Hill — A quantum dot attached to electrodes with magnetizations that can be switched between parallel and anti-parallel alignment has been proposed as a platform for investigating quantum criticality associated with the destruction of Kondo entanglement. We have fabricated single molecule break junction devices with elliptical ferromagnetic electrodes designed to suit this purpose. Low temperature transport measurements, supported by micromagnetic simulations, were used to investigate the magnetoresistance response on control samples during the magnetization reversal process. We show results of Kondo-correlated transport as the source and drain contacts are switched between parallel and anti-parallel magnetization configurations.

**9:36AM A24.00009 Tuning Charge and Correlation Effects for a Single Molecule on a Graphene Device**, HSIN-ZON TSAI, UCB Physics, SEBASTIAN WICKENBURG, UCB Physics and LBNL MSD, JIONG LU, UCB Physics, NUS Chemistry, NUS GRC, JOHANNES LISCHNER, UCB Physics, LBNL MSD, ARASH A. OMRANI, ALEXANDER RISS, CHRISTOPH KARRASCH, HAN SAE JUNG, RAMIN KHAJEH, DILLON WONG, UCB Physics, KENJI WATANABE, TAKASHI TANIGUCHI, NIMS Japan, ALEX ZETTL, UCB Physics, LBNL MSD, and Kavli ENSI, STEVEN G. LOUIE, UCB Physics and LBNL MSD, MICHAEL F. CROMMIE, UCB Physics, LBNL MSD, and Kavli ENSI — Controlling electronic devices down to the single molecule level is a grand challenge of nanotechnology. Single-molecules have been integrated into devices capable of tuning electronic response, but a drawback for these systems is that their microscopic structure remains unknown due to inability to image molecules in the junction region. Here we present a combined STM and nc-AFM study demonstrating gate-tunable control of the charge state of individual F4TCNQ molecules at the surface of a graphene field effect transistor. This is different from previous studies in that the Fermi level of the substrate was continuously tuned across the molecular orbital energy level. Using STS we have determined the resulting energy level evolution of the LUMO, its associated vibronic modes, and the graphene Dirac point (ED). We show that the energy difference between ED and the LUMO increases as EF is moved away from ED due to electron-electron interactions that renormalize the molecular quasiparticle energy. This is attributed to gate-tunable image-charge screening in graphene and corroborated by ab initio calculations.

**9:48AM A24.00010 Probing voltage induced bond rupture in a molecular junction**<sup>1</sup>, HAIXING LI, Department of Applied Physics and Applied Mathematics, Columbia University, TIMOTHY SU, NATHANIEL KIM, Department of Chemistry, Columbia University, PIERRE DARANCET, Argonne National Laboratory Center for Nanoscale Materials, JAMES LEIGHTON, MICHAEL STEIGERWALD, COLIN NUCKOLLS, Department of Chemistry, Columbia University, LATHA VENKATARAMAN, Department of Applied Physics and Applied Mathematics, Columbia University — We use scanning tunneling microscope break junction to study electric field breakdown at the single molecule level. We investigate breakdown phenomena in atomic chains composed of Si—Si, Si—O, Si—C, Ge—Ge and C—C bonds that are commonly found in the low- $\kappa$  dielectric material. We see different bond rupture behaviors in a range of molecular backbones, and use the results from a statistically large number of measurements to determine which bond breaks. We find that Si—Si and Ge—Ge bonds rupture above a 1V bias. We also find that the Si—C bond is more robust than Si—O or Si—Si bond at above 1V. Finally, we illustrate how an additional conductance pathway in parallel to the Si—Si bond changes bond rupture behavior under an electric field. We carry out ab initio calculations on these systems and demonstrate that the mechanism for bond rupture under electric field involves "heating" of the molecule through electron-vibrational mode coupling.

**10:00AM A24.00011 ABSTRACT WITHDRAWN —**

**10:12AM A24.00012 Bias-dependent enhancement of the Fano factor in atomic-scale Au junctions**, LOAH STEVENS, PAVLO ZOLOTAVIN, RUOYU CHEN, DOUGLAS NATELSON, Rice University — We report measurements of current noise in STM-style Au break junctions at 77K, focusing on the dependence of the Fano factor on applied bias. In room temperature investigations of similar systems, measured noise at low bias (<150 mV) was observed to agree well with Landauer-Büttiker theory for shot noise at a fixed electronic temperature. At higher biases, however, measured noise exhibited a superlinear dependence on scaled bias above the low bias expectations. In the present experiment at cryogenic temperatures, we also observe this nonlinear increase of noise. We will discuss this behavior in terms of an enhancement of the Fano factor above the predicted model for minimum open transmission channels, and how the data constrain possible explanations of this excess noise. Furthermore, we will examine channel mixing in transport through the junction from measured Fano factor and conductance.

**10:24AM A24.00013 Electron Transport in Short Peptide Single Molecules**<sup>1</sup>, JING CUI, Department of Physics, Columbia University, JOSEPH BRISENDINE, Department of Physics, The City College of New York, FAY NG, COLIN NUCKOLLS, Department of Chemistry, Columbia University, RONALD KODER, Department of Physics, The City College of New York, LATHA VENKATARAMAN, Department of Applied Physics and Applied Mathematics — We present a study of the electron transport through a series of short peptides using scanning tunneling microscope-based break junction method. Our work is motivated by the need to gain a better understanding of how various levels of protein structure contribute to the remarkable capacity of proteins to transport charge in biophysical processes such as respiration and photosynthesis. We focus here on short mono, di and tri-peptides, and probe their conductance when bound to gold electrodes in a native buffer environment. We first show that these peptides can bind to gold through amine, carboxyl, thiol and methyl-sulfide termini. We then focus on two systems (glycine and alanine) and show that their conductance decays faster than alkanes terminated by the same linkers. Importantly, our results show that the peptide bond is less conductive than a sigma carbon-carbon bond.

**10:36AM A24.00014 Controlled fabrication of DNA molecular templates for the deposition and electrical measurement of 1D metal nanowires**, JORGE BARREDA, LONGQIAN HU, LIUQI YU, ZHIBIN WANG, JUNFEI XIA, JINGJIAO GUAN, PENG XIONG, Florida State University, GUAN'S GROUP TEAM, XIONG'S GROUP TEAM — Stretched DNA nanowires (NWs) offer a convenient substrate for the fabrication and measurement of 1D metal NWs of width down to nm [1]. So far the fabrication of the DNA templates has relied on somewhat random self-assembly processes. Here we demonstrate a process with high degree of control over the length, spacing, diameter, and orientation of the metal NWs: A one-step dewetting of a DNA solution on a PDMS stamp with an array of micropillars with well-defined pitch yields DNA NWs suspended across the micropillars along a chosen direction [2]. The DNA NWs are then transferred via micro-contact printing onto a Si/SiO<sub>2</sub>/SiN<sub>x</sub> substrate with a lithographically fabricated trench defined by an opening in the SiN<sub>x</sub> layer and undercut in the SiO<sub>2</sub> layer. The template with DNA NWs stretched across the trench is placed in a high-vacuum evaporator for metal deposition, resulting in a metal NW of width defined by the diameter of the DNA template (<10 nm) and length determined by the width of the trench. Quasi-four terminal I-V measurements are performed in situ with incremental metal deposition. Concomitant with a transition from strongly nonlinear IV to Ohmic behavior with increasing thickness, the NW resistance is observed to decrease exponentially. [1] Hopkins, David S., et al. Science 308.5729 (2005): 1762-1765. [2] Guan, Jingjiao, et al. Soft Matter 3.11 (2007): 1369-1371.

**10:48AM A24.00015 Electron field emission from Ge nanoclusters on Si.**, VERONIKA BUROBINA, University of California - San Diego — We analyzed the electron field emission from Ge nanoclusters grown on Si substrate by the method of molecular beam epitaxy. The emission properties were studied with the use of scanning tunneling microscopy. The phenomenological model of the field emission mechanism was applied to estimate current density from the surface of the pointed Ge/Si nanostructures.

**8:00AM A25.00001 Identifying detrimental effects for multi-band superconductivity - Application to Sr<sub>2</sub>RuO<sub>4</sub>**<sup>1</sup>, ALINE RAMIRES, Institute for Theoretical Sciences - ETH Zurich, MANFRED SIGRIST, Institute for Theoretical Physics - ETH Zurich — Spin polarization and anti-symmetric spin-orbit coupling are detrimental to Cooper pairing in the spin singlet and spin triplet channel, respectively. These are the well-known features of paramagnetic limiting and selection rules in non-centrosymmetric superconductors. We propose a general scheme to probe the compatibility of arbitrary pairing states with given normal state properties in model systems. This yields a universal criterion which we validate with results based on weak coupling analysis of the stability of different superconducting gaps under time-reversal and inversion symmetry breaking fields. Our criterion does, however, not address directly any aspects concerned with the pairing mechanism. A merit of the criterion is that it can be easily applied to the stability analysis of superconducting states in multi-band systems, to establish gap structures favourable within a given complex band structure. As such it can serve as a tool to identify non-trivial mechanisms to suppress superconductivity under various external influences, in particular, magnetic fields or distortions. We apply our criterion to the multi-band superconductor Sr<sub>2</sub>RuO<sub>4</sub> with the aim to explore possible explanations for the limiting feature observed in the in-plane upper critical field.

**8:12AM A25.00002 Experimentally observable signatures of odd-frequency pairing in multi-band superconductors**, LUCIA KOMENDOVA, Uppsala University, Sweden, ALEXANDER V. BALATSKY, Nordita, Stockholm, Sweden and Los Alamos National Laboratory, US, ANNICA M. BLACK-SCHAFFER, Uppsala University, Sweden — We report on how hybridization (single-quasiparticle scattering) between two superconducting bands induces odd-frequency superconductivity in a multiband superconductor. Using the Green's functions formalism we derived the odd-frequency pairing correlation and its full frequency dependence. We found that the density of states is modified, at higher energies, from the sum of the two BCS spectra to also include additional hybridization gaps with strong coherence peaks when odd-frequency pairing is present. These gaps constitute clear experimentally measurable signatures of odd-frequency pairing in multiband superconductors. [1] L. Komendova, A. V. Balatsky, and A. M. Black-Schaffer, Phys. Rev. B 92, 094517 (2015).

**8:24AM A25.00003 Odd-parity superconductivity in the vicinity of inversion symmetry breaking in spin-orbit-coupled systems**<sup>1</sup>, VLADYSLAV KOZII, LIANG FU, Massachusetts Institute of Technology, MASSACHUSETTS INSTITUTE OF TECHNOLOGY TEAM — We study superconductivity in spin-orbit-coupled systems in the vicinity of inversion symmetry breaking. We find that due to the presence of spin-orbit coupling, fluctuations of the incipient parity-breaking order generate an attractive pairing interaction in an odd-parity pairing channel, which competes with the *s*-wave pairing. We show that Coulomb repulsion or an external Zeeman field suppresses the *s*-wave pairing and promotes the odd-parity superconducting state. Our work provides a new mechanism for odd-parity pairing and opens a route to novel topological superconductivity.

**8:36AM A25.00004 Triplet p<sub>z</sub>-wave pairing in quasi-one-dimensional A<sub>2</sub>Cr<sub>3</sub>As<sub>3</sub> superconductors (A = K,Rb,Cs)**<sup>1</sup>, FAN YANG, School of Physics, Beijing Institute of Technology, XIANXIN WU, JIANGPING HU, CONGCONG LE, HENG FAN, Institute of Physics, Chinese Academy of Sciences — We construct minimum effective models to investigate the pairing symmetry in the newly discovered quasi-one-dimensional superconductor K<sub>2</sub>Cr<sub>3</sub>As<sub>3</sub>. We show that a minimum three-band model based on the d<sub>z<sup>2</sup></sub>, d<sub>xy</sub>, and d<sub>x<sup>2</sup>-y<sup>2</sup></sub> orbitals of one Cr sublattice can capture the band structures near Fermi surfaces. In both weak and strong coupling limits, the standard random phase approximation and mean-field solutions consistently yield the triplet p<sub>z</sub>-wave pairing as the leading pairing symmetry for physically realistic parameters. The triplet pairing is driven by the ferromagnetic fluctuations within the sublattice. The gap function of the pairing state possesses line gap nodes on the k<sub>z</sub> = 0 plane on the Fermi surfaces. Experimental consequences of the triplet p<sub>z</sub>-wave pairing are also discussed, including the NMR, superfluid density and phase-sensitive dc SQUID experiments.

**8:48AM A25.00005 Leggett modes in the multi-band superconductor  $\text{Sr}_2\text{RuO}_4$ <sup>1</sup>**, WEN HUANG, McMaster University, MANFRED SIGRIST, Institute for Theoretical Physics, ETH Zurich, CATHERINE KALLIN, McMaster University —  $\text{Sr}_2\text{RuO}_4$  is a prototypical multi-band superconductor, with three bands crossing the Fermi level. These bands exhibit distinct dimensional characteristics, with one quasi-2D  $\gamma$ -band and two quasi-1D  $\alpha$ - and  $\beta$ - bands. As a consequence, the superconducting order parameter on the  $\gamma$ - and  $\alpha/\beta$ -bands may only be weakly Josephson-coupled, in contrast to the stronger coupling between the quasi-1D bands. In this work, we study the Leggett modes associated with the relative phase fluctuations between the bands. We show that a soft Leggett mode exists in the case of comparatively weaker inter-band Josephson coupling between the  $\gamma$ - and  $\alpha/\beta$ -bands. We further analyze the dependence of the inter-band Josephson coupling on spin-orbit coupling, and discuss the possibility of an exotic time-reversal symmetry breaking phase when the Josephson coupling is comparable between all pairs of bands.

**9:00AM A25.00006 Microscopic model of the Knight shift in anisotropic and correlated metals<sup>1</sup>**, RICHARD KLEMM, BIANCA HALL, University of Central Florida — We present a microscopic model of nuclear magnetic resonance in metals. The spins of the spin-1/2 local nucleus and its surrounding orbital electrons interact with the arbitrary constant  $B_0$  and perpendicular time-oscillatory magnetic inductions  $B_1(t)$  and with each other via an anisotropic hyperfine interaction. An Anderson-like Hamiltonian describes the excitations of the relevant occupied local orbital electrons into the conduction bands, each band described by an anisotropic effective mass with corresponding Landau orbits and an anisotropic spin  $g$  tensor. Local orbital electron correlation effects are included using the mean-field decoupling procedure of Lacroix. The Knight resonance frequency and corresponding linewidth shifts are evaluated to leading orders in the hyperfine and Anderson excitation interactions. While respectively proportional to  $(B_1/B_0)^2$  and a constant for weak  $B_0 \gg B_1$ , both highly anisotropic shifts depend strongly upon  $B_0$  when a Landau level is near the Fermi energy. Electron correlations affect the anisotropy of the linewidth shift.

**9:12AM A25.00007 Odd-frequency Superconductivity in Driven Systems**, CHRISTOPHER TRIOLA, Nordita, ALEXANDER BALATSKY, IMS, Los Alamos National Lab and Center for Quantum Materials, Nordita — We show that Berezinskiis classification of the symmetries of Cooper pair amplitudes in terms of parity under transformations that invert spin, space, time, and orbital degrees of freedom holds for driven systems even in the absence of translation invariance. We then discuss the conditions under which pair amplitudes which are odd in frequency can emerge in driven systems. Considering a model Hamiltonian for a superconductor coupled to an external driving potential, we investigate the influence of the drive on the anomalous Greens function, density of states, and spectral function. We find that the anomalous Greens function develops odd in frequency component in the presence of an external drive. Furthermore we investigate how these odd-frequency terms are related to satellite features in the density of states and spectral function. Supported by US DOE BES E 304.

**9:24AM A25.00008 Majorana zero modes in  $p + ip$  superconducting rings with half quantum flux in the presence of a  $d$ -soliton<sup>1</sup>**, ALI BEYRAMZADEH MOGHADAM, KIRILL SHTENGEL, University of California - Riverside — Half-integer flux quantization has been observed in mesoscopic rings of superconducting  $\text{Sr}_2\text{RuO}_4$ <sup>2</sup>. This finding suggests a chiral  $p + ip$  nature of the superconducting order parameter. Under the assumption that the  $d$ -vector (which parametrizes the triplet pairing) lies in the plane of a 2D superconductor, such rings are expected to support Majorana zero modes at their inner and outer edges. However, such modes have not been directly observed in experiments. More recently, H.-Y. Kee and M. Sigrist argued that the spin-orbit coupling in such systems can stabilize a different spin texture, also consistent with half-quantum vortices<sup>3</sup>. That spin texture is characterized by the presence of a so-called  $d$ -soliton — a radial domain wall between the regions where the  $d$ -vector is oriented in the positive and negative  $z$ -directions. Our theoretical investigation of superconducting rings with  $d$ -solitons confirms the existence of two Majorana zero modes, one at each boundary. Furthermore, the presence of a  $d$ -soliton enhances the hybridization between the localized Majorana modes at the inner and outer boundaries.

**9:36AM A25.00009 Scanning SQUID Microscopy of  $\text{Sr}_2\text{RuO}_4$  Under Anisotropic Strain**, CHRISTOPHER A. WATSON, HILARY NOAD, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, Menlo Park, CA, USA, ALEXANDRA GIBBS, ANDREW P. MACKENZIE, CLIFFORD W. HICKS, Max Planck Institute for Chemical Physics of Solids, Dresden, Germany, KATHRYN A. MOLER, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, Menlo Park, CA, USA — The proposed  $p_x \pm ip_y$  topological superconducting state of  $\text{Sr}_2\text{RuO}_4$  has motivated a great deal of experimental effort. While some experimental results are consistent with this order parameter, others are not, and the question of the order parameter remains unsettled. Furthermore, it is possible that multiple order parameters are nearly degenerate, such that perturbing the sample may induce a change in order parameter. It was recently demonstrated that  $T_c$  is strongly enhanced under anisotropic strain with  $\langle 100 \rangle$  principle axes; the dependence on strain was essentially quadratic, but with an anomaly at low strains. In this work, we will use a scanning SQUID susceptometer to study the local diamagnetic response of the superconducting state as a function of temperature and applied strain. We will investigate the homogeneity of the superconductivity and the precise dependence of  $T_c$  on strain without inhomogeneity-related broadening.

**9:48AM A25.00010 Realization of a mixed-symmetry superconducting gap in correlated organic metals<sup>1</sup>**, MICHAELA ALTMAYER, DANIEL GUTERDING, HARALD O. JESCHKE, Institute for Theoretical Physics, Goethe-University Frankfurt, Germany, SANDRA DIEHL, TORSTEN METHFESSEL, Institute for Physics, Johannes Gutenberg-University Mainz, Germany, ULRICH TUTSCH, HARALD SCHUBERT, MICHAEL LANG, JENS MÜLLER, MICHAEL HUTH, Department of the Physical Institute, Goethe-University Frankfurt, Germany, MARTIN JOURDAN, HANS-JOACHIM ELMERS, Institute for Physics, Johannes Gutenberg-University Mainz, Germany, ROSER VALENTI, Institute for Theoretical Physics, Goethe-University Frankfurt, Germany — Recent scanning tunneling spectroscopy measurements on the organic charge transfer salt  $\kappa$ -(BEDT-TTF)<sub>2</sub>Cu[N(CN)<sub>2</sub>]Br show clear evidence of a highly anisotropic gap structure. Based on an *ab initio* derived model Hamiltonian we employ random phase approximation spin fluctuation theory yielding a composite order parameter of (extended)  $s + d_{x^2-y^2}$  symmetry. Taking explicitly also the shape of the Fermi surface into account we calculate STS spectra that are in excellent agreement to the experimental observations [1]. Moreover we determine the minimal tight binding model to describe the general lattice structure of these compounds accurately and generate a phase diagram for the gap symmetry by varying the hopping parameters. Based on *ab initio* derived parameter sets we predict the gap symmetry of other superconducting  $\kappa$  charge transfer salts.

**10:00AM A25.00011 Quasiparticles near domain walls in hexagonal superconductors<sup>1</sup>**, SOUMYA MUKHERJEE, KIRILL SAMOKHIN, Brock University, Department of Physics — We calculate the energy spectrum of quasiparticles trapped by a domain wall separating different time reversal symmetry-breaking ground states in a hexagonal superconductor, such as UPt<sub>3</sub>. The bound state energy is found to be strongly dependent on the gap symmetry, the domain wall orientation, the quasiparticle's direction of semiclassical propagation, and the phase difference between the domains. We calculate the corresponding density of states and show how one can use its prominent features, in particular, the zero-energy singularity, to distinguish between different pairing symmetries.

**10:12AM A25.00012 Dynamic Quantum Phase Transitions in Holographic Superconductors**, MOON JIP PARK, MATTHEW GILBERT, Univ of Illinois - Urbana — A non-equilibrium quench that crosses a quantum critical point is known to exhibit distinct behavior from trivial quench. This is readily apparent via examination of the Loschmidt echo that contains the Yang-Lee (YL) zeros in the non-equilibrium quench within the vanishing returning rate of ground state when the quantum critical point is crossed. While previous studies on the dynamical quenches are restricted within non-interacting systems, we use of the Loschmidt echo to understand quenches within strongly interacting conformal field theories using holographic mapping. We show that the free energy of the gravitational dual possesses YL zeros at the superconducting critical temperature. We argue that, on the gravitational side, the presence of YL zeros implies that the free energy is invariant under a set of discrete deformations of the metric characterized by the time at which the returning rate vanishes. We illustrate these ideas using a holographic superconductor constructed via the coupling of AdS gravity with a Maxwell field and charged scalar.

**10:24AM A25.00013 Knight shift and spin relaxation in the single band 2D Hubbard model.**, JAMES LEBLANC, XI CHEN, EMANUEL GULL, Univ of Michigan - Ann Arbor — We study in detail the roles of spin and charge fluctuations in the single band 2D Hubbard model. Using dynamical mean field theory and cluster extensions such as the dynamical cluster approximation (DCA), we compute the full two particle susceptibilities in the spin and charge representations. By performing analytic continuations we obtain the temperature and doping dependence of the spin-lattice relaxation ( $T_1^{-1}$ ) and knight shift in the 2D Hubbard model relevant to NMR results on doped cuprates and connect these to RPA results in weak coupling limits.

**10:36AM A25.00014 Magnetism and experimental consequences of  $p_z$ -wave spin triplet state in quasi-one-dimensional  $A_2Cr_3As_3$  superconductors**, XIANXIN WU, Institute of Physics, Chinese Academy of Sciences, FAN YANG, 2School of Physics, Beijing Institute of Technology, CONGCONG LE, JING YUAN, SHENGSHAN QIN, HENG FAN, JIANGPING HU, Institute of Physics, Chinese Academy of Sciences — The recently discovered quasi-one dimensional superconductors  $A_2Cr_3As_3$  ( $A=K,Rb,Cs$ ), are found to possess strong frustrated magnetic fluctuations and are nearby a novel in-out co-planar magnetic ground state. Then, we find that the triplet  $p_z$ -wave pairing is strongly favored. Finally, with  $p_z$  wave pairing state, we obtain the specific heat, superfluid density, Knight shift and spin relaxation rate and find that all these properties at low temperature ( $T \ll T_c$ ) show powerlaw behaviors and are consistent available experiments. Particularly, the superfluid density determined by the  $p_z$ -wave pairing state in this quasi-one dimensional system is anisotropic: the in-plane superfluid density varies as  $\Delta\rho_{\parallel} \sim T$  but the out-plane one varies as  $\Delta\rho_{\perp} \sim T^3$  at low temperature. The anisotropic upper critical field reported in experiment is consistent with the  $S_z = 0$  (i.e.,  $(\uparrow\downarrow + \downarrow\uparrow)$ )  $p_z$ -wave pairing state. We also suggest the phase-sensitive dc-SQUID measurements to pin down the triplet  $p_z$ -wave pairing state. References: [1] X. Wu et al., Chin. Phys. Lett. 32, 057401 (2015). [2] X. **8:00AM A26.00001 Ultrafast Optical Reflectivity Study of Photo-Carrier Relaxation Dynamics in Perovskite Iridates**, HAO CHU, LIUYAN ZHAO, Caltech, TOM HOGAN, STEPHEN WILSON, University of California, Santa Barbara, DAVID HSIEH, Caltech, CALTECH COLLABORATION, UNIVERSITY OF CALIFORNIA, SANTA BARBARA COLLABORATION — The Ruddlesden-Popper series of perovskite iridates  $Sr_{n+1}Ir_nO_{3n+1}$  lie close to a localization-delocalization boundary, evolving from a Mott-like magnetic insulator in the single layer ( $n=1$ ) compound to a paramagnetic semi-metal in the infinite layer ( $n=\infty$ ) compound. We will discuss the insulator-to-metal transition in perovskite iridates from the point of view of time-resolved optical reflectivity measurements. This technique probes the relaxation dynamics of photo-generated carriers, which are strongly affected by the presence of a charge gap.

**8:12AM A26.00002 Ionic liquid gating  $Sr_2IrO_4$  single crystal<sup>1</sup>**, BOYI YANG, ALLEN GOLDMAN, Univ of Minnesota - Twin Cities — The 5d iridates have attracted much interest due to the prediction of novel electronic phases driven by the interplay of spin-orbit coupling with onsite Coulomb interaction. The compound  $Sr_2IrO_4$ , with a crystal structure similar to that of  $La_2CuO_4$ , was identified as a spin-orbital Mott insulator. It has been doped in various ways in search of a possible superconducting state considering its similarities to the cuprates. Unlike the common ionic liquid gated thin film field effect transistor (FET), here we have fabricated an ionic liquid (DEME-TFSI) gated FET based on the cleaved ab plane surface of a  $Sr_2IrO_4$  single crystal. Due to the insulating behavior of the bulk, the sensitive surface gating effect can be characterized with transport property measurements. We find an insulator to metal transition around 75K upon hole doping, while a minimal gating effect is observed on electron accumulation at the cleaved single crystal surface. The low temperature metallic behavior will be further studied in detail and the latest experimental results will be reported.

**8:24AM A26.00003 Decoupling of the Antiferromagnetic and Insulating States in Tb doped  $\text{Sr}_2\text{IrO}_4$** <sup>1</sup>, H. ZHENG, Center for Advanced Materials and Department of Physics and Astronomy University of Kentucky, Lexington, KY 40506, USA, J.C. WANG, F. YE, Quantum Condensed Matter Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, S. ASWARTHAM, J. TERZIC, S.J. YUAN, Center for Advanced Materials and Department of Physics and Astronomy University of Kentucky, Lexington, KY 40506, USA, D. HASKEL, Y. CHOI, Advanced Photon Source, Argonne National Laboratory, Argonne IL 60439, USA, S. CHIKARA, National High Magnetic Field Laboratory, Los Alamos National Laboratory, Los Alamos, NM 87545, USA, P. SCHLOTTMANN, Department of Physics, Florida State University, Tallahassee, FL 32306, USA, R. CUSTELCEAN, Chemical Science Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, G. CAO, Center for Advanced Materials and Department of Physics and Astronomy University of Kentucky, Lexington, KY 40506, USA — We report results of a comprehensive study of single-crystal  $\text{Sr}_2\text{Ir}_{1-x}\text{Tb}_x\text{O}_4$  ( $0 \leq x \leq 0.03$ ). This study found that mere 3% ( $x=0.03$ ) tetravalent  $\text{Tb}^{4+}$  substituting for  $\text{Ir}^{4+}$  (rather than  $\text{Sr}^{2+}$ ) completely suppresses the long-range collinear AFM transition but retains the insulating state. Tb doping effectively changes the relative strength of the SOI and the tetragonal CEF and enhances the Hund's rule coupling that competes with the SOI, and destabilizes the AFM state. We observe unconventional correlation between the AFM and insulating states in which the magnetic transition plays no critical role in the formation of the charge gap in the iridate.

<sup>1</sup>This work was supported by NSF through grant DMR-1265162.

**8:36AM A26.00004 Switching the d-wave gap in layered perovskite iridates via spin reorientation**, BUMJOON KIM, Max Planck Institute for Solid State Research — We demonstrate switching of the *d*-wave charge gap in electron-doped  $\text{Sr}_3\text{Ir}_2\text{O}_7$  through changing the spin easy axis. The pristine, undoped  $\text{Sr}_3\text{Ir}_2\text{O}_7$  has *c*-axis collinear antiferromagnetic structure with strong Ising anisotropy, which gaps out magnons with an unprecedentedly large energy scale of 90 meV. However, a metastable phase with *ab* easy-plane anisotropy is found in some surfaces of  $\text{Sr}_3\text{Ir}_2\text{O}_7$ , for which low-energy magnons are expected. Doping electrons to the latter leads to opening of a *d*-wave charge gap below ~30 K, which is not found in the former. Our results indicate the magnetic origin of the *d*-wave gap in electron-doped layered perovskite iridates, and suggest a mechanism to control the charge gap via the spin degrees of freedom.

**9:12AM A26.00005 Isotropic and anisotropic regimes of the spin-dynamics in  $\text{Sr}_2\text{IrO}_4$  : Field-dependent Raman scattering study**<sup>1</sup>, Y. GIM, A. SETHI, Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, 104 South Goodwin Avenue, Urbana, Illinois 61801-2902, Q. ZHAO, J.F. MITCHELL, Material Science Division, Argonne National Laboratory, Argonne, Illinois 60439, USA, G. CAO, Center for Advanced Materials, University of Kentucky, Lexington, Kentucky 40506, USA, S.L. COOPER, Frederick Seitz Materials Research Laboratory, University of Illinois at Urbana-Champaign, 104 South Goodwin Avenue, Urbana, Illinois 61801-2902 — Experimental studies of the strong spin-orbit coupled material,  $\text{Sr}_2\text{IrO}_4$ , have provided evidence that the spin dynamics of this material can be described by an isotropic two-dimensional effective Heisenberg description. To study how well this description describes the spin-dynamics of  $\text{Sr}_2\text{IrO}_4$  in different magnetic field regimes, in this talk, we present field-dependent Raman scattering studies of the low-energy spin-dynamics in  $\text{Sr}_2\text{IrO}_4$ . We find that for  $H > 1.5$  T, the spin-dynamics of  $\text{Sr}_2\text{IrO}_4$  are well described by an isotropic, 2D description. However, at low fields,  $H < 1.5$  T, the spin dynamics show evidence for the effects of in-plane anisotropy and interlayer coupling. These effects must therefore be considered when modeling the low-field magnetic and dynamical properties of  $\text{Sr}_2\text{IrO}_4$ .

**9:24AM A26.00006 From  $J_{\text{eff}} = 1/2$  insulator to p-wave superconductor in single-crystal  $\text{Sr}_2\text{Ir}_{1-x}\text{Ru}_x\text{O}_4$  ( $0 \leq x \leq 1$ )**<sup>1</sup>, SHUJUAN YUAN, SAICHARAN ASWARTHAM, JASMINKA TERZIC, HAO ZHENG, HENGDI ZHAO, Center for Advanced Materials, Department of Physics and Astronomy, University of Kentucky, Lexington, Kentucky 40506, USA, PEDRO SCHLOTTMANN, Physics Department, Florida State University, Tallahassee, FL 32306, USA, GANG CAO, Center for Advanced Materials, Department of Physics and Astronomy, University of Kentucky, Lexington, Kentucky 40506, USA —  $\text{Sr}_2\text{IrO}_4$  is a magnetic insulator assisted by strong spin-orbit coupling (SOC) whereas the  $\text{Sr}_2\text{RuO}_4$  is a p-wave superconductor. Our investigation of structural, transport, and magnetic properties reveals that substituting 4d  $\text{Ru}^{4+}$  ( $4d^4$ ) ions for 5d  $\text{Ir}^{4+}$  ( $5d^5$ ) ions in  $\text{Sr}_2\text{IrO}_4$  directly adds holes to the  $t_{2g}$  bands, reduces the SOC and thus rebalances the competing energies in single-crystal  $\text{Sr}_2\text{Ir}_{1-x}\text{Ru}_x\text{O}_4$ . A profound effect of Ru doping driving a rich phase diagram is a structural phase transition from a distorted  $I4_1/acd$  to a more ideal  $I4/mmm$  tetragonal structure near  $x=0.50$  that accompanies a phase transition from an antiferromagnetic-insulating state to a paramagnetic-metal state. We also make a comparison drawn with Rh doped  $\text{Sr}_2\text{IrO}_4$ , highlighting important similarities and differences.

**9:36AM A26.00007 Probing Novel States of Iridates and Ruthenates under Extreme Conditions**<sup>1</sup>, JASMINKA TERZIC, HAO ZHENG, Center for Advanced Materials and Department of Physics and Astronomy, University of Kentucky, Lexington, KY 40506, USA, PANPAN KONG, CHANQING JIN, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, DANIEL HASKEL, Advanced Photon Source, Argonne National Laboratory, Argonne, Illinois 60439, USA, OLEKSANDR KORNETA, Center for Correlated Electron Systems, Institute for Basic Science (IBS), Seoul National University, Seoul 151-742, Korea, SHUJUAN YUAN, GANG CAO, Center for Advanced Materials and Department of Physics and Astronomy, University of Kentucky, Lexington, KY 40506, USA — The highly delicate balance between competing energies in materials of interest makes high-pressure and high-magnetic-field powerful probes for generating novel states. Our studies have uncovered a number of remarkable properties of iridates and ruthenates under extreme conditions: avoidance of metallization at high pressures, absent conventional correlations between magnetic and insulating states in iridates; coexistence of a bulk insulating state and quantum oscillations period in  $1/B$  or  $B$  (depending on the orientation of  $B$  which is applied magnetic field), and colossal magnetoresistivity without spin polarization in ruthenates. We will present and discuss our results with comparison drawn with relevant systems.

**9:48AM A26.00008 Mott Physics in lightly doped  $(\text{Sr}_{1-x}\text{La}_x)_3\text{Ir}_2\text{O}_7$** , GREGORY AFFELDT, TOM HOGAN, University of California, Berkeley and Lawrence Berkeley National Laboratory, CHRISTOPHER SMALLWOOD, University of California, Berkeley, TANMOY DAS, Los Alamos National Laboratory, JONATHAN DENLINGER, SUNG-KWAN MO, Lawrence Berkeley National Laboratory, STEPHEN WILSON, University of California, Santa Barbara, ALESSANDRA LANZARA, University of California, Berkeley and Lawrence Berkeley National Laboratory — The layered perovskite iridates  $\text{Sr}_2\text{IrO}_4$  and  $\text{Sr}_3\text{Ir}_2\text{O}_7$  exhibit a spin-orbit Mott insulating state that becomes metallic upon sufficient carrier doping. While  $\text{Sr}_2\text{IrO}_4$  presents striking similarities to cuprates upon electron doping,  $\text{Sr}_3\text{Ir}_2\text{O}_7$  appears to be a correlated metal. We show a detailed doping and temperature-dependent ARPES study which reveals important similarities between  $(\text{Sr}_{1-x}\text{La}_x)_3\text{Ir}_2\text{O}_7$  and doped  $\text{Sr}_2\text{IrO}_4$ , as well as other doped Mott insulators.

**10:00AM A26.00009 Shubnikov-de Haas oscillation of  $\text{KTaO}_3$  based electron gases**, LUDI MIAO, RENZHONG DU, QI LI, The Pennsylvania State University, QI LI'S LAB TEAM — Two-dimensional electron gases (2DEGs) at transition metal oxide (TMO) surfaces and interfaces have attracted much attention due to their exotic properties such as superconductivity, and ferromagnetism. Recently, 5d TMOs are hotly investigated due to their strong spin-orbit coupling (SOC), an indispensable element for topological insulating states. Among them,  $\text{KTaO}_3$  not only hosts 2DEGs but also involves strong SOC. We have created  $\text{KTaO}_3$  based electron gases, with low temperature mobility as large as  $8000\text{cm}^2\text{V}^{-1}\text{s}^{-1}$ . Shubnikov de Haas oscillations in magnetoresistance have been observed at 1.8 K for field applied along various directions. Contributions from  $d_{xy}$  and  $d_{xz/yz}$  bands are both seen. These oscillation curves exhibit a field direction dependence with 4-fold symmetry, revealing the cubic symmetry of Fermi surface of  $\text{KTaO}_3$  based electron gases. Moreover, the intercept of oscillation indices is close to 0.5, a typical value for systems that involve strong SOC. Our results provide unique insights into the electronic structures of  $\text{KTaO}_3$  based electron gases via magnetotransport measurements.

**10:12AM A26.00010 Pulsed laser deposition and characterizations of pyrochlore iridate thin films**, MATTHEW STARR, JAIME AVILES-ACOSTA, Indiana University, Bloomington, YUANTAO XIE, Virginia Tech, WENKA ZHU, Indiana University, Bloomington, ZHEN LI, Indiana University, Bloomington; Los Alamos National Laboratory, AIPING CHEN, NAN LI, Los Alamos National Laboratory, CHENGGANG TAO, Virginia Tech, QUANXI JIA, Los Alamos National Laboratory, J. J. HEREMANS, Virginia Tech, S. X. ZHANG, Indiana University, Bloomington — Pyrochlore iridates have attracted growing interest in recent years because of their potential to realize novel topological phases. While most of the previous studies have focused on polycrystalline and single crystalline bulk samples, epitaxial thin films offer a unique platform for controllable tuning of material parameters such as oxygen stoichiometry and elastic strain to achieve new electronic states. In this talk, we will present the growth and characterizations of epitaxial thin films of pyrochlore  $\text{Y}_2\text{Ir}_2\text{O}_7$  and  $\text{Bi}_2\text{Ir}_2\text{O}_7$  that are predicted to host topologically non-trivial states. The iridate thin films were grown by pulsed laser deposition at different conditions, and a narrow window for epitaxial growth was determined. Characterizations of crystalline structures were performed using X-ray diffraction and transmission electron microscopy to establish a growth parameter-structure phase diagram. The compositions of thin films were determined by energy dispersive X-ray spectroscopy, and the surface morphologies were characterized using atomic force microscopy and scanning tunneling microscopy. Magneto-transport studies indicate a strong dependence of transport properties on the oxygen stoichiometry and the film thickness.

**10:24AM A26.00011 Strongly enhanced Rashba splitting in the perovskite tantalate-hafnate heterostructure**, SUK BUM CHUNG, Seoul Natl Univ, MINSUNG KIM, Ames Laboratory / Iowa State University — In addition to superconductivity and magnetism, one notable ingredient of the two-dimensional electron gas (2DEG) emerging at the transition metal oxide surface is the Rashba-Dresselhaus spin-orbit interaction, the momentum-dependent spin splitting due to the broken inversion symmetry and atomic spin-orbit coupling. However, it has not been understood how this splitting can be maximized in a physical system without applying external electric field. Here, we present a promising route to realize significant Rashba-type band splitting using thin film heterostructure. Based on a first-principles method and analytic model analysis, a tantalate layer on  $\text{BaHfO}_3$  is shown to host a two-dimensional bands originating from Ta  $t_{2g}$  orbitals with strongly enhanced Rashba-Dresselhaus spin splittings at both the band minima and saddle points. A significant  $t_{2g}$ - $e_g$  coupling that contributes to this enhanced splitting is likely to be a generic feature for the surface 2DEG of transition metal oxide with maximal inversion symmetry breaking. Our results could be important in realizing topological superconductivity and potentially useful for spintronics application.

**10:36AM A26.00012 Elastic and inelastic scattering in  $\text{SrTiO}_{3-\delta}$** , KAMRAN BEHNIA, XIAO LIN, BENOIT FAUQU, ESPCI — Scattering among electrons generates a distinct contribution to electrical resistivity that follows a quadratic temperature dependence. We show that the prefactor of this  $T^2$  resistivity can be tuned by four orders of magnitude in metallic  $\text{SrTiO}_3$  by tuning the concentration of the carriers and consequently, the Fermi energy. The  $T^2$  behavior persists in the single-band dilute limit despite the absence of two known mechanisms for  $T^2$  behavior, distinct electron reservoirs and Umklapp processes. The ultimate origin of the small residual resistivity is the long Bohr radius, which, in a shallow Fermi sea caused by a random distribution of dopants, sets the zero-temperature mobility.

Session A27 DMP: Carbon Nanotube & Related Materials: Growth, Separation, and Assembly  
326 - Zhihong Chen, Purdue University

**8:00AM A27.00001 Nonequilibrium statistical mechanics of nanotube nucleation**, VASILII I. ARTYUKHOV, BORIS I. YAKOBSON, Rice University — A key problem that advanced carbon nanotube applications face is the difficulty of producing pure single-helicity samples. As the elementary processes of nanotube growth are difficult to observe in situ, theoretical understanding of the process is especially important. Direct molecular dynamics simulations offer limited insight due to computational intractability of space- and time-scales involved. We formulated a theory that explains a class of helicity-selective growth experiments, based on classical nucleation theory and crystal growth kinetics.<sup>1</sup> However, a general theory of nanotube growth must also include fast irreversible growth beyond the classical near-equilibrium assumption. Here we construct a coarse-grained model allowing us to rigorously investigate the statistical mechanics of nanotube nucleation and trace how helicity emerges from the global nucleation trajectory ensemble. Importantly, our model can handle the whole range of conditions from perfect reversibility driven by energetics to perfect irreversibility driven by configurational entropy of nanotube caps and edges. Our theory generalizes earlier models in a large advance towards ultimate understanding of helicity-selective synthesis. <sup>1</sup> V.I. Artyukhov, E.S. Penev, and B.I. Yakobson, Nat. Commun. 5, 4892 (2014)

**8:12AM A27.00002 Adsorption of SDS surfactant inside and around carbon nanotubes with DPD simulation**, MINH VO, The University of Oklahoma, DIMITRIOS PAPAVALASSILOU, National Science Foundation — The inner diameter of a carbon nanotube (CNT) is generally from 1 to 20 nm, while its inner space could be filled by certain compounds. In our study, Dissipative Particle Dynamics (DPD) simulations were utilized to investigate the ability of sodium dodecyl sulfate (SDS) to adsorb inside a single-walled CNT. First of all, the DPD interaction parameters for SDS surfactants were validated by determining the CMC of surfactants from DPD calculation. The SDS micelle shape and size in water were also calculated. Water-CNT interactions were obtained from a prior study [1]. When the SDS aqueous system reached equilibrium, an open-ended, hydrophobic CNT (a hollow cylinder in the simulation) was inserted into the solution. The diameter of the CNT varied from 1 to 5 nm. All simulations were run up to  $2 \times 10^6$  time steps at room temperature. For the system of water and CNT, the radial and axial density profiles of water were computed and compared with published Molecular Dynamics results. In the presence of SDS, the distribution of water and SDS inside the CNT was found to be comparable to that in bulk solution after the system reached equilibrium. In addition, the diffusivity and residence time of water and SDS inside CNTs of different were calculated. This study would give insights into the dynamics and morphology of surfactants in nanoconfined structures. References [1] Vo, M.; Papavassiliou, D. V., Molecular Simulation, 2015, DOI:10.1080/08927022.2015.1089989

**8:24AM A27.00003 Intensity Ratio of Resonant Raman Modes for  $(n, m)$  Enriched Semiconducting Carbon Nanotubes**, YANMEI PIAO, National Institute of Standards and Technology, JEFFREY SIMPSON, Towson University, JASON STREIT, GEYOU AO, JEFFREY FAGAN, ANGELA HIGHT WALKER, National Institute of Standards and Technology — Relative intensities of resonant Raman spectral features, specifically the radial breathing mode (RBM) and G modes, of eleven, chirality-enriched, single-wall carbon nanotube (SWCNT) species were established under second-order optical transition excitation. The results demonstrate a significantly under-recognized complexity in the evaluation of Raman spectra for the assignment of  $(n, m)$  population distributions. Strong chiral angle and mod dependencies affect the intensity ratio of the RBM to G modes and can result in misleading interpretations. Furthermore, we report five additional values for chirality dependent  $G^+$  and  $G^-$  Raman peak positions and intensities, supporting accuracy in literature values, and extending the available data to cover more of the small diameter regime by including the first (5,4) second-order, resonance Raman spectra. Together, the Raman spectral library is demonstrated to be sufficient for decoupling multiple species via a spectral fitting process, and enable fundamental characterization even in mixed chiral population samples.

**8:36AM A27.00004 Structure-Controlled Synthesis of Single-Walled Carbon Nanotubes<sup>1</sup>**, YAN LI, Peking University, Beijing, China — Single-walled carbon nanotubes (SWNTs) present structure-determined outstanding properties and SWNTs with a single  $(n, m)$  type are needed in many advanced applications. However, the chirality-specific growth of SWNTs is always a great challenge. Carbon nanotubes and their caps or catalysts can all act as the structural templates to guide the formation of SWNTs with a specified chirality. SWNT growth via a catalyzed chemical vapor deposition CVD process is normally more efficient and therefore of great interest. We developed a new family of catalyst, tungsten-based intermetallic nanocrystals, to grow SWNTs with specified chiral structures. Such intermetallic nanocrystals present unique structure and atomic arrangements, which are distinctly different from the normal alloy nanoparticles or simple metal nanocrystals, therefore can act as the template to grow SWNTs with designed  $(n, m)$  structures. Using W<sub>6</sub>Co<sub>7</sub> catalysts, we realized the selective growth of (12, 6), (16, 0), (14, 4) and other chiralities. By the cooperation of thermodynamic and kinetic factors, SWNTs with high chirality purity can be obtained. .

<sup>1</sup>Structure-Controlled Synthesis of Single-Walled Carbon Nanotubes

**9:12AM A27.00005 Growth of Single-Walled Carbon Nanotubes by High Melting Point Metal Oxide Catalysts<sup>1</sup>**, YANG QIAN, RONG XIANG, HUA AN, TAIKI INOUE, SHOHEI CHIASHI, Department of Mechanical Engineering, The University of Tokyo, SHIGEO MARUYAMA, Department of Mechanical Engineering, The University of Tokyo; National Institute of Advanced Industrial Science and Technology (AIST) — We report on the growth of single-walled carbon nanotubes (SWNTs) from Co oxide catalysts. The concept is using the relatively lower mobility of metal oxide (than metal) to suppress catalyst aggregation at high temperatures. Compared to the SWNTs grown by pre-reduced catalysts, SWNTs grown from oxidized Co catalysts have shown narrower diameter distribution and smaller average diameter. Different growth parameters are discussed regarding the resulting morphology of SWNTs. Transmission electron microscopy (TEM) investigations reveal the information that Co catalysts are transformed to Co<sub>3</sub>O<sub>4</sub> after reduction-calcination process. X-ray photoelectron spectroscopy (XPS) investigations indicate that Co<sub>3</sub>O<sub>4</sub> has decomposed to CoO before growth at a typical growth temperature (800 C) in Ar atmosphere. We propose that CoO has higher melting point than Co and thus is more stable during the growth. Our results indicate that besides the bimetallic catalysts, monometallic catalytic system could also be useful in stabilizing the catalysts to grow chirality-specific SWNTs by transforming the relatively low melting point metal catalysts to high melting point metal oxide catalysts.

**9:24AM A27.00006 Endohedral Volume Control for Improved Single-Wall Carbon Nanotubes**, JOCHEN CAMPO, JEFFREY FAGAN, Materials Science and Engineering Division, National Institute of Standards and Technology, Gaithersburg, Maryland — Liquid-phase processing of single-wall carbon nanotubes (SWCNTs) generally results in the exposure of their core volumes to the environment (opening) due to energy input necessary for purification and solubilization. For aqueous processing this results in SWCNTs routinely getting filled with water, which is detrimental to several properties. Importantly, water filling leads to significant redshifts to, and inhomogeneous broadening of, the electronic transitions of the SWCNTs, as well as a substantial decrease to their fluorescence quantum efficiency. Selection of (remaining) empty (end-capped) SWCNTs to avoid these adverse effects is possible by means of ultracentrifugation, but is a natively low yield process. In this work, SWCNTs are prefilled with linear alkanes or similar organic compounds, serving as a passive, highly homogeneous spacer, blocking the ingestion of water and hence preventing the detrimental consequences. Moreover, the low dielectric nature of the alkane core only weakly affects the local electronic wavefunction of the SWCNTs, effectively simulating empty core conditions and hence yielding much more resolved optical spectra with blue shifted peak positions compared to water filled SWCNTs. It is demonstrated that a wide variety of linear as well as cyclic alkanes can be applied for this purpose, in combination with various SWCNT materials.

**9:36AM A27.00007 Optical excitation of carbon nanotubes drives stoichiometric reaction with diazonium salts**, LYNDSEY POWELL, University of Maryland, YANMEI PIAO, NIST, YUHUANG WANG, University of Maryland, YUHUANG WANG RESEARCH GROUP TEAM — Covalent chemistry is known to lack the precision required to tailor the physical properties of carbon nanostructures. Here we show that, for the first time, light can be used to drive a typically inefficient reaction with single-walled carbon nanotubes in a more stoichiometric fashion. Specifically, our experimental results suggest that light can enhance the reaction rate of diazonium salt with carbon nanotubes by as much as 35-fold, making possible stoichiometric control of the covalent bonding of a functional group to the sp<sup>2</sup> carbon lattice. This light-controlled reaction paves the way for the possibility of highly selective and precise chemistry on single-walled carbon nanotubes and other graphitic nanostructures.

**9:48AM A27.00008 Chirality-controlled synthesis and macro-electronic applications of carbon nanotubes**, CHONGWU ZHOU, University of Southern California — Carbon nanotubes (CNTs) are promising materials for electronic applications due to their interesting properties. Chirality and electronic property controlled preparation are key challenges which need to be solved for practical use of CNTs in electronics. In this talk, I will first introduce our research on chirality-controlled synthesis of CNTs using metal-free carbon seeds. I will talk about chirality-controlled growth of SWCNTs using chirality-sorted nanotube seeds via a vapour phase epitaxy (VPE) cloning approach. Observations on the chirality-dependent growth rate and active lifetime of the nanotube seeds in the VPE process will be presented. Later, I will talk about selective growth of small diameter semiconducting CNTs using organic chemistry synthesized molecular seeds. In the second part, I will talk about the use of pre-separated, semiconducting-enriched CNTs for macro-electronics, printed electronics, and integrated circuits. Our work on the use of CNTs for thin-film transistors, CNT-IGZO hybrid CMOS circuits, and flexible, bendable, and transparent CNT devices and circuits will be presented. These works demonstrate the great potential of CNTs as advanced electronic materials.

**10:24AM A27.00009 Uniformly spaced arrays of purely semiconducting carbon nanotubes**, ABRAM FALK<sup>1</sup>, BHARAT KUMAR, GEORGE TULEVSKI, DAMON FARMER, JAMES HANNON, SHU-JEN HAN, IBM T. J. Watson Research Center, Yorktown Heights, NY — Patterning uniformly spaced arrays of carbon nanotubes (CNTs) is a key challenge for carbon electronics. Our group adopts a hybrid approach to meeting this goal. We use top-down lithography to pattern trenches on chips. We then use surface-selective chemical monolayers to facilitate the bottom-up assembly of solution-processed CNTs into these trenches. Previously, we showed large-scale integration of CNTs based on this approach [1], but modifications to this process have been needed in order to improve the yield and decrease the fraction of non-switching devices. Our latest results show a high degree of selectivity, alignment and yield of successfully placed CNTs at a 100 nm pitch. Electrical measurements confirm that these chemically placed CNTs are nearly 100% semiconducting and of similar quality to randomly dispersed ones. I will then discuss our strategies for increasing the CNT density and extending these results from chip- to wafer-scale electronics. [1] Park et al., Nature Nanotechnology 7, 787-791 (2012)

**10:36AM A27.00010 Nanoscale Structure and Interaction of Compact Assemblies of Carbon Nano-Materials.**, RAJU TIMSINA, XIANGYUN QIU, George Washington University, Washington DC — Carbon-based nano-materials (CNM) are a diverse family of multi-functional materials under research and development world wide. Our work is further motivated by the predictive power of the physical understanding of the underlying structure-interaction-function relationships. Here we present results from recent studies of the condensed phases of several model CNMs in complexation with biologically derived molecules. Specifically, we employ X-ray diffraction (XRD) to determine nanoscale structures and use the osmotic stress method to quantify their interactions. The systems under investigation are dsDNA-dispersed carbon nanotubes (dsDNA-CNT), bile-salt-dispersed carbon nanotubes, and surfactant-assisted assemblies of graphene oxides. We found that salt and molecular crowding are both effective in condensing CNMs but the resultant structures show disparate phase behaviors. The molecular interactions driving the condensation/assembly sensitively depend on the nature of CNM complex surface chemistry and range from hydrophobic to electrostatic to entropic forces.

**10:48AM A27.00011 Synthesis and Investigation of Millimeter-Scale Vertically Aligned Boron Nitride Nanotube Arrays**, ROLAND TAY, HONGLING LI, SIU HON TSANG, LIN JING, DUNLIN TAN, EDWIN HANG TONG TEO, Nanyang Tech Univ — Boron nitride nanotubes (BNNTs) have shown potential in a wide range of applications due to their superior properties such as exceptionally high mechanical strength, excellent chemical and thermal stabilities. However, previously reported methods to date only produced BNNTs with limited length/density and insufficient yield at high temperatures. Here we present a facile and effective two-step synthesis route involving template-assisted chemical vapor deposition at a relatively low temperature of 900 degree C and subsequent annealing process to fabricate vertically aligned (VA) BN coated carbon nanotube (VA-BN/CNT) and VA-BNNT arrays. By using this method, we achieve the longest VA-BN/CNTs and VA-BNNTs to date with lengths of over millimeters (exceeding two orders of magnitude longer than the previously reported length of VA-BNNTs). In addition, the morphology, chemical composition and microstructure of the resulting products, as well as the mechanism of coating process are systematically investigated. This versatile BN coating technique and the synthesis of millimeter-scale BN/CNT and BNNT arrays pave a way for new applications especially where the aligned geometry of the NTs is essential such as for field-emission, interconnects and thermal management.

**Session A28 DMP DCMP: Topological Phases** 327 - Yong Chen, Purdue University

**8:00AM A28.00001 Predicting, Realizing and Exploiting Exotic Topological Phases of Quantum Matter**<sup>1</sup>, ARUN BANSIL, Northeastern University — The revolution started by the discovery of topological insulators a few years ago has turned out to be the proverbial tip of the much larger iceberg of exotic phases harbored by quantum matter. Consideration of electronic states protected by time-reversal, crystalline and particle-hole symmetries has led to the prediction of many novel 3D materials, which can support Weyl, Dirac and Majorana fermions, and to new types of insulators such as topological crystalline insulators and topological Kondo insulators, as well as 2D quantum spin Hall insulators with large band gaps capable of surviving room temperature thermal excitations. [1] In this talk, I will discuss our recent theoretical work aimed at predicting topological materials beyond the standard topological insulators and identify cases where robust experimental evidence has been obtained toward their successful materials realization. [2-10] I will also comment on the potential of topological materials as next generation platforms for manipulating spin and charge transport and other applications. [1] A. Bansil, H. Lin and T. Das, Reviews of Modern Physics (2015). [2] S.-Y. Xu et al., Science 349, 613 (2015). [3] I. Zeljkovic et al., Nature Materials 14, 318 (2015). [4] J. He et al., Nature Materials 14, 577 (2015). **8:36AM A28.00002 Electronic structure of Na<sub>3</sub>Bi near the Dirac point: Optical measurements**<sup>1</sup>, GREGORY S. JENKINS, A. B. SUSHKOV, R. L. CAREY, H. D. DREW, U. of Md College Park, J. KRIZAN, S. KUSHWAHA, R. CAVA, Princeton U., TAY-RONG CHANG, HORNG-TAY JENG, National Tsing Hua U., H. LIN, NUS, C. LANE, B. BARBIELLINI, A. BANSIL, Northeastern U. — The first optical characterization of Na<sub>3</sub>Bi is reported. Reflection measurements on c-plane oriented single-crystals, over the spectral range from 3 meV to 2.5 eV and temperature ranging from 8 to 250K, show a low frequency response consistent with the low doping level  $n \sim 10^{17} \text{ cm}^{-3}$ . The number of observed phonons in the optical spectra is >5, which eliminates the P6<sub>3</sub>/mmc symmetry since point group analysis indicates only 2 IR active phonons. A striking, strongly temperature dependent plasma edge reverses direction at  $T \sim 100\text{K}$ . The behavior is consistent with thermal population effects in a Dirac cone permitting an estimation of the Fermi level. The Lifshitz gap energy is reported.

**8:48AM A28.00003 Electronic structure of  $\text{Na}_3\text{Bi}$  near the Dirac point: Theory<sup>1</sup>**, CHRIS LANE, B. BARBIELLINI, A. BANSIL, Northeastern U., TAY-RONG CHANG, HORNG-TAY JENG, National Tsing Hua U., H. LIN, NUS, J. KRIZAN, S. KUSHWAHA, R. CAVA, Princeton U., G. S. JENKINS, A. B. SUSHKOV, R. L. CAREY, H. D. DREW, U. of Md College Park — Band structure calculations have been performed and compared with recent optical experiments. The ground state of the system is found to be not the highly symmetric  $\text{P6}_3/\text{mmc}$  structure, but instead the  $\text{P}\bar{3}\text{c}1$  that involves buckling of the Na-Bi hexagonal planes. The band structure shows very little change between various symmetry configurations, yet the low-energy optical transition matrix elements are dramatically enhanced in the  $\text{P}\bar{3}\text{c}1$  symmetry compared with  $\text{P6}_3/\text{mmc}$ , which results in an electronic response that agrees much more closely with optical data. A peak in the joint density of states driven by the particle-hole asymmetry of the band structure along the  $\Gamma - A$  momentum direction results in a large peak in the imaginary part of the dielectric function. Systematic changes are observed in the low energy Dirac cone Fermi velocity and Lifshitz gap energy with lattice spacing and spin-orbit coupling. The large anisotropies of the Dirac cone and small energy gaps are discussed.

**9:00AM A28.00004 Universal signatures of Fermi arcs in quasiparticle interference on the surface of Weyl semimetals**, STEFANOS KOURTIS, JIAN LI, ZHI JUN WANG, B. ANDREI BERNEVIG, Department of Physics, Princeton University, Princeton, NJ 08544, USA — Weyl semimetals constitute a newly discovered class of three-dimensional topological materials with linear touchings of valence and conduction bands in the bulk. The most striking property of topological origin in these materials, so far only observed in photoemission experiments, is the presence of open constant-energy contours in the boundary density of states — the so-called Fermi arcs. In this work, we establish the universal characteristics of Fermi-arc contributions to surface quasiparticle interference. Using a general phenomenological model, we determine the defining interference patterns stemming from the existence of Fermi arcs in a surface band structure. We then trace these patterns in both simple tight-binding models and realistic ab initio calculations. Our results show that definitive signatures of Fermi arcs can be observed in existing and proposed Weyl semimetals using current scanning tunneling spectroscopy setups.

**9:12AM A28.00005 Probing spin-momentum locking of Weyl nodes with neutron scattering**, MICHAEL BJERNGAARD, Department of Physics and Astronomy, Johns Hopkins University, Baltimore, United States of America, BOGDAN GALILO, Department of Mathematics, Imperial College London, London, United Kingdom, ARI TURNER, Department of Physics and Astronomy, Johns Hopkins University, Baltimore, United States of America — We explain how a Weyl semimetal phase can be uniquely identified in the differential cross-section measured by an unpolarized neutron experiment. This differential cross-section has unique features that reflect the scattering between Weyl nodes of either same or opposite Chern numbers / spin-momentum locking. Hence, an unpolarized neutron experiment can uniquely identify Weyl semimetals of both inversion- and time-reversal symmetric classes. This is very desirable, as no experimental probe has yet directly confirmed such phases. Further, we describe how the neutron spectrum can distinguish proposed Weyl semimetals from Dirac semimetals.

**9:24AM A28.00006 Tuning Weyl nodes with a magnetic field**, JENNIFER CANO, BARRY BRADLYN, Princeton Center for Theoretical Science, ZHIJUN WANG, MAX HIRSCHBERGER, N. PHUAN ONG, B. ANDREI BERNEVIG, Princeton University — For Weyl fermions to exist, either inversion or time reversal symmetry must be broken. Here, we consider materials with a normal and/or inverted band structure that display a four band (Dirac) crossing in the presence of both these symmetries. We show that when a magnetic field is applied, thus breaking time reversal, the four band crossing splits into several Weyl nodes, depending on the direction in which the magnetic field is applied as well as on the symmetry group that protected the Dirac crossing. For a particular material realization, relevant to current experiments performed in Princeton, we use a symmetry analysis to predict the position of the Weyl nodes when the magnetic field is along a high-symmetry axis. While the symmetry is not necessary to protect the Weyl crossings, it is a useful tool to find them. Our results agree with both an ab initio and a  $k \cdot p$  effective Hamiltonian analysis.

**9:36AM A28.00007 Spiraling Fermi arcs in Weyl materials<sup>1</sup>**, SONGCI LI, ANTON ANDREEV, Univ of Washington — In Weyl materials the valence and conduction electron bands touch at an even number of isolated points in the Brillouin zone. In the vicinity of these points the electron dispersion is linear and may be described by the massless Dirac equation. This results in nontrivial topology of Berry connection curvature. One of its consequences is the existence of peculiar surface electron states whose Fermi surfaces form arcs connecting projections of the Weyl points onto the surface plane. Band bending near the boundary of the crystal also produces surface states. We show that in Weyl materials band bending near the crystal surface gives rise to spiral structure of energy surfaces of arc states. The corresponding Fermi surface has the shape of a spiral that winds about the projection of the Weyl point onto the surface plane. The direction of the winding is determined by the helicity of the Weyl point and the sign of the band bending potential. For close valleys arc state morphology may be understood in terms of avoided crossing of oppositely winding spirals.

**9:48AM A28.00008 Creating chiral anomalies**, BARRY BRADLYN, JENNIFER CANO, ZHIJUN WANG, MAX HIRSCHBERGER, N. PHUAN ONG, B. ANDREI BERNEVIG, Princeton University — Materials with intrinsic Weyl points should present exotic magneto-transport phenomena due to spectral flow between Weyl nodes of opposite chirality - the so-called “chiral anomaly”. However, to date, the most definitive transport data showing the presence of a chiral anomaly comes from Dirac (not Weyl) materials. These semimetals develop Weyl fermions only in the presence of an externally applied magnetic field, when the four-fold degeneracy is lifted. In this talk we examine Berry phase effects on transport due to the emergence of these field-induced Weyl point and (in some cases) line nodes. We pay particular attention to the differences between intrinsic and field-induced Weyl fermions, from the point of view of kinetic theory. Finally, we apply our analysis to a particular material relevant to current experiments performed at Princeton.

**10:00AM A28.00009 Visualizing Weyl Fermions in  $\text{MoTe}_2$  Using Scanning Tunneling Microscopy**, AYELET NOTIS, ERICK ANDRADE, Columbia University, SANG-WOOK CHEONG, Rutgers University, ABHAY PASUPATHY, Columbia University —  $\text{MoTe}_2$ , a transition metal dichalcogenide, has a metastable orthorhombic phase at temperatures below 250 K. This phase is predicted to be a type II Weyl semimetal, providing us an exciting new opportunity to explore Weyl Fermions, a type of particle long sought after but only recently realized as a quasiparticle excitation in a crystal. A topological consequence of the existence of Weyl points in a crystal is the existence of Fermi arc surface states that connect pairs of Weyl points. Here, we present scanning tunneling microscopy and spectroscopy (STM and STS) studies investigating the topography and electronic structure of this material. We resolve the crystal structure of the orthorhombic phase in STM topography, and probe the electronic structure of the Fermi arc states using quasiparticle interference imaging.

**10:12AM A28.00010 Stable Dirac semi-metal in the allotrope of IV elements**, PEIZHE TANG, Stanford Univ, WENDONG CAO, Tsinghua Univ, SHOU-CHENG ZHANG, Stanford Univ, WENHUI DUAN, Tsinghua Univ, ANGEL RUBIO, Max Planck Institute for the Structure and Dynamics of Matter and Center for Free-Electron Laser Science,, ZHANG'S GROUP COLLABORATION, ANGEL'S GROUP COLLABORATION, DUAN'S GROUP COLLABORATION — Three dimensional (3D) topological Dirac semi-metals (SM) represent a novel state of quantum matter with exotic electronic structures, in which a pair of Dirac points with the linear dispersion along all three momentum directions exist in the bulk and are protected by the rotation symmetry. Regarded as the copies of 3D Weyl SMs, the Dirac SMs possess unique Fermi-arcs with helical spin textures on some specific surface planes. Herein, by using first principles calculations with the hybrid functional, we discover a new metastable allotrope of Ge and Sn with the staggered layered dumbbell structure, named as germancite and stancite, to be 3D Dirac SMs with a pair of Dirac points on the rotation axis of  $C_3$ . On the surface parallel to the rotation axis, a pair of topologically non-trivial Fermi arcs are observed to be coexisting with the trivial surface states; and via tuning the Fermi level, the hybridization between them induces a Lifshitz transition on the Fermi surface. Furthermore, the quantum thin film of the germancite is found to be the quantum spin Hall insulator without applying external electric field. These discoveries explore the metastable allotrope of Ge and Sn as topological Dirac SMs showing novel physical properties and future applications.

**10:24AM A28.00011 Chiral magnetic effect and natural optical activity in (Weyl) metals<sup>1</sup>**, DMYTRO PESIN, JING MA, Univ of Utah — We consider the phenomenon of natural optical activity, and related chiral magnetic effect in metals with low carrier concentration. To reveal the correspondence between the two phenomena, we compute the optical conductivity of a noncentrosymmetric metal to linear order in the wave vector of the light wave, specializing to the low-frequency regime. We show that it is the orbital magnetic moment of quasiparticles that is responsible for the natural optical activity, and thus the chiral magnetic effect. While for purely static magnetic fields the chiral magnetic effect is known to have a topological origin and to be related to the presence of Berry curvature monopoles (Weyl points) in the band structure, we show that the existence of Berry monopoles is not required for the dynamic chiral magnetic effect to appear; the latter is thus not unique to Weyl metals. The magnitude of the dynamic chiral magnetic effect in a material is related to the trace of its gyrotropic tensor. We discuss the conditions under which this trace is non-zero; in noncentrosymmetric Weyl metals it is found to be proportional to the energy-space dipole moment of Berry curvature monopoles. The calculations are done within both the semiclassical kinetic equation, and Kubo linear response formalisms.

**10:36AM A28.00012 Symmetry-based Search for Topological Weyl Nodes and Nodal-lines in Realistic Materials**, MOTOAKI HIRAYAMA, SHUICHI MURAKAMI, Dept. of Physics, Tokyo Tech.; TIES, Tokyo Tech., RYO OKUGAWA, Dept. of Physics, Tokyo Tech., SHOJI ISHIBASHI, TAKASHI MIYAKE, CD-FMat, National Institute of Advanced Industrial Science and Technology — Topological semimetals such as Weyl semimetals and nodal-line semimetals have been under intensive investigation recently. In this study, to realize such semimetals, we start from any insulators without inversion symmetry, and assume that the gap closes by changing some parameter. We then show that after the gap-closing there are only two possibilities; one is a Weyl semimetal phase, and the other is a nodal-line semimetal, depending on the symmetry and the position of the gap-closing point. Our analysis tells us which cases lead to Weyl semimetal and to the nodal-line semimetal, and this result can be used to find realistic topological semimetals. As an example, we study tellurium [1] using ab initio calculation based on relativistic density functional theory. The electronic structure is calculated by OpenMX [2] and the structural optimization is executed by QMAS [3]. We find that HfS has the nodal line in the mirror symmetry plane, and the nodal-line vanishes by pressure or atomic substitution. We also propose some materials showing the spinless nodal lines and its topological surface states. [1] M. Hirayama, R. Okugawa, S. Ishibashi, S. Murakami, and T. Miyake, Phys. Rev. Lett. 114, 206401 (2015). [2] <http://www.openmx-square.org/> [3] <http://www.qmas.jp/>

**10:48AM A28.00013 Boundary Conditions and Self-Adjoint Extensions of a Continuum Weyl Semimetal Hamiltonian<sup>1</sup>**, MICHAEL VENNETTILLI, Ursinus College, BABAK SERADJEH, Indiana University - Bloomington, ARIJIT KUNDU, Technion - Israel Institute of Technology & Indiana University - Bloomington, MOSTAFA TANHAYI AHARI, Indiana University - Bloomington — A Weyl semimetal is a Dirac material where the spin degeneracy of the energy-momentum Dirac cones is broken. The surface states of Weyl semimetals are expected to permit Fermi arcs connecting the surface-projections of the two Weyl nodes. The existence and physical properties of these surface states depends crucially on the boundary conditions at the surface. Generally speaking, boundary conditions placed on an unbounded Hermitian operator have an intimate relationship with the possible self-adjoint extensions of the operator. Indeed, determining the self-adjoint extensions of the operator naturally classifies all physical boundary conditions on the wavefunctions. We have studied the self-adjoint extensions of a model continuum Hamiltonian for Weyl semimetals and their corresponding classes of surface states. In this way, all possible physical surface spectra of the Weyl semimetal corresponding to different physical realizations of the surface are contained within our result.

**Monday, March 14, 2016 8:00AM - 11:00AM —**  
**Session A29 DCMP: Dirac Semimetal** 328 - Jeffrey Teo, University of Virginia

**8:00AM A29.00001 Ultrafast reflectance of photoexcited Weyl and Dirac semimetals TaAs and ZrSiS**, CHRISTOPHER WEBER, BRYAN BERGGREN, Santa Clara University, KESHAV DANI, Okinawa Institute of Science and Technology, MAZHAR ALI, STUART PARKIN, IBM-Almaden Research Center, LESLIE SCHOOP, BETTINA LOTSCH, Max Planck Institute for Solid State Research, LINGXIAO ZHAO, GENFU CHEN, Beijing National Laboratory for Condensed Matter Physics, — We report ultrafast pump-probe and transient-grating (TG) measurements of the Weyl semimetal TaAs and the Dirac line-node semimetal ZrSiS, and contrast these results with prior measurements on the Dirac semimetal Cd<sub>3</sub>As<sub>2</sub>. After absorption of photons from the pump pulse, we monitor the samples' recovery to equilibrium by measuring the change in reflectance of a time-delayed probe pulse. For TaAs, the reflectance recovers in just 1.2 ps, significantly faster than the 3.1 ps measured in Cd<sub>3</sub>As<sub>2</sub>. This rapid recovery appears not to change when temperature is varied from 300 K to 8 K, when a magnetic field of order 0.3 T is applied, or when the excitation fluence is increased by a factor of 20. TG measurements allow us to assign the changes in reflectance to changes in either the dispersive (real) or absorptive (imaginary) parts of the index of refraction. Intriguingly, and in contrast to Cd<sub>3</sub>As<sub>2</sub>, the initial change in reflectance is caused by an abrupt reduction in the dispersive part, followed by a slower reduction in the absorptive part. For ZrSiS, the recovery after photoexcitation is even faster, at 0.3 ps. We will discuss the implications of these findings for carrier dynamics in topological semimetals.

**8:12AM A29.00002 Ultrafast Photo-Carrier Dynamics and Coherent Phonon Excitations in Topological Dirac Semimetal  $\text{Cd}_3\text{As}_2$** <sup>1</sup>, FEI SUN, QIONG WU, YANLING WU, YICHAO TIAN, YOUGUO SHI, JIMIN ZHAO, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences — Three dimensional (3D) topological Dirac semimetal has attracted growing research interest owing to its intriguing quantum properties such as high bulk carrier mobility and quantum spin Hall effects. However, so far, the ultrafast dynamics of a typical 3D topological Dirac semimetal,  $\text{Cd}_3\text{As}_2$ , as well as its coherent phonon has not been thoroughly investigated. Here we report the ultrafast dynamics of  $\text{Cd}_3\text{As}_2$  by using femtosecond pump-probe spectroscopy. Two distinct relaxation processes was observed, with the lifetimes (at 5 K) of 2.4 ps and 18.6 ps, respectively. Variable temperature experiment from 5 K to 295 K also reveals signatures of phase transitions. Furthermore, coherent optical (8.1 meV) and acoustic (0.036 THz) phonon modes were generated and detected, respectively, with signatures of hybrid-excitation of the two modes.

**8:24AM A29.00003 Gate-tunable quantum oscillations in ambipolar  $\text{Cd}_3\text{As}_2$  thin films**, YANWEN LIU, CHENG ZHANG, XIANG YUAN, TANG LEI, CHAO WANG, Fudan Univ, DOMENICO DI SANTE, SILVIA PICOZZI, CNR-SPIN, LIANG HE, Nanjing University, AWADHESH NARAYAN, STEFANO SANVITO, Trinity College, RENCHAO CHE, FAXIAN XIU, Fudan Univ —  $\text{Cd}_3\text{As}_2$ , a three-dimensional (3D) analog of graphene with extraordinary carrier mobility, was predicted to be a 3D Dirac semimetal, a feature confirmed by recent experiments. Here we report on the first observation of a gate-induced transition from band conduction to hopping conduction in single-crystalline  $\text{Cd}_3\text{As}_2$  thin films via electrostatic doping by solid electrolyte gating. The extreme charge doping enables the unexpected observation of p-type conductivity in a 50-nm-thick  $\text{Cd}_3\text{As}_2$  thin film grown by molecular beam epitaxy. More importantly, the gate-tunable Shubnikov-de Haas oscillations and the temperature-dependent resistance reveal a unique band structure and bandgap opening when the dimensionality of  $\text{Cd}_3\text{As}_2$  is reduced. This is also confirmed by our first-principle calculations. The present results offer new insights toward nanoelectronic and optoelectronic applications of Dirac semimetals and provide new routes in the search for the intriguing quantum spin Hall effect in low-dimension Dirac semimetals. **8:36AM A29.00004 Quantum Oscillations in Weyl and Dirac Semimetal Ultra-Thin Films**, DANIEL BULMASH, XIAO-LIANG QI, Stanford University — We show that a thin film of Weyl or Dirac semimetal with a strong in-plane magnetic field becomes a novel two-dimensional Fermi liquid with interesting properties. The Fermi surface in this system is strongly anisotropic, consisting of a combination of chiral bulk channels and the Fermi arcs. The area enclosed by the Fermi surface is proportional to the magnetic field component parallel to the Weyl/Dirac node splitting, which leads to unusual behavior in quantum oscillations when the magnetic field is tilted out of the plane. We estimate the oscillation frequencies and the regimes where such effects could be seen in  $\text{Cd}_3\text{As}_2$  and TaAs.

**8:48AM A29.00005 Dirac Cone Protected by Non-Symmorphic Symmetry and highly dispersive 3D Dirac crossings in  $\text{ZrSiS}$** , LESLIE SCHOOP, Max Planck Institute for Solid State Research, MAZHAR ALI, IBM-Almaden Research Center, CAROLA STRASSER, VIOLA DUPPEL, Max Planck Institute for Solid State Research, STUART PARKIN, IBM-Almaden Research Center, BETTINA LOTSCH, CHRISTIAN AST, Max Planck Institute for Solid State Research — Materials harboring exotic quasiparticles, such as Dirac and Weyl fermions have garnered much attention from the physics and material science communities. Here, we show with angle resolved photoemission studies supported by ab initio calculations that the highly stable, non-toxic and earth-abundant material,  $\text{ZrSiS}$ , has an electronic band structure that hosts several Dirac cones which form a Fermi surface with a diamond-shaped line of Dirac nodes. We also experimentally show, for the first time, that the square Si lattice in  $\text{ZrSiS}$  is an excellent template for realizing the new types of 2D Dirac cones protected by non-symmorphic symmetry and image an unforeseen surface state that arises close to the 2D Dirac cone. Finally, we find that the energy range of the linearly dispersed bands is as high as 2 eV above and below the Fermi level; much larger than of any known Dirac material so far. We will discuss why these characteristics make  $\text{ZrSiS}$  very promising for future applications.

**9:00AM A29.00006 Helical Spin Order from Topological Dirac and Weyl Semimetals**, XIAO-QI SUN, SHOUCHENG ZHANG, Stanford University, ZHONG WANG, Tsinghua University — We study dynamical mass generation and the resultant helical spin orders in topological Dirac and Weyl semimetals, including the edge states of quantum spin Hall insulators, the surface states of weak topological insulators, and the bulk materials of Weyl semimetals. In particular, the helical spin textures of Weyl semimetals manifest the spin-momentum locking of Weyl fermions in a visible manner. The spin-wave fluctuations of the helical order carry electric charge density; therefore, the spin textures can be electrically controlled in a simple and predictable manner.

**9:12AM A29.00007 Magnetotransport in Dirac semimetals: Chiral magnetic effect and quantum oscillations**, GUSTAVO MONTEIRO, ALEXANDER ABANOV, DMITRI KHARZEEV, Stony Brook University — Dirac semimetals are characterized by the linear dispersion of fermionic quasiparticles, with the Dirac point hidden inside a Fermi surface. We study the magnetotransport in these materials using chiral kinetic theory to describe within the same framework both the negative magnetoresistance caused by the chiral magnetic effect and quantum oscillations in the magnetoresistance due to the existence of the Fermi surface [1]. We also consider the role of Fermi Arcs and their contribution for the SdH modes. We discuss the relevance of obtained results to recent measurements on  $\text{Cd}_3\text{As}_2$ .

**9:24AM A29.00008 Are the surface Fermi arcs in Dirac semimetals topologically protected?**<sup>1</sup>, YUAN MING LU, Department of Physics, The Ohio State University, Columbus, OH 43210, MEHDI KARGARIAN, Department of Physics, University of Maryland, College Park, MD 20742, MOHIT RANDERIA, Department of Physics, The Ohio State University, Columbus, OH 43210 — Motivated by recent experiments probing double Fermi arcs on the surface of Dirac semimetals (DSMs)  $\text{Na}_3\text{Bi}$  and  $\text{Cd}_3\text{As}_2$ , we raise the question posed in the title. We find that, in marked contrast to Weyl semimetals, the Fermi arcs of DSMs are not topologically protected in general, except at certain time-reversal invariant momenta. For a simple 4-band model with a pair of Dirac nodes at  $\mathbf{k} = (0, 0, Q)$  gapless surface states are protected only at  $k_z = 0$ . We identify symmetry allowed bulk perturbations that destroy Fermi arcs, but show that they are necessarily small, i.e., higher order than terms kept in usual  $\mathbf{k} \cdot \mathbf{p}$  theory. We validate our conclusions about the absence of a topological invariant protecting the surface states in DSMs using a K-theory analysis for the space groups of  $\text{Na}_3\text{Bi}$  and  $\text{Cd}_3\text{As}_2$

**9:36AM A29.00009 Angular Magnetoresistance and Hall Measurements in New Dirac Material, ZrSiS**, MAZHAR ALI, IBM-Almaden, MPI-Microstructure Physics, LESLIE SCHOOP, BETTINA LOTSCH, MPI-Solid State Research, STUART PARKIN, IBM-Almaden, MPI-Microstructure Physics — Dirac and Weyl materials have shot to the forefront of condensed matter research in the last few years. Recently, the square-net material, ZrSiS, was theorized and experimentally shown (via ARPES) to host several highly dispersive Dirac cones, including the first Dirac cone demanded by non-symmorphic symmetry in a Si square net. Here we report the magnetoresistance and Hall Effect measurements in this compound. ZrSiS samples with  $RRR = 40$  were found to have MR values up to 6000% at 2 K, be predominantly p-type with a carrier concentration of  $\sim 8 \times 10^{19} \text{ cm}^{-3}$  and mobility  $\sim 8500 \text{ cm}^2/\text{Vs}$ . Angular magnetoresistance measurements reveal a peculiar behavior with multiple local maxima, depending on field strength, indicating of a sensitive and sensitive Fermi surface. SdH oscillations analysis confirms Hall and angular magnetoresistance measurements. These results, in the context of the theoretical and ARPES results, will be discussed.

**9:48AM A29.00010 Observation of quasi-two-dimensional Dirac fermions in ZrTe<sub>5</sub>**, XIANG YUAN, CHENG ZHANG, YANWEN LIU, SHOUDONG SHEN, XING SUI, JIE XU, HAOCHI YU, ZHENG HUA AN, JUN ZHAO, HUGEN YAN, FAXIAN XIU, Fudan University — Since the discovery of graphene, layered materials have attracted extensive interests owing to their unique electronic and optical characteristics. Among them, Dirac semimetal, one of the most appealing categories, has been a long-sought objective in layered systems beyond graphene. Recently, layered pentatelluride ZrTe<sub>5</sub> was found to host signatures of Dirac semimetal. However, the low Fermi level in ZrTe<sub>5</sub> strongly hinders a comprehensive understanding of the whole picture of electronic states through photoemission measurements, especially in the conduction band. Here, we report the observation of Dirac fermions in ZrTe<sub>5</sub> through magneto-optics and magneto-transport. By applying magnetic field, we observe a square-root-B-dependence of inter-Landau-level resonance and Shubnikov-de Haas oscillations with non-trivial Berry phase, both of which are hallmarks of Dirac fermions. The angular-dependent SdH oscillations show a clear quasi-two-dimensional feature with highly anisotropic effective mass and Fermi velocity, in stark contrast to the 3D Dirac semimetal such as CdAs<sub>2</sub>. With the confined interlayer dispersion and reducible dimensionality, our work establishes ZrTe<sub>5</sub> as an ideal platform for exploring exotic physical phenomena of Dirac fermions. Another work about the optics on CdAs<sub>2</sub> thin film will also be discussed.

**10:00AM A29.00011 Angle-resolved photoemission study on potential topological insulator ZrTe<sub>5</sub>**, HONGYU XIONG, Stanford University and SLAC National Accelerator Laboratory, JONATHAN SOBOTA, Stanford University, SLAC National Accelerator Laboratory, and Lawrence Berkeley National Laboratory, SHUOLONG YANG, Stanford University and SLAC National Accelerator Laboratory, DOMINIK LEUENBERGER, HADAS SOIFER, SLAC National Accelerator Laboratory, YAN-FENG CHEN, XU HAN, SI-YUAN YU, MING-HUI LU, Nanjing University, MAKOTO HASHIMOTO, DONGHUI LU, PATRICK KIRCHMANN, SLAC National Accelerator Laboratory, ZHI-XUN SHEN, Stanford University and SLAC National Accelerator Laboratory — ZrTe<sub>5</sub> is a layered-structure material which is predicted to exhibit the quantum spin hall effect in its monolayer limit. Bulk ZrTe<sub>5</sub> material is of scientific interest as well, as it might lie within the transition boundary between weak and strong topological insulator. We are using angle-resolved photoemission spectroscopy (ARPES) to investigate the band structure of bulk ZrTe<sub>5</sub>. Synchrotron data with varied photon energies shows little  $k_z$  dependence, which indicates a quasi-two-dimensional band structure; in addition, we observe circular dichroism, which suggests possible spin polarization. We are also working on time-resolved ARPES measurements, hoping to reveal the band structure above the Fermi level, which might give information about the materials topological properties.

**10:12AM A29.00012 Magneto-infrared spectroscopy of Landau levels and Zeeman splitting of three-dimensional massless Dirac Fermions in ZrTe<sub>5</sub>**, R. Y. CHEN, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China, Z. G. CHEN, National High Magnetic Field Laboratory, Tallahassee, Florida 32310, USA, X.-Y. SONG, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China, J. A. SCHNEELOCH, G. D. GU, Brookhaven National Lab, Upton, New York 11973, USA, F. WANG, N. L. WANG, International Center for Quantum Materials, School of Physics, Peking University, Beijing 100871, China — We present a magneto-infrared spectroscopy study on a newly identified three-dimensional (3D) Dirac semimetal ZrTe<sub>5</sub>. We observe clear transitions between Landau levels and their further splitting under magnetic field. Both the sequence of transitions and their field dependence follow quantitatively the relation expected for 3D massless Dirac fermions. The measurement also reveals an exceptionally low magnetic field needed to drive the compound into its quantum limit, demonstrating that ZrTe<sub>5</sub> is an extremely clean system and ideal platform for studying 3D Dirac fermions. The splitting of the Landau levels provides a direct and bulk spectroscopic evidence that a relatively weak magnetic field can produce a sizeable Zeeman effect on the 3D Dirac fermions, which lifts the spin degeneracy of Landau levels. Our analysis indicates that the compound evolves from a Dirac semimetal into a topological line-node semimetal under current magnetic field configuration. Refs: R. Y. Chen et al., Phys. Rev. B 92, 075107 (2015); R. Y. Chen et al., Phys. Rev. Lett. 115, 176404 (2015).

**10:24AM A29.00013 Detection of chiral anomaly and valley transport in Dirac semimetals**, CHENG ZHANG, ENZE ZHANG, YANWEN LIU, Fudan Univ, ZHIGANG CHEN, The University of Queensland, SIHANG LIANG, JUNZHI CAO, XIANG YUAN, LEI TANG, QIAN LI, TENG GU, YIZHENG WU, Fudan Univ, JIN ZOU, The University of Queensland, FAXIAN XIU, Fudan Univ — Chiral anomaly is a non-conservation of chiral charge pumped by the topological nontrivial gauge field, which has been predicted to exist in the emergent quasiparticle excitations in Dirac and Weyl semimetals. However, so far, such pumping process hasn't been clearly demonstrated and lacks a convincing experimental identification. Here, we report the detection of the charge pumping effect and the related valley transport in Cd<sub>3</sub>As<sub>2</sub> driven by external electric and magnetic fields ( $\mathbf{E} \times \mathbf{B}$ ). We find that the chiral imbalance leads to a non-zero gyrotropic coefficient, which can be confirmed by the  $\mathbf{E} \times \mathbf{B}$ -generated Kerr effect. By applying B along the current direction, we observe a negative magnetoresistance despite the giant positive one at other directions, a clear indication of the chiral anomaly. Remarkably, a robust nonlocal response in valley diffusion originated from the chiral anomaly is persistent up to room temperature when B is parallel to E. The ability to manipulate the valley polarization in Dirac semimetal opens up a brand-new route to understand its fundamental properties through external fields and utilize the chiral fermions in valleytronic applications.

**10:36AM A29.00014 A coupled wire model of topological Weyl and Dirac semimetal I: topological insulating texture and gapping interaction**, SYED RAZA, ALEXANDER SIROTA, JEFFREY TEO, University of Virginia — Weyl and Dirac semimetals in three dimensions have semi-robust massless electronic structures. We mimic these gapless systems using an array of coupled Dirac wires, and analytically study the gapping effect of many-body interactions. The Dirac wires are arranged in a way so that the charge conserving model exhibits an antiferromagnetic time reversal symmetry as well as a p2mg wallpaper group symmetry, which contains twofold rotations, reflections and glide planes. The gapless electrons can acquire a mass upon symmetry breaking dimerizations, or more interestingly, symmetry preserving many-body interactions. This involves the introduction of a topological insulating texture in the bulk supported by layers of gapped symmetric interacting surfaces of topological insulators. The resulting massive system is a three dimensional *geometric topological state*.

**10:48AM A29.00015 A coupled wire model of topological Weyl and Dirac fermion II: three-dimensional geometric topological phase**, ALEXANDER SIROTA, SYED RAZA, JEFFREY TEO, University of Virginia — We mimic Weyl and Dirac semimetals in three dimensions by a coupled Dirac wire model, and introduce many-body gapping interactions that preserve symmetries. The construction relies on additional layers of gapped symmetric interacting surfaces of topological insulators, each carrying fractional charge excitations and containing Ising-like surface topological order. The three dimensional stack supports mutually non-local fractional point charges and flux tubes. Moreover the flux tubes, when directed in an appropriate direction, can carry Majorana zero modes and give rise to non-Abelian "3-loop braiding". Due to the highly anisotropic nature of the coupled wire model, the topological phase also exhibits geometric properties beyond a topological field theory description.

**8:00AM A30.00001 Observation of Polar Vortices in Oxide Superlattices**, R RAMESH, Univ of California - Berkeley — The complex interplay of spin, charge, orbital, and lattice degrees of freedom has provided for a plethora of exotic phase and physical phenomena. Among these, in recent years, topological states of matter and spin textures have emerged as fascinating consequences of the electronic band structure and the interplay between spin and spin-orbit coupling in materials. In this work, we leverage the competition between charge, orbital, and lattice degrees of freedom in superlattices of  $\text{PbTiO}_3/\text{SrTiO}_3$  to produce complex, vortex-antivortex pairs (that exhibit smoothly varying ferroelectric polarization with a 10 nm periodicity) that are reminiscent of topological features such as skyrmions and merons. Using a combination of advanced layer-by-layer growth techniques, atomic-resolution mapping of structure and local polar distortions using scanning-transmission electron microscopy, and phase-field modeling approaches we present a comprehensive picture of the nature of the varying polarization profile in such vortex states. The continuous rotation of the polar state into the vortex structures is thought to occur from an interplay of polar discontinuities at the  $\text{PbTiO}_3/\text{SrTiO}_3$  interface (where), the phase transformation strain and gradient energy in the  $\text{PbTiO}_3$  layer, and the strain imposed by the substrate. Finally, the implications of these observations are discussed as they pertain to producing new states of matter and phenomena in ferroic materials.

**8:36AM A30.00002 The ultrafast response of polar vortices under optical excitation**, STOICA, YAKUN YUAN, Pennsylvania State University, ZIJIAN HONG, Materials Science and Engineering, Pennsylvania State University, ANOOP DAMODARAN, University of California, Berkeley, YI ZHU, HUA ZHOU, DONALD WALKO, JOHN FREELAND, APS, Argonne National Laboratory, LONG-QING CHEN, Pennsylvania State University, RAMAMOORTHY RAMESH, VENKATRAMAN GOPALAN, Pennsylvania State University — Polar vortices were recently discovered in  $\text{PbTiO}_3\text{-SrTiO}_3$  nanoscale in the presence of depolarizing fields and mechanical stresses. We have found that these exotic structures, not only possess rich ultrafast responses to fs laser excitation, which is attractive for high-density information storage and nanoscale excitation above the bandgap of  $\text{PbTiO}_3$  layers and structural and second harmonic generation probes of ferroelectric order, but also irreversible nano-ordering transitions were observed. X-ray diffraction and diffuse scattering on nanodomains aided the phase transition measurements. In this talk, we will discuss the dynamic interplay between collinear and toroidal ferroelectric domains aided by the modelling. [1] A.K. Yadav, R. Ramesh et al., "Observation of Polar Vortices in Oxide Superlattices", accepted, Nature (2016).

**8:48AM A30.00003 Ultra-thin single crystal perovskite ferroelectric on Silicon.**, SAIDUR BAKAUL, CLAUDY SERRAO, RAMESH RAMAMOORTHY, SAYEED SALAHUDDIN, University of California Berkeley — Single crystalline ultra-thin films (sub-10 nm) of ferroelectric complex oxides are important for tunnelling memory [1] devices. Commercially viable realization of such devices requires their integration with the peripheral Si-based input-output electronics. Integration of single crystalline films of such oxides using direct synthesis remains challenging due to the fundamental crystal chemistry and mechanical incompatibility of dissimilar interfaces. In this work we report epitaxial transfer of ultra-thin single crystalline, oxide films (down to 1 unit cell) onto Si substrates, at room temperature. The thickness of the transferred films has been confirmed by atomic force microscopy. Piezoelectric force microscopy shows ferroelectric property is retained in the transferred film. Electrical transport studies on these transferred ultra-thin films are ongoing. [1] Z. Wen, C. Li, D. Wu, A. Li and N. Ming, Ferroelectric-field-effect-enhanced electroresistance in metal/ferroelectric/semiconductor tunnel junctions. Nat. Mater. 12, 617 (2013)

**9:00AM A30.00004 First-principles simulation of negative capacitance in a polydomain ferroelectric-paraelectric bilayer capacitor under bias**, SHUSUKE KASAMATSU, The Institute for Solid State Physics, the University of Tokyo, SATOSHI WATANABE, Department of Materials Engineering, the University of Tokyo, CHEOL SEONG HWANG, SEUNGWU HAN, Department of Materials Science and Engineering, Seoul National University — The use of negative capacitance materials is gaining attention in recent years as a path to achieving further scaling of nanoelectronic devices [1]. For example, it has been reported that the ferroelectric thin film in a ferroelectric (FE)-paraelectric (PE) bilayer capacitor exhibits negative capacitance, i.e., the bilayer capacitor has a higher capacitance than the capacitor with a single PE layer [2]. However, the mechanism for this effect, especially with regard to the dynamics of polarization domains under bias voltage, is poorly understood. To tackle this issue, we performed first-principles simulation of a metal/FE/PE/metal capacitor with 180° stripe domains under bias using our recently developed orbital-separation approach [3]. We find an antiferroelectric-like behavior with a polydomain-monodomain transition under 0.3 V. Capacitance boost (i.e., negative capacitance) is observed within the monodomain regime, and the transition itself is also found to be a source of capacitance enhancement. [1] G. Catalan et al., Nature Mater. 14, 137 (2015). [2] D. Appleby et al., Nano Lett. 14, 3864, (2014); A. I. Khan et al., Appl. Phys. Lett. 99, 113501 (2011). [3] S. Kasamatsu et al., Phys. Rev. B 84, 085120 (2011); Phys. Rev. B 92, 115124 (2015).

**9:12AM A30.00005 Negative Capacitance in a Ferroelectric Capacitor**, ASIF KHAN, KOROK CHATTERJEE, BRIAN WANG, STEVEN DRAPCHO, LONG YOU, CLAUDY SERRAO, SAIDUR BAKAUL, RAMAMOORTHY RAMESH, SAYEED SALAHUDDIN, UC Berkeley, UC BERKELEY TEAM — The Boltzmann distribution of electrons poses a fundamental barrier to lowering energy dissipation in conventional electronics, often termed as Boltzmann Tyranny<sup>1</sup>. Negative capacitance in ferroelectric materials, which stems from the stored energy of phase transition, could provide a solution, but a direct measurement of negative capacitance has so far been elusive. Here we demonstrate the negative differential capacitance in an epitaxial ferroelectric film, by constructing a simple R-C network and monitoring the voltage dynamics across the ferroelectric capacitor<sup>2</sup>. When a voltage pulse is applied, the voltage across the ferroelectric capacitor is found to be decreasing with time—in exactly the opposite direction to which voltage for a regular capacitor should change. The results are analyzed on the basis of the Landau-Khalatnikov equation, which shows that as the ferroelectric polarization switches its direction, it passes through the unstable negative capacitance region. Analysis of this behavior from a capacitor presents an unprecedented insight into the intrinsic energy profile of the ferroelectric material.

**9:24AM A30.00006 The interface between ferroelectric and 2D material for a Ferroelectric Field-Effect Transistor**, NAHEE PARK, Center for Integrated Nanostructure Physics, Institute for Basic Science, DOES, Sungkyunkwan University, HAERYONG KANG, DOES, Sungkyunkwan University, SANG-GOO LEE, IBULE Photonics Co. Ltd., YOUNG HEE LEE, DONGSEOK SUH, Center for Integrated Nanostructure Physics, Institute for Basic Science, DOES, Sungkyunkwan University — We have studied electrical property of ferroelectric field-effect transistor which consists of graphene on hexagonal Boron-Nitride (h-BN) gated by a ferroelectric, PMN-PT (i.e.  $(1-x)\text{Pb}(\text{Mg}_{1/3}\text{Nb}_{2/3})\text{O}_{3-x}\text{PbTiO}_3$ ) single-crystal substrate. The PMN-PT was expected to have an effect on polarization field into the graphene channel and to induce a giant amount of surface charge. The hexagonal Boron-Nitride (h-BN) flake was directly exfoliated on the PMN-PT substrate for preventing graphene from directly contacting on the PMN-PT substrate. It can make us to observe the effect of the interface between ferroelectric and 2D material on the device operation. Monolayer graphene as 2D channel material, which was confirmed by Raman spectroscopy, was transferred on top of the hexagonal Boron-Nitride (h-BN) by using the conventional dry-transfer method. Here, we can demonstrate that the structure of graphene/hexagonal-BN/ferroelectric field-effect transistor makes us to clearly understand the device operation as well as the interface between ferroelectric and 2D materials by inserting h-BN between them. The phenomena such as anti-hysteresis, current saturation behavior, and hump-like increase of channel current, will be discussed by in terms of ferroelectric switching, polarization-assisted charge trapping.

**9:36AM A30.00007 Symmetry, strain, defects, and the nonlinear optical response of crystalline BaTiO<sub>3</sub>/silicon.**<sup>1</sup>, KRISTY KORMONDY, The University of Texas at Austin, STEFAN ABEL, YOURI POPOFF, MARILYNE SOUSA, DANIELE CAIMI, HEINZ SIEGWART, CHIARA MARCHIORI, IBM Research – Zurich, Säumerstrasse 4, 8803 Rüschlikon, Switzerland, MARTA ROSSELL, Electron Microscopy Center, Empa, ALEX DEMKOV, The University of Texas at Austin, JEAN FOMPEYRINE, IBM Research – Zurich, Säumerstrasse 4, 8803 Rüschlikon, Switzerland — Recent progress has been made towards exploiting the linear electro-optic or Pockels effect in ferroelectric BaTiO<sub>3</sub> (BTO) for novel integrated silicon photonics devices. In such structures, the crystalline symmetry and domain structure of BTO determine which electro-optic tensor elements are accessible under application of an external electric field. For epitaxial thin films of BTO on Si (001), the role of defects in strain relaxation can lead to very different crystalline symmetry even for films of identical thickness. Indeed, through geometric phase analysis of high-resolution scanning transmission electron microscopy images, we map changes of the in-plane and out-of-plane lattice parameters across two 80-nm-thick BTO films. A corresponding 20% difference in the effective electro-optic response was measured by analyzing induced rotation of the polarization of a laser beam ( $\lambda = 1550$  nm) transmitted through lithographically defined electrodes. Understanding, controlling, and modelling the role of BTO symmetry in nonlinear optics is of fundamental importance for the development of a hybrid BTO/Si photonics platform..

**9:48AM A30.00008 Memristive behavior in BaTiO<sub>3</sub> thin films integrated with semiconductors**, SRINIVASA RAO SINGAMANANI, NORTH CAROLINA STATE UNIVERSITY, JOHN PRATER, Army Research Office, JAY NARAYAN, NORTH CAROLINA STATE UNIVERSITY — BaTiO<sub>3</sub> has been studied for emerging non-volatile memory applications. However, most of the previous work has focused on this material when it was deposited on insulating oxide substrates such as SrTiO<sub>3</sub>. Unfortunately, this substrate is not suitable for CMOS-based microelectronics applications. This motivated us to carry out the present work. We have studied the resistive switching behavior in BaTiO<sub>3</sub>/La<sub>0.7</sub>Sr<sub>0.3</sub>MnO<sub>3</sub> (BTO/LSMO) heterostructures integrated with Si (100) using pulsed laser deposition<sup>1,2</sup>. I-V measurements were conducted on BTO (500nm)/LSMO (25nm) devices at 200K, with the compliance current of 10mA. Here, Pt was used as a top electrode and LSMO served as bottom electrode. A few important observations are noted: (a) broad hysteresis in forward and reverse voltage sweeps –ideal for memory applications, (b) the ratio of high resistance to low resistance state is ~600 –important for switching devices, (c) the device is stable at least up to 50 cycles. However, we found that hysteretic behavior was collapsed after 36 cycles upon oxygen annealing of the device at 1 atmospheric pressure, 200° C for 1 hour, inferring the important role of oxygen vacancies in the resistive switching behavior of BTO/LSMO device. The comprehensive experimental data will be presented and discussed.<sup>1,2</sup>S.R.S., et al., J. Appl. Phys., 116, 094103 (2014); J. Appl. Phys., 116, 224104 (2014).

**10:00AM A30.00009 Non-local domain switching in ferroelectric nanostructures**, SEURI JEONG, KWANG-EUN KIM, CHAN-HO YANG, Korea Adv Inst of Sci & Tech — Nanoscale ferroic materials have attracted considerable interest due to their novel properties including electronic, electromechanical and magnetoelectric properties. Until now, exotic ferroelectric structures have been described theoretically such as flux-closure domains, but experimental studies for ferroelectric multi-domains in nanostructures have been a lack of research due to their large domain wall energy. In this study, we realized the radial-quadrant domain structures using strain relaxation known as flexoelectricity. Moreover, we observed that local electric polarization switching can affect distant domain regions to minimize free energy. Our findings provide basic concepts to demonstrate and understand ferroelectric nano-scale multi-domain structures.

**10:12AM A30.00010 Removing pinhole shorts during large scale ferroelectric switching through ionic liquid interfaces**<sup>1</sup>, ANTHONY WONG, University of Tennessee, ANDREAS HERKLOTZ, NINA WISINGER, Oak Ridge National Laboratory, PHILIP RACK, University of Tennessee, THOMAS WARD, Oak Ridge National Laboratory — Ferroelectrics are a classification of materials that spontaneously polarize, accumulating charge at interfaces, and have non-linear hysteretic polarization curves. Switching fields required for ferroelectric materials are often very high, requiring thin insulating layers and high applied voltages. This commonly leads to electric pinholes and limits the areal sizes that can be polarized at a time. Ionic liquids have recently received heavy interest for the formation of electronic double layers which lead to huge electric fields at interfacial regions with low applied biases, and without the thickness constraint associated with conventional capacitors. We will show recent results which demonstrate that ionic liquid gating may offer the ideal solution to switch large regions of a ferroelectric film without limitations associated with pinhole defects. This has great importance to practical applications and fundamental interface studies that require large sample regions to be uniformly polarized.

**10:24AM A30.00011 ABSTRACT WITHDRAWN —**

**10:36AM A30.00012 Investigation of properties of lithium niobate crystals in confined geometries**, KEITH VEENHUIZEN, Lehigh University, GREG STONE, Pennsylvania State University, BASTIAN KNABE, Department of Microsystems Engineering (IMTEK), SEAN MCANANY, Lehigh University, KARSTEN BUSE, Fraunhofer Institute for Physical Measurement Techniques, HIMANSHU JAIN, VOLKMAR DIEROLF, Lehigh University — The properties of ferroelectric materials in confined geometries, specifically lithium niobate nanocrystals and crystal lines in glass, were studied. Batches of LiNbO<sub>3</sub> nanocrystals have been synthesized from various initial ratios of lithium to niobium using the sol-gel method. The batches were analyzed via Raman spectroscopy and SEM imaging to gain information about their size, morphology, stoichiometry, and defect content. The nanocrystals are very sensitive to the initial stoichiometric ratio in the synthesis step. Raman spectra reveal the resultant nanocrystal stoichiometry depends on the initial stoichiometry of the batch, the spectra also reveal an extra phase is present besides LiNbO<sub>3</sub> in some batches, and high quality spherical nanocrystals can be synthesized at certain initial stoichiometric ratios. In addition, lines of LiNbO<sub>3</sub> were crystallized in lithium-niobo-silica glass systems with varying amounts of silica to understand and control the nucleation and crystallization of the crystals in glass.

**10:48AM A30.00013 Direct writing of functional ferroelectric waveguides in glass**, CARL LIEBIG, JONATHAN GOLDSTEIN, GARY COOK, Air Force Research Laboratories — Femtosecond lasers modify the refractive index of many transparent materials for writing high quality waveguides due to their ability to confine the optical damage to an intended region [1]. They also can precipitate microcrystalline structures in glass and have demonstrated the production of ferroelectric crystals that can be used for optical waveguiding [2,3]. Ferroelectric crystals such as lithium niobate are some of the most widely used optical materials due to their strong electro-optic, piezoelectric, and photorefractive properties. The structure and alignment of the precipitated ferroelectric crystals can be controlled through the incident beam profile, writing speed and the starting material composition[2]. In this study crystalline waveguide structures were be written in 33LiO<sub>2</sub>-33Nb<sub>2</sub>O<sub>5</sub>-34SiO<sub>2</sub> (mol%) glass, characterized, the structural orientation determined, and their waveguiding performance tested. This procedure was then modified to functionalize the precipitated waveguides for photonic and holographic applications. [1] C. Mauchair et al., Opt. Exp. 16, (2008). [2] A. Stone et al., Sci. Reports 5, 10391 (2015). [3] T. Komatsu et al., J. Sol. State Chem. 184, 411 (2011).

**8:00AM A31.00001 SCAN: An Efficient Density Functional Yielding Accurate Structures and Energies of Diversely-Bonded Materials<sup>1</sup>**, JIANWEI SUN, Temple Univ — The accuracy and computational efficiency of the widely used Kohn-Sham density functional theory (DFT) are limited by the approximation to its exchange-correlation energy  $E_{xc}$ . The earliest local density approximation (LDA) overestimates the strengths of all bonds near equilibrium (even the vdW bonds). By adding the electron density gradient to model  $E_{xc}$ , generalized gradient approximations (GGAs) generally soften the bonds to give robust and overall more accurate descriptions, except for the vdW interaction which is largely lost. Further improvement for covalent, ionic, and hydrogen bonds can be obtained by the computationally more expensive hybrid GGAs, which mix GGAs with the nonlocal exact exchange. Meta-GGAs are still semilocal in computation and thus efficient. Compared to GGAs, they add the kinetic energy density that enables them to recognize and accordingly treat different bonds, which no LDA or GGA can [1]. We show here that the recently developed non-empirical strongly constrained and appropriately normed (SCAN) meta-GGA [2] improves significantly over LDA and the standard Perdew-Burke-Ernzerhof GGA for geometries and energies of diversely-bonded materials (including covalent, metallic, ionic, hydrogen, and vdW bonds) at comparable efficiency. Often SCAN matches or improves upon the accuracy of a hybrid functional, at almost-GGA cost. [1] J. Sun et al., Phys. Rev. Lett. 111, 106401 (2013). [2] J. Sun, A. Ruzsinszky, and J.P. Perdew, Phys. Rev. Lett. 115, 036402 (2015).

**8:36AM A31.00002 SCAN+rVV10: A promising van der Waals density functional<sup>1</sup>**, HAOWEI PENG, ZENG-HUI YANG, JIANWEI SUN, JOHN PERDEW, Department of Physics, Temple Univeristy — The newly developed “strongly constrained and appropriately normed” (SCAN) meta-generalized-gradient approximation (meta-GGA) can generally improve over the non-empirical Perdew-Burke-Ernzerhof (PBE) GGA not only for strong chemical bonding, but also for the intermediate-range van der Waals (vdW) interaction. However, the long-range vdW interaction is still missing. To remedy this, we propose here pairing SCAN with the non-local correlation part from the rVV10 vdW density functional, with only two empirical parameters. The resulting SCAN+rVV10 yields excellent geometric and energetic results not only for molecular systems, but also for solids and layered-structure materials, as well as the adsorption of benzene on coinage metal surfaces. Especially, SCAN+rVV10 outperforms all current methods with comparable computational efficiencies, accurately reproducing the three most fundamental parameters—the inter-layer binding energies, inter-, and intra-layer lattice constants—for 28 layered-structure materials. Hence, we have achieved with SCAN+rVV10 a promising vdW density functional for general geometries, with minimal empiricism.

**8:48AM A31.00003 The optimized effective potential of meta-generalized gradient approximations in solids<sup>1</sup>**, ZENGHUI YANG, JOHN PERDEW, Department of Physics, Temple University — Unlike the local density approximation(LDA) and the generalized gradient approximation(GGA), calculations with meta-GGAs are usually done according to the generalized Kohn-Sham(gKS) formalism. The exchange-correlation potential of the gKS equation is non-multiplicative, which prevents systematic comparison of meta-GGA bandstructures to those of the LDA and the GGA. We implement the optimized effective potential(OEP) of the meta-GGA for periodic systems, which allows us to carry out meta-GGA calculations in the same KS manner as for the LDA and the GGA. We apply the OEP to several popular meta-GGAs, including the new SCAN functional[Phys. Rev. Lett. 115, 036402(2015)]. We find that the KS gaps of meta-GGAs are close to those of GGAs, and they are smaller than the gKS gaps of meta-GGAs. The well-known grid sensitivity of meta-GGAs is much more severe in OEP calculations.

**9:00AM A31.00004 Characterization of Thin Film Materials using SCAN MetaGGA, an Accurate Nonempirical Density Functional**, IOANA-GIANINA BUDA, CHRISTOPHER LANE, BERNARDO BARBIELLINI, Northeastern University, ADRIENN RUZSINSZKY, JIANWEI SUN, JOHN P. PERDEW, Temple University, ARUN BANSIL, Northeastern University — The exact ground-state properties of a material can be derived from the single-particle Kohn-Sham equations within the framework of the Density Functional Theory (DFT), provided the exact exchange-correlation potential is known. The simplest approximation is the local density approximation (LDA), but it usually leads to overbinding in molecules and solids. On the other hand, the generalized gradient approximation (GGA) introduces corrections that expand and soften bonds. The newly developed nonempirical SCAN (strongly-constrained and appropriately-normed) MetaGGA [Phys. Rev. Lett. 115, 036402] has been shown to be comparable in efficiency to LDA and GGA, and to significantly improve LDA and the Perdew-Burke-Ernzerhof version of the GGA for ground-state properties such as equilibrium geometry and lattice constants for a number of standard datasets for molecules and solids. Here we discuss the performance of SCAN MetaGGA for thin films and monolayers and demonstrate improvements of predicted ground-state properties. Examples include graphene, phosphorene and MoS<sub>2</sub>.

**9:12AM A31.00005 Comparative first-principles study of clean-surface properties of metals**, ABHIRUP PATRA, JIANWEI SUN, JOHN P. PERDEW, Department of Physics, Temple University — Metal surfaces are widely used in different applications from nano-devices to heterogeneous catalysis. Clean-surface properties such as the surface energy, work function and interlayer spacing importantly determine the behavior of metal surfaces. Prior work has been done to understand these properties using high-level methods including the local density approximation (LDA) and the generalized gradient approximation (PBE). In this work, we study (111) (100) and (110) surfaces of Pt, Pd, Cu, Al, Au, Ag, Rh and Ru by extrapolation from a finite number of layers. These surfaces are studied using SCAN, a new member of the computationally-efficient meta-GGA family of density functionals. We have compared the performance of SCAN and three other standard density functionals - LDA, PBE and PBEsol - to available experimental results. We find that the performance of the general-purpose SCAN is at the level of the more-specialized PBEsol, giving accurate metallic properties. **9:24AM A31.00006 A Non-Local, Energy-Optimized Kernel: Recovering Second-Order Exchange and Beyond in Extended Systems**, JEFFERSON BATES, SAVIO LARICCHIA<sup>1</sup>, ADRIENN RUZSINSZKY, Temple University — The Random Phase Approximation (RPA) is quickly becoming a standard method beyond semi-local Density Functional Theory that naturally incorporates weak interactions and eliminates self-interaction error. RPA is not perfect, however, and suffers from self-correlation error as well as an incorrect description of short-ranged correlation typically leading to underbinding. To improve upon RPA we introduce a short-ranged, exchange-like kernel that is one-electron self-correlation free for one and two electron systems in the high-density limit. By tuning the one free parameter in our model to recover an exact limit of the homogeneous electron gas correlation energy we obtain a non-local, energy-optimized kernel that reduces the errors of RPA for both homogeneous and inhomogeneous solids. To reduce the computational cost of the standard kernel-corrected RPA, we also implement RPA renormalized perturbation theory for extended systems, and demonstrate its capability to describe the dominant correlation effects with a low-order expansion in both metallic and non-metallic systems. Furthermore we stress that for norm-conserving implementations the accuracy of RPA and beyond RPA structural properties compared to experiment is inherently limited by the choice of pseudopotential.

**9:36AM A31.00007 Semiclassical origins of density functionals<sup>1</sup>**, KIERON BURKE, UC Irvine — By careful numerical analysis of non-relativistic atomic correlation energies, we show that (a) the local density approximation becomes relatively exact for the correlation energy as the atomic number approaches infinity, (b) we find the leading correction, which is about 38.5 milliHartrees per atom, (c) show how this correction dominates for larger atoms and (d) how to construct a generalized gradient approximation that respects this limit (See KB, A. Cancio, T. Gould, S. Pittalis, arXiv:1409.4834). The relevance to density functional calculations will also be explained.

<sup>1</sup>Support provided by NSF CHE-1464795

**10:12AM A31.00008 Semiclassical potential functionals for semiconductor quantum wells**, ATTILA CANGI, Max Planck Institute of Microstructure Physics — Parabolic semiconductor quantum wells are considered promising candidates for constructing devices emitting radiation in the largely unexplored THz regime. However, progress is impeded by the difficulty of fine-tuning intersubband transitions in these quantum wells which is achieved by modifying the quantum-well geometry and mixing different materials. We predict the electronic structure of parabolic semiconductor quantum wells highly efficiently by iterating the Kohn-Sham self-consistent cycle without solving the Kohn-Sham equations[1]. We achieve this by combining potential functionals[2,3] with a recently derived semiclassical approximation[4]. This (1) demonstrates our method's efficiency and accuracy for realistic systems and (2) illustrates its utility as a high-throughput method for predicting the electronic structure of technologically intriguing microstructures. [1] A. Cangi, C.R. Proetto, S. Pittalis, K. Burke, and E.K.U. Gross, submitted (2016). [2] A. Cangi, D. Lee, P. Elliott, K. Burke, and E.K.U. Gross, PRL 106, 236404 (2011). [3] A. Cangi, E. K. U. Gross, and K. Burke, PRA 88, 062505 (2013). [4] R.F. Ribeiro, D. Lee, A. Cangi, P. Elliott, and K. Burke, PRL 114, 050401 (2015).

**10:24AM A31.00009 Thermal Corrections to Density Functional Simulations of Warm Dense Matter**, JUSTIN SMITH, AURORA PRIBRAM-JONES, KIERON BURKE, University of California, Irvine — Present density functional calculations of warm dense matter often use the Mermin-Kohn-Sham (MKS) scheme at finite temperature, but employ ground-state approximations to the exchange-correlation (XC) free energy. In the simplest solvable non-trivial model, an asymmetric Hubbard dimer, we calculate the exact many-body energies, the exact Mermin-Kohn-Sham functionals for this system, and extract the exact XC free energy. For moderate temperatures and weak correlation, we show this approximation is excellent, but fails for stronger correlations. Additionally, we use this system to test various conditions that must be satisfied.

**10:36AM A31.00010 Study of the large reduced density gradient limit for the exchange energy**, JOSE GAZQUEZ, JAVIER CARMONA-ESPINDOLA, Universidad Autonoma Metropolitana-Iztapalapa, ALBERTO VELA, Centro de Investigacin y de Estudios Avanzados, SAM TRICKEY, University of Florida — The generalized gradient approximation (GGA) for the Kohn-Sham exchange-correlation functional has become widely used in electronic structure calculations of small, medium and large systems, because it provides rather reasonable results with moderate computational effort. Usually the GGA for exchange (X) is expressed in terms of an analytical expression of the X enhancement function,  $F_x(s)$ , where  $s$  is the reduced density gradient. When a non-empirical approach based on constraint satisfaction is followed, the analytical expression of  $F_x(s)$  is the result of interpolating between the small- and large- $s$  limits. However, neither of those limits is uniquely defined. In both cases there are several possibilities. The present work is a study of the influence of the several large- $s$  limit possibilities upon the calculation of properties that depend on energy differences, versus those that depend on response functions, and excitation energies.

**10:48AM A31.00011 Study of adiabatic connection in ground-state density functional theory**, MANOJ HARBOLA, RABEET CHAUHAN, Indian Inst of Tech-Kanpur, RABEET S. CHAUHAN COLLABORATION — By employing modified [1] variational form of Le-Sech wavefunctions [2] for two-electron systems, accurate wavefunctions for He-like atoms corresponding to their ground-state density are obtained for varying strength, given by a parameter  $\alpha$  ( $0 \leq \alpha \leq 1$ ), of electron-electron interaction. Using these, it is shown explicitly that (i) the total energy varies almost linearly as a function of  $\alpha$ , and (ii) the ionization potential remains unchanged [3] as  $\alpha$  is varied. Furthermore, kinetic energy contribution to the density-functional exchange-correlation energy is calculated using the adiabatic connection formula [4] and shown to match that calculated on the basis of Kohn-Sham calculation. Finally, the exchange-correlation energy obtained for different values of  $\alpha$  is employed to analyze several hybrid exchange-correlation energy functionals in use. [1] R.S. Chauhan and M.K. **8:00AM A33.00001 Ionomer Self-assembly in Dilute Solution: a Coarse-grained Molecular Dynamics Study.** , MAHDI GHELICHI, KOUROSH MALEK, MICHAEL EIKERLING, Simon Fraser University — Self-assembly of semiflexible ionomer chains in dilute solution is studied by classical molecular dynamics (MD). Ionomer molecules consist of hydrophobic backbones, grafted with pendant side chains that are terminated by anionic headgroups. Coarse-grained MD simulations show the self-assembly of the semiflexible ionomer chains into cylindrical bundle-like aggregates. Bundles are comprised of a core of backbone chains surrounded by a surface layer of charged anionic headgroups and a diffuse halo of counterions. Parametric studies of bundle properties explored the role of backbone hydrophobicity, strength of electrostatic interactions between charged moieties, side chain content, and counterion valence. Expectedly, the size of bundles increases with backbone hydrophobicity. The aggregate size depends nonmonotonically on the value of the Bjerrum length. Increasing the grafting density of pendant side chains results in smaller bundles and the counterion valence exerts a strong effect on bundle size and counterion localization in the near-bundle area. Results are interpreted in terms of the interplay of the surface energy of hydrophobic chains and the electrostatic repulsion among the anionic headgroups. The findings are discussed within the context of experimental studies on the formation of rodlike structures in ionomer solution.

**8:12AM A33.00002 Electrostatic Effect on the Solution Structure and Dynamics of PEDOT:PSS** , MICHAEL LEAF, MURUGAPPAN MUTHUKUMAR, Department of Polymer Science and Engineering, University of Massachusetts at Amherst, Amherst MA 01003 — Poly(3,4-ethylenedioxythiophene):poly(styrene sulfonic acid) (PEDOT:PSS) is a popular material used in organic electronic devices as a conductor. It consists of PEDOT polycations complexed with PSS polyanions which are initially suspended in aqueous solution and eventually cast into a film. Various annealing and doping methods dramatically enhance PEDOT:PSS film conductivity. To understand the physical interactions at play, we explore structural and dynamic aspects of PEDOT:PSS solutions through scattering and rheology techniques. We highlight several aspects of the phase behavior of PEDOT:PSS, and the significance of electrostatic interactions.

**8:24AM A33.00003 Ion Correlation and Transport in Polymer Electrolytes at Finite Salt Concentrations; Coarse-Grained Simulation Study** , UMI YAMAMOTO, ZHEN-GANG WANG, California Institute of Technology — We present results from coarse-grained simulation for ion dynamics and structures in dry polymer electrolytes. To capture the thermodynamic, kinetic, and system-specific aspects of ion solvation and clustering, cation-monomer complexation is modeled via functionalized physical bonds whose functionality and lifetime vary due to local availability of binding monomers and competition with Coulombic interaction. By varying salt concentration, cation-monomer binding energy, dielectric constant, and maximal functionality of the physical bonds, we systematically study the growth of ion clustering activity as characterized by packing structures, and associated changes in electric conductivity via single-ion and collective charge mobility. Deviations from Nernst-Einstein predictions, and comparisons with existing experiments for concentration dependence of conductivity will be discussed.

**8:36AM A33.00004 Explicit-ion Effects in the Coil-Globule Transition of Weak Polyelectrolytes** , BENJAMIN J. SIKORA, JONATHAN K. WHITMER, University of Notre Dame — The first-order coil-globule transition in weak (annealed) polyelectrolytes involves a subtle balance of pH, charge strength, and solvation forces. In this work, we utilize a coarse-grain hybrid grand-canonical Monte Carlo and Molecular Dynamics approach to explore the free energetic topography of a model hydrophobic polybase [representing poly(2-vinylpyridine) (P2VP)] and explore the role of salt concentration/valency in influencing polyelectrolyte conformations using both an implicit Debye-Hückel and explicit salt approach. Our simulations reproduce the experimentally measured behavior for dilute annealed polyelectrolytes, and present a solid foundation for understanding pH responsive polyelectrolyte materials.

**8:48AM A33.00005 The effect of ionic correlations on ion distribution across polyelectrolyte blend interfaces<sup>1</sup>** , HA-KYUNG KWON, MONICA OLVERA DE LA CRUZ, Department of Materials Science and Engineering, Northwestern University, Evanston, Illinois 60208 — Recent developments in high-density energy storage and generation devices have identified as polyelectrolyte blends and copolymers as suitable candidate materials for use in these applications, as they combine the low volatility and high flexibility of polymers with ion-selective conductivity of the charge-carrying backbone. It has been shown that in polyelectrolyte melts, where the dielectric constant is relatively low, ionic correlations can significantly reduce miscibility, inducing phase separation even at negative values of  $\chi_N$ . At selected values of ionic coupling strengths, the polyelectrolyte blend exhibits a triple point, where coexistence is observed between phases with different concentrations and ordering of ions. When salt is added, the system undergoes re-entrant behavior as electrostatic effects are screened out. Using a hybrid of self-consistent field and liquid state theories (SCFT-LS), we investigate the distribution of ions across the interface in polyelectrolyte blends. We demonstrate that the inclusion of ionic correlations induces complex charge-dependent adsorption behavior at the interface, leading to changes in the interfacial width and miscibility of the blend.

**9:00AM A33.00006 Effect of Charge Patterning on the Phase Behavior of Polymer Coacervates for Charge Driven Self Assembly** , MITHUN RADHAKRISHNA, CHARLES E. SING, University of Illinois at Urbana-Champaign — Oppositely charged polymers can undergo associative liquid-liquid phase separation when mixed under suitable conditions of ionic strength, temperature and pH to form what are known as 'polymeric complex coacervates'. Polymer coacervates find use in diverse array of applications like microencapsulation, drug delivery, membrane filtration and underwater adhesives. The similarity between complex coacervate environments and those in biological systems has also found relevance in areas of bio-mimicry. Our previous works have demonstrated how local charge correlations and molecular connectivity can drastically affect the phase behavior of coacervates. The precise location of charges along the chain therefore dramatically influences the local charge correlations, which consequently influences the phase behavior of coacervates. We investigate the effect of charge patterning along the polymer chain on the phase behavior of coacervates in the framework of the Restricted Primitive Model using Gibbs Ensemble Monte Carlo simulations. Our results show that charge patterning dramatically changes the phase behavior of polymer coacervates, which contrasts with the predictions of the classical Voorn-Overbeek theory. This provides the basis for designing new materials through charge driven self assembly by controlling the positioning of the charged monomers along the chain.

**9:12AM A33.00007 Connectivity and Excluded Volume Effects in Polymeric Complex Coacervates** , CHARLES SING, MITHUN RADHAKRISHNA, University of Illinois at Urbana-Champaign — Oppositely-charged polyelectrolytes in salt solutions can undergo phase separation to form complex coacervates. This charge-driven phase behavior is the basis for emerging motifs in self-assembly. Traditional uses for coacervates are in food and personal care products, while applications in technologies for drug delivery and sensory materials are being developed. One of the primary theories driving understanding of complex coacervates is the Voorn-Overbeek (V-O) theory, which is a precursor to more sophisticated field theories. We present both theory and simulation that provides an alternate picture of coacervates, specifically addressing the limitations of V-O. Our theoretical approach is based on PRISM, which is a liquid-state theory that specifically accounts for connectivity. This is compared with Monte Carlo-based simulations, which likewise provide a molecular picture of coacervation. We demonstrate that a combination of connectivity-based correlations and excluded volume has a profound effect on coacervation phase behavior, suggesting that favorable comparison of V-O to experiment benefits from a cancellation of errors. The influence of connectivity on coacervate phase behavior hints at new opportunities for molecular-based design in electrostatically-driven self-assembly.

**9:24AM A33.00008 Salting-out and Salting-in in Polyelectrolyte Solutions**, PENGFEI ZHANG, Division of Chemistry & Chemical Engineering, California Institute of Technology, JIANZHONG WU, Department of Chemical and Environmental Engineering, University of California, Riverside, ZHEN-GANG WANG, Division of Chemistry and Chemical Engineering, California Institute of Technology — The phase behavior of polyelectrolyte (PE) solutions is governed by complicated interplay involving the mixing entropy, excluded volume, chain connectivity, and electrostatic interactions. Here we study the phase behavior of PE solutions in both salt-free condition and with added salt using a liquid-state (LS) theory based thermodynamic model. The LS model accounts for the hard-core repulsion by the Canahan-Starling equation of state, correlations due to chain connectivity by the first-order thermodynamic perturbation theory, and electrostatic correlations by the mean-spherical approximation. In comparison to the prediction from the well-known Voorn-Overbeek theory, the LS model predicts loop-type binodal curves in the salt-PE concentration diagram at temperatures slightly above the critical temperature of PE solution in salt-free case, consistent with the experimental study. The phase separated region shrinks with increasing temperature. Three scenarios of salting-out and salting-in phenomenon are predicted with addition of salts based, depending on the PE concentration.

**9:36AM A33.00009 Influence of Higher Valence Ions on Flexible Polyelectrolytes Stiffness and Counter-ion Distribution**<sup>1</sup>, ALEXANDROS CHREMOS, JACK F. DOUGLAS, NIST - Natl Inst of Stds & Tech — We investigate the influence of counter-ion valency on the flexibility of highly charged flexible polymer chains by molecular dynamics simulations that include both salt and an explicit solvent. A theoretical understanding of solutions of these molecules (e.g., DNA, RNA, and sulfonate polystyrene) has been slow to develop due to the complex coupling between the polyelectrolyte conformation and the ionic species in solution due to their long range Coulomb interactions. As observed experimentally, we find that divalent counter-ions greatly reduce the chain persistence length, in comparison to monovalent counter-ions, an effect correlated with the tendency of the polyelectrolyte chain to become distorted by divalent counter-ions. We rationalize these results by with the substantial increase of counter-ion population at the interface with the polyelectrolyte, which not only leads to a more effective screening of the bare charge, but also leads to charge inversion in the trivalent counter-ion case. These conformational changes with counter-ion valency are also associated with a drastic increase of the number of contacts the counter-ions have at the interface with polyelectrolyte, an effect associated with polyelectrolyte chain coiling around the counter-ions.

**9:48AM A33.00010 Understanding and Controlling Transitions in Polyelectrolyte Complex Materials**, SARAH PERRY, LI-WEI CHANG, YALIN LIU, BRIAN MOMANI, JON VELEZ, H. HENNING WINTER, University of Massachusetts Amherst — Polyelectrolyte complexation can be used in the self-assembly of a wide range of responsive soft materials ranging from dehydrated thin film and bulk solids to dense, polymer-rich liquid complex coacervates, and more complex hierarchical structures such as micelles and hydrogels. This responsivity can include swelling and dissolution, or liquid-to-solid transitions, typically as a function of ionic strength and/or pH. The patterning or presentation of charges and other chemical functionalities represents a powerful strategy for the design and manipulation of this type of responsiveness and the corresponding material properties. We utilize polypeptides and polypeptide derivatives as a model platform for the study of sequence and patterning effects on materials self-assembly. We also utilize rheology to understand the nature of the solid-to-liquid transition that has been observed in some systems. The goal of this systematic investigation of the effects of charge patterning is to elucidate design rules that facilitate the tailored creation of materials based on polyelectrolyte complexation with defined properties for a wide range of applications.

**10:00AM A33.00011 Complexation of two oppositely charged polyelectrolytes**, HAMIDREZA SHOJAEI, MURUGAPPAN MUTHUKUMAR, University of Massachusetts Amherst — Existence of both polycation and polyanion in a solution will lead to complexation. We investigate both dynamics and the steady state solution for complexation of two oppositely charged polyelectrolytes in a salty solution. By use of Smoluchowski equation, both dynamic and steady-state properties of a complexation event occurring were studied.

**10:12AM A33.00012 Morphology-induced low temperature conductivity in ionic liquids**.<sup>1</sup>, AYKUT ERBAS, MONICA OLVERA DE LA CRUZ, Northwestern University, OLVERA DE LA CRUZ TEAM — Ionic liquids exhibit nano-scale liquid crystalline order depending on the polymeric details of salt molecules. The resulting morphology and temperature behavior are key factors in determining the room temperature conductivity of ionic liquids. Here we discuss the phase behavior and related ionic conductivities of dry ionic liquids with volume fractions close to unity by using extensive molecular dynamics simulations. Temperature dependence, effective persistence length of tails, and excluded volume symmetry of amphiphilic ionic liquid molecules are investigated in large scale systems with short and long-range electrostatics. Our results suggest that by adjusting stiffness of the amphiphilic molecules and excluded volume interactions, lamellar or interconnected 3D phases can be obtained. Resulting phases have significant effects on the conductive properties. If there is no excluded volume asymmetry along the molecules, mostly lamellar phases with anisotropic conductivities emerge. If the excluded volume interactions become asymmetric, lamellar phases are replaced by interconnected phases consist of charged groups. Within temperature ranges that morphological phases are observed, conductivities exhibit low-temperature maxima in accord with experiments of ionic liquid-based liquid

**10:24AM A33.00013 Structural Dynamics of Star-Shaped Weak Polyelectrolytes in Dilute Aqueous Solution**, CHEN QU, Univ of Notre Dame, Y. ELAINE ZHU, Wayne State University — Weak polyelectrolyte (PE) bearing tunable charges along their backbones show great potential as “smart” polymer materials for diverse applications from drug delivery to energy storage. With the introduction of branched topology, the local counterion distribution in the vicinity to the polyelectrolyte segments becomes highly inhomogeneous. To experimentally investigate the interplay between structural dynamics and local electric environment of a branched polyelectrolyte, in this work we custom synthesized star-shaped poly(2-vinylpyridine) (P2VP) using reversible addition fragmentation chain transfer (RAFT) polymerization and labeled P2VP stars with pH-sensitive fluorophore precisely either in the center or periphery. By employing fluorescence correlation spectroscopy (FCS) with photon counts histogram (PCH) analysis, we observed gradual stretched-to-collapses conformational transition with increasing solution pH for both P2VP stars of different fluorophore labeling locations. However, the measured local pH, or local proton concentration, shows strong dependence of the fluorophore labeling locations. Higher electric potential yet lower ionization degree was observed in the core of P2VP star than that in the periphery. Ongoing work is carried out to examine the scaling behaviors of P2VP star sizes with varied number of arms, arm lengths and counterion concentrations in dilute aqueous solutions.

**10:36AM A33.00014 Thermodynamics and Phase Behavior of Phosphonated Block Copolymers Containing Ionic Liquids**, HA YOUNG JUNG, Pohang Univ of Sci & Tech, MOON JEONG PARK, Pohang Univ of Sci Tech — Charge-containing copolymers have drawn intensive attention in recent years for their uses in wide range of electrochemical devices such as fuel cells, lithium batteries and actuators. Particularly, the creation of microphase-separated morphologies in such materials by designing them in block and graft configurations has been the subject of extensive studies, in order to establish a synergistic means of optimizing ion transport properties and mechanical integrity. Interest in this topic has been further stimulated by intriguing phase behavior from charge-containing polymers, which was not projected from conventional phase diagrams of non-ionic polymers. Herein, we investigate thermodynamics and phase behavior of a set of phosphonated block copolymers. By synthesizing low-molecular weight samples with degree of polymerization ( $N$ ) < 35, we observed order-disorder transition that enabled us to estimate effective Flory-Huggins interaction parameters ( $\chi$ ) by using random phase approximation. We further examined the systems by adding various ionic liquids, where noticeable increases in  $\chi$  values and modulated microphase separation behavior were observed. The morphology-conductivity relationship has been elucidated by taking into account the segmental motion of polymer chains, volume of conducting phases, and the molecular interactions between phosphonated polymer chains and cations of ionic liquids.

**8:00AM A34.00001 And yet it moves - propulsion of colloidal clusters under reciprocal actuation<sup>1</sup>**, GABI STEINBACH, Technische Universität Chemnitz, SIBYLLE GEMMING, ARTUR ERBE, Helmholtz-Zentrum Dresden-Rossendorf — In the regime of low Reynolds numbers, the challenge of torque-based magnetic actuation lies in the conversion of torque into an effective force via symmetry breaking without inertial effects. Most reported systems rely on the hydrodynamic coupling between rotation and translation by an asymmetry in the environment (surfaces/interfaces) or the object shape. There, net translation can be realized only under non-reciprocal actuation given by precessing and rotating fields. In contrast, under oscillating fields, which are easier to realize, hydrodynamic coupling intrinsically leads to cyclic, reciprocal translation (Scallop theorem) unless the object has a certain flexible shape such as a flagellum. We present an alternative approach where symmetry breaking can be realized by magnetically interacting colloids which have been effectively modeled by spheres with shifted dipoles. If such colloids self-assemble, they form rigid clusters. We show how the collective, non-equilibrium dynamics of the colloids under oscillating fields propel the cluster. Depending on the configuration of the cluster it can rotate, translate and perform screw-like motion.

**8:12AM A34.00002 Hyperuniformity in periodically sheared dilute suspensions**, SAM WILKEN, RO-DRIGO GUERRA, DAVID J PINE, PAUL M CHAIKIN, New York University — Periodically sheared dilute, non-Brownian suspensions explore new configurations through collisions in an otherwise reversible flow. Below a critical strain, the particles remain active until they find a configuration with no collisions and reach an absorbing state. Recent simulations by Hexner and Levine have shown that the configuration of particles in the critically absorbing state is hyperuniform. The particle number fluctuations of hyperuniform systems decrease with counting box size more rapidly than random systems (like the same suspension that is not in a critically absorbing state). We built a compact, lightweight uni-axial shear cell where particle coordinates can be measured while shearing with a confocal microscope. We have identified hyperuniform structures with density fluctuation measurements in colloidal suspensions of up to 40% volume fraction in the critically absorbing state with a strain ramp down protocol and find hyperuniform scaling of the density fluctuations.

**8:24AM A34.00003 Convection-driven aggregation of micron sized capsules**, OLEG SHKLYAEV, HENRY SHUM, ANNA BALAZS, Department of Chemical Engineering, The University of Pittsburgh — Collective dynamics of microcapsules often serve as a model for understanding behavior observed in colonies of biological cells. Using computer simulations, we explore the capability of chemically generated convection to assemble microcapsules into a colony with neighbors close enough to facilitate chemical communication. The microcapsules are assumed to carry a supply of chemical fuel. When this fuel, leaking out of the capsules, reacts at enzyme-covered sites of the chamber, the reaction generates fluid density variations driving flows. These flows carry the microcapsules, which tend to aggregate into colonies on and near the enzyme-covered sites. This aggregation continues until the reagent has been depleted and convection stops. We show that capsule colonies of predesigned shapes can be assembled by patterning the enzyme-covered surface.

**8:36AM A34.00004 Electric-field mediated propulsion in binary colloidal suspensions**, LAURA COLON-MELENDEZ, MATTHEW SPELLINGS, SHARON C. GLOTZER, MICHAEL J. SOLOMON, University of Michigan — We observe propulsion of pairs of unequally sized dielectric colloidal spheres in a plane perpendicular to the applied AC electric field. The fully reversible and reconfigurable effect is observed at different applied voltages and frequencies. Using confocal microscopy and particle tracking methods, we study the degree of active motion as a function of the number of particles in the dynamic clusters. The observed phenomenon is consistent with previous observations of asymmetric dumbbell propulsion in electric fields attributed to asymmetric electrohydrodynamic flow (Ma et al, PNAS 2015 112 (20) 6307-6312).

**8:48AM A34.00005 Self-assembly of active colloidal molecules with dynamic function**, RODRIGO SOTO, Universidad de Chile, RAMIN GOLESTANIAN, University of Oxford — Catalytically active colloids maintain non-equilibrium conditions in which they produce and deplete chemicals at their surface. While individual colloids that are symmetrically coated do not exhibit dynamical activity, the concentration fields resulting from their chemical activity decay as  $1/r$  and produce gradients that attract or repel other colloids depending on their surface chemistry and ambient variables. This results in a non-equilibrium analogue of ionic systems, but with the remarkable novel feature of action-reaction symmetry breaking. In dilute conditions these active colloids join up to form molecules via generalized ionic bonds. Colloids are found to join up to form self-assembled molecules that could be inert or have spontaneous activity in the form of net translational velocity and spin depending on their symmetry properties and their constituents. As the interactions do not satisfy detailed-balance, it is possible to achieve structures with time dependent functionality. We study a molecule that adopts spontaneous oscillations and another that exhibits a run-and-tumble dynamics similar to bacteria. Our study shows that catalytically active colloids could be used for designing self-assembled structures that possess dynamical functionalities.

**9:00AM A34.00006 Optimal Navigation of Self-Propelled Colloids in Microstructured Mazes**, YUGUANG YANG, MICHAEL BEVAN, Johns Hopkins University — Controlling navigation of self-propelled microscopic 'robots' subject to random Brownian motion in complex microstructured environments (e.g., porous media, tumor vasculature) is important to many emerging applications (e.g., enhanced oil recovery, drug delivery). In this work, we design an optimal feedback policy to navigate an active self-propelled colloidal rod in complex mazes with various obstacle types. Actuation of the rods is modelled based on a light-controlled osmotic flow mechanism, which produces different propulsion velocities along the rod's long axis. Actuator-parameterized Langevin equations, with soft rod-obstacle repulsive interactions, are developed to describe the system dynamics. A Markov decision process (MDP) framework is used for optimal policy calculations with design goals of colloidal rods reaching target end points in minimum time. Simulations show that optimal MDP-based policies are able to control rod trajectories to reach target regions order-of-magnitudes faster than uncontrolled rods, which diverges as maze complexity increases. An efficient multi-graph based implementation for MDP is also presented, which scales linearly with the maze dimension.

**9:12AM A34.00007 Active colloids that slosh through passive matrices.**, JIE ZHANG, University of Illinois at Urbana-Champaign, STEVE GRANICK, IBS Center for Soft & Living Matter — Studies of natural and artificial active matter have focused on systems with a large mismatch of the time and length scales for active and passive elements, but in a variety of non-equilibrium condensed matter systems, including numerous biological processes, actively driven elements have a crowded environment of surrounding passive "solvent" elements of comparable size. Here we study self-propelled colloidal particles in a passive matrix of comparable size. Particles with high activity take straight lines and sharp turns through the soft 2-D crystal matrix to ensure rapid healing of the crystal structure. Effective attraction between active particles arises when the concentration of active particles or the hardness of the matrix increases; active particles tend to segregate in the grain boundaries of the crystal matrix.

**9:24AM A34.00008 Diffusion of torqued active Brownian particles** , FRANCISCO J SEVILLA, Instituto de Física, Universidad Nacional Autónoma de México — An analytical approach is used to study the diffusion of active Brownian particles that move at constant speed in three-dimensional space, under the influence of passive (external) and active (internal) torques. The Smoluchowski equation for the position distribution of the particles is obtained from the Kramer-Fokker-Planck equation corresponding to Langevin equations for active Brownian particles subject to torques. In addition to giving explicit formulas for the mean square-displacement, the non-Gaussian behavior is analyzed through the kurtosis of the position distribution that exhibits an oscillatory behavior in the short-time limit. FJS acknowledges support from PAPIIT-UNAM through the grant IN113114

**9:36AM A34.00009 ABSTRACT WITHDRAWN** —

**9:48AM A34.00010 Motile Microbots from Dynamically Interacting and Self-Reconfiguring Assemblies of Metallo-Dielectric Janus Microcubes**<sup>1</sup> , KOOHEE HAN, North Carolina State Univ, C. WYATT SHIELDS IV, Duke University, BHUVNESH BHARTI, North Carolina State Univ, GABRIEL P. LOPEZ, Duke University, ORLIN D. VELEV, North Carolina State Univ — A new class of dynamically and reversibly reconfigurable active matter made by magnetic assembly and actuation of metallo-dielectric microcubes will be presented. We describe how magnetically responsive Janus microcubes can be assembled hierarchically into dynamically reconfiguring microclusters. Ferromagnetic cobalt patches of the cubes act as assembly directors. The residual magnetic polarization of the metal-coated facets leads to directional dipole-dipole and field-dipole interactions and reconfiguration of the neighboring cubic particles, which is directed by the conformational restrictions. Dynamic reconfiguration of assembled clusters can be achieved by on-demand switching between the dipole-field interaction and the residual dipole-dipole interaction when the field is turned on and off. We show how pre-assembled Janus microcube clusters can be directionally motile in non-Newtonian fluids by applying asymmetric magnetic fields. The modulation of the viscosity of non-Newtonian fluids upon varying the shear rate allowed demonstrating directional motion, resulting from time-asymmetric stroke patterns (e.g., rapid opening and slow closing). These motile clusters can serve as early prototypes of self-propelling microswimmers capable of *in-situ* assembly.

**10:00AM A34.00011 Spontaneous Oscillations in an Active Matter System** , ROBERT HAYES, BOYCE TSANG, University of Illinois, STEVE GRANICK, IBS Center for Soft & Living Matter and UNIST — Active matter (which consumes energy to move about) can organize into dynamic structures more interesting than those possible at steady-state. Here we show spontaneous periodic self-assembly in a simple three-component system of water, oil phase, and surfactant at constant room temperature, with emphasis on one model system. Benchtop experiments show that liquid crystal oil droplets spontaneously and collectively oscillate like a 'beating heart' for several hours; contract, relax, and subsequently re-contract in a petri dish at a rate of a few 'beats' per minute. These oscillations, emergent from the cooperative interaction of the three components, are driven by the competition between positive and negative feedback processes. This illustration of feedback in action reveals a new way to program self-assembled structures to vary with time.

**10:12AM A34.00012 Catalytic particles induced Marangoni flow: motion, pumping and self-assembly** , PAOLO MALGARETTI, Max Planck Institute Stuttgart, ALVARO DOMINGUEZ, Universidad de Sevilla, MIHAIL N POPESCU, SIEGFRIED DIETRICH, Max Planck Institute Stuttgart — When catalytic particles, such as Janus particles, or enzymes are in the vicinity of a fluid-fluid interface, their behavior can be strongly modulated by the presence of the interface and/or by the inhomogeneity in the transport properties of the two fluid phases. Hence, the effective interaction with the interface can lead to novel dynamical regimes absent in homogeneous fluids. For example, if the by-products of the catalysis are surface active their spatial distribution will affect the local value of the surface tension. In such a scenario, when a catalytic particle approaches a fluid-fluid interface a Marangoni flow will set up as a response to the inhomogeneity in the surface tension induced by the byproducts of the catalysis. The onset of such a flow will attract the catalytic particle towards the interface. Interestingly the strength of such an effective attraction is strongly affected by the affinity of the byproduct to the interface as well as by the transport properties of the two fluid phases. In particular, for water-oil interfaces such an effect overwhelms other means of active transport such as self-diffusiophoresis and makes it suitable to enhance particle accumulation close to fluid-fluid interfaces. Finally I will discuss the onset of collective behavior.

**10:24AM A34.00013 Dynamics of fractal cluster colloidal gels with embedded active Janus particles** , MICHAEL SOLOMON, MEGAN SZAKASITS, WENXUAN ZHANG, University of Michigan — We find that fractal cluster gels of colloids in which platinum-coated Janus particles have been embedded exhibit enhanced mobility when the Janus particles are made active by the addition of hydrogen peroxide. Gelation is induced through addition of a divalent salt, magnesium chloride, to an initially stable suspension of Janus and polystyrene colloids, each of size about 1 micron. After the gels have been created, the embedded Janus colloids are activated by hydrogen peroxide, which is delivered to the system through a porous hydrogel membrane. We vary the ratio of active to passive colloids in the gels from about 1:20 to 1:8. Changes in structure and dynamics are visualized by two channel confocal laser scanning microscopy. By image analysis, we determine the particle positions and compute the mean squared displacement (MSD) of all particles in the gel. We measure the mobility enhancement in the fractal gels as a function of hydrogen peroxide concentration and Janus particle concentration and discuss the results in terms of the force provided by each active particle to the fractal gel network.

**10:36AM A34.00014 Rotation-translation hydrodynamic coupling of a particle in a gradient of viscosity** , NAOMI OPPENHEIMER, Princeton University, SHAHIN NAVARDI, Texas Tech University, HOWARD STONE, Princeton University — We study the translation-rotation hydrodynamic coupling of spherical particles in Stokes flow where there are gradients of viscosity. In particular, we examine cases in which symmetry is broken by temperature gradients in the fluid. Using the Lorentz reciprocal theorem, we derive analytical expressions for the coupling tensor when the viscosity variations caused by the temperature gradients are small. We examine two cases. In the first, the temperature gradient is external and the particle moves perpendicular to it. In the second the translating object is a Janus sphere that creates its own local temperature gradient. We find that in the first case, translation induces rotation, and in the second it suppresses it. Our results may illuminate recent experimental results of Janus particles activated by light.

**8:00AM A35.00001 Self-organization of stress patterns drives state transition in actin cortices** , NIKITA FAKHRI, Massachusetts Institute of Technology —

**8:36AM A35.00002 Spontaneous actin dynamics in contractile rings<sup>1</sup>**, KARSTEN KRUSE, Theoretical Physics, Saarland University, 66123 Saarbrücken, VIKTORIA WOLLRAB<sup>2</sup>, RAGHAVAN THIAGARAJAN, Laboratory of Cell Physics, Institut de Science et d'Ingénierie Supramoléculaires, 67083 Strasbourg, France, ANNE WALD, Theoretical Physics, Saarland University, 66123 Saarbrücken, DANIEL RIVELINE, Laboratory of Cell Physics, Institut de Science et d'Ingénierie Supramoléculaires, 67083 Strasbourg, France — Networks of polymerizing actin filaments are known to be capable to self-organize into a variety of structures. For example, spontaneous actin polymerization waves have been observed in living cells in a number of circumstances, notably, in crawling neutrophils and slime molds. During later stages of cell division, they can also spontaneously form a contractile ring that will eventually cleave the cell into two daughter cells. We present a framework for describing networks of polymerizing actin filaments, where assembly is regulated by various proteins. It can also include the effects of molecular motors. We show that the molecular processes driven by these proteins can generate various structures that have been observed in contractile rings of fission yeast and mammalian cells. We discuss a possible functional role of each of these patterns.

**8:48AM A35.00003 Fluctuations and nematic order in collective motion of filamentous bacteria<sup>1</sup>**, DAIKI NISHIGUCHI, The University of Tokyo, KEN H. NAGAI, JAIST, MASAKI SANO, The University of Tokyo — Although there are many numerical and theoretical studies on Vicsek-like models, there have been no convincing experiments that clearly observe predicted properties of collective motion such as giant number fluctuations. To realize such experiments with a biological system, we used filamentous bacteria, which are 20 times as long as usual bacteria. Due to strong alignment interactions arising from their elongated shapes, these bacteria exhibit a nematic state when their dense suspensions are confined in a quasi-two-dimensional plane. We have quantitatively evaluated the nematic order parameter in this ordered state and concluded that it has true long-range order, and we have obtained giant number fluctuations in this true long-range ordered state. All the obtained experimental results are consistent with a Vicsek-like model with the same symmetry as our experiments, namely, the Vicsek-like self-propelled rods model, in which each particle has polarity and their interactions are nematic.

<sup>1</sup>This work is supported by a Grant-in-Aid for Japan Society for Promotion of Science (JSPS) Fellows (Grant No. 26-9915) and KAKENHI (No. 25103004, Fluctuation & Structure) from MEXT, Japan.

**9:00AM A35.00004 Modeling flexible active nematics<sup>1</sup>**, MICHAEL VARGA, ROBIN SELINGER, Liquid Crystal Institute, Kent State University — We study active nematic phases of self-propelled flexible chains in two dimensions using computer simulation, to investigate effects of chain flexibility. In a “dry” phase of self-propelled flexible chains, we find that increasing chain stiffness enhances orientational order and correlation length, narrows the distribution of turning angles, increases persistence length, and increases the magnitude of giant density fluctuations. We further adapt the simulation model to describe behavior of microtubules driven by kinesin molecular motors in two different environments: on a rigid substrate with kinesin immobilized on the surface; and on a lipid membrane where kinesin is bonded to lipid head groups and can diffuse. Results are compared to experiments by L. Hirst and J. Xu. Lastly, we consider active nematics of flexible particles enclosed in soft, deformable encapsulation in two dimensions, and demonstrate novel mechanisms of pattern formation that are fundamentally different from those observed in bulk.

**9:12AM A35.00005 Active nematics confined within a shell**, RUI ZHANG, YE ZHOU, MOHAMMAD RAHIMI, JUAN DE PABLO, University of Chicago, DEPABLO TEAM — Active fluids exhibit many striking flow patterns when confined within complex geometries. For example, recent work has demonstrated that when a thin film of extensile microtubules is confined within a vesicle, the four  $+1/2$  defects periodically oscillate between a tetrahedral and a planar configuration (Keber, *et al.* Science (2014)). Here we employ hybrid lattice Boltzmann simulations to study the dynamics of active nematics confined between two concentric spherical surfaces. We find that in both extensile and contractile systems, the four defects are coupled with noticeable macroscopic velocities and they move along their symmetry axes, even though in different patterns. We observe that in extensile systems with moderate activity, defects repel each other due to elastic forces, and their collective motion leads to the same patterned dynamics as observed in the above experiment. We further show that this periodic dynamics is accompanied by oscillations of the defect velocity, system's elastic energy, and the emergence and annihilation of vortices. We also observe that with stronger activity, the extensile system evolves to chaos. In contrast, the contractile system remains passive for the entire activity range, with defects being attracted to each other in pairs.

**9:24AM A35.00006 Active Cellular Nematics**, GUILLAUME DUCLOS, CHRISTOPH ERLINKAEMPER, SIMON GARCIA, HANNAH YEVICK, JEAN-FRANÇOIS JOANNY, PASCAL SILBERZAN, Physico-Chimie Curie, UMR 168, UPMC, Institut Curie, BIOLOGY INSPIRED PHYSICS AT MESOSCALES TEAM, PHYSICAL APPROACH OF BIOLOGICAL PROBLEMS TEAM — We study the emergence of a nematic order in a two-dimensional tissue of apolar elongated fibroblast cells. Initially, these cells are very motile and the monolayer is characterized by giant density fluctuations, a signature of far-from-equilibrium systems. As the cell density increases because of proliferation, the cells align with each other forming large perfectly oriented domains while the cellular movements slow down and eventually freeze. Therefore topological defects characteristic of nematic phases remain trapped at long times, preventing the development of infinite domains. By analogy with classical non-active nematics, we have investigated the role of boundaries and we have shown that cells confined in stripes of width smaller than typically 500 nm are perfectly aligned in the stripe direction. Experiments performed in cross-shaped patterns show that both the number of cells and the degree of alignment impact the final orientation. *Reference:* Duclos G., Garcia S., Yevick H.G. and Silberzan P., “Perfect nematic order in confined monolayers of spindle-shaped cells”, *Soft Matter*, 10, 14, 2014

**9:36AM A35.00007 Defect dynamics and ordering in compressible active nematics.<sup>1</sup>**, PRASHANT MISHRA, Department of Physics, Syracuse University, PRAGYA SRIVASTAVA, The Francis Crick Institute, M. CRISTINA MARCHETTI, Department of Physics, Syracuse University — Active nematics, such as suspensions of biopolymers activated by molecular motors or bacteria swimming in passive liquid crystals, exhibit complex self-sustained flow, excitability and defect generation. Activity renders the defect themselves self-propelled particles, capable of organizing in emergent ordered structures. We have developed a minimal model of compressible active nematics on a substrate. We eliminate the flow velocity in favor of the nematic order parameter via the balance of frictional dissipation and active driving to obtain a dynamical description entirely in terms of the nematic alignment order parameter. Activity renormalizes the bend and splay elastic constants rendering them anisotropic and driving them to zero or even negative, resulting in the appearance of modulated states and defective structures. Using linear stability analysis and numerics we organize the various regimes into a phase diagram and discuss the relation to experiments.

**9:48AM A35.00008 Directed and persistent movement arises from mechanochemistry of the ParA/ParB system**, LONGHUA HU, National Heart, Lung, and Blood Institute, National Institutes of Health, ANTHONY G. VECCHIARELLI, KIYOSHI MIZUUCHI, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, KEIR C. NEUMAN, JIAN LIU, National Heart, Lung, and Blood Institute, National Institutes of Health — The segregation of DNA prior to cell division is essential for faithful genetic inheritance. In many bacteria, segregation of the low-copy-number plasmids involves an active partition system composed of ParA ATPase and its stimulator protein ParB. Recent experiments suggest that ParA/ParB system motility is driven by a diffusion-ratchet mechanism in which ParB-coated plasmid both creates and follows a ParA gradient on the nucleoid surface. However, the detailed mechanism of ParA/ParB-mediated directed and persistent movement remains unknown. We develop a theoretical model describing ParA/ParB-mediated motility. We show that the ParA/ParB system can work as a Brownian ratchet, which effectively couples the ATPase-dependent cycling of ParA-nucleoid affinity to the motion of the ParB bound cargo. Paradoxically, the resulting processive motion relies on quenching diffusive plasmid motion through a large number of transient ParA/ParB-mediated tethers to the nucleoid surface. Our work sheds light on a new emergent phenomenon in which non-motor proteins work collectively via mechanochemical coupling to propel cargos — an ingenious solution shaped by evolution to cope with the lack of processive motor proteins in bacteria.

**10:00AM A35.00009 Decoupling tissue and cell scale stresses using embedded oil microdroplets<sup>1</sup>**, ELIJAH SHELTON, FRIEDHELM SERWANE, ALESSANDRO MONGERA, ADAM LUCIO, OTGER CAMPÀS, University of California Santa Barbara — Embryonic development and organ morphogenesis require mechanical stresses to be patterned in space and time over length scales ranging from cellular to tissue level. While several approaches use 4D live-imaging to infer forces from the observed flow fields, few techniques allow direct measurements of stress in vivo and in situ. We use oil microdroplets injected in between cells as direct stress sensors. Through confocal imaging and custom software for high resolution 3D droplet surface reconstruction, we can directly measure the patterns of stress by looking at the deformations of the drop. This analysis allows us to decouple the stresses at the tissue scale from those generated at cellular scales by disentangling ellipsoidal drop deformation modes from higher order drop deformations. Using this technique we measure both tissue and cell scale stresses within aggregates of mesenchymal cells as well as within developing zebrafish embryonic tissues. The decoupling of mechanical stresses at cell and tissue scales makes our technique uniquely suited for understanding how tissue scale reorganizations emerge from cell scale interactions.

**10:12AM A35.00010 Volume Changes During Active Shape Fluctuations in Cells**, CATERINA A. M. LA PORTA, ALESSANDRO TALONI, University of Milan, ELENA KARDASH, University of Geneva, OGUZ UMUT SALMAN, CNRS, Paris, LEV TRUSKINOVSKY, CNRS, Ecole Polytechnique, Palaiseau, STEFANO ZAPPERI, University of Milan — Cells modify their volume in response to changes in osmotic pressure but it is usually assumed that other active shape variations do not involve significant volume fluctuations. Here we report experiments demonstrating that water transport in and out of the cell is needed for the formation of blebs, commonly observed protrusions in the plasma membrane driven by cortex contraction. We develop and simulate a model of fluid-mediated membrane-cortex deformations and show that a permeable membrane is necessary for bleb formation which is otherwise impaired. Taken together, our experimental and theoretical results emphasize the subtle balance between hydrodynamics and elasticity in actively driven cell morphological changes <sup>1</sup>.

**10:24AM A35.00011 Probing the Dynamics of the Cellular Actomyosin Network with Magnetic Microposts**, YU SHI, Department of Physics and Astronomy, Johns Hopkins University, STEVEN HENRY, JOHN CROCKER, Department of Chemical and Biomolecular Engineering, University of Pennsylvania, DANIEL REICH, Department of Physics and Astronomy, Johns Hopkins University — The actomyosin network in living cells is commonly accepted as an archetypal example of an active matter system. To characterize the dynamic properties and the effects of non-thermal motion of such a system requires simultaneously measuring the fluctuation spectrum of internal stresses as well as its local viscoelasticity. Via use of PDMS micropost arrays with magnetic nanowires embedded in selected posts, we measure the local complex modulus of cells through mechanical actuation of the magnetic microposts using a dual magnetic tweezer system. The microposts are also used as passive probes to measure the force fluctuations inside the cytoskeleton. The active and passive responses of fibroblasts will be presented, together with measurements of correlations between different subcellular regions, and the influence of cytoskeletal and myosin inhibitors. Results on the anisotropy of internal stress fluctuations and their response to chemical perturbations will also be discussed.

**10:36AM A35.00012 Active Contraction of Microtubule Networks**, PETER FOSTER, John A. Paulson School of Engineering and Applied Sciences and FAS Center For Systems Biology, Harvard University, SEBASTIAN FRTHAUER, Courant Institute of Mathematical Science, New York University and Department of Molecular and Cellular Biology, Harvard University, MICHAEL SHELLEY, Courant Institute of Mathematical Science, New York University, DANIEL NEEDLEMAN, John A. Paulson School of Engineering and Applied Sciences, FAS Center For Systems Biology, Harvard University — Many cellular processes are driven by cytoskeletal assemblies. It remains unclear how cytoskeletal filaments and motor proteins organize into cellular scale structures and how molecular properties of cytoskeletal components affect the large scale behaviors of these systems. Here we investigate the self-organization of stabilized microtubules in *Xenopus* oocyte extracts and find that they can form macroscopic networks that spontaneously contract. We propose that these contractions are driven by the clustering of microtubule minus ends by dynein. Based on this idea, we construct an active fluid theory of network contractions which predicts a dependence of the timescale of contraction on initial network geometry, a development of density inhomogeneities during contraction, a constant final network density, and a strong influence of dynein inhibition on the rate of contraction, all in quantitative agreement with experiments. These results demonstrate that the motor-driven clustering of filament ends is a generic mechanism leading to contraction.

**10:48AM A35.00013 Collective dynamics during cell division**, STEFANO ZAPPERI, University of Milan, ZSOLT BERTALAN, ZOE BUDRIKIS, ISI Foundation, CATERINA A. M. LA PORTA, University of Milan — In order to correctly divide, cells have to move all their chromosomes at the center, a process known as congression. This task is performed by the combined action of molecular motors and randomly growing and shrinking microtubules. Chromosomes are captured by growing microtubules and transported by motors using the same microtubules as tracks<sup>1</sup>. Coherent motion occurs as a result of a large collection of random and deterministic dynamical events. Understanding this process is important since a failure in chromosome segregation can lead to chromosomal instability one of the hallmarks of cancer. We describe this complex process in a three dimensional computational model involving thousands of microtubules. The results show that coherent and robust chromosome congression can only happen if the total number of microtubules is neither too small, nor too large. Our results allow for a coherent interpretation a variety of biological factors already associated in the past with chromosomal instability and related pathological conditions<sup>2</sup>.

**8:00AM A36.00001 Simultaneous three-dimensional imaging and manipulation of grain boundaries in colloidal crystals**, KAZEM V. EDMOND, YANYAN LIU, ARRAN CURRAN, DIRK G.A.L. AARTS, University of Oxford, STEFANO SACANNA, New York University, ROEL P.A. DULLENS, University of Oxford — Characterizing the properties of grains and grain boundaries is critical for understanding and controlling material properties. We investigate the dynamics of grain boundaries in crystalline materials using concentrated colloidal suspensions of microspheres. The micron-sized particles are suspended in a mixture of solvents whose refractive index and density nearly match those of the particles, enabling three-dimensional visualization and negating gravitational effects. Throughout the sample we disperse specially designed core-shell particles whose cores have a higher refractive index that can be optically trapped. Via optical tweezing, these core-shell particles enable us to directly interact with and probe grain boundaries in 3D within the colloidal crystal. We use a uniquely developed optical microscopy system that combines confocal imaging with holographic trapping, enabling quantitative imaging and precise manipulation simultaneously in three dimensions<sup>1</sup>. Our experiments provide direct insight into the properties of grain boundaries in crystals.

**8:12AM A36.00002 Capturing "glasslites": structures and dynamics of colloidal liquids under spherical confinement**, BO ZHANG, XIANG CHENG, University of Minnesota-Twin Cities — Recent theories have predicted that when a supercooled liquid approaches the glass transition, "glasslites"-amorphously-ordered particle clusters-nucleate within the liquid, which lead to static correlations dictating the dramatic slowdown of liquid relaxation. The prediction, however, has yet to be verified in 3D experiments. Here, we design a 3D colloidal system, where particles are confined inside spherical cavities with an amorphous layer of particles pinned at boundary. Using this novel system, we capture the glasslites proposed in theories and demonstrate the development of a static correlation. Moreover, by investigating the dynamics of spherically confined samples, we reveal a profound and unexpected influence of the static correlation on the underlying colloidal glass transition. These measurements provide crucial information on how the configurational entropy of a confined supercooled liquid varies when approaching the glass transition.

**8:24AM A36.00003 Tunable Time-Dependent Colloidal Interactions**, ANDREW M. BERGMAN, W. BENJAMIN ROGERS, VINOTHAN N. MANOHARAN, Harvard University — Self-assembly of colloidal particles can be driven by changes in temperature, density, or the concentration of solutes, and it is even possible to program the thermal response and equilibrium phase transitions of such systems [1]. It is still difficult, however, to tune how the self-assembly process varies in time. We demonstrate control over the time-dependence of colloidal interactions, using DNA-functionalized colloidal particles with binding energies that are set by the concentration of a free linker strand in solution. We control the rate at which this free strand is consumed using a catalytic DNA reaction [2], whose rate is governed by the concentration of a catalyst strand. Varying the concentration of the linker, its competitor, and the catalyst at a fixed temperature, we can tune the rate and degree of the formation of colloidal aggregates and their following disassembly. Close to the colloidal melting point, the timescales of these out-of-equilibrium assembly and disassembly processes are determined by the rate of the catalytic reaction. Far below the colloidal melting point, however, the effects from varying our linker and competitor concentrations dominate. [1] Rogers and Manoharan, *Science* **347** (6222): 639-642 (2015). **8:36AM A36.00004 Transitions in colloidal crystals induced by changes in interparticle interactions<sup>1</sup>**, BARTHOLOMEUS MACHIELSE, MATTHEW GRATALE, ZOIEY DAVIDSON, ARJUN YODH, Univ of Pennsylvania — We experimentally study the phase diagram of two-dimensional colloidal crystals as the interparticle interactions transition from weakly attractive to strongly attractive. Simulations have shown that crystals transition from a crystal phase into fluid-crystal coexistence at high attraction strengths. To control the interaction between colloids, we use temperature sensitive, rod-like surfactant micelles as depletants. As the temperature of the system increases, the rod length of the micelles grows, leading to an increase in both the range and strength of interparticle attractions. As the attraction strength increases we observe a decrease in the lattice constant of the crystal, and the creation of tears in the crystal structure. These tears allow a colloidal fluid to form, thus yielding the fluid-crystal coexistence phase predicted by previous simulations. These tears and their corresponding phase separation occur simultaneously with a peak in the susceptibility of the orientational order parameter. By creating colloidal systems with various packing fractions and slowly increasing the temperature, which increases the attraction strength between colloids, we attempt to accurately map out the phase diagram of two-dimensional colloidal crystals with attractive interactions.

**8:48AM A36.00005 Probing Dynamical Heterogeneity in Dense Colloidal Suspensions with Depletion Attraction<sup>1</sup>**, ZACHERY BROWN, GREGORY HOGAN, Department of Physics, Saint Joseph's University, MATTHEW GRATALE, ARJUN G. YODH, Department of Physics and Astronomy, University of Pennsylvania, PIOTR HABDAS, Department of Physics, Saint Joseph's University — We directly observe the particle dynamics in dense colloidal suspensions. Using depletion attraction, we vary inter particle potential to study the reentrant glass transition. Confocal microscopy and particle tracking allow us to follow particle trajectories over time. By varying inter particle attraction strength for a fixed volume fraction of colloidal suspensions, we observe three qualitatively different states. Mean square displacement and long time diffusion constant vary with the depletant concentration and indicate a glass state for low attraction strengths, ergodic liquid state for moderate attraction strengths, and attractive arrested state for the highest attraction strengths. Variance in the self overlap function gives the four point susceptibility, a measure of dynamical heterogeneity over a range of length scales and lag times. Results show that the lag times corresponding to the most heterogeneous dynamics are longer for arrested states than for fluid states. The length scale that maximizes four point susceptibility across a range of attraction strengths exhibits a reentrant glass behavior similar to that of the long time diffusion constant.

**9:00AM A36.00006 Particle dynamics and vibrational properties of disordered colloidal packings with varying interparticle attraction strength<sup>1</sup>**, PIOTR HABDAS, Department of Physics, Saint Joseph's University, MATTHEW GRATALE, ZOIEY DAVIDSON, TIM STILL, ARJUN G. YODH, Department of Physics and Astronomy, University of Pennsylvania — We experimentally study dynamical and vibrational properties of disordered colloidal packings as a function of the strength of the interparticle attraction. Specifically, we probe the structural and dynamical changes in disordered colloidal glasses as the interparticle interaction between constituent particles evolves from nearly hard-sphere repulsive to attractive. This increase of the interparticle attraction is achieved through use of temperature-tunable surfactant micelle depletants. The depletion-driven entropic attraction between particles in suspension grows with increasing temperature. Increasing temperature changes particle interactions in a dense colloidal packing from repulsive (weakly attractive) to strongly attractive, and accompanying variations in structure and dynamics is investigated. Preliminary experiments on these disordered systems show a continuous change in particle dynamics as attraction strength increases. Interestingly, vibrational properties show a more sudden change reflected in the behavior of the vibrational density of states.

<sup>1</sup>Z.B., G.H., and P.H. acknowledge financial support of the NSF Grant RUI-1306990. M.G., Z.D., T.S., and A.G.Y. acknowledge financial support of the NSF Grant DMR-1205463, NSF MRSEC Grant DMR-1120901, and NASA Grant NNX08AO0G.

**9:12AM A36.00007 On Determination of the Equation of State of Colloidal Suspensions<sup>1</sup>**, KRITTANON SIRORATTANAKUL, Department of Physics, Lehigh University, HAO HUANG, Department of Chemical and Biomechanical Engineering, Lehigh University, CHRISTOPHER UHL, Bioengineering Program, Lehigh University, DANIEL OU-YANG, Department of Physics, Lehigh University — Colloidal suspensions are the main ingredients for a variety of materials in our daily life, e.g., milk, salad dressing, skin lotions and paint for wall coatings. Material properties of these systems require an understanding of the equation of state of these materials. Our project aims to experimentally determine the equation of state of colloidal suspensions by microfluidics, dielectrophoresis (DEP) and optical imaging. We use fluorescent polystyrene latexes as a model system for this study. Placing semi-permeable membranes between microfluidics channels, which made from PDMS, we control the particle concentration and ionic strengths of the suspension. We use osmotic equilibrium equation to analyze the particle concentration distribution in a potential force field created by DEP. We use confocal optical imaging to measure the spatial distribution of the particle concentration. We compare the results of our experimental study with data obtained by computer simulation of osmotic equilibrium of interacting colloids.

**9:24AM A36.00008 Non-equilibrium steady-state distributions of colloids in a tilted periodic potential<sup>1</sup>**, XIAO GUANG MA, University of Pennsylvania, PIK-YIN LAI, National Central University, BRUCE ACKERSON, Oklahoma State University, PENDER TONG, Hong Kong University of Science and Technology — A two-layer colloidal system is constructed to study the effects of the external force  $F$  on the non-equilibrium steady-state (NESS) dynamics of the diffusing particles over a tilted periodic potential, in which detailed balance is broken due to the presence of a steady particle flux. The periodic potential is provided by the bottom layer colloidal spheres forming a fixed crystalline pattern on a glass substrate. The corrugated surface of the bottom colloidal crystal provides a gravitational potential field for the top layer diffusing particles. By tilting the sample with respect to gravity, a tangential component  $F$  is applied to the diffusing particles. The measured NESS probability density function  $P_{ss}(x, y)$  of the particles is found to deviate from the equilibrium distribution depending on the driving or distance from equilibrium. The experimental results are compared with the exact solution of the 1D Smoluchowski equation and the numerical results of the 2D Smoluchowski equation. Moreover, from the obtained exact 1D solution, we develop an analytical method to accurately extract the 1D potential  $U_0(x)$  from the measured  $P_{ss}(x)$ .

**9:36AM A36.00009 Diffusing colloids in the vicinity of a surface: Anomalous yet Brownian diffusion?**, MAXIME IGNACIO, MYKYTA V. CHUBYNSKY, GARY W. SLATER, University of Ottawa — Anomalous yet Brownian diffusion refers to a process with a linear mean-square displacement coexisting with a non-Gaussian Displacement Distribution (DispD) [1]. Chubynsky and Slater [2] proposed a model of this phenomenon in which the diffusion coefficient varies randomly in time ("diffusing diffusivity"). Recently, Bechhoefer's group has showed experimentally that diffusion of colloids near a wall exhibits non-Gaussian DispD with exponential tails. Due to hydrodynamic interactions, the diffusivity  $D(r)$  is space-dependent and therefore varies in time as the particle moves in space. Qualitatively, the experimental results agree with the predictions of the diffusing diffusivity model. However, the two situations differ in details. First, space-dependent diffusivity implies the possibility of different interpretations of the stochastic term in the overdamped Langevin equation (i.e. the Ito-Stratonovich dilemma). Second, in the system of Bechhoefer et al, there is an external potential due to gravity and the electrostatic repulsion from the wall. Using Lattice Monte Carlo simulations, we explore the role of these effects. [1] B. Wang et al., PNAS 106, 15160 (2009), [2] M. V. Chubynsky and G. W. Slater, PRL 113, 098302 (2014)

**9:48AM A36.00010 Non-Gaussian yet normal diffusion of a bead near a wall<sup>1</sup>**, MPUMELELO MATSE, JOHN BECHHOEFER, Simon Fraser University — Brownian motion of microscopic particles in a simple fluid exhibits two key properties: the mean-squared displacement (MSD) increases linearly with time ( $\langle \Delta x^2 \rangle = 2D\Delta t$ , where  $D$  is the diffusivity) and the displacement distribution is Gaussian. Although linear MSD ("normal diffusion") was initially assumed to always imply Gaussian displacements, recent experiments by Granick et al. show that this is not so. Chubynsky et al. [PRL 113, 098302, 2014] have argued that such behavior arises when  $D$  has temporal and/or spatial fluctuations that are convoluted together and form a non-Gaussian distribution. Experiments to date have been in complex settings where direct measurements of  $D(x, t)$  have not been possible. Here, we report experiments on a simple system where  $D(x, t)$  is known: the Brownian motion of a colloidal sphere near a wall. By choosing the particle size carefully, we ensure that the bead explores a wide range of  $D$ . We observe a linear MSD curve and non-Gaussian displacements for vertical motion and directly confirm the proposed mechanism of Chubynsky et al. for such "diffusing diffusivity."

**10:00AM A36.00011 Structural relaxation of vapour-deposited colloidal glass<sup>1</sup>**, XIN CAO, HUIJUN ZHANG, YILONG HAN, Hong Kong Univ of Sci & Tech, YILONG GROUP COLLABORATION — Freshly made glasses by vapor deposition exhibit ultra-stability similar to fully aged glasses formed by quenching liquids. It has been suggested that the mobile surface layers in vapor deposition accelerates the aging process, but its mechanism is unclear. Here we study the vapor deposition process of colloidal glass by video microscopy and MD simulation with single-particle dynamics. We found that the structural relaxation near the surface, characterized by cooperative-rearrangement regions (CRRs), is much stronger during the deposition process than after deposition due to the perturbation of newly attached particles. Near the surface, a thermal-induced vacancy can triggered a large CRR which propagates from the vacancy to the surface. Deep inside the bulk, CRRs are rare, smaller and cannot propagate to the surface. By measuring the evolution of free-volume entropy, we found that the strong structural relaxation is accompanied by local free energy decreasing.

**10:12AM A36.00012 Assembly of colloidal strings in a simple fluid flow**, YU ABE, Toray Industries, Inc. University of Minnesota, LORRAINE FRANCIS, XIANG CHENG, University of Minnesota — Colloidal particles self-assemble into ordered structures ranging from face- and body-centered cubic crystals to binary ionic crystals and to kagome lattices. Such diverse micron-scale structures are of practical importance for creating photonic materials and also of fundamental interest for probing equilibrium and non-equilibrium statistical mechanics. As a particularly interesting example, 1D colloidal strings provide a unique system for investigating non-equilibrium dynamics of crystal lattices. Here, we report a simple experimental method for constructing 1D colloidal crystals, where colloidal particles self-assemble into flow-aligned string structures near solid boundary under unidirectional flows. Using fast confocal microscopy, we explore the degree of particle alignment as functions of flow rate, particle concentrations, wetting properties of solid boundary and ionic strength of solvent. Through our systematic experiments, we show that these colloidal strings arise from hydrodynamic coupling, facilitated by electrostatic attractions between particles and the boundary. Compared with previous methods, our work provides a much simpler experimental procedure for assembling a large number of colloidal strings.

**10:24AM A36.00013 Hiding in plain view: Colloidal self-assembly from polydisperse populations**, LUCAS GOEHRING, Max Planck Institute for Dynamics and Self-Organization, BERNARD CABANE, ESPCI ParisTech, JOAQUIM LI, Max Planck Institute for Dynamics and Self-Organization, FRANCK ARTZNER, University of Rennes, ROBERT BOTET, University Paris-Sud, CHRISTOPHE LABBEZ, GUILLAUME BAREIGTS, University of Bourgogne, MICHAEL SZTUCKI, ESRF – The European Synchrotron — We report small-angle x-ray scattering (SAXS) experiments on aqueous dispersions of colloidal silica with a broad monomodal size distribution (polydispersity 14%, size  $a = 8$  nm). This distribution of sizes was expected to destroy any long-range order of the particles. However, we found ordered states when the particles repelled each other with soft ionic potentials of range  $\sim a$ . Over a range of volume fractions the particles segregated to build first one, then two distinct sets of colloidal crystals. These dispersions thus demonstrate fractional crystallization and multiple-phase (bcc, Laves AB<sub>2</sub>, liquid) coexistence. Their remarkable ability to build complex crystal structures from a polydisperse population originates from the intermediate-range nature of interparticle forces, and suggests routes for designing self-assembling colloidal crystals from the bottom-up.

**10:36AM A36.00014 Controlling Chirality of Entropic Crystals<sup>1</sup>**, PABLO DAMASCENO, Applied Physics Program, University of Michigan, ANDREW KARAS, Chemical Engineering Department, University of Michigan, BENJAMIN SCHULTZ, Physics Department, University of Michigan, MICHAEL ENGEL, SHARON GLOTZER, Chemical Engineering Department, University of Michigan — Colloidal crystal structures with complexity and diversity rivaling atomic and molecular crystals have been predicted and obtained for hard particles by entropy maximization. However, thus far homochiral colloidal crystals, which are candidates for photonic metamaterials, are absent. Using Monte Carlo simulations we show that chiral polyhedra exhibiting weak directional entropic forces self-assemble either an achiral crystal or a chiral crystal with limited control over the crystal handedness. Building blocks with stronger faceting exhibit higher selectivity and assemble a chiral crystal with handedness uniquely determined by the particle chirality. Tuning the strength of directional entropic forces by means of particle rounding or the use of depletants allows for reconfiguration between achiral and homochiral crystals. We rationalize our findings by quantifying the chirality strength of each particle, both from particle geometry and potential of mean force and torque diagrams.

**10:48AM A36.00015 Realization of atomistic transitions with colloidal nanoparticles using an ultrafast laser**, GURSOY AKGUC, SERIM ILDAY, OMER ILDAY, OGUZ GULSEREN, GHAITH MAKEY, KORAY YAVUZ, ONUR TOKEL, IHOR PAVLOV, OZGUN YAVUZ, bilkent university — We report on realization of rapid atomistic transitions with colloidal nanoparticles in a setting that constitutes a dissipative far-from-equilibrium system subject to stochastic forces. Large colloidal crystals (comprising hundreds of particles) can be formed and transitions between solid-liquid-gas phases can be observed effortlessly and within seconds. Furthermore, this system allows us to form and dynamically arrest metastable phases such as glassy structures and to controllably transform a crystal pattern from square to hexagonal lattices and vice versa as well as to observe formation and propagation of crystal defects (i.e. line defects, point defects, planar defects). The mechanism largely relies on an interplay between convective forces induced by femtosecond pulses and strong Brownian motion; the former drags the colloids to form and reinforce the crystal and the latter is analogous to lattice vibrations, which makes it possible to observe phase transitions, defect formation and propagation and lattice transformation. This unique system can help us get insight into the mechanisms underlying various solid state phenomena that were previously studied under slowly evolving (within hours/days), near-equilibrium colloidal systems.

Session A37 GSOF DBIO: Phase Transitions and Self-Assembly in Biological Systems I 340 -

Jens Glaser, University of Michigan

**8:00AM A37.00001 Study of the Effect of Ellipsoidal Shape on the Kern and Frenkel Patch Model<sup>1</sup>**, THIENBAO NGUYEN, JAMES GUNTON, JEFFREY RICKMAN, Lehigh University — In their work on the self-assembly of complex structures, Glotzer and Solomon (Nature Materials 6, 557 - 562 (2007)) identified both interaction and shape anisotropy as two of several means to build complex structures. Advances in fabricating materials and new insights into protein biology have revealed the importance of these types of interactions. The Kern and Frenkel (J. Chem. Phys. 118, 9882 (2003)) model of hard spheres carrying interaction patches of various sizes has been used extensively to describe interaction anisotropies important in protein phase transitions. However their model did not also account for shape anisotropy. We studied the role of both shape and interaction anisotropy by applying N=2 and N=4 attractive Kern and Frenkel patches with an interaction range to hard ellipsoids with various aspect ratios and patch coverages. Following Kern and Frenkel, we studied the liquid-liquid phase separation of our particles using a Monte Carlo simulation. We found the critical temperatures for our model using the approximate law of rectilinear diameter and compared them with the original results of Kern and Frenkel. We found that the critical temperatures increased both with aspect ratio and percent coverage.

**8:12AM A37.00002 Effects of Coulomb Repulsion on the Phase Diagram of the Asakura-Oosawa Model<sup>1</sup>**, JASON HAAGA, Lehigh University, ELIZABETH PEMBERTON, Drew University, JAMES GUNTON, JEFFREY RICKMAN, Lehigh University — We investigate the effect of adding a screened Coulomb charge to a model colloidal system interacting via the Asakura-Oosawa depletion potential. This model has previously been used to study the early stages of amelogenin self-assembly, a crucial process in the formation of dental enamel, by Li et al (Biophysical Journal 101, 2502 (2011)). By employing Monte Carlo simulations, we explore the role of interaction strengths and ranges on phase behavior. We find that charge strength and range have a strong influence on the stable, in the case of long range depletion potential, or metastable, in the case of short range depletion, fluid-fluid phase separation. Coulomb repulsion narrows and flattens the coexistence curve with increasing charge. This talk will also discuss solid-solid transitions present for certain interaction ranges.

**8:24AM A37.00003 Mapping Liquid-liquid protein phase separation using ultra-fast-scanning fluorescence correlation spectroscopy.**, MING-TZO WEI, SHANA ELBAUM-GARFINKLE, CRAIG B. ARNOLD, RODNEY D. PRIESTLEY, CLIFFORD P. BRANGWYNNE, Princeton University — Intrinsically disordered proteins (IDPs) are an understudied class of proteins that play important roles in a wide variety of biological processes in cells. We've previously shown that the C. elegans IDP LAF-1 phase separates into P granule-like droplets in vitro. However, the physics of the condensed phase remains poorly understood. Here, we use a novel technique, ultra-fast-scanning fluorescence correlation spectroscopy, to study the nano-scale rheological properties of LAF-1 droplets. Ultra-fast-scanning FCS uses a tunable acoustic gradient index of refraction (TAG) lens with an oil immersion objective to control axial movement of the focal point over a length of several micrometers at frequencies of 70kHz. Using ultra-fast-scanning FCS allows for the accurate determination of molecular concentrations and their diffusion coefficient, when the particle is passing through an excitation volume. Our work reveals an asymmetric LAF-1 phase diagram, and demonstrates that LAF-1 droplets are purely viscous phases which are highly tunable by salt concentration.

**8:36AM A37.00004 Using Symmetry to Design Self-Assembling Protein Cages and Nanomaterials on the Mid-Nanometer Scale**, TODD YEATES, UCLA Department of Chemistry and Biochemistry — Self-assembling molecular structures having diverse cellular functions are widespread in nature. Some of the largest and most sophisticated types are built from many copies of the same or similar protein molecules arranged following principles of symmetry. A long-standing engineering goal has been to design novel protein molecules to self-assemble into geometrically specific structures similar to the extraordinary structures that have evolved in Nature. Practical routes to this goal have been developed by using ideas in symmetry to articulate the minimum design requirements for achieving various types of symmetric architectures, including cages, extended two-dimensional layers, and three-dimensional crystalline materials. The key requirement is that two distinct self-associating interfaces, each conferring one element of rotational symmetry, have to be engineered into the protein molecule (or molecules), following particular geometric specifications. The main principle is that combining two separate symmetry elements into a single molecular entity produces a molecule that necessarily assembles into an architecture dictated by a symmetry group that is the product of the two simpler contributing symmetries. Recent experiments have demonstrated success using a variety of symmetry-based strategies. Strategic variations are emerging that differ from each other with respect to biophysical features such as flexibility vs rigidity in the assembled structures, and with respect to design aspects such as whether the protein interfaces are inherited from natural oligomeric proteins or are designed de novo by advanced computational methods. The success of these strategies has been proven by determining crystal structures of several giant, self-assembling protein cages and clusters (10-25 nm in diameter), created by design. The ability to create sophisticated supramolecular structures from designed protein subunits opens the way to broad applications in synthetic biology and nanotechnology.

**9:12AM A37.00005 Hierarchical assembly of protein nanocrystals into macroscopic gels**, DANIEL GREENE, STANLEY SANDLER, NORMAN WAGNER, ABRAHAM LENHOFF, Univ of Delaware — From crystallization screens to downstream processing, protein gel phases are common during protein solution processing. While the structure of crystalline protein is well known, very little is known about the structure of these gel phases. We recently measured the microstructure of a salted-out ovalbumin dense phase and found that nanocrystalline protein clusters, which are only a few unit cells in size, percolate 5 micron gel beads. It is unclear if the behavior seen for ovalbumin is representative of a more general phenomenon. Here we present microstructural measurements on a salted-out monoclonal antibody (mAb) and salted-out ribonuclease-a that support this possibility. Using small-angle x-ray and neutron scattering (SAS) and transmission electron microscopy (TEM), we find both salted-out mAb and ribonuclease-a gels exhibit nanocrystalline regions. Within the mAb gel, the mAb aggregates into hollow tubular structures that are hundreds of nanometers long, have an inner diameter of approximately 15-20 nm and an outer diameter of approximately 20-30 nm. The SAS intensity from these structures contains a peak at high-q that is commensurate with scattering from idealized mAb nanocrystals that are 1-2 unit cells wide. Ribonuclease-a does not appear to form tubular structures, but the SAS intensity contains peaks at high-q that are consistent with the scattering from a nanocrystal 2-3 unit cells wide. Power-law scattering at low-q indicates the nanocrystals aggregate into a gel with fractal dimension 2.5. This research provides insight into the nanostructure and formation of protein gel phases.

**9:24AM A37.00006 The mechanical properties of phase separated protein droplets**, LOUISE JAWERTH, MAHDIYE IJAVI, AVINASH PATEL, SHAMBADITYA SAHA, Max Planck Institute of Molecular Cell Biology and Genetics, FRANK JLICHER, Max Planck Institute for the Physics of Complex Systems, ANTHONY HYMAN, Max Planck Institute of Molecular Cell Biology and Genetics — In vivo, numerous proteins associate into liquid compartments by de-mixing from the surrounding solution, similar to oil molecules in water. Many of these proteins and their corresponding liquid compartments play a crucial role in important biological processes, for instance germ line specification in *C. elegans* or in neurodegenerative diseases such as Amyotrophic lateral sclerosis (ALS). However, despite their importance, very little is known about the physical properties of the resulting droplets as well as the physical mechanisms that control their phase separation from solution. To gain a deeper understanding of these aspects, we study a few such proteins in vitro. When these proteins are purified and added to a physiological buffer, they phase separate into droplets ranging in size from a few to tens of microns with liquid-like behavior similar to their physiological counterparts. By attaching small beads to the surface of the droplets, we can deform the droplets by manipulating the beads directly using optical tweezers. By measuring the force required to deform the droplets we determine their surface tension, elasticity and viscosity as well as the frequency response of these properties. We also measure these properties using passive micro-rheology.

**9:36AM A37.00007 Phase separation and the formation of cellular bodies**, BIN XU, Department of Physics, Princeton University, CHASE P. BROEDERSZ, Faculty of Physics, Ludwig-Maximilians-University of Munich, YIGAL MEIR, Department of Physics, Ben-Gurion University, NED S. WINGREEN, Lewis-Sigler Institute for Integrative Genomics, Princeton University — Cellular bodies in eukaryotic cells spontaneously assemble to form cellular compartments. Among other functions, these bodies carry out essential biochemical reactions. Cellular bodies form micron-sized structures, which, unlike canonical cell organelles, are not surrounded by membranes. A recent in vitro experiment[1] has shown that phase separation of polymers in solution can explain the formation of cellular bodies. We constructed a lattice-polymer model to capture the essential mechanism leading to this phase separation. We used both analytical and numerical tools to predict the phase diagram of a system of two interacting polymers, including the concentration of each polymer type in the condensed and dilute phase.

**9:48AM A37.00008 Nucleic Acid-Peptide Complex Phase Controlled by DNA Hybridization**, JEFFREY VIEREGG, MICHAEL LUECKHEIDE, LORRAINE LEON, AMANDA MARCIEL, MATTHEW TIRRELL, University of Chicago — When polyanions and polycations are mixed, counterion release drives formation of polymer-rich complexes that can either be solid (precipitates) or liquid (coacervates) depending on the properties of the polyelectrolytes. These complexes are important in many fields, from encapsulation of industrial polymers to membrane-free segregation of biomolecules such as nucleic acids and proteins. Condensation of long double-stranded DNA has been studied for several decades, but comparatively little attention has been paid to the polyelectrolyte behavior of oligonucleotides. We report here studies of DNA oligonucleotides (10 - 88 nt) complexed with polylysine (10 - 100 aa). Unexpectedly, we find that the phase of the resulting complexes is controlled by the hybridization state of the nucleic acid, with double-stranded DNA forming precipitates and single-stranded DNA forming coacervates. Stability increases with polyelectrolyte length and decreases with solution salt concentration, with complexes of the longer double-stranded polymers undergoing precipitate/coacervate/soluble transitions as ionic strength is increased. Mixing coacervates formed by complementary single-stranded oligonucleotides results in precipitate formation, raising the possibility of stimulus-responsive material design.

**10:00AM A37.00009 The Ion-Specific, Non-Equilibrium Structural Behavior of DNA Hydrogels.** , DAN NGUYEN<sup>1</sup>, OMAR SALEH<sup>2</sup>, University of California Santa Barbara — The highly tunable, sequence-dependent hybridization of DNA has enabled construction of DNA hydrogels with applications ranging from drug delivery to responsive materials. Though many have examined the structural characteristics of DNA hydrogels at equilibrium, relatively little is known about their non-equilibrium behavior, apart from their degradation rates when delivering molecular payloads. Here, we examine the effect of changing salt concentration on the dynamic formation, ageing, and degradation of DNA hydrogels comprised of branched DNA nanostars with palindromic overhangs. First, we observe that hydrogel phase is sensitive to the presence of a single unpaired base on the overhang, resulting in either a percolated network or a liquid-liquid phase separated state at high salt concentrations. Particular to the percolated network, we can induce the system to either contract or relax by changing the salt concentration. Decreasing monovalent NaCl induces the network to irreversibly contract whereas decreasing divalent MgCl<sub>2</sub> induces the network to reversibly expand; this behavior runs counter to what is expected solely from electrostatic screening. We qualitatively understand these results by assuming that the monovalent salt modulates the dynamic hybridization between nanostar binding partners, whereas the divalent salt drives the dramatic/reversible induction of the 'stacked-X' conformation in the DNA nanostars.

**10:12AM A37.00010 Counterion Distribution Around Protein-SNAs probed by Small-angle X-ray scattering** , KURINJI KRISHNAMOORTHY, MICHAEL BEDZYK, SUMIT KEWALRAMANI, LIANE MOREAU, CHAD MIRKIN, Northwestern University — Protein-DNA conjugates couple the advanced cell transfection capabilities of spherical DNA architecture and the biocompatible enzymatic activity of a protein core to potentially create therapeutic agents with dual functionality. An understanding of their stabilizing ionic environment is crucial to better understand and predict their properties. Here, we use Small-angle X-ray scattering techniques to decipher the structure of the counterion cloud surrounding these DNA coated nanoparticles. Through the use of anomalous scattering techniques we have mapped the local concentrations of Rb<sup>+</sup> ions in the region around the Protein-DNA constructs. These results are further corroborated with simulations using a geometric model for the excess charge density as function of radial distance from the protein core. Further, we investigate the influence of solution ionic strength on the structure of the DNA corona and demonstrate a reduction in the extension of the DNA corona with increasing concentration of NaCl in solution for the case of both single and double stranded DNA shells. Our work reveals the distribution of counterions in the vicinity of Protein-DNA conjugates and decouples the effect of solution ionic strength on the thickness of the DNA layer.

**10:24AM A37.00011 Electrolyte-Mediated Assembly of Charged Nanoparticles** , SUMIT KEWALRAMANI, MICHAEL BEDZYK, GUILLERMO GUERRERO-GARCA, LIANE MOREAU, JOS ZWANIKKEN, CHAD MIRKIN, MONICA OLVERA DE LA CRUZ, Northwestern University — Solutions at high salt concentrations are used to crystallize or segregate colloids, proteins and polyelectrolytes via an unknown mechanism referred to as "salting-out". Here, we show salting-out is a long-range interaction controlled by electrolyte concentration and nanoparticle charge density. Small-angle X-ray scattering (SAXS) shows that DNA-coated Au nanoparticles designed to prevent inter-particle assembly via Watson-Crick hybridization undergo "gas" to FCC to "glass-like" transitions with increasing NaCl or CaCl<sub>2</sub> concentration. Simulations reveal that the crystallization is concomitant with inter-particle interactions changing from purely repulsive to a long-range potential well condition. Liquid-state theory explains this attraction as a sum of cohesive and depletion forces. Our work reveals the mechanism behind salting-out and suggests new routes for the successful crystallization of colloids and proteins using concentrated salts.

**10:36AM A37.00012 Modeling of DNA-Mediated Self-Assembly from Anisotropic Nanoparticles: A Molecular Dynamics Study** , JAIME MILLAN, MARTIN GIRARD, JEFFREY BRODIN, MATT O'BRIEN, CHAD MIRKIN, MONICA OLVERA DE LA CRUZ, Northwestern University — The programmable selectivity of DNA recognition constitutes an elegant scheme to self-assemble a rich variety of superlattices from versatile nanoscale building blocks, where the natural interactions between building blocks are traded by complementary DNA hybridization interactions. Recently, we introduced and validated a scale-accurate coarse-grained model for a molecular dynamics approach that captures the dynamic nature of DNA hybridization events and reproduces the experimentally-observed crystallization behavior of various mixtures of spherical DNA-modified nanoparticles. Here, we have extended this model to robustly reproduce the assembly of nanoparticles with the anisotropic shapes observed experimentally. In particular, we are interested in two different particle types: (i) regular shapes, namely the cubic and octahedral polyhedra shapes commonly observed in gold nanoparticles, and (ii) irregular shapes akin to those exhibited by enzymes. Anisotropy in shape can provide an analog to the atomic orbitals exhibited by conventional atomic crystals. We present results for the assembly of enzymes or anisotropic nanoparticles and the co-assembly of enzymes and nanoparticles.

**10:48AM A37.00013 Two-stages of chiral selectivity in the molecular self-assembly of tryptophan**<sup>1</sup> , NATHAN GUISSINGER, Argonne National Laboratory — Both chirality and molecular assembly are essential and key components to life. In this study we explore the molecular assembly of the amino acid tryptophan (both L- and D- chiralities) on Cu(111). Our investigation utilizes low temperature scanning tunneling microscopy to observe resulting assemblies at the molecular scale. We find that depositing a racemic mixture of both L- and D-tryptophan results in the assembly of basic 6 molecule "Lego" structures that are enantiopure. These enantiopure "Legos" further assemble into 1-dimensional chains one block at a time. These resulting chains are also enantiopure with chiral selectivity occurring at two stages of assembly. Utilizing scanning tunneling spectroscopy we are able to probe the electronic structure of the chiral Legos that give insight into the root of the observed selectivity.

<sup>1</sup>Two-stages of chiral selectivity in the molecular self-assembly of tryptophan

**8:00AM A38.00001 Plasmonic Gold Nanorod Dispersions with Electrical and Optical Tunability** , CHRISTOPHER GRABOWSKI, CLARE MAHONEY, KYOUNGWEON PARK, ALI JAWAID, TIMOTHY WHITE, RICHARD VAIA, Air Force Research Laboratory, WPAFB — The transmissive, absorptive, electrical, and thermal properties of plasmonic gold nanorods (NRs) have led to their employment in a broad range of applications. These electro-optical properties - governed by their size, shape, and composition - are widely and precisely tunable during synthesis. Gold NRs show promise for large scale optical elements as they have been demonstrated to align faster than liquid crystal films ( $\mu$ s) at low fields (1 V/ $\mu$ m). Successfully dispersing a high volume fraction of gold NRs requires a strategy to control particle-particle separation and thus avoid aggregation. Herein, we discuss the role of theta temperature and the ability to swell or collapse the chains of polymer-grafted gold NRs to alter the interaction potential between particles. UV-Vis spectroscopy, scattering, and electrical susceptibility characterization methods were employed to determine nanoparticle dispersion along with the degree of gold NR alignment. The development of new agile photonic materials, controllable with both light and electric fields, will help address emerging needs in laser hardening (agile filters) and variable transmission visors.

**8:12AM A38.00002 Molecular dynamics study of reversible thermal stiffening in viscoelastic polymer blends and nanocomposites**, WEI PENG, RAGHAVAN RANGANATHAN, FIONA KINE, RAHMI OZISIK, PAWEL KEBLINSKI, Rensselaer Polytech Inst, STEVEN COLLEGE COLLABORATION — We use non-equilibrium molecular dynamics simulations to model stiffening mechanisms in viscoelastic polymer blends and nanocomposites with the overarching goal to understand the mechanisms for reversible thermal stiffening (stiffening while heating and softening up on cooling). The blend is comprised of two kinds of polymer chains with differing stiffness and glass transition temperatures ( $T_g$ ) and the nanocomposite consists of nanoparticles grafted to the high  $T_g$  polymer phase in addition to the soft matrix phase. We employ both constant shear-rate and oscillatory shear deformations to characterize stiffening. Upon heating above the  $T_g$  of both polymeric phases, we show that significant stiffening arises due to the coupled relaxation and dynamics of both polymeric phases. The effects of shear rate, interaction strength between phases and the corresponding structural changes and dynamics leading to reversible stiffening are studied and are corroborated with experimental findings.

**8:24AM A38.00003 Role of bound polymer mobility on multiscale dynamics of PEO in attractive nanocomposites**, ERKAN SENSES, Univ of Maryland-College Park & NIST Center for Neutron Research, ANTONIO FARAONE, NIST Center for Neutron Research, PINAR AKCORA, Stevens Institute of Technology — We study intermediate and large scale chain dynamics in nanocomposites where particle-bound polymer (PMMA) and matrix (PEO) chains are chemically different, miscible, and have very large  $T_g$  difference ( $\Delta T_g \approx 200$  K). These nanocomposites with dynamically asymmetric 'polymer blend interphases' were shown to exhibit an unusual reversible thermal-stiffening accompanied by vitreous-to-rubbery transition of PMMA.\* Using quasi-elastic neutron scattering, this work examines the impact of mobility of the bound-polymer on segmental and collective dynamics of the matrix chains at sub-ns to 100 ns range. While bare silica particles appear to slow down the segmental relaxation, in the composites with PMMA coated particles the Rouse dynamics of PEO is identical to its bulk behavior, possibly due to the negligible enthalpic interaction inherent to this blend system. On larger scale, we observed  $\approx 25\%$  increase in the apparent tube diameter of PEO when PMMA is glassy. Remarkably, the tube size recovers its bulk value as PMMA softens at elevated temperatures. The resulting disentanglement-entanglement transition of PEO under hard and soft confinement well relates to the macroscopic softening-stiffening transition of these composites as evidenced from the bulk rheology. (\*ACS Appl. Mater. Interfaces, 2015, 7 (27), pp 14682–14689)

**8:36AM A38.00004 Hierarchical Nanocomposites for Device Applications**, JAMES WATKINS, University of Massachusetts — We have outlined templating strategies for electronic and optical device fabrication that include self-assembly of well-ordered polymer/nanoparticle hybrids and nanoimprint lithography using novel materials sets. Using additive-driven self-assembly, for example, we demonstrate the formation of periodic nanocomposites with tunable magnetic and optical characteristics containing up to 70 wt. % of metal, metal oxide and/or semiconducting nanoparticles through phase specific interactions of the particles with either linear block copolymer or brush block copolymer (BBCP) templates. The BBCP templates provide direct access to large domain spacings for optical applications and spontaneous alignment within large volume elements. We have further developed highly filled nanoparticle/polymer hybrids for applications that require tailored dielectric constant or refractive index and a new imprinting process that allows direct printing of patterned 2-D and 3-D crystalline metal oxide films and composites with feature sizes of less than 100 nm. Applications in flexible electronics, light and energy management, and sensors and will be discussed.

**9:12AM A38.00005 Driving degradation within biodegradable polymers with embedded nanoparticles<sup>1</sup>**, RUSSELL GORGA, GABRIEL FIRESTONE, DANIELA FONTECHA, JASON BOCHINSKI, LAURA CLARKE, NC State University — The ability to controllably trigger breaking of chemical bonds enables a substance that has robust material properties during use but can be re-worked or deteriorated upon command. Photothermal heating creates intense local heat at isolated nanoparticle locations within a sample and can result in very different material responses than those achievable with conventional (uniform) heating. In this process, irradiation with visible light resonant with the nanoparticle's surface plasmon resonance results in dramatic local heating of the particles and the surrounding material. This work studies intentional thermal degradation of poly ethyl cyanoacrylate-starch composites doped with metal nanoparticles, and explores differences in degradation speed, efficiency, and resultant mechanical properties when heated via the photothermal effect.

<sup>1</sup>This work was supported by the National Science Foundation, Grant : CMMI-1462966

**9:24AM A38.00006 Waveguiding Actuators Based on Photothermally Responsive Hydrogels**, YING ZHOU, ADAM HAUSER, NAKUL BENDE, Univ of Mass - Amherst, MARK KUZYK, Washington State University, RYAN HAYWARD, Univ of Mass - Amherst — A simple means to achieve rapid and highly reversible photo-responsiveness in a hydrogel is to combine a thermally-responsive gel such as poly(N-isopropyl acrylamide) (PNIPAM), with the photothermal effect of gold nanoparticles. Relying on such composite gels, we fabricate micro-scale bilayer photoactuators by photolithographic patterning, and demonstrate their controlled bending/unbending behavior in response to visible light. In addition to actuation by flood exposure, 532 nm laser light can be waveguided through a plastic optical fiber to direct it into the photoactuator, providing the possibility for remotely controllable actuators that do not require line-of-sight access. The actuators show large magnitude responses within time-scales of  $\sim 1$  s, consistent with the small dimensions of the actuators, but also exhibit smaller-scale responses over much longer times, suggesting the possibility of slow internal relaxations within the network. Based on our study on this bilayer system, we further explore fabrication methods for cylindrical actuators that are able to bend in arbitrary directions.

**9:36AM A38.00007 In-situ curing of liquid epoxy via gold-nanoparticle mediated photothermal heating<sup>1</sup>**, GABRIEL FIRESTONE, JU DONG, JASON BOCHINSKI, RUSSELL GORGA<sup>2</sup>, LAURA CLARKE<sup>3</sup>, North Carolina State Univ — The ability to selectively alter material properties in-situ is important for many biological applications where an initially flexible part (needed for ease of placement) would ideally be rigidified once in position (for instance, within a broken bone as a tissue scaffold). Thermoset epoxies harden from viscous liquids into solid materials when heated. In this work, metal nanoparticle-epoxy-hardener composites are formed and utilized to enable in-situ crosslinking by drawing a pattern on a shallow bath of liquid epoxy with a laser. This approach capitalizes on the photothermal effect of metal nanoparticles where irradiation with light resonant with the nanoparticle surface plasmon resonance leads to dramatic local heating. We discuss challenges to incorporating metal particles into epoxy-hardener, observation of changes in the heat profile within the epoxy due to the intensity and rastering speed of the laser, and show that the mechanical properties of internally cured epoxy are the same as those cured conventionally. The ability to selectively fabricate a part from a liquid (with no mold or waste) may be an important alternative manufacturing approach.

**9:48AM A38.00008 High Thermal Conductivity Aligned Polyethylene-Graphene Nanocomposites**, JIVTESH GARG, MORTAZA SAEIDIJAVASH, University of Oklahoma — We investigate enhancement of thermal conductivity in polyethylene-graphene nanocomposites. The effect of alignment of both the polymer chains and the dispersed graphene flakes on thermal conductivity enhancement will be reported. In this work nanocomposites are prepared through microextrusion of polyethylene pellets and graphene nanopowder. Alignment is achieved through mechanical stretching of the nanocomposites. Thermal conductivity is measured using both Angstrom method and Laser flash. Variables involved in the study are the draw ratio and the weight percentage of graphene nanopowder. Results will shed light on the role of alignment of graphene flakes on enhancing thermal transport and provide new avenues to achieve ultra-high thermal conductivity in polymeric materials.

**10:00AM A38.00009 Mechanical Properties of Polymeric Nanocomposites with Liquid Inclusions<sup>1</sup>**, HEYI LIANG, ZHEN CAO, ANDREY DOBRYNIN, Univ of Akron — We study mechanical properties of polymeric nanocomposites of liquid inclusions in network matrix using molecular dynamics simulations and analytical calculations. The shear modulus of nanocomposite is shown to be a non-monotonic function of the elastocapillary number  $\gamma_{SL}/(G_N R)$ , where  $\gamma_{SL}$  is the interfacial energy network/liquid interface,  $G_N$  is the shear modulus of network and  $R$  is the initial size of liquid inclusion. First, in the range of elastocapillary numbers,  $\gamma_{SL}/(G_N R) < 1$ , the composite shear modulus increases with increasing this parameter value. In this interval of elastocapillary numbers, a liquid inclusion softens the network such that the composite modulus  $G_{comp}$  is smaller than  $G_N$ . This is in agreement with the classical Eshelby theory. However, for elastocapillary numbers  $\gamma_{SL}/(G_N R) \approx 1$ , the liquid inclusions reinforces the network,  $G_{comp} > G_N$ . In this range of parameters the surface energy of the deformed liquid inclusions strengthens the composite. When the elastocapillary number increases further,  $\gamma_{SL}/(G_N R) \gg 1$ , the interfacial energy of network/liquid interface dominates the mechanical response of the composite resulting in composite weakening. Analysis of the elongation ratio of the liquid inclusion shows that it decreases with increasing elastocapillary number  $\gamma_{SL}/(G_N R)$ . The classical Eshelby's theory of inclusions fails to explain this phenomenon. We develop a new linear elasticity model of this class of nanocomposite materials capable to explain this unusual mechanical response of nanocomposite materials.

**10:12AM A38.00010 Tailoring the Structure of Polymer Networks with Photo-Controlled Radical Polymerization**, AWANEESH SINGH, OLGA KUKSENOK, Clemson University, JEREMIAH A. JOHNSON, Massachusetts Institute of Technology, ANNA C. BALAZS, Univ of Pittsburgh — Using dissipative particle dynamics (DPD) approach, we developed a novel computational model to study the photo-controlled radical polymerization (photo-CRP) within polymer networks with embedded iniferters. The polymerization process can be turned “on” or “off” in response to light and the polymerization rate can be modulated by altering the light intensity. This “photo-growth” approach allows us to impart changes in the gel network pore size and composition to form photo-tunable smart materials. For example, our approach allows us to design gel composites that are comprised of two distinct layers made of two compatible components at low photo-iniferter concentrations or gel composites that are comprised of two incompatible components that are relatively well intermixed at high photo-iniferter concentration.

**10:24AM A38.00011 Use Electrospinning to Introduce Graphene into Poly(4-Vinylpyridine) (P4VP) Polymer Fibers and Their Biocompatibility with Dental Pulp Stem Cells (DPSCs)<sup>1</sup>**, LINXI ZHANG, CHUNG-CHUEH CHANG, MIRIAM RAFAILOVICH, Stony Brook University — Graphene-polymer composite materials have been popularized in tissue engineering due to the outstanding thermal, electrical and mechanical properties of graphene. Most of the current studies, however, focus on 2-D structured films which hardly represent the real conditions of scaffolds in vivo environment and dispersion of graphene in polymer matrix has always been challenging since the graphene tends to aggregate. In our study, we have successfully introduced graphene nanoplatelets (GNPs) into poly(4-vinylpyridine) (P4VP) matrix and fabricated nano- and micro-scale size fibers by using electrospinning technique. SEM and TEM reveal uniform defect-free fiber structures and good dispersion of graphene; DSC and AFM indicate the enhancement of physical properties. The biocompatibility of the electrospun 3-D scaffolds with dental pulp stem cells (DPSCs) has been examined. Our results show that the cells can accelerate proliferation to respond to the existence of GNPs. SEM with EDAX reveals a deposition of mineralized calcium matrix on the fibers after 35-day incubation, which has possibly been caused by cell differentiation induced by fibrous scaffolds.

<sup>1</sup> Electrospinning Nano- and Micro-scale size Poly(4-vinylpyridine) Fibers Loaded with Graphene Nano Platelets (GNPs)

**10:36AM A38.00012 Studies of a new class of high electro-thermal performing Polyimide embedded with 3D scaffold in the harsh environment of outer space**, MANUELA LOEBLEIN, Nanyang Tech Univ, ASAF BOLKER, Soreq NRC, SIU HON TSANG, Temasek Laboratories@NTU, NURIT ATAR, Soreq NRC, CECILE UZAN-SAGUY, Technion - Israel Institute of Technology, RONEN VERKER, IRINA GOUZMAN, EITAN GROSSMAN, Soreq NRC, EDWIN HANG TONG TEO, Nanyang Tech Univ — The polymer class of Polyimides (PIs) has been wide-spread in the use of outer space coatings due to their chemical stability and flexibility. Nevertheless, their poor thermal conductivity and completely electrically insulating characteristics have caused severe limitations, such as thermal management challenges and spacecraft electrostatic charging, which forces the use of additional materials such as brittle ITO in order to completely resist the harsh environment of space. For this reason, we developed a new composite material via infiltration of PI with a 3D scaffold which improves PIs performance and resilience and enables the use of only a single flexible material to protect spacecraft. Here we present a study of this new material based on outer-space environment simulated on ground. It includes an exhaustive range of tests simulating space environments in accordance with European Cooperation for Space Standard (ECSS), which includes atomic oxygen (AO) etching, Gamma-ray exposure and outgassing properties over extended periods of time and under strenuous mechanical bending and thermal annealing cycles. Measurement methods for the harsh environment of space and the obtained results will be presented.

**10:48AM A38.00013 Biocompatible Silk-Poly(Pyrrole) Composite Trilayer Actuators**, CARLY FENGEL, NATHAN BRADSHAW, SEAN SEVERT, AMANDA MURPHY, JANELLE LEGER, Western Washington Univ — Biocompatible materials capable of controlled actuation are in high demand for use in biomedical applications such as dynamic tissue scaffolding, valves, and steerable surgical tools. Conducting polymers (CPs) have some desirable traits for use as an actuator, such as the ability to operate in biologically relevant fluids and responsiveness to low voltages. However CPs alone are limited due to their brittle nature and poor solubility. Recently we have shown that a composite material of silk and the CP poly(pyrrole) (PPy) shows promising characteristics as an actuator; it is mechanically robust as well as fully biocompatible. Initial proof-of-concept experiments demonstrated that these composites bend under an applied voltage (or current) using a simple bilayer device. Here we present trilayer devices composed of two silk-PPy composite layers separated by an insulating silk layer. This configuration results in more charge is passed in comparison to the analogous bilayer system, as well as a more sustainable current response through cycling, resulting in a larger angle of deflection per volt applied. In addition, the motion of the trilayer devices is more symmetric than that of the bilayer analogs, resulting in a more repeatable movement. We will discuss the fabrication and characterization of these devices, as well as their performance and future applications of this technology.

**Session A39 DBIO DPOLY DCOMP: Physics of Proteins: Bio Meets Quantum** 342 - Mark Tuominen, University of Massachusetts Amherst

**8:00AM A39.00001 Hidden Linear Quantum States in Proteins: Did Davydov Get the Sign Wrong?** , ROBERT AUSTIN, Princeton University, AIHUA XIE, Oklahoma State University, BRITTA REDLICH, LEX VAN DER MEER, Radboud University Nijmegen — A fair amount of time has been spent hunting down one prospective quantum mechanical model, namely the Davydov soliton along the  $\alpha$ -helix backbone of the protein. These experiments were challenging, we used a tunable ps mid-IR Free Electron Laser to try and observe the long-term (microsecond or greater) trapping of coherent excitation in proteins which had been proposed by a several theorists. These experiments were successful in the sense that we directly observed vibrational excited state population relaxation on the picosecond time scale, and transfer of coherent excitation into the incoherent thermal bath: but we did not see the trapping on the microsecond time scale of short (ps) coherent light pulses in the amide I band of a generic  $\alpha$ -helix rich protein, myoglobin. However, we would like to revisit that experiment one more time in this paper to analyze and try to understand something puzzling that we did observe, in the context a possible unusual “hidden” quantum phenomena in proteins which probably is of no biological consequences, but bears re-examination.

**8:12AM A39.00002 Single-Molecule Electronic Measurements of the Dynamic Flexibility of Histone Deacetylases** , JAMES FROBERG, SEUNGYONG YOU, Dept. Physics, North Dakota State Univ., USA, JUNRU YU, Dept. Chemistry, North Dakota State Univ., USA, MANAS HALDAR, Dept. Pharm. Sci, North Dakota State Univ., USA, ABBAS SEDIGH, Dept. Chemistry, North Dakota State Univ., USA, SANKU MALLIK, Dept. Pharm. Sci., North Dakota State Univ., USA, D.K. SRIVASTAVA, Dept. Chemistry, North Dakota State Univ., USA, YONGKI CHOI, Dept. Physics, North Dakota State Univ., USA — Due to their involvement in epigenetic regulation, histone deacetylases (HDACs) have gained considerable interest in designing drugs for treatment of a variety of human diseases including cancers. Recently, we applied a label-free, electronic single-molecule nano-circuit technique to gain insight into the contribution of the dynamic flexibility in HDACs structure during the course of substrates/ ligands binding and catalysis. We observed that HDAC8 has two major (dynamically interconvertible) conformational states, “ground (catalytically unfavorable)” and “transition (catalytically favorable)”. In addition, we found that its cognate substrates/ligands reciprocally catalyze the transition of the ground to the transition state conformation of HDAC8. Thus, we propose that both enzymes and their substrates/ligands serve as “catalysts” in facilitating the structural changes of each other and promoting the overall chemical transformation reaction. Such new information provides the potential for designing a new class of mechanism-based inhibitors and activators of HDAC8 for treating human diseases.

**8:24AM A39.00003 Single-Molecule Electronic Monitoring of DNA Polymerase Activity** , DENYS O. MARUSHCHAK, KAITLIN M. PUGLIESE, MACKENZIE W. TURVEY, YONGKI CHOI, O. TOLGA GUL, TIVOLI J. OLSEN, ARITH J. RAJAPAKSE, GREGORY A. WEISS, PHILIP G. COLLINS, Univ of California - Irvine — Single-molecule techniques can reveal new spatial and kinetic details of the conformational changes occurring during enzymatic catalysis. Here, we investigate the activity of DNA polymerases using an electronic single-molecule technique based on carbon nanotube transistors. Single molecules of the Klenow fragment (KF) of polymerase I were conjugated to the transistors and then monitored via fluctuations in electrical conductance. Continuous, long-term monitoring recorded single KF molecules incorporating up to 10,000 new bases into single-stranded DNA templates. The duration of individual incorporation events was invariant across all analog and native nucleotides, indicating that the precise structure of different base pairs has no impact on the timing of incorporation. Despite similar timings, however, the signal magnitudes generated by certain analogs reveal alternate conformational states that do not occur with native nucleotides. The differences induced by these analogs suggest that the electronic technique is sensing KF's O-helix as it tests the stability of nascent base pairs [1]. [1] K.M. Pugliese, et. al., "Processive Incorporation of Deoxynucleoside Triphosphate Analogs by Single-Molecule DNA Polymerase I (Klenow Fragment) Nanocircuits." JACS 137, 9587 (2015).

**8:36AM A39.00004 Observation of an electrical signal from a single molecule** , AROOJ ASLAN, NOOR SHAHEEN, KYLE DOBISZEWSKI, ALOKIK KANWAL, REGINALD FARROW, GORDON THOMAS, NJIT Physics — We have attached a folded protein molecule to the tip of a carbon nanotube using electrophoresis. We have then measured the electrons produced when the protein catalyzes a series of reactions. As an initial example of the reactions, we have used the catalysis by glucose-oxidase of glucose. We can show that the characteristic dynamic signals from the molecule scale with the glucose concentration. The molecule on the carbon nanotube tip is stable with respect to time under controlled conditions. The signals also indicate the glucose diffusion as its concentration is locally depleted at the nanotube by the catalysis. We use a second carbon nanotube with a laccase molecule on its tip to complete the circuit with an oxygen reaction. In a previous stage of this process, the other end of the nanotube is attached with a low-impedance electrical connection to a Ti thin film and the measuring circuitry. This work is an early step toward investigating the feasibility of an implantable glucose monitor to help treat diabetes.

**8:48AM A39.00005 Relevance of Aromatic Amino Acids for Electron Conduction along *Geobacter* Pili Protein.**<sup>1</sup> , RAMESH ADHIKARI, University of Massachusetts Amherst, NIKHIL MALVANKAR, Yale University, MARK TUOMINEN, DEREK LOVLEY, University of Massachusetts Amherst — It has been proposed that the charge transport through *Geobacter sulfurreducens* pili protein occurs through the aromatic amino acids forming helical conducting chain within pili.[1] X-ray studies of pili show that the aromatic amino acids are packed close enough (3-4 Å) for  $\pi$ -stacking to occur. Conductivity of the pili network increases with lowering temperature indicating metallic-like transport mechanism. [2] However due to the complexity of charge percolation path in 3D network, the intrinsic conductivity of an individual pili was not known. Here, we report transport measurements of individual pili of *G. sulfurreducens*. The conductivity, similar to that of organic polymers, shows that the pili may have implications in materials research. In addition, the conductivity value is sufficient to explain the respiration rate of the *G. sulfurreducens*. Further studies of pili from different natural and genetically modified species with varying amount of aromatic amino acid density demonstrate that it can play a decisive role on the magnitude of the conductivity. **9:00AM A39.00006 Finite Difference Frequency Domain (FDFD) Band Structure Calculations of Diatom Frustules** , JONATHAN MISHLER, STEPHEN BAUMAN, SALVADOR BARRAZA-LOPEZ, Department of Physics, University of Arkansas, ANDREW ALVERSON, Department of Biology, University of Arkansas, JOSEPH HERZOG, Department of Physics, University of Arkansas — Diatoms are single-celled photosynthetic algae commonly known for their siliceous cell walls, called frustules. Over the last decade, the uncanny resemblance of their frustules to manufactured photonic crystals has led researchers to study their photonic properties with the hope of using them as self-constructing photonic crystals or biomimetic templates for artificial photonic crystals. The 2D photonic band structures of the foramen, areolae, and cribrum of the diatom species *Coscinodiscus* sp. were calculated using the finite difference frequency domain (FDFD) method in both water and air. These calculations revealed the effects of all three layers on a frustule's photonic properties, both in and out of their natural environment.

**9:12AM A39.00007 Protein separation using an electrically tunable membrane<sup>1</sup>**, INING JOU, DMITRIY MELNIKOV, MARIA GRACHEVA<sup>2</sup>, Clarkson University — Separation of small proteins by charge with a solid-state porous membrane requires control over the protein's movement. Semiconductor membrane has this ability due to the electrically tunable electric potential profile inside the nanopore. In this work we investigate the possibility to separate the solution of two similar sized proteins by charge. As an example, we consider two small globular proteins abundant in humans: insulin (negatively charged) and ubiquitin (neutral). We find that the localized electric field inside the pore either attracts or repels the charged protein to or from the pore wall which affects the delay time before a successful translocation of the protein through the nanopore. However, the motion of the uncharged ubiquitin is unaffected. The difference in the delay time (and hence the separation) can be further increased by the application of the electrolyte bias which induces an electroosmotic flow in the pore.

**9:24AM A39.00008 Investigating the Binding of Peptides to Graphene Surfaces for Biosensing Applications**, AMANDA GARLEY, NABANITA SAIKIA, University of Colorado - Boulder, STEPHEN BARR, GARY LEUTY, RAJIV BERRY, Air Force Research Laboratory, HENDRIK HEINZ, University of Colorado - Boulder — The Air Force Research Lab is focused on developing highly selective and sensitive graphene-based sensors functionalized with peptides for biomolecule detection. To achieve this there is a need to model interfacial binding interactions between the organic and inorganic components to complement ongoing experimental investigations. It is important to characterize the binding behavior of individual amino acids, with the goal of predicting binding of large peptides. Since polarization is important in graphene systems, a new force field which includes polarizability is used. This allows for an in depth exploration of pi-pi interactions, electrostatics and van der Waals forces involved with binding. The binding strength is determined via enthalpy and free energy calculations. Additionally, structural quantities are computed, such as how aromatic rings align with the graphene surface and the arrangement of various residue substituents in relation to the surface and water layers. Computational results are useful in guiding experimental methods focused on rapidly screening optimal peptide sequence for binding.

**9:36AM A39.00009 The formation of bio-corona on graphene and boron nitride**, ACHYUT RAGHAVENDRA, BISHWAMBHAR SENGUPTA, Clemson Nanomaterials Center, Dept., of Physics and Astronomy, Clemson University, JINGYI ZHU, Clemson Nanomaterials Center, Dept., of Physics and Astronomy, Clemson University, Clemson, SC USA 29634., APPARAO RAO, RAMAKRISHNA PODILA, Clemson Nanomaterials Center, Dept., of Physics and Astronomy, Clemson University, Clemson, Laboratory of Nano-biophysics and COMSET — The increase in applications of engineered two-dimensional (2D) materials has raised concerns over their discharge into the environment. The inadvertent fouling of 2D-materials with natural organic matter (NOM) results in the formation of biocorona, which in turn determines the transport and fate of 2D-materials. Our experiments showed that the physicochemical characteristics of 2D-materials play an important role in biocorona formation. In particular, the formation of biocorona is determined by: i) the amount of aromatic content in NOM, and ii) the distribution of pi-electrons in 2D-materials such as graphene and BN. More importantly, we found that the delocalized pi-electron cloud in NOM results in significant charge transfer while while the charge transfer does not occur for the case of BN wherein the electron cloud is centered near N atoms. A detailed analysis of 2D-material biocorona formation and the impacts on 2D-material transport and fate will be presented.

**9:48AM A39.00010 First principles simulations of nano-peptides on copper surfaces.<sup>1</sup>**, DUY LE, TALAT S. RAHMAN, University of Central Florida — Protein folding is the process in which a protein structure finds its stable conformation or functional shape. It is considered as a robust way for self-assembling proteins into conformations with desired functionalities. In this work, to obtain a microscopic understanding of the protein folding phenomenon, as influenced by a metallic environment, we perform density functional theory based simulations of the folding of a 9-amino-acid nano-peptide on various copper surfaces. We show that the considered nano-peptides fold into stable monomers or dimers with different conformations depending on the crystallographic orientation of the surface. Comparison of our simulated Scanning Tunneling Microscopy (STM) image with available experimental results [1] provides insights into the microscopic forces responsible for dimerization on Cu(100). **10:00AM A39.00011 “Cold Denaturation” induces inversion of dipole and spin transfer in chiral peptide monolayers**, SOUMYAJIT SARKAR, MEITAL ECKSHAIN-LEVI, EYAL CAPUA, SIVAN REFAELY-ABRAMSON, YULIAN GAVRILOV, SHINTO MATHEW, Weizmann Institute of Science, YOSSIE PALTIEL, The Hebrew University, Jerusalem, YAAKOV LEVY, LEEOR KRONIK, RON NAAMAN, Weizmann Institute of Science — Using a combination of several experimental and computational techniques, we show that the  $\alpha$ -helix structure of oligopeptides based on alanine and aminoisobutyric acid is transformed to a more linear conformation upon cooling, due to interaction with neighboring molecules in a self-assembled monolayer (SAM) structure. This process is similar to the known “cold denaturation” in peptides, but here the SAM plays the role of the solvent. Our DFT-based first principles calculations show that the structural change results in a flip in the direction of the electrical dipole moment of the adsorbed molecules. The dipole flip is accompanied by an associated change in the spin channel that is preferred in electron transfer through the molecules. This is also experimentally observed via a new solid state hybrid organic-inorganic device that is based on the Hall effect, but operates with no external magnetic field or magnetic material.

**10:12AM A39.00012 A New Apparatus for Studies of Nucleotide Molecules**, JESSICA DURON, LEIGH HARGREAVES, Cal State Univ — by-product of radiation cancer therapy, have been shown to be a strong driver of DNA damage. These challenges include the low-vapor pressure of commercial samples (which are powders at room temperature), and the need for high energy electron sources, required to establish the absolute scale of the measurements [2], a new apparatus is presently undergoing commissioning at the California State University. We will make the first cross-section measurements for slow ( $E_0 \leq 30$  eV) electron collisions with nucleotides. We will also make the commissioning of this new experiment.

**10:24AM A39.00013 Resonant soft X-ray scattering on protein solutions**, DAN YE, THINH LE, Department of Chemical Engineering, The Pennsylvania State University, CHENG WANG, Advanced Light Source, Lawrence Berkeley National Laboratory, PETER ZWART, Berkeley Center for Structural Biology, Lawrence Berkeley National Laboratory, ESTHER GOMEZ, Department of Chemical Engineering, Department of Biomedical Engineering, The Pennsylvania State University, ENRIQUE GOMEZ, Department of Chemical Engineering, Materials research institute, The Pennsylvania State University — Protein structure is crucial for biological function, such that characterizing protein folding and packing is important for the design of therapeutics and enzymes. We propose resonant soft X-ray scattering (RSOXS) as an approach to study proteins and other biological assemblies in solution. Calculations of the scattering contrast suggest that soft X-ray scattering is more sensitive than hard X-ray scattering, because of contrast generated at the absorption edges of constituent elements such as carbon, nitrogen and oxygen. We have examined the structure of bovine serum albumin (BSA) in solution by RSOXS. We find that by varying incident X-ray energies, we are able to achieve higher scattering contrast near the absorption edge. From our RSOXS scattering result we are able to reconstruct the structure of BSA in 3D. These RSOXS results also agree with hard X-ray experiments, including crystallographic data. Our study demonstrates the potential of RSOXS for studying protein structure in solution.

**10:36AM A39.00014 Strontium and Barium in aqueous solution and an ion channel blocking site.**, MANGESH CHAUDHARI, SUSAN REMPE, Sandia National Labs — Ion hydration structure and free energy establish criteria for understanding selective ion binding in potassium ( $K^+$ ) ion channels, and may be significant to understanding blocking mechanisms as well. Recently, we investigated the hydration properties of  $Ba^{2+}$ , the most potent blocker of  $K^+$  channels among the simple metal ions. Here, we use a similar method of combining ab-initio molecular dynamics simulations, statistical mechanical theory, and electronic structure calculations to probe the fundamental hydration properties of  $Sr^{2+}$ , which does not block bacterial  $K^+$  channels. The radial distribution of water around  $Sr^{2+}$  suggests a stable 8-fold geometry in the local hydration environment, similar to  $Ba^{2+}$ . While the predicted hydration free energy of  $-331.8$  kcal/mol is comparable with the experimental results of  $-334$  kcal/mol, the value is significantly more favorable than the  $-305$  kcal/mol hydration free energy of  $Ba^{2+}$ . When placed in an innermost  $K^+$  channel blocking site, the solvation free energies and lowest energy structures for both  $Sr^{2+}$  and  $Ba^{2+}$  are nearly unchanged compared with their respective hydration properties. That result suggests that difference in blocking behavior may arise due to kinetic properties associated with exchange of water ligands for channel ligands instead of equilibrium thermodynamic properties.

**10:48AM A39.00015 An Efficient Single-Molecule Resolution Method for Simulating Spatio-Temporal Dynamics of Protein Interaction Networks that Involve the Cell Membranes<sup>1</sup>**, OSMAN N. YOGURTCU, MARGARET E. JOHNSON, Johns Hopkins University — A significant number of the cellular protein interaction networks, such as the receptor mediated signaling and vesicle trafficking pathways, includes membranes as a molecular assembly platform. Computer simulations can provide insight into the dynamics of complex formation and help identify the principles that govern recruitment and assembly on the membranes. Here, we introduce the Free-Propagator Re-weighting (FPR) algorithm, a recently developed method that efficiently simulates the spatio-temporal dynamics of multiprotein complex formation both in the solution and on the membranes. In the FPR, the position of each protein is propagated using the Brownian motion and the reactions between pairs of proteins can occur upon collisions. Depending on the dimensionality of the interaction, the association probabilities are determined by solving the Smoluchowski diffusion equations in 2D or 3D and trajectory reweighting allows us to obtain the exact association rates for all the reactive pairs. Using the FPR, in this presentation, we investigate the interaction dynamics of the receptor mediated endocytic network as a case study and discuss the possible effects of membrane binding and molecular crowding on the formation of complexes.

**8:00AM A40.00001 Jarzynski equality for non-Hamiltonian dynamics<sup>1</sup>**, DIBYENDU MANDAL, Department of Physics, University of California Berkeley, MICHAEL R. DEWEESE, Department of Physics, Redwood Center for Theoretical Neuroscience, and Helen Wills Neuroscience Institute, University of California Berkeley — Recent years have witnessed major advances in our understanding of nonequilibrium processes. The Jarzynski equality, for example, provides a link between equilibrium free energy differences and finite-time, nonequilibrium dynamics. We propose a generalization of this relation to non-Hamiltonian dynamics, relevant for active matter systems, continuous feedback, and computer simulation. Surprisingly, this relation allows us to calculate the free energy difference between the desired initial and final states using arbitrary dynamics. As a practical matter, this dissociation between the dynamics and the initial and final states promises to facilitate a range of techniques for free energy estimation in a single, universal expression.

**8:12AM A40.00002 Field Theoretic Description of Nonequilibrium Work Relations**, BENJAMIN VOLLMAYR-LEE, Bucknell University, ANDREW BAISH, UC Santa Barbara — We develop Doi-Peliti field theory for driven, interacting particles coupled to a thermal bath. This mapping of classical particles to a field theory does not require any assumption of large particle numbers or slow modes. As an application we consider nonequilibrium work relations. With the introduction of an auxiliary complex field, the Jarzynski relation emerges from the field theory as direct consequence of time reversal.

**8:24AM A40.00003 Extending Landauer's Bound from Bit Erasure to Arbitrary Computation**, DAVID WOLPERT, Santa Fe Institute — Recent analyses have calculated the minimal thermodynamic work required to perform any computation  $\pi$  whose output is independent of its input, e.g., bit erasure. First I extend these analyses to calculate the work required even if the output of  $\pi$  depends on its input. Next I show that if a physical computer  $C$  implementing a computation  $\pi$  will be re-used, then the work required depends only on the dynamics of the logical variables under  $\pi$ , independent of the physical details of  $C$ . This establishes a formal identity between the thermodynamics of (re-usable) computers and theoretical computer science. To illustrate this identity, I prove that the minimal work required to compute a bit string  $\sigma$  on a (physical) Turing machine  $M$  is  $k_B T \ln(2) [K(\sigma) + \log(\mu(\sigma)) + \log(h(M))]$ . I also prove that uncertainty about the distribution over inputs to the computer increases the minimal work required to run the computer. I end by using these results to relate the free energy flux incident on an organism / robot / biosphere to the maximal amount of computation that the organism / robot / biosphere can do per unit time.

### 8:36AM A40.00004 Average work measurement below the Landauer limit for memory erasure<sup>1</sup>

, MOMČILO GAVRILOV, JOHN BECHHOEFER, Simon Fraser University — Landauer's Principle states that erasing a one-bit memory requires an average work of at least  $kT \ln 2$ . Recent experiments have confirmed this prediction for a one-bit memory represented by a symmetric double-well potential. However, if a memory is represented by a non-equilibrium state in an asymmetric double-well potential, theoretical studies predict that one can measure work below  $kT \ln 2$ . Using a feedback trap, we have confirmed this prediction. Surprisingly, we found that two different erasure protocols give two different values for the asymptotic work. We can explain this result by noting that one protocol is symmetric with the respect to time reversal and the other is not.

### 8:48AM A40.00005 Dynamics and thermodynamics of open chemical networks , MASSIMILIANO

ESPOSITO, University of Luxembourg — Open chemical networks (OCN) are large sets of coupled chemical reactions where some of the species are chemostated (i.e. continuously restored from the environment). Cell metabolism is a notable example of OCN. Two results will be presented. First, dissipation in OCN operating in nonequilibrium steady-states strongly depends on the network topology (algebraic properties of the stoichiometric matrix)<sup>1</sup>. An application to oligosaccharides exchange dynamics performed by so-called D-enzymes will be provided<sup>2</sup>. Second, at low concentration the dissipation of OCN is in general inaccurately predicted by deterministic dynamics (i.e. nonlinear rate equations for the species concentrations). In this case a description in terms of the chemical master equation is necessary. A notable exception is provided by so-called deficiency zero networks, i.e. chemical networks with no hidden cycles present in the graph of reactant complexes<sup>3</sup>.

### 9:00AM A40.00006 Cost and consequences of breaking the fluctuation dissipation relation in biochemical networks<sup>1</sup> , YUHAI TU, IBM — Living systems need to be highly responsive, and also to keep fluctuations low. These goals

are incompatible in equilibrium systems due to the Fluctuation Dissipation Theorem (FDT). Here, we show that biological sensory systems, driven far from equilibrium by free energy consumption, can reduce their intrinsic fluctuations while maintaining high responsiveness. By developing a continuum theory of the *E. coli* chemotaxis pathway, we demonstrate that adaptation can be understood as a non-equilibrium phase transition controlled by free energy dissipation, and it is characterized by a breaking of the FDT [1]. We show that the maximum response at short time is enhanced by free energy dissipation. At the same time, the low frequency fluctuations and the adaptation error decrease with the free energy dissipation algebraically and exponentially, respectively. [1] "Free Energy Cost of Reducing Noise while Maintaining a High Sensitivity", Pablo Sartori and Yuhai Tu, Phys. Rev. Lett. 2015. 115: 118102.

### 9:12AM A40.00007 Mimicking Nonequilibrium Steady States with Time-Periodic Driving ,

OREN RAZ, YIGIT SUBASI, CHRISTOPHER JARZYNSKI, Univ of Maryland-College Park — Under static conditions, a system satisfying detailed balance generically relaxes to an equilibrium state in which there are no currents: to generate persistent currents, either detailed balance must be broken or the system must be driven in a time-dependent manner. A stationary system that violates detailed balance evolves to a nonequilibrium steady state (NESS) characterized by fixed currents. Conversely, a system that satisfies instantaneous detailed balance but is driven by the time-periodic variation of external parameters - also known as a stochastic pump (SP) - reaches a periodic state with non-vanishing currents. In both cases, these currents are maintained at the cost of entropy production. Are these two paradigmatic scenarios effectively equivalent? For discrete-state systems we establish a mapping between NESS and SP. Given a NESS characterized by a particular set of stationary probabilities, currents and entropy production rates, we show how to construct a SP with exactly the same (time-averaged) values. The mapping works in the opposite direction as well. These results establish a proof of principle: they show that SP are able to mimic the behavior of NESS, and vice-versa, within the theoretical framework of discrete-state stochastic thermodynamics.

### 9:24AM A40.00008 The thermal vacuum for non-equilibrium steady state , RYOSUKE IMAI, YUKIRO

KUWAHARA, YUSUKE NAKAMURA, YOSHIYA YAMANAKA, Waseda Univ — Our purpose is to construct a theoretical description of non-equilibrium steady state (NESS), employing thermo field dynamics (TFD). TFD is the operator-based formalism of thermal quantum field theory, where every degree of freedom is doubled and thermal averages are given by expectation values of the thermal vacuum<sup>1</sup>. To specify the thermal vacuum for NESS is a non-trivial issue, and we attempt it on the analogy between the superoperator formalism and TFD<sup>2</sup>. Using the thermal vacuum thus obtained, we analyze the NESS which is realized in the two-reservoir model. It will be shown that the NESS vacuum of the model coincides with the fixed point solutions of the quantum transport equation derived by the self-consistent renormalization of the self-energy in non-equilibrium TFD<sup>3</sup>.

### 9:36AM A40.00009 Closed hierarchies and non-equilibrium steady states of driven systems ,

ISRAEL KLICH, University of Virginia — We present a class of tractable non-equilibrium dynamical quantum systems which includes combinations of injection, detection and extraction of particles interspersed by unitary evolution. We show how such operations generate a hierarchy of equations tying lower correlation functions with higher order ones. The hierarchy closes for particular choices of measurements and leads to a rich class of evolutions whose long time behavior can be simulated efficiently. In particular, we use the method to describe the dynamics of current generation through a generalized quantum exclusion process, and exhibit an explicit formula for the long time energy distribution in the limit of weak driving.

### 9:48AM A40.00010 Mechanical autonomous stochastic heat engines , MARC SERRA-GARCIA, ANDRE FOEHR,

MIGUEL MOLERO, Swiss Federal Institute of Technology (ETH), JOSEPH LYDON, jlydon@ethz.ch, CHRISTOPHER CHONG, Bowdoin College, CHIARA DARAIO, Swiss Federal Institute of Technology (ETH), . TEAM — Stochastic heat engines extract work from the Brownian motion of a set of particles out of equilibrium. So far, experimental demonstrations of stochastic heat engines have required extreme operating conditions or nonautonomous external control systems. In this talk, we will present a simple, purely classical, autonomous stochastic heat engine that uses the well-known tension induced nonlinearity in a string. Our engine operates between two heat baths out of equilibrium, and transfers energy from the hot bath to a work reservoir. This energy transfer occurs even if the work reservoir is at a higher temperature than the hot reservoir. The talk will cover a theoretical investigation and experimental results on a macroscopic setup subject to external noise excitations. This system presents an opportunity for the study of non equilibrium thermodynamics and is an interesting candidate for innovative energy conversion devices.

**10:00AM A40.00011 A dissipation bound for thermodynamic control** , BENJAMIN MACHTA, Princeton Univ — Biological and engineered systems operate by coupling function to the transfer of heat and/or particles down a thermal or chemical gradient. In idealized *deterministically* driven systems, thermodynamic control can be exerted reversibly, with no entropy production, as long as the rate of the protocol is made slow compared to the equilibration time of the system. Here we consider *fully realizable, entropically driven* systems where the control parameters themselves obey rules that are reversible and that acquire directionality in time solely through dissipation. We show that when such a system moves in a directed way through thermodynamic space, it must produce entropy that is on average larger than its generalized displacement as measured by the Fisher information metric. This distance measure is sub-extensive but cannot be made small by slowing the rate of the protocol.

**10:12AM A40.00012 Thermodynamic second law in a feedback process with time delay** , JAEGON UM, Korea Institute for Advanced Study, CHULAN KWON, Myongji University, HYUNGGYU PARK, Korea Institute for Advanced Study — We investigate a realistic feedback process repeated in multiple steps where a feedback protocol from measurement is applied with delay and maintains for a finite duration until next step. Unlike a feedback without delay, a composite system consists of the system and two memories where previous and present measurement outcomes are stored, leading to the 3-state Shannon entropy for the composite system. Then according to the thermodynamic second law, the change of the 3-state Shannon entropy provides the upper bound for heat flow from reservoir to system during the feedback and relaxation process. However, if the feedback protocol is depending on memory states sequentially, it turns out that the tighter bound for heat production can be obtained by integrating out the irrelevant memory state. We exemplify a cold damping case where a velocity of a particle is measured and a dissipative protocol is applied by feedback, and it is confirmed that the Shannon-entropy change of the reduced composite system gives the tighter bound for heat production.

**10:24AM A40.00013 Direct measurement of the Einstein relation in a macroscopic, non-equilibrium system of chaotic surface waves** , KYLE WELCH, ALEXANDER LIEBMAN-PELAEZ, ERIC CORWIN, University of Oregon — Equilibrium statistical mechanics is traditionally limited to thermal systems. Can it be applied to athermal, non-equilibrium systems that nonetheless satisfy the basic criteria of steady-state chaos and isotropy? We answer this question using a macroscopic system of chaotic surface waves which is, by all measures, non-equilibrium. The waves are generated in a dish of water that is vertically oscillated above a critical amplitude. We have constructed a rheometer that actively measures the drag imparted by the waves on a buoyant particle, a quantity entirely divorced in origin from the drag imparted by the fluid in which the particle floats. We also perform a separate, passive measurement, extracting a diffusion constant and effective temperature. Having directly measured all three properties (temperature, diffusion constant, and drag coefficient) we go on to show that our macroscopic, non-equilibrium case is wholly consistent with the Einstein relation, a classic result for equilibrium thermal systems.

**10:36AM A40.00014 Least action and entropy considerations of self-organization in Benard cells** , GEORGI GEORGIEV, WPI and Assumption College, GERMANO IANNACCHIONE, WPI — We study self-organization in complex systems using first principles in physics. Our approach involves the principle of least action and the second law of thermodynamics. In far from equilibrium systems, energy gradients cause internal ordering to facilitate the dissipation of energy in the environment. This internal ordering decreases their internal entropy in order to obey the principle of least action, minimizing the product of time and energy for transport through the system. We are considering the connection between action and entropy decrease inside Benard cells in order to derive some general features of self-organization. We are developing mathematical treatment of this coupling and comparing it to results from experiments and simulations.

**10:48AM A40.00015 Dissipation and irreversibility for models of mechanochemical machines** , AIDAN BROWN, DAVID SIVAK, Simon Fraser University — For biological systems to maintain order and achieve directed progress, they must overcome fluctuations so that reactions and processes proceed forwards more than they go in reverse. It is well known that some free energy dissipation is required to achieve irreversible forward progress, but the quantitative relationship between irreversibility and free energy dissipation is not well understood. Previous studies focused on either abstract calculations or detailed simulations that are difficult to generalize. We present results for mechanochemical models of molecular machines, exploring a range of model characteristics and behaviours. Our results describe how irreversibility and dissipation trade off in various situations, and how this trade-off can depend on details of the model. The irreversibility-dissipation trade-off points towards general principles of microscopic machine operation or process design. Our analysis identifies system parameters which can be controlled to bring performance to the Pareto frontier.

Session A41 DBIO GSOF: Cellular Biophysics 344 - Bo Sun, Oregon State University

**8:00AM A41.00001 Effects of Matrix Alignment and Mechanical Constraints on Cellular Behavior in 3D Engineered Microtissues.**<sup>1</sup> , PRASENJIT BOSE, Johns Hopkins University, JEROEN EYCKMANS, CHRISTOPHER CHEN, Boston University, DANIEL REICH, Johns Hopkins University — The adhesion of cells to the extracellular matrix (ECM) plays a crucial role in a variety of cellular functions. The main building blocks of the ECM are 3D networks of fibrous proteins whose structure and alignments varies with tissue type. However, the impact of ECM alignment on cellular behaviors such as cell adhesion, spreading, extension and mechanics remains poorly understood. We present results on the development of a microtissue-based system that enables control of the structure, orientation, and degree of fibrillar alignment in 3D fibroblast-populated collagen gels. The tissues self-assemble from cell-laden collagen gels placed in micro-fabricated wells containing sets of elastic pillars. The contractile action of the cells leads to controlled alignment of the fibrous collagen, depending on the number and location of the pillars in each well. The pillars are elastic, and are utilized to measure the contractile forces of the microtissues, and by incorporating magnetic material in selected pillars, time-varying forces can be applied to the tissues for dynamic stimulation and measurement of mechanical properties. Results on the effects of varying pillar shape, spacing, location, and stiffness on microtissue organization and contractility will be presented.

**8:12AM A41.00002 Dynamics of Cancer Cell near Collagen Fiber Chain** , JIHAN KIM, BO SUN, Oregon State University — Cell migration is an integrated process that is important in life. Migration is essential for embryonic development as well as homeostatic processes such as wound healing and immune responses. When cell migrates through connective extracellular matrix (ECM), it applies cellular traction force to ECM and senses the rigidity of their local environment. We used human breast cancer cell (MDA-MB-231) which is highly invasive and applies strong traction force to ECM. As cancer cell applies traction force to type I collage-based ECM, it deforms collagen fibers near the surface. Patterns of deforming collagen fibers are significantly different with pairs of cancer cells compared to a single cancer cell. While a pair of cancer cells within 60 um creates aligned collagen fiber chains between them permanently, a single cancer cell does not form any fiber chains. In this experiment we measured a cellular response and an interaction between a pair of cells through the chain. Finally, we analyzed correlation of directions between cancer cell migration and the collagen chain alignment.

**8:24AM A41.00003 The Characteristics of Force Production of Kinesin-5 on MCF7 Microtubules**, MITRA SHOJANIA FEIZABADI, Seton Hall University — Unlike neural mammalian microtubules with class II of beta tubulin as the major beta tubulin in their compositions, MCF7 microtubules composed of 0% class II beta tubulin isotype, 39.1% class I beta tubulin isotype, 2.5% class III beta tubulin isotype and 58.4% class IV beta tubulin isotype. Recent studies have revealed that function of some of motor proteins can be affected by the structural composition of microtubules. In this work, we will show how the function of mitotic kinesin (Kin-5) under external load changed when moving along bovine versus MCF7 microtubules. Along MCF7 microtubules, the detachment force was reduced and the force-velocity curve was different as compared to those related to bovine brain. We will also show that the elimination of the C-terminal tails made the transport almost similar to the two sets of microtubules. This suggests that the C-terminal tails of tubulin plays a regulatory role in Kinesin-5's function.

**8:36AM A41.00004 On the robustness of SAC silencing in closed mitosis<sup>1</sup>**, DONOVAN RUTH, JIAN LIU, Natl Inst of Health - NIH — Mitosis equally partitions sister chromatids to two daughter cells. This is achieved by properly attaching these chromatids via their kinetochores to microtubules that emanate from the spindle poles. Once the last kinetochore is properly attached, the spindle microtubules pull the sister chromatids apart. Due to the dynamic nature of microtubules, however, kinetochore-microtubule attachment often goes wrong. When this erroneous attachment occurs, it locally activates an ensemble of proteins, called the spindle assembly checkpoint proteins (SAC), which halts the mitotic progression until all the kinetochores are properly attached by spindle microtubules. The timing of SAC silencing thus determines the fidelity of chromosome segregation. We previously established a spatiotemporal model that addresses the robustness of SAC silencing in open mitosis for the first time. Here, we focus on closed mitosis by examining yeast mitosis as a model system. Though much experimental work has been done to study the SAC in cells undergoing closed mitosis, the processes responsible are not well understood. We leverage and extend our previous model to study SAC silencing mechanism in closed mitosis. We show that a robust signal of the SAC protein accumulation at the spindle pole body can be achieved. This signal is a nonlinear increasing function of number of kinetochore-microtubule attachments, and can thus serve as a robust trigger to time the SAC silencing. Together, our mechanism provides a unified framework across species that ensures robust SAC silencing and fidelity of chromosome segregation in mitosis.

**8:48AM A41.00005 Stochastic model of profilin-actin polymerization**, BRANDON HORAN, DIMITRIOS VAVYLONIS, Lehigh University — A driving factor in cell motility and other processes that involve changes of cell shape is the rapid polymerization of actin subunits into long filaments. This process is regulated by profilin, a protein which binds to actin subunits and regulates elongation of actin filaments. Whether profilin stimulates polymerization by coupling to hydrolysis of ATP-bound actin is debated. Previous studies have proposed indirect coupling to ATP hydrolysis using rate equations, but did not include the effects of fluctuations that are important near the critical concentration. We developed stochastic simulations using the Gillespie algorithm to study single filament elongation at the barbed end in the presence of profilin. We used recently measured rate constants and estimated the rate of profilin binding to the barbed end such that detailed balance is satisfied. Fast phosphate release at the tip of the filament was accounted for. The elongation rate and length diffusivity as functions of profilin and actin concentration were calculated and used to extract the critical concentrations of free actin and of total actin. We show under what conditions profilin leads to an increase in the critical concentration of total actin but a decrease in the critical concentration of free actin.

**9:00AM A41.00006 Surface deformation and shear flow in ligand mediated cell adhesion<sup>1</sup>**, SARTHOK SIRCAR, ANTHONY ROBERTS, University of Adelaide, SARTHOK SIRCAR / ANTHONY ROBERTS COLLABORATION — We present a unified, multiscale model to study the attachment/detachment dynamics of two deforming, near spherical cells, coated with binding ligands and subject to a slow, homogeneous shear flow in a viscous fluid medium. The binding ligands on the surface of the cells experience attractive and repulsive forces in an ionic medium and exhibit finite resistance to rotation via bond tilting. The microscale drag forces and couples describing the fluid flow inside the small separation gap between the cells, are calculated using a combination of methods in lubrication theory and previously published numerical results. For a select range of material and fluid parameters, a hysteretic transition of the sticking probability curves (i.e., the function  $g^*$ ) between the adhesion phase (when  $g^* \geq 0.5$ ) and the fragmentation phase (when  $g^* < 0.5$ ) is attributed to a nonlinear relation between the total nanoscale binding forces and the separation gap between the cells. We show that adhesion is favored in highly ionic fluids, increased deformability of the cells, elastic binders and a higher fluid shear rate (until a critical value). Continuation of the limit points (i.e., the turning points where the slope of the function  $g^*$  changes sign within a select range of critical shear

**9:12AM A41.00007 Nanoparticle Distributions in Cancer and other Cells from Light Transmission Spectroscopy**, ALISON DEATSCH, NAN SUN, JEFFERY JOHNSON, SHARON STACK, CAROL TANNER, STEVEN RUGGIERO, University of Notre Dame — We have measured the optical properties of whole cells and lysates using light transmission spectroscopy (LTS). LTS provides both the optical extinction coefficient in the wavelength range from 220 to 1100 nm and (by spectral inversion using a Mie model) the particle distribution density in the size range from 1 to 3000 nm. Our current work involves whole cells and lysates of cultured human oral cells and other plant and animal cells. We have found systematic differences in the optical extinction between cancer and normal whole cells and lysates, which translate to different particle size distributions (PSDs) for these materials. We have also found specific power-law dependences of particle density with particle diameter for cell lysates. This suggests a universality of the packing distribution in cells that can be compared to ideal Apollonian packing, with the cell modeled as a fractal body comprised of spheres on all size scales.

**9:24AM A41.00008 Simulation of the effect of confinement in actin ring formation**, MARAL ADELI KOUDEHI, DIMITRIOS VAVYLONIS, Lehigh University, HAOSU TANG TEAM, DIMITRIOS VAVYLONIS TEAM — Actin filaments are vital for different network structures in living cells. During cytokinesis, they form a contractile ring containing myosin motor proteins and actin filament cross-linkers to separate one cell into two cells. Recent experimental studies have quantified the bundle, ring, and network structures that form when actin filaments polymerize in confined environments in vitro, in the presence of varying concentrations of cross-linkers. In this study, we performed numerical simulations to investigate the effect of actin spherical confinement and cross-linking in ring formation. We used a spring-bead model and Brownian dynamics to simulate semiflexible actin filaments that polymerize in a confining sphere with a rate proportional to the monomer concentration. Applying the model for different size of the confining spheres shows that the probability of ring formation decreases by increasing the radius (at fixed initial monomer concentration), in agreement with prior experimental data. We describe the effect of persistence length, orientation-dependent cross-linking, and initial actin monomer concentration. Simulations show that equilibrium configurations can be reached through zipping and unzipping of actin filaments in bundles and transient ring formation.

**9:36AM A41.00009 Signaling and Dynamic Actin Responses of B Cells on Topographical Substrates**, CHRISTINA KETCHUM, Biophysics Program, University of Maryland, XIAOYU SUN, JOHN FOURKAS, Department of Chemistry, University of Maryland, WENXIA SONG, Department of Biology and Molecular Genetics, University of Maryland, ARPITA UPADHYAYA, Department of Physics, University of Maryland — B cells become activated upon physical contact with antigen on the surface of antigen presenting cells, such as dendritic cells. Binding of the B cell receptor with antigen initiates actin-mediated spreading of B cells, signaling cascades and eventually infection fighting antibodies. Lymphocytes, including B cells and T cells, have been shown to be responsive to the physical parameters of the contact surface, such as antigen mobility and substrate stiffness. However the roll of surface topography on lymphocyte function is unknown. Here we investigate the degree to which substrate topography controls actin-mediated spreading and B cell activation using nano-fabricated surfaces and live cell imaging. The model topographical system consists of 600 nanometer tall ridges with spacing varying between 800 nanometers and 5 micrometers. Using TIRF imaging we observe actin dynamics, B cell receptor motion and calcium signaling of B cells as they spread on the ridged substrates. We show that the spacing between ridges had a strong effect on the dynamics of actin and calcium influx on B cells. Our results indicate that B cells are highly sensitive to surface topography during cell spreading and signaling activation.

**9:48AM A41.00010 Mechanisms of T Lymphocyte Activation Exposed by Super Resolution Microscopy<sup>1</sup>**, LEONARD CAMPANELLO, WOLFGANG LOSERT, Univ of Maryland-College Park, MARIA TRAVER, BRIAN SCHAEFER, Uniformed Services University of the Health Sciences, ANDREW YORK, HARI SCHROFF, National Institutes of Health — In order to avoid the deleterious consequences of an uncontrolled immune response, tight regulatory control of positive and negative regulators during lymphocyte activation is needed. Utilizing cutting-edge super-resolution imaging technologies in combination with quantitative image analysis we explore the interplay between positive and negative regulation in activated T lymphocytes and investigate whether intercellular signaling is possibly governed by the degradation of a complex intracellular structure called the POLKADOTS signalosome. In segmenting the POLKADOTS signalosome structure by the betweenness centrality of its 3D medial axis skeleton, it was discovered that autophagosomes, small degradative intracellular organelles, localize preferentially to the ends of the filamentous POLKADOTS signalosome. These results provide new insight into the mechanisms behind the complex regulatory process that govern T lymphocyte activation.

<sup>1</sup>This research was supported by an Irvington Postdoctoral Fellowship from the Cancer Research Institute (awarded to MT) and a U01 grant from the National Institutes of Health (GM109887-01, awarded to BS and WL).

**10:00AM A41.00011 Single molecule analysis of B cell receptor motion during signaling activation**, IVAN REY SUAREZ, Biophysics Program, University of Maryland, PETER KOO, SIMON MOCHRIE, Department of Physics, Yale University, WENXIA SONG, Dept. of Cell Biology and Molecular Genetics, University of Maryland, ARPITA UPADHYAYA, Department of Physics, University of Maryland — B cells are an essential part of the adaptive immune system. They patrol the body looking for signs of infection in the form of antigen on the surface of antigen presenting cells. The binding of the B cell receptor (BCR) to antigen induces signaling cascades that lead to B cell activation and eventual production of high affinity antibodies. During activation, BCR organize into signaling microclusters, which are platforms for signal amplification. The physical processes underlying receptor movement and aggregation are not well understood. Here we study the dynamics of single BCRs on activated murine primary B cells using TIRF imaging and single particle tracking. The tracks obtained are analyzed using perturbation expectation-maximization (pEM) a systems-level analysis that allows the identification of different short-time diffusive states from a set of single particle tracks. We identified five different diffusive states on wild type cells, which correspond to different molecular states of the BCR. By using actin polymerization inhibitors and mutant cells lacking important actin regulators we were able to identify the BCR molecule configuration associated with each diffusive state.

**10:12AM A41.00012 Targeting cancer cell invasiveness using homing peptide-nanocomplexes**, GIULIA SUARATO, Materials Science and Engineering, Stony Brook University, JILLIAN CATHCART, Molecular and Cellular Pharmacology, Stony Brook University, WEIYI LI, Materials Science and Engineering, Stony Brook University, JIAN CAO, Medicine, Cancer Prevention, Stony Brook University, YIZHI MENG, Materials Science and Engineering, Stony Brook University — Matrix metalloproteinase-14 (MMP-14) plays critical roles in digesting the basement membrane and extracellular matrix and inducing cancer migration. We recently unraveled a unique role in cell invasion of the hemopexin (PEX) domain of MMP-14. The minimal motif located at the outmost strand of the fourth blade of the PEX domain was identified to form homodimers of MMP-14. A peptide (IVS4) mimicking the binding motif was shown to interrupt MMP-14 dimerization and decrease MMP-14-mediated functions. Since most invasive cancer cells express upregulated MMP-14 at the surface, IVS4 could be used as a cancer homing peptide to specifically deliver cytotoxic drugs for cancer therapy. We developed cancer homing nanocarriers by linking IVS4 to polysaccharide-based micellar nanoparticles (NPs). To determine if conjugation of IVS4 to NPs maintains the IVS4 inhibition of MMP-14 function, substrate degradation and cell migration assays were performed. IVS4-NPs efficiently prevented MMP-14-mediated substrate degradation and cell migration, and were minimally uptaken by non-cancer cells. Importantly, IVS4 confers an uptake advantage compared to the control peptide in MMP-14-expressing cells. Taken together, our findings demonstrate the potential use of IVS4-NPs as novel cancer nanotherapeutics.

**10:24AM A41.00013 Gating mechanosensitive channels in bacteria with an atomic force microscope.**, RENATA GARCES, University of Goettingen, SAMANTHA MILLER, University of Aberdeen, CHRISTOPH F. SCHMIDT, University of Goettingen, THIRD INSTITUTE OF PHYSICS TEAM, SCHOOL OF MEDICAL SCIENCES COLLABORATION — The regulation of growth and integrity of bacteria is critically linked to mechanical stress. Bacteria typically maintain a high difference of osmotic pressure (turgor pressure) with respect to the environment. This pressure difference (on the order of 1 atm) is supported by the cell envelope, a composite of lipid membranes and a rigid cell wall. Turgor pressure is controlled by the ratio of osmolytes inside and outside bacteria and thus, can abruptly increase upon osmotic downshock. For structural integrity bacteria rely on the mechanical stability of the cell wall and on the action of mechanosensitive (MS) channels: membrane proteins that release solutes in response to stress in the cell envelope. We here present experimental data on MS channels gating. We activate channels by indenting living bacteria with the cantilever of an atomic force microscope (AFM). We compare responses of wild-type and mutant bacteria in which some or all MS channels have been eliminated.

**10:36AM A41.00014 Impedance spectroscopy of micro-Droplets reveals activation of Bacterial Mechanosensitive Channels in Hypotonic Solutions**, AIDA EBRAHIMI, MUHAMMAD A. ALAM, Purdue University — Rapid detection of bacterial pathogens is of great importance in healthcare, food safety, environmental monitoring, and homeland security. Most bacterial detection platforms rely on binary fission (i.e. cell growth) to reach a threshold cell population that can be resolved by the sensing method. Since cell division depends on the bacteria type, the detection time of such methods can vary from hours to days. In contrast, in this work, we show that bacteria cells can be detected within minutes by relying on activation of specific protein channels, i.e. mechanosensitive channels (MS channels). When cells are exposed to hypotonic solutions, MS channels allow efflux of solutes to the external solution which leads to release the excessive membrane tension. Release of the cytoplasmic solutes, in turn, results in increase of the electrical conductance measured by droplet-based impedance sensing. The approach can be an effective technique for fast, pre-screening of bacterial contamination at ultra-low concentration.

**10:48AM A41.00015 Physics of Bacteria During Osmotic Shock**, JORDAN PRICE, WILLIAM KLUG, Department of Mechanical and Aerospace Engineering, UCLA — Bacteria combat hypoosmotic shocks by opening mechanosensitive ion channels located within the inner membrane. These channels are believed to act as “emergency release valves, reducing transient pressure during the shock by regulating solute and water flux. Recent experiments have shown that cell survivability depends strongly on channel populations and the rate of osmotic shock. However, the understanding of the physical mechanisms behind osmotic protection remains unclear. We investigate how channel deletions, variations in shock rate, and cell envelope mechanics affect survivability by constructing theoretical elasticity and transport models. We find that reducing the number of channels and applying faster shocks significantly increases the time-dependent stress of the cell membrane and wall. This result provides insight into physical mechanisms that govern cell failure, including membrane rupture and wall fracture.

**Monday, March 14, 2016 8:00AM - 10:48AM —**

**Session A42 DPOLY: Polymer Thin Films: Patterning and Flow** 345 - Justin Pye, Emory University

**8:00AM A42.00001 Deformation of Thin Free-standing Films with Sessile Droplets Through the Glass Transition**, ADAM FORTAIS, RAFAEL SCHULMAN, KARI DALNOKI-VERESS, McMaster University — Droplets on a rigid substrate will form a contact angle determined by interfacial tensions according to Young's law. Likewise, the Laplace pressure of a droplet will deform a liquid substrate, and the contact line geometry can be determined through a Neumann construction. We explore the intermediate case of micro-droplets placed on thin, highly compliant, free-standing films. The Laplace pressure of the droplet deforms the free-standing film, creating a spherical bulge. The film's tension is modulated by changing temperature continuously from well below the glass transition into the melt state of the film. The contact angle of the liquid droplet with the undeformed film as well as the angle of the bulge with the film is measured and compared to the contact angles predicted by a force balance at the contact line.

**8:12AM A42.00002 Measuring spatially distributed rheology of thin polymer films by non-contact shearing.**, MITHUN CHOWDHURY, Chemical and Biological Engineering, Princeton University, NJ 08544, USA, YUNLONG GUO, University of Michigan Shanghai Jiao Tong University Joint Institute, Shanghai 200240, P.R. China, RODNEY D. PRIESTLEY, Chemical and Biological Engineering, Princeton University, NJ 08544, USA — For nearly two decades, a great deal of research has been devoted to understand the impact of nanoscale confinement on the glassy and viscoelastic properties of thin polymer films. Prior works in supported films mostly used indirect mechano-rheological means, due to the complexity associated to probe such small volume. Here we present a non-contact shearing method 'blow-off', induced by the laminar flow of an inert gas through a narrow channel in order to generate a well-defined shear stress on a rectangular edge of a properly placed polymer thin film on a solid substrate. By appropriate control of temperature/ time during shearing, we explored effective viscosity and shear mobility, spatially from free surface to the material interior. In general, we found film surface has higher shear mobility and lower effective viscosity in comparison to its interior.

**8:24AM A42.00003 Photodirecting Marangoni Flow to Pattern Thin Polymer Films: Decoupling Viscosity and Diffusivity**, CHAE BIN KIM, AMANDA JONES, DUSTIN JANES, TALHA ARSHAD, ROGER BONNECAZE, CHRISTOPHER ELLISON, The University of Texas at Austin — The Marangoni effect causes liquids to flow towards localized regions of higher surface tension. In thin polymer films, this effect could offer a practically useful route to manufacture topographically patterned surfaces. In this presentation, we report a photochemical strategy to harness Marangoni flow as a versatile patterning method along with comparisons to a theoretical model that reveals the underlying physics of this process. The model agrees well with experiments with no adjustable parameters. It further indicates that higher aspect ratio features are favored by large surface tension gradients, low diffusivities and low viscosities. However, as described by the Rouse model, low viscosities are generally correlated with high diffusivities; diffusivity is also an important factor in the timescale by which the spatial surface tension patterns decay. This coupling between diffusivity and viscosity could critically limit feature aspect ratio for any given surface tension pattern. A potential strategy that decouples diffusivity and viscosity of the film components will be presented.

**8:36AM A42.00004 The Parametric Study of Focused Laser-Induced Marangoni Dewetting for Patterning Polymer Thin Films**, JONATHAN SINGER, TIANXING MA, Rutgers University, STEVEN KOOL, Massachusetts Institute of Technology, EDWIN THOMAS, Rice University — Highly-localized focused laser spike (FLaSk) heating of polymer thin films is a resist- and developer-free alternative to 2D laser direct write for creating patterns on the single micron or, by exploiting overlap effects, submicron scale. The massive temporal and spatial thermal gradients and resulting thermal Marangoni stresses generated by FLaSk are an effective means for the directed dewetting and patterning of such films. Here, the general applicability of this technique to glassy amorphous polymer thin film systems is investigated through systematic investigation of film thickness, glass transition temperature, and polymer mobility. The results reveal that the important parameters are the film thickness (coupled to the optical heating effects through anti-reflection coating effects) and the high-temperature polymer melt mobility, allowing for generation of single features with linewidths of down to 1  $\mu\text{m}$ . Further, the introduction of spatial mobility variations by using polymer brushes, bilayers, and microphase separated block copolymers leads to additional profile manipulation effects (*i.e.* spontaneous 2D pattern generation and flattened top profiles).

**8:48AM A42.00005 Degrafting of polymer brushes from substrates enables insight about the brush structure and facilitates surface patterning.**, ROHAN PATIL, North Carolina State Univ, SALOMON TURGMAN-COHEN, Kettering University, JIRI SROGL, North Carolina State Univ, DOUGLAS KISEROW, Army Research Office, JAN GENZER, North Carolina State Univ — Polymers end-grafted to surfaces or interfaces, commonly referred to as polymer brushes, enable tailoring physico-chemical properties of material surfaces. Many applications of polymer brushes require information about the molecular weight (MW) and grafting density (GD) of polymer brushes. For brushes synthesized by surface initiated polymerization (SIP) determining these attributes was always a challenge. We have developed a simple method of measuring MW and GD of these systems by degrafting SIP from silica-based surfaces by using tetrabutyl ammonium fluoride (TBAF), which attacks selectively Si-O bonds and enables complete degrafting of poly(methyl methacrylate) (PMMA) brushes from silica based substrates without damaging the backbone. The rate of PMMA degrafting decreases with reaction time and depends on the concentration of TBAF, temperature, and the initial GD of the system. The molecular weight distribution of the degrafted PMMA was measured using size exclusion chromatography. The GD was calculated from known MW and dry thickness of the PMMA brush. Spatial patterns of degrafted regions on the substrate can be prepared by either localizing the TBAF to certain regions or by gradually immersing homogeneous samples into TBAF solution.

**9:00AM A42.00006 Fabrication of Converging and Diverging Polymeric Microlens Arrays By A Thermocapillary Replication Technique<sup>1</sup>**, SOON WEI DANIEL LIM, KEVIN FIEDLER, SANDRA TROIAN, California Institute of Technology, 1200 E. California Blvd, MC 128-95, Pasadena, CA — Thermocapillary forces offer a powerful method for sculpting interfaces at microscale dimensions. Here we demonstrate how periodic arrays of cooled pins placed in close proximity to the surface of a molten polymer nanofilm can be used to fabricate various large area microlens arrays, which when solidified exhibit ultrasmooth surfaces and excellent focusing capability. This technique was used to fabricate both homogeneous converging and diverging microlens shapes by application of various thermal distributions. The converging arrays were incorporated into a Shack-Hartmann wavefront sensor able to image moving currents of airborne spray droplets. Feature overlap was also used to achieve hierarchical arrays comprising two superimposed patterns. By varying the width of the cooled pins, it was also possible to fabricate converging microlens structures featuring a caldera-like depression at the vertex able to focus collimated light into a sharp annulus. These demonstrations prove that with suitable microscale control over the thermal distributions projected onto molten nanofilms, a diverse set of micro-optical components can be fabricated by thermocapillary replication from a nearby mask without contact and in a single step.

**9:12AM A42.00007 Ultrasmooth, Polydopamine Modified Surfaces for Block Copolymer Nanopatterning on Inert and Flexible Substrates**, REIKA KATSUMATA, JOON HEE CHO, SUNSHINE ZHOU, CHAE BIN KIM, AUSTIN DULANEY, The University of Texas at Austin, DUSTIN JANES, U.S. Food and Drug Administration, CHRISTOPHER ELLISON, The University of Texas at Austin — Nature has engineered universal, catechol-containing adhesives that can be synthetically mimicked in the form of polydopamine (PDA). We exploited PDA to enable block copolymer (BCP) nanopatterning on a variety of soft material surfaces in a way that can potentially be applied to flexible electrical devices. Applying BCP nanopatterning to soft substrates is challenging because soft substrates are often chemically inert and possess incompatible low surface energies. In this study, we exploited PDA to enable the formation of BCP nanopatterns on a variety of surfaces such as Teflon, poly(ethylene terephthalate) (PET), and Kapton. While previous studies produced a PDA coating layer too rough for BCP nanopatterning, we succeeded in fabricating conformal and ultra-smooth surfaces of PDA by engineering the PDA coating process and post-sonication procedure. This chemically functionalized, biomimetic thin film (3 nm thick) served as a reactive platform for subsequently grafting a surface treatment to perpendicularly orient a lamellae-forming BCP layer. Furthermore, we demonstrated that a perfectly nanopatterned PDA-PET substrate can be bent without distorting or damaging the nanopattern in conditions that far exceeds typical bending curvatures in roll-to-roll manufacturing.

**9:24AM A42.00008 Adsorption and Pattern Recognition of Polymer at Complex Heterogeneous Surfaces**, LEILA RAJABIBONAB, Victoria University of Wellington, SHAUN HENDY, University of Auckland, SHAUN HENDY TEAM, LEILA RAJABI TEAM — The statistical mechanics of polymer adsorption on a substrate has been well studied. However, there has been recent interest in the conformational behaviour of polymer chains on patterned heterogeneous surfaces, where absorption strength varies. Here we report on Monte Carlo simulations of the adsorption of homo-polymer chains on patterned surfaces. One difficulty in studying polymer self-assembly on a patterned surface is the fluctuation of polymer conformations, which can make calculating the free energy a challenge. To overcome this we apply an expanded ensemble method to compute free energy differences. Applying this approach enables us to identify different adsorbed phases at a range of temperatures. The simplest case of heterogeneous surface is striped pattern, but we consider heterogeneous surfaces with four other that are structured on different length scales. At low temperatures we find that the polymer chain will recognise the pattern, by conformationally adapting as it adsorbs before eventually becoming fully relaxed on the surface. Polymers are found to adsorb on simple patterns at higher temperatures than on complex patterns.

**9:36AM A42.00009 Wake and wave resistance on viscous thin films**, RENE LEDESMA-ALONSO, MICHAEL BENZAQUEN, THOMAS SALEZ, ELIE RAPHAEL, Gulliver UMR 7083, ESPCI, PHYSICO-CHIMIE THEORIQUE TEAM — The effect of an external pressure disturbance, which is displaced with constant speed along the free surface of a viscous thin film, is studied theoretically in the lubrication approximation in one- and two-dimensional geometries. In the comoving frame, the imposed pressure field creates a stationary deformation of the interface - a wake - that spatially vanishes in the far region. The shape of the wake and the way it vanishes depend on both the speed  $v$  and size  $a$  of the external source and the properties of the film: density  $\rho$ , air-liquid surface tension  $\gamma$ , shear viscosity  $\mu$ , and film thickness  $h_0$ . The wave resistance, namely the force that has to be externally furnished in order to maintain the disturbance speed and the stationary wake, is analyzed in detail. For finite-size pressure disturbances, it increases with the speed, up to a certain transition value above which a monotonic decrease occurs. The role of the horizontal extent of the pressure field is studied as well, revealing that for a smaller disturbance the latter transition occurs at a higher speed. Eventually, for a Dirac pressure source, the wave resistance either saturates for a 1D geometry, or diverges for a 2D geometry.

**9:48AM A42.00010 Plug flow in a viscous freely-suspended film**, KARI DALNOKI-VERESS, MARK ILTON, MILES COUCHMAN, Department of Physics and Astronomy, McMaster University, Hamilton, Ontario, Canada, L8S 4M1, THOMAS SALEZ, MICHAEL BENZAQUEN, Laboratoire de Physico-Chimie Théorique, UMR CNRS Gulliver 7083, ESPCI ParisTech, PSL Research University, 75005 Paris, France, PAUL FOWLER, Department of Physics and Astronomy, McMaster University, Hamilton, Ontario, Canada, L8S 4M1, ELIE RAPHAEL, Laboratoire de Physico-Chimie Théorique, UMR CNRS Gulliver 7083, ESPCI ParisTech, PSL Research University, 75005 Paris, France — The flow of viscous polymer liquids supported by a solid substrate has been well characterized by a variety of experimental techniques. Previous studies found that the velocity profile within a flowing liquid film depends strongly on the friction at the liquid-substrate interface. For the case of low interfacial friction, liquid molecules can slide along the solid substrate. This is the “slip” boundary condition. Here we probe flow in a system with no interfacial friction: a viscous polymer film suspended at its edges. Using AFM, we measure the capillary-driven relaxation of freestanding polymer films with an initially stepped film thickness profile. The time evolution of the profile is consistent with plug flow. A freely-suspended viscous polymer film provides a physical realization of an idealized infinite slip boundary condition. Interestingly, in such a context, the profile evolution satisfies a diffusion-like equation, thus allowing for the use of a broad mathematical and physical toolbox by analogy.

**10:00AM A42.00011 Understanding and Improving the Quality of Inter-Layer Interfaces in FDM 3-D Printing**, EDWARD DURANTY, BRANDON SPRADLIN, MADELINE STARK, University of Tennessee, MARK DADMUN, University of Tennessee, Oak Ridge National Laboratory — We have studied the effect of thermal history and material diffusion on inter-filament bonding in FDM 3D printed parts and developed methods to improve interlayer adhesion in 3D printed samples. The available thermal energy during the FDM print environment was determined quantitatively by tracking the temperature of the bottom most printed layer using a thermocouple attached to the print bed. The role of the thermal history of the filaments during the deposition process on the quality of inter-layer bonding in an FDM ABS part was monitored using a T-peel test and an innovative sample design. Additionally, the interfacial adhesion between 3D printed layers was improved by the addition of a chemical cross-linking agent 4,4'-diaminodiphenylmethane (DADPM). These studies have increased our understanding of the importance of the complex thermal history of a filament in the 3D printing process and its impact on the interfaces that form during the fused deposition modeling print process. Furthermore, the chemical crosslinking process demonstrates a potential method to covalently link layers in FDM printed parts, improving the bulk strength of the part. The insight provided in this work may aid in the development of techniques that can produce FDM parts that could be used as replacement parts in structural applications, or as completely standalone products.

**10:12AM A42.00012 Modelling Polymer Deformation during 3D Printing**, CLAIRE MCILROY, PETER OLMSTED, Georgetown University — Three-dimensional printing has the potential to transform manufacturing processes, yet improving the strength of printed parts, to equal that of traditionally-manufactured parts, remains an underlying issue. The fused deposition modelling technique involves melting a thermoplastic, followed by layer-by-layer extrusion to fabricate an object. The key to ensuring strength at the weld between layers is successful inter-diffusion. However, prior to welding, both the extrusion process and the cooling temperature profile can significantly deform the polymer micro-structure and, consequently, how well the polymers are able to “re-entangle” across the weld. In particular, polymer alignment in the flow can cause de-bonding of the layers and create defects. We have developed a simple model of the non-isothermal extrusion process to explore the effects that typical printing conditions and material rheology have on the conformation of a polymer melt. In particular, we incorporate both stretch and orientation using the Rolie-Poly constitutive equation to examine the melt structure as it flows through the nozzle, the subsequent alignment with the build plate and the resulting deformation due to the fixed nozzle height, which is typically less than the nozzle radius.

**10:24AM A42.00013 Fundamental characterization of soft matter 3D printing processes**, KALMAN MIGLER, JONATHAN SEPPALA, CHELSEA DAVIS, KAITLYN HILLGARTNER, NIST — In fused filament fabrication (FFF), a material extrusion 3D printing method, thermoplastic filament is extruded through a rastering nozzle on the previous layer. The resulting strength of the FFF produced part is limited by the strength of the weld between each layer. While numerous factors can affect the weld strength, the temperature of the extrudate and the previous layer dictate the amount of interdiffusion and thus the weld strength. Temperature measurements were performed using forward looking infrared imaging. Interdiffusion estimates were calculated from temperature profiles, normalized using horizontal shift factors from offline rheological measurements of the neat polymer. Weld strength was measured directly by Mode III Fracture using a simplified geometry limiting the measurement to a single weld. Since the processing conditions are known a priori this approach provides the data needed to estimate the final build strength at time of design. The resulting agreement between interdiffusion estimates and weld strength for a range of printing conditions are discussed.

**10:36AM A42.00014 Pinch-off dynamics, extensional viscosity and relaxation time of dilute and ultradilute aqueous polymer solutions**, MADELEINE BIAGIOLI, JELENA DINIC, LEIDY NALLELY JIMENEZ, VIVEK SHARMA, Chemical Engineering, University of Illinois at Chicago — Free surface flows and drop formation processes present in printing, jetting, spraying, and coating involve the development of columnar necks that undergo spontaneous surface-tension driven instability, thinning, and pinch-off. Stream-wise velocity gradients that arise within the thinning neck create an extensional flow field, which induces micro-structural changes within complex fluids that contribute elastic stresses, changing the thinning and pinch-off dynamics. In this contribution, we use dripping-onto-substrate (DoS) extensional rheometry technique for visualization and analysis of the pinch-off dynamics of dilute and ultra-dilute aqueous polyethylene oxide (PEO) solutions. Using a range of molecular weights, we study the effect of both elasticity and finite extensibility. Both effective relaxation time and the transient extensional viscosity are found to be strongly concentration-dependent even for highly dilute solutions.

**8:00AM A43.00001 Critical Dynamics Near the Erosion Onset**, LE YAN, Kavli Institute for Theoretical Physics, UCSB, MATTHIEU WYART, Ecole Polytechnique Federale de Lausanne, Switzerland — Erosion shapes the Earth's landscape. Experiments reveal that there is an erosion threshold of a granular bed sheared by a viscous fluid. The granular particles start to flow when the shearing force is above the threshold  $\theta_c$ . Near  $\theta_c$ , the particle flux grows linearly  $J \sim \theta - \theta_c$ . The stationary state is reached after a transient time  $t_{conv}$ , which diverges as  $t_{conv} \sim |\theta - \theta_c|^{-z}$ . We theoretically study this dynamical transition by introducing a model capturing both the drainage effect of the disordered landscape and the interactions among the granular particles. Based on the model, we make the first time quantitative testable predictions for the drainage pattern — how the granular flux is spatially distributed and correlated. Our model enables us to rationalize the critical dynamics of erosion, which may also apply to the plastic depinning transition of vortex lattices in dirty superconductors.

**8:12AM A43.00002 Critical scaling with strain rate in overdamped sheared disordered solids<sup>1</sup>**, JOEL CLEMMER, Johns Hopkins University, KENNETH SALERNO, Sandia National Laboratories, MARK ROBBINS, Johns Hopkins University — In the limit of quasistatic shear, disordered solids demonstrate non-equilibrium critical behavior including power-law distributions of avalanches<sup>2</sup>. Using molecular dynamics simulations of 2D and 3D overdamped binary LJ glasses, we explore the critical behavior in the limit of finite strain rate. We use finite-size scaling to find the critical exponents characterizing shear stress, kinetic energy, and measures of temporal and spatial correlations. The shear stress of the system rises as a power  $\beta$  of the strain rate. Larger system size extends this power law to lower rates. This behavior is governed by a power law drop of the dynamic correlation length with increasing shear stress defined by the exponent  $\nu$ . This finite-size effect also impacts the scaling of the RMS kinetic energy with strain rate as avalanches begin nucleating simultaneously leading to continuous deformation of the solid. As system size increases, avalanches begin overlapping at lower rates. The correlation function of non-affine displacement exhibits novel anisotropic power law scaling with the magnitude of the wave vector. Its strain rate dependence is used to determine the scaling of the dynamic correlation length.

**8:24AM A43.00003 Scaling theory of the process zone of quasibrittle materials: an avalanche crossover analysis**, JARON KENT-DOBIAS, Physics, Cornell University, ASHVINI SHEKHAWAT, Materials Science and Engineering, Berkeley, JAMES SETHNA, Physics, Cornell University — We present progress towards a natural theory of the process zone surrounding cracks in quasibrittle materials using renormalization group methods. Quasibrittle or disordered brittle materials like concrete evade usual fracture analysis because of strong finite-size effects and a large disordered process zone. Unlike metals, where the process zone is relatively small and dominated by plasticity, microcracking relieves stress around the tip of quasibrittle cracks, a process that is not well understood. Recently, a scaling crossover theory was developed by Sethna and Shekhawat to explain the influence of finite size on the fracture mechanism and avalanche precursors. We extend this theory to model the scaling of stress and distribution of microcracking in the process zone.

**8:36AM A43.00004 Avalanches and local force evolution in a granular stick-slip experiment<sup>1</sup>**, AGHIL ABED ZADEH, JONATHAN BARES, ROBERT BEHRINGER, Duke University — We carry out experiments to characterize stick-slip for granular materials. In our experiment, a constant speed stage pulls a slider which rests on a vertical bed of circular photoelastic particles in a 2D system. The stage is connected to the slider by a spring. We measure the force on the spring by a force sensor attached to the spring. The distributions of energy release and time duration of avalanches during slip obey power laws. We analyze the power spectrum of the force signal to understand the effect of the loading speed and of the spring stiffness on the statistical behavior of the system. From a more local point of view and by using a high speed camera and the photoelastic properties of our particles, we characterize the internal granular structure during avalanches. By image processing and analyzing the skeleton of force network inside the media, we try to understand the flow of particles and evolution of force chains inside the media and during avalanches.

**8:48AM A43.00005 Avalanche-like fluidization of a non-Brownian particle gel<sup>1</sup>**, AIKA KUOKAWA, Earthquake Research Institute, VALÉRIE VIDAL, ENS Lyon, KEI KURITA, Earthquake Research Institute, THIBAUT DIVOUX, CNRS, CRPP - Bordeaux, SÉBASTIEN MANNEVILLE, ENS Lyon — We report on the fluidization dynamics of an attractive gel composed of non-Brownian particles made of fused silica colloids. Extensive rheology coupled to ultrasonic velocimetry allows us to characterize the global stress response together with the local dynamics of the gel during shear startup experiments. In practice, after being rejuvenated by a preshear, the gel is left to age during a time  $t_w$  before being submitted to a constant shear rate  $\dot{\gamma}$ . We investigate in detail the effects of both  $t_w$  and  $\dot{\gamma}$  on the fluidization dynamics and build a detailed state diagram of the gel response to shear startup flows. The gel may either display transient shear banding towards complete fluidization, or steady-state shear banding. In the former case, we unravel that the progressive fluidization occurs by successive steps that appear as peaks on the global stress relaxation signal. Flow imaging reveals that the shear band grows up to complete fluidization of the material by sudden avalanche-like events which are distributed heterogeneously along the vorticity direction and correlated to large peaks in the slip velocity at the moving wall.

**9:00AM A43.00006 Spatiotemporal stick-slip phenomena in a coupled continuum-granular system**, ROBERT ECKE, Los Alamos National Laboratory — In sheared granular media, stick-slip behavior is ubiquitous, especially at very small shear rates and weak drive coupling. The resulting slips are characteristic of natural phenomena such as earthquakes and well as being a delicate probe of the collective dynamics of the granular system. In that spirit, we developed a laboratory experiment consisting of sheared elastic plates separated by a narrow gap filled with quasi-two-dimensional granular material (bi-dispersed nylon rods). We directly determine the spatial and temporal distributions of strain displacements of the elastic continuum over 200 spatial points located adjacent to the gap. Slip events can be divided into large system-spanning events and spatially distributed smaller events. The small events have a probability distribution of event moment consistent with an  $M^{-3/2}$  power law scaling and a Poisson distributed recurrence time distribution. Large events have a broad, log-normal moment distribution and a mean repetition time. As the applied normal force increases, there are fractionally more (less) large (small) events, and the large-event moment distribution broadens. The magnitude of the slip motion of the plates is well correlated with the root-mean-square displacements of the granular matter. Our results are consistent with mean field descriptions of statistical models of earthquakes and avalanches. We further explore the high-speed dynamics of system events and also discuss the effective granular friction of the sheared layer. We find that large events result from stored elastic energy in the plates in this coupled granular-continuum system.

**9:36AM A43.00007 Tuning Parameters and Scaling For Avalanches On A Slowly-Driven Conical Bead Pile with Cohesion**<sup>1</sup>, SUSAN LEHMAN, D. T. JACOBS, PAROMA PALCHOUDHURI, AVI VAJPEYI, JUSTINE WALKER, College of Wooster, KARIN DAHMEN, MICHAEL LEBLANC, University of Illinois at Urbana-Champaign, JONATHAN UHL, Retired — Slip avalanches on a slowly driven pile are investigated experimentally using a 3D conical pile built from uniform 3 mm steel beads. Beads are added to the pile by dropping them onto the apex one at a time; avalanches are measured through changes in pile mass. We investigate the dynamic response of the pile by recording avalanches from the pile over the course of tens of thousands of bead drops. The statistical properties of the avalanches, including probability of particular avalanche sizes and the time between avalanches of given size, are well-characterized by universal power laws and scaling functions. By adding a uniform magnetic field, we may systematically vary the cohesion between the beads and tune the critical behavior of the system. As the cohesion increases we observe an increase in both size and number for very large avalanches and decreases in the mid-size avalanches, causing a deviation from the power law. A full study of the effect of cohesion on the size and time distributions is in process, combining the experimental results with predictions from an analytical mean-field model [Dahmen, Nat Phys 7, 554 (2011)].

**9:48AM A43.00008 Universality and depinning models for plastic yield in amorphous materials.**, ZOE BUDRIKIS, ISI Foundation, via Alassio 11/c 10126 Torino, Italy, DAVID FERNANDEZ CASTELLANO, STEFAN SANDFELD, MICHAEL ZAISER, 8-Materials Simulation, FAU University of Erlangen-Nuremberg, Germany, STEFANO ZAPPERI, Dipartimento di Fisica, Università di Milano, Italy — Plastic yield in amorphous materials occurs as a result of complex collective dynamics of local reorganizations, which gives rise to rich phenomena such as strain localization, intermittent dynamics and power-law distributed avalanches. While such systems have received considerable attention, both theoretical and experimental, controversy remains over the nature of the yielding transition. We present a new fully-tensorial coarsegrained model in 2D and 3D, and demonstrate that the exponents describing avalanche distributions are universal under a variety of loading conditions, system dimensionality and size, and boundary conditions. Our results show that while depinning-type models in general are apt to describe the system, mean field depinning models are not.

**10:00AM A43.00009 Atomic-scale reversibility in sheared glasses**, MENG FAN, MINGLEI WANG, YANHUI LIU, JAN SCHROERS, Department of Mechanical Engineering and Materials Science, Yale University, MARK SHATTUCK, Department of Physics and Benjamin LeVich Institute, The City College of the City University of New York, New York, COREY O'HERN, Department of Mechanical Engineering and Materials Science, Yale University — Systems become irreversible on a macroscopic scale when they are sheared beyond the yield strain and begin flowing. Using computer simulations of oscillatory shear, we investigate atomic scale reversibility. We employ molecular dynamics simulations to cool binary Lennard-Jones liquids to zero temperature over a wide range of cooling rates. We then apply oscillatory quasistatic shear at constant pressure to the zero-temperature glasses and identify neighbor-switching atomic rearrangement events. We determine the critical strain  $\gamma^*$ , beyond which atoms in the system do not return to their original positions upon reversing the strain. We show that for more slowly cooled glasses, the average potential energy is lower and the typical size of atomic rearrangements is smaller, which correlates with larger  $\gamma^*$ . Finally, we connect atomic- and macro-scale reversibility by determining the number of and correlations between the atomic rearrangements that occur as the system reaches the yield strain.

**10:12AM A43.00010 Multiscale minimal modeling of microscale crystal plasticity: Finite-size scaling and stochastic plastic flow**, STEFANOS PAPANIKOLAOU, Johns Hopkins University, PETER ISPANOVITY, Eötvös University — We investigate the multiscale description from continuum to discrete modeling of crystal plasticity in the context of a minimal model. We develop a continuum plasticity description of discrete edge dislocations moving athermally in a single slip system; Our continuum modeling not only matches the statistical behavior of the model, but also the onset of emergent length scales as load increases. We perform quasistatic stress-controlled simulations of our continuum model and compare it with the corresponding discrete dislocation dynamics model, which describes crystal plasticity at a smaller spatiotemporal discretization scale. We investigate the properties of strain bursts (dislocation avalanches) occurring during plastic deformation, as well as the onset of a dislocation patterning lengthscale, and compare in detail the continuum and discrete descriptions. Our approach provides a pathway to multiscale modeling of complex, multi-slip and three dimensional crystal plasticity.

**10:24AM A43.00011 The effectiveness of mean-field theory for avalanche distributions**, EDWARD LEE, ARCHISHMAN RAJU, JAMES SETHNA, Cornell University — We explore the mean-field theory of the pseudogap found in avalanche systems with long-range anisotropic interactions using analytical and numerical tools. The pseudogap in the density of low-stability states emerges from the competition between stabilizing interactions between spins in an avalanche and the destabilizing random movement towards the threshold caused by anisotropic couplings. Pazmandi et al. have shown that for the Sherrington-Kirkpatrick model, the pseudogap scales linearly and produces a distribution of avalanche sizes with exponent  $t=1$  in contrast with that predicted from RFIM  $t=3/2$ . Lin et al. have argued that the scaling exponent  $t$  of the pseudogap depends on the tail of the distribution of couplings and on non-universal values like the strain rate and the magnitude of the coupling strength. Yet others have argued that the relationship between the pseudogap scaling and the distribution of avalanche sizes is dependent on dynamical details. Despite the theoretical arguments, the class of RFIM mean-field models is surprisingly good at predicting the distribution of avalanche sizes in a variety of different magnetic systems. We investigate these differences with a combination of theory and simulation.

**10:36AM A43.00012 Elasto-plastic automata with realistic near field interactions: avalanches and diffusion**, CRAIG MALONEY, Northeastern, BOTOND TYUKODI, DAMIEN VANDEMBROUCQ, ESPCI — We present results on an elasto-plastic automaton model of an athermal amorphous solid under shear. We study four different variants of the model with two different loading geometries and two different stochastic prescriptions (random yield thresholds or random strain amplitudes). We perform a finite size scaling analysis for the avalanche size distribution and single-site displacement and strain statistics. The avalanche size distribution in all four cases is inconsistent with mean-field depinning results. For three of the four variants, the distribution is consistent with previous results from atomistic simulations and other related elasto-plastic models. The fourth seems to exhibit different scaling properties and may lie in a different universality class. The mean-squared displacement exhibits a pronounced dependence on the microscopic ingredients of the model and is completely non-universal. These results show that while certain microscopic ingredients of the model may be irrelevant for the individual avalanches, they may exhibit a profound impact on long-time correlations and long-lived shear localization.

**10:48AM A43.00013 Rearrangements in deformed foams near jamming**, MERLIJN VAN DEEN, VERA JANSSEN, ALEXANDER SIEMENS, MARTIN VAN HECKE, Huygens-Kamerlingh Onnes Lab, Leiden University — We deform two-dimensional foams at different densities and show there are two distinct regimes: a high density regime where bubbles deform affinely until the built up stress is released in rapid events (shear transformation zones), and a low density regime where bubbles are continuously in motion and rapid events are rare.

**Session A44 GQI: Quantum Information with Majorana Fermions & Parafermions** 347 - David Aasen, California Institute of Technology

**8:00AM A44.00001 Milestones toward Majorana-based quantum computing: Fusion rule detection and topological qubit validation**, RYAN V. MISHMASH, DAVID AASEN, Caltech, MICHAEL HELL, Lund University and NBI, Copenhagen, ANDREW HIGGINBOTHAM, Harvard and NBI, Copenhagen, JEROEN DANON, NBI, Copenhagen, MARTIN LEIJNSE, Lund University, THOMAS S. JESPERSEN, NBI, Copenhagen, JOSHUA A. FOLK, NBI, Copenhagen and UBC, CHARLES M. MARCUS, KARSTEN FLENSBERG, NBI, Copenhagen, JASON ALICEA, Caltech — We introduce a scheme for preparation, manipulation, and readout of Majorana zero modes in semiconducting wires coated with mesoscopic superconducting islands. Our approach synthesizes recent advances in materials growth with tools commonly used in quantum-dot experiments, including gate-control of tunnel barriers and Coulomb effects, charge sensing, and charge pumping. Recently, we have outlined a sequence of relatively modest milestones which interpolate between zero-mode detection and longer term quantum computing applications. In this talk, I will discuss two of these milestones: (1) detection of fusion rules for non-Abelian anyons using either proximal charge sensing or Majorana-mediated charge pumping and (2) validation of a prototype topological qubit via unconventional scaling relations between the time-averaged qubit splitting and its decoherence times  $T_1$  and  $T_2$ . Both of these proposed experiments require only a single wire with two islands—a hardware configuration already available in the laboratory. Furthermore, these pre-braiding experiments can be adapted to other manipulation and readout schemes as well.

**8:12AM A44.00002 Gate-controlled charging effects in superconducting nanowires: low-energy spectrum and time scales for Majorana manipulation**, MICHAEL HELL, Division of Solid State Physics and NanoLund, Lund Univ., Sweden / Center for Quantum Devices and Station Q Copenhagen, Univ. of Copenhagen, Denmark, JEROEN DANON, Center for Quantum Devices and Station Q Copenhagen and Niels Bohr International Academy, Univ. of Copenhagen, Denmark, MARTIN LEIJNSE, Division of Solid State Physics and NanoLund, Lund Univ., Sweden / Center for Quantum Devices and Station Q Copenhagen, Univ. of Copenhagen, Denmark, KARSTEN FLENSBERG, Center for Quantum Devices and Station Q Copenhagen, Univ. of Copenhagen, Denmark — In this talk, we investigate the gate-controlled crossover between different operating regimes of a superconducting nanowire segmented into two islands each Josephson-coupled to a bulk superconductor. This device may host two pairs of Majorana bound states and could be realized in the near future as a platform for testing Majorana fusion rules. We present a numerical study of the low-energy spectrum of this device covering both the charge-dominated regime utilizable for initialization and readout of the Majorana bound states as well as the Josephson-dominated transmon regime allowing for Majorana manipulations. Depending on the relative size of the energy scales associated with the Majorana coupling, the charging energy, and the transmon frequency, the fine structure of the low-energy spectrum differs. We finally discuss the associated time scales for implementing a fusion-rule testing protocol discussed in the talks by J. Alicea and R. V. Mishmash.

**8:24AM A44.00003 Demonstrating non-Abelian statistics of Majorana fermions using twist defects**, HUAIXIU ZHENG, ARPIT DUA, LIANG JIANG, Yale University — We study the twist defects in the toric code model introduced by Bombin [Phys. Rev. Lett. 105, 030403 (2010)]. Using a generalized 2D Jordan-Wigner transformation and a projective construction, we show explicitly the twist defects carry unpaired Majorana zero modes. In addition, we propose a quantum non-demolition measurement scheme of the parity of Majorana modes. Such a scheme provides an alternative avenue to demonstrate the non-Abelian statistics of Majorana fermions. The braiding operation is simulated by an efficient measurement-based approach that removes the uncertainty associated with the previous forced measurement scheme.

**8:36AM A44.00004 Parafermions in spin lattices**, ARPIT DUA, HUAIXIU ZHENG, LIANG JIANG, Yale Univ — We investigate the twist defects in the  $Z_N$  Toric code model first introduced by Bombin [Phys. Rev. Lett. 105, 030403 (2010)] for the  $Z_2$  model and then generalized and studied by You et al. [Phys. Rev. B 86, 161107(R) (2012)]. Using topological entanglement entropy (TEE) and generalized Jordan-Wigner transformation, we show explicitly that the twist defects carry unpaired Parafermion zero modes. We also demonstrate the fusion rules of these Parafermion modes using the TEE calculation. In addition, we propose a scheme for quantum non-demolition measurement of the topological charge of these modes. This scheme can be used to implement measurement-based braidings (MBBs) on Parafermions to implement gates for quantum computing.

**8:48AM A44.00005 Odd-frequency superconductivity in a nanowire coupled to Majorana zero modes<sup>1</sup>**, SHU-PING LEE, University of Alberta, ROMAN M. LUTCHYN, Microsoft Station Q, JOSEPH MACIEJKO, University of Alberta — Odd-frequency superconductivity, originally proposed by Berezinskii in 1974, is an exotic phase of matter in which pairing is entirely dynamical in nature. The pair potential is an odd function of frequency, leading to a vanishing static superconducting order parameter and exotic types of pairing seemingly inconsistent with Fermi statistics, such as spin triplet (singlet) pairing in an s-wave (p-wave) superconductor. Motivated by recent experimental progress in the realization of Majorana zero modes in semiconducting nanowires, we show that a spin-polarized nanowire coupled to a one-dimensional array of Majorana zero modes becomes an odd-frequency superconductor.

<sup>1</sup>This work was supported by NSERC, CRC, CIFAR, and the University of Alberta.

**9:00AM A44.00006 Readout scheme for Majorana parity states using a quantum dot<sup>1</sup>**, DARRYL HOVING, KAVEH GHARAVI, JONATHAN BAUGH, University of Waterloo — We propose and numerically study a scheme for reading out the parity state of a pair of Majorana bound states using a tunnel coupled quantum dot. The dot is coupled to one end of the topological wire but isolated from any reservoir, and is capacitively coupled to a charge sensor for measurement. The combined parity of the MBS-dot system is conserved and charge transfer between MBS and dot only occurs through resonant tunnelling. Resonance is controlled by the dot potential through a local gate and by the MBS splitting due to the overlap of the MBS pair wavefunctions. The latter splitting can be controlled by changing the position of the spatially separated, uncoupled MBS via a set of keyboard gates. Our simulations show that the oscillatory nature of the MBS splitting versus separation does not prevent high-fidelity readout. Indeed, the scheme can also be applied to measure the splitting versus separation, which would yield a clear signature of the topological state. With experimentally realistic parameters we find parity readout fidelities  $>99\%$  should be feasible.

**9:12AM A44.00007 Majorana Fermion Rides on a Magnetic Domain Wall<sup>1</sup>** , SE KWON KIM, Univ of California - Los Angeles, SUMANTA TEWARI, Clemson University, YAROSLAV TSERKOVNYAK, Univ of California - Los Angeles — Owing to the recent progress on endowing the electronic structure of magnetic nanowires with topological properties, the associated topological solitons in the magnetic texture—magnetic domain walls—appear as very natural hosts for exotic electronic excitations. Here, we propose to use the magnetic domain walls to engender Majorana fermions [1], which has several notable advantages compared to the existing approaches. First of all, the local tunneling density-of-states anomaly associated with the Majorana zero mode bound to a smooth magnetic soliton is immune to most of parasitic artifacts associated with the abrupt physical ends of a wire, which mar the existing experimental probes. Second, a viable route to move and braid Majorana fermions is offered by domain-wall motion. In particular, we envision the recently demonstrated heat-current induced motion of domain walls in insulating ferromagnets as a promising tool for nonintrusive displacement of Majorana modes. This leads us to propose a feasible scheme for braiding domain walls within a magnetic nanowire network, which manifests the non-Abelian exchange statistics within the Majorana subspace.

**9:24AM A44.00008 Majorana Fermion Surface Code for Universal Quantum Computation** , SAGAR VIJAY, TIM HSIEH, LIANG FU, MIT — We introduce an exactly solvable model of interacting Majorana fermions realizing  $Z_2$  topological order with a  $Z_2$  fermion parity grading and lattice symmetries permuting the three fundamental anyon types. We propose a concrete physical realization by utilizing quantum phase slips in an array of Josephson-coupled mesoscopic topological superconductors, which can be implemented in a wide range of solid state systems, including topological insulators, nanowires or two-dimensional electron gases, proximitized by  $s$ -wave superconductors. Our model finds a natural application as a Majorana fermion surface code for universal quantum computation, with a single-step stabilizer measurement requiring no physical ancilla qubits, increased error tolerance, and simpler logical gates than a surface code with bosonic physical qubits. We thoroughly discuss protocols for stabilizer measurements, encoding and manipulating logical qubits, and gate implementations.

**9:36AM A44.00009 Physical Architecture for a Universal Topological Quantum Computer based on a Network of Majorana Nanowires<sup>1</sup>** , JAY SAU, University of Maryland, MAISSAM BARKESHLI, Station Q, Microsoft Research — The idea of topological quantum computation (TQC) is to encode and manipulate quantum information in an intrinsically fault-tolerant manner by utilizing the physics of topologically ordered phases of matter. Currently, the most promising platforms for a topological qubit are either in terms of Majorana fermion zero modes (MZMs) in spin-orbit coupled superconducting nanowires or in terms of the Kitaev  $Z_2$  surface code. However, the topologically robust operations that are possible in these systems are not sufficient for realizing a universal gate set for topological quantum computation. Here, we show that an array of coupled semiconductor/superconductor nanowires with MZM edge states can be used to realize a more sophisticated type of non-Abelian defect, a  $\pi$ -anyon in an Ising  $X$  Ising topological state. This leads to a possible implementation of the missing topologically protected  $\pi/8$  phase gate and thus paves a path for universal topological quantum computation based on semiconductor-superconductor nanowire technology. We provide detailed numerical estimates of the relevant energy scales, which we show to lie within accessible ranges. [1] Barkeshli, Sau, arXiv:1509.07135 (2015).

**9:48AM A44.00010 Braiding Majorana fermions in  $p+ip$  superfluids with particle number conservation** , YIRUO LIN, ANTHONY LEGGETT, University of Illinois at Urbana-Champaign — We discuss braiding statistics of Majorana zero modes localized in vortices in 2D spinless  $p+ip$  superfluids with conserved total particle number. In the standard particle non-conserved context, it has been argued that braiding these zero Majorana fermions yields non-abelian statistics. With particle number conservation, We show that in certain geometry, the Berry phase of interchanging two Majorana zero modes is proportional to angular momentum of the system with the presence of two vortices, which can then be calculated in the thermodynamic limit. The braiding statistics turns out to be consistent with the standard result. We then discuss the possible complication due to finite size effect. We'll argue that in a finite size system, the abelian phase of interchanging two vortices is non-topological. We'll finish the discussion by sketching out ongoing work in which we investigate the possible modification of BdG quasi-particle wave functions beyond the BdG mean-field approximation, which can have dramatic effect on topological properties of Majorana zero modes and their braiding statistics.

**10:00AM A44.00011 Beyond parafermions: Defects and zero-modes in non-Abelian phases** , NETANEL LINDNER, Technion - Israel Institute of Technology, EREZ BERG, ADY STERN, Weizmann Institute of Science — Non-Abelian topological phases of matter can be utilized to encode and manipulate quantum information in a non-local manner, such that it is protected from imperfections in the implemented protocols and from interactions with the environment. The condition that the non-Abelian statistics of the anyons supports a computationally universal set of gates sets a very stringent requirement which is not met by many topological phases. We consider the possibility to enrich the possible topological operations supported by a non-Abelian topological phase by introducing defects into the system. We show that such defects bind zero modes which form a unique algebra that goes beyond the algebra of parafermions which describes defects in Abelian phases. For the case of a bi-layer containing Ising anyons, we show that by coupling zero modes one can obtain a set of topological operations that implements a universal set of gates.

**10:12AM A44.00012 Tunable Splitting of the Ground-State Degeneracy in 1D Parafermionic Wires** , CHUN CHEN, FIONA BURNELL, Univ of Minn - Minneapolis — Systems with topologically protected ground-state degeneracies are currently of great interest due to their potential applications in quantum computing. In practise this degeneracy is never exact, and the magnitude of the ground-state degeneracy splitting imposes constraints on the timescales over which information is topologically protected. In this Letter we use an instanton approach to evaluate the splitting of topological ground-state degeneracy in quasi-1D systems with parafermion zero modes, in the specific case where parafermions are realized by inducing a superconducting gap in pairs of fractional quantum Hall (FQH) edges. We show that, like 1D topological superconducting wires, this splitting has an oscillatory dependence on the chemical potential, which arises from an intrinsic Berry phase that produces interference between distinct instanton tunneling events. These Berry phases can be mapped to chiral phases in a (dual) quantum clock model using a Fradkin-Kadanoff transformation. Comparing our low-energy spectrum to that of phenomenological parafermion models allows us to evaluate the real and imaginary parts of the hopping integral between adjacent parafermionic zero modes as functions of the chemical potential.

**8:00AM A45.00001 Spin qubits in quantum dots – beyond nearest-neighbour exchange<sup>1</sup>**, LIEVEN VANDERSYPEN, QuTech and Kavli Institute of Nanoscience — The spin of a single electron is the canonical two-level quantum system. When isolated in a semiconductor quantum dot, a single electron spin provides a well-lived quantum bit. So far, two-qubit gates in this system have relied on the spin exchange interaction that arises when the wave functions of neighbouring electrons overlap. Furthermore, experimental demonstrations of controlled spin-exchange have been limited to 1D quantum dot arrays only. Here we explore several avenues for scaling beyond 1D arrays with nearest-neighbour coupling. First, we show that second-order tunnel processes allow for coherent spin-exchange between non-nearest neighbour quantum dots. The detuning of the intermediate quantum dot controls the frequency of the exchange-driven oscillations of the spins. Second, we demonstrate shuttling of electrons in quantum dot arrays preserving the spin projection for more than 500 hops. We use this technique to read out multiple spins in a way analogous to the operation of a CCD. Finally, we develop superconducting resonators that are resilient to magnetic field and with a predicted tenfold increase in vacuum electric field amplitudes. This makes coupling spin qubits via superconducting resonators in a circuit-QED approach a realistic possibility. [1] F.R. Braakman et al, Nature Nano 8, 432, 2013 [2] T.A. **8:36AM A45.00002 Characterization of accumulation-mode Si/SiGe triple quantum dots<sup>1</sup>**, T. M. HAZARD, D. M. ZAJAC, X. MI, S. S. ZHANG, J. R. PETTA, Department of Physics, Princeton University — The transition from quantum dots fabricated from doped Si/SiGe quantum wells to undoped accumulation-mode structures has greatly improved the performance of few-electron quantum dots. Our accumulation-mode devices<sup>2</sup> are reconfigurable and allow for operation as single, double, or triple quantum dots. In these devices, we measure typical charging energies  $E_c = 5.7$  meV, orbital excited state energies as large as  $E_o = 2.9$  meV, and valley splittings of up to  $E_v = 80$   $\mu$ eV. With the device configured as a triple quantum dot, we easily reach the (1,1,1) charge configuration. The gate architecture allows the interdot tunnel coupling to be tuned over a wide range, which is important for operation as an exchange-only spin qubit.<sup>3</sup>

**8:48AM A45.00003 Characterization of a gate-defined double quantum dot in a Si/SiGe nanomembrane<sup>1</sup>**, T. J. KNAPP, R. T. MOHR, YIZE STEPHANIE LI, BRANDUR THORGRIMSSON, RYAN H. FOOTE, XIAN WU, DANIEL R. WARD, D. E. SAVAGE, M. G. LAGALLY, MARK FRIESEN, S. N. COPPERSMITH, M. A. ERIKSSON, University of Wisconsin: Madison — We report the characterization of a gate-defined double quantum dot formed in a Si/SiGe nanomembrane. Previously, all heterostructures used to form quantum dots were created using the strain-grading method of strain relaxation, a method that necessarily introduces misfit dislocations into a heterostructure and thereby degrades the reproducibility of quantum devices. Using a SiGe nanomembrane as a virtual substrate eliminates the need for misfit dislocations but requires a wet-transfer process that results in a non-epitaxial interface in close proximity to the quantum dots. We show that this interface does not prevent the formation of quantum dots, and is compatible with a tunable inter-dot tunnel coupling, the identification of spin states, and the measurement of a singlet-to-triplet transition as a function of the applied magnetic field. This work was supported in part by ARO (W911NF-12-0607), NSF (DMR-1206915, PHY-1104660), and the United States Department of Defense. **9:00AM A45.00004 Gate-defined quantum dot devices in undoped Si/SiGe heterostructures for spin qubit applications<sup>1</sup>**, CHRISTIAN VOLK, FREDERICO MARTINS, CHARLES M. MARCUS, FERDINAND KUEMMETH, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, 2100 Copenhagen, Denmark — Spin qubits based on few electron quantum dots in semiconductor heterostructures are among the most promising systems for realizing quantum computation. Due to its low concentration of nuclear-spin-carrying isotopes, silicon is of special interest as a host material. We characterize gate-defined double and triple quantum dot devices fabricated from undoped Si/Si<sub>0.7</sub>Ge<sub>0.3</sub> heterostructures. Our device architecture is based on integrating all accumulation and depletion mode gates in a single gate layer. This allows us to omit the commonly used global accumulation gate in order to achieve a more local control of the potential landscape in the device. We present our recent progress towards implementing spin qubits in these structures.

**9:12AM A45.00005 Observation of multiple exchange oscillation frequencies in Si/SiGe spin qubits**, MATTHEW RAKHER, HRL Laboratories, LLC — An all-electrical approach to quantum information processing with spin qubits in Si/SiGe quantum wells relies on the ability to quickly turn on and off the exchange interaction between electrons in neighboring quantum dots [1]. The quality of gates enabled by this technique depends critically on reliably achieving a specific value of exchange coupling for a given control voltage. In recent experiments [2], we have observed multiple exchange oscillation frequencies at the same control bias for several different devices. In particular, Fourier transforms of exchange oscillations measured as a function of evolution time reveal the presence of multiple frequencies over a wide range of pulse amplitudes. The data are suggestive of unwanted population of an excited singlet-triplet manifold that behaves similarly with bias as the qubit ground state pair. The occupation of excited singlet-triplet states can degrade gate performance in exchange-based quantum devices and we outline methods to observe and investigate these states. [1] K. Eng et al, Science Advances 1 (2015) [2] M.D. Reed et al, arxiv:1508.01223 (2015)

**9:24AM A45.00006 Predicting the valley physics of silicon quantum dots directly from a device layout<sup>1</sup>**, JOHN KING GAMBLE, Sandia National Laboratories, PATRICK HARVEY-COLLARD, Sandia National Laboratories and Université de Sherbrooke, N. TOBIAS JACOBSON, ANDREW D. BACEWSKI, ERIK NIELSEN, INÉS MONTAÑO, MARTIN RUDOLPH, MALCOLM S. CARROLL, RICHARD P. MULLER, Sandia National Laboratories — Qubits made from electrostatically-defined quantum dots in Si-based systems are excellent candidates for quantum information processing applications. However, the multi-valley structure of silicon's band structure provides additional challenges for the few-electron physics critical to qubit manipulation. Here, we present a theory for valley physics that is predictive, in that we take as input the real physical device geometry and experimental voltage operation schedule, and with minimal approximation compute the resulting valley physics. We present both effective mass theory and atomistic tight-binding calculations for two distinct metal-oxide-semiconductor (MOS) quantum dot systems, directly comparing them to experimental measurements of the valley splitting. We conclude by assessing these detailed simulations utility for engineering desired valley physics in future devices. Sandia is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the US Department of Energy's National Nuclear Security Administration under Contract No. DE-AC04-94AL85000.

### 9:36AM A45.00007 Gate fidelity and coherence time of an electron spin in a Si/SiGe quantum dot

, ERIKA KAWAKAMI, THIBAUT JULLIEN, PASQUALE SCARLINO, Delft Univ of Tech, D. R. WARD, D. E. SAVAGE, M. G. LAGALLY, University of Wisconsin-Madison, V. V. DOBROVITSKI, Ames Laboratory, MARK FRIESEN, S. N. COPPERSMITH, M. A. ERIKSSON, University of Wisconsin-Madison, L. M. K. VANDERSYPEN, Delft Univ of Tech — Electron spins in Si/SiGe quantum dots are one of the most promising candidates for a quantum bit for their potential scalability and long dephasing time. We realized coherent control of an individual electron spin in a single quantum dot (QD), lithographically defined in a Si/SiGe 2D electron gas. Spin rotations are achieved by applying microwave excitation to one of the gates, which oscillates the electron wave function back and forth in the gradient field produced by cobalt micromagnets fabricated near the dot. Thanks to the long intrinsic dephasing time  $T_2^* = 900$  ns and Rabi frequency of 1.4 MHz, we were able to obtain an average single qubit gate fidelity of an electron spin in a Si/SiGe quantum dot of 99 %, measured via randomized benchmarking. The dephasing time is extended to 70  $\mu$ s using Hahn echo, and up to 400  $\mu$ s with multipulse dynamical decoupling (128  $\pi$  pulses). We extract the noise spectrum in the range of 5 kHz -1 MHz using dynamical decoupling and show that the gate fidelity is well explained by this noise characteristic. We discuss the mechanism that induces this noise and is responsible for decoherence.

### 9:48AM A45.00008 Epitaxial deposition of highly enriched $^{28}\text{Si}$ films with <1 nm roughness

, K. J. DWYER, HYUN-SOO KIM, A. N. RAMANAYAKA, D. S. SIMONS, VLADIMIR OLESHKO, J. M. POMEROY, National Institute of Standards and Technology — Low temperature epitaxial deposition of thin films with less than 1 nm rms roughness is achieved using a  $^{28}\text{Si}$  ion beam deposition source. These films are enriched *in situ* to <140 ppb  $^{29}\text{Si}$  isotope fraction for quantum computing devices. Removal of the 4.7 %  $^{29}\text{Si}$  nuclear spins in natural silicon allows for exceedingly long coherence ( $T_2$ ) times of qubits, making incorporation of highly enriched  $^{28}\text{Si}$  into devices critical for solid state quantum information. Low roughness epitaxial  $^{28}\text{Si}$  thin films are achieved by depositing in an island growth mode at temperatures of 300 C to 400 C, and the morphology is verified using scanning tunneling microscopy. Further, the crystalline quality of the films is shown using cross-sectional transmission electron microscopy. Finally, the chemical purity and broader electrical properties of the  $^{28}\text{Si}$  films are assessed by secondary ion mass spectroscopy as well as capacitance-voltage profiling, schottky diode measurements, and hall measurements.

### 10:00AM A45.00009 First measurements of charge carrier density and mobility of in-situ enriched $^{28}\text{Si}$ .

, A. N. RAMANAYAKA, Joint Quantum Institute, National Institute of Standards and Technology, K. J. DWYER, HYUN-SOO KIM, University of Maryland, M. D. STEWART, JR., J. M. POMEROY, National Institute of Standards and Technology — Magnetotransport in top gated Hall bar devices is investigated to characterize the electrical properties of in-situ enriched  $^{28}\text{Si}$ . Isotopically enriched  $^{28}\text{Si}$  is an ideal candidate for quantum information processing devices as the elimination of unpaired nuclear spins improves the fidelity of the quantum information. Using mass filtered ion beam deposition we, in-situ, enrich and deposit epitaxial  $^{28}\text{Si}$ , achieving several orders of magnitude better enrichment compared to other techniques. In order to explore the electrical properties and optimize the growth conditions of in-situ enriched  $^{28}\text{Si}$  we perform magnetotransport measurements on top gated Hall bar devices at temperatures ranging from 300 K to cryogenic temperatures and at moderate magnetic fields. Here, we report on the charge carrier density and mobility extracted from such experiments, and will be compared among different growth conditions of in-situ enriched  $^{28}\text{Si}$ .

### 10:12AM A45.00010 Thermal oxidation of Si/SiGe heterostructures for use in quantum dot qubits

, SAMUEL F. NEYENS, RYAN H. FOOTE, T. J. KNAPP, THOMAS MCJUNKIN, D. E. SAVAGE, M. G. LAGALLY, S. N. COPPERSMITH, M. A. ERIKSSON, Wisconsin Institute for Quantum Information, University of Wisconsin-Madison — Here we demonstrate dry thermal oxidation of a Si/SiGe heterostructure at 700°C and use a Hall bar device to measure the mobility after oxidation to be  $43,000 \text{ cm}^2 \text{V}^{-1} \text{s}^{-1}$  at a carrier density of  $4.1 \times 10^{11} \text{ cm}^{-2}$ . Surprisingly, we find no significant reduction in mobility compared with an  $\text{Al}_2\text{O}_3$  device made with atomic layer deposition on the same heterostructure, indicating thermal oxidation can be used to process Si/SiGe quantum dot devices. This result provides a path for investigating improvements to the gate oxide in Si/SiGe qubit devices, whose performance is believed to be limited by charge noise in the oxide layer. This work was supported in part by ARO (W911NF-12-0607) and NSF (DMR-1206915 and PHY-1104660). Development and maintenance of the growth facilities used for fabricating samples is supported by DOE (DE-FG02-03ER46028). This research utilized NSF-supported shared facilities at the University of Wisconsin-Madison.

### 10:24AM A45.00011 Electrode-induced In-plane Strain Variation in Si Quantum Well

, JOONKYU PARK, YOUNGJUN AHN, DONALD SAVAGE, University of Wisconsin Madison, JONATHAN PRANCE, Lancaster University, CHRISTINE SIMMONS, MAX LAGALLY, SUSAN COPPERSMITH, University of Wisconsin Madison, MARTIN HOLT, Argonne National Laboratory, MARK ERIKSSON, PAUL EVANS, University of Wisconsin Madison — Silicon quantum devices are often formed in electrostatically defined quantum dots within Si/SiGe heterostructures incorporating a strained silicon quantum well. Structural variations within the quantum well arise from several sources, including the plastic relaxation of the SiGe substrate and stresses arising from electrodes. The residual stress in the electrode causes an elastic bending distortion of the quantum well that modifies the energy by which the two split-off conduction minima in the silicon quantum well are shifted by biaxial strain. We report a synchrotron hard x-ray nanobeam diffraction study of the quantum well distortion (i) near isolated Pd electrodes and (ii) within a complex quantum dot pattern. The strain difference between the two interfaces of the 10-nm-thick silicon quantum well has a magnitude of up to  $10^{-5}$  in (i) while it is as large as  $10^{-4}$  in (ii) which is far larger than the strain difference arising from the plastic relaxation of the SiGe substrate. Mechanical analysis using the edge-force model, shows that the residual stress in the Pd electrode was 350 MPa. We expect that similar effects will arise in all quantum electronic systems with metal-electrode-defined devices.

### 10:36AM A45.00012 Are quantum dots in unexpected locations due to strain?

, NEIL ZIMMERMAN, NIST, TED THORBECK, University of Wisconsin-Madison — It is a fairly common occurrence that, in top-gated Si quantum dots, the dots appear in reproducible but unexpected positions. For instance, sometimes a group will make gates in order to electrostatically generate tunnel barriers, but discover that the quantum dot is formed underneath the gate rather than between two barrier gates. We will discuss the possibility that such quantum dots arise from the mechanical strain induced by the gate. The model is simple: i) We simulate metal or polysilicon gates on top of a Si/SiO $_2$  wafer, and calculate the stress and strain from differential thermal contraction of the materials; ii) Using the fact that the energy of the Si conduction band depends on strain through the deformation potential, we then convert the strain modulation to a potential energy modulation. As an example, we find that, for a single Al gate, there is a potential well directly underneath the gate with the size of a few meV, in agreement with recent experimental results. We also show that polysilicon gates will not produce such strain-induced quantum dots.

### 10:48AM A45.00013 Atomic scale quantum circuits in Si

, A. DUSKO, IF, UFRJ, Brazil / DP, uOttawa, Canada, M. KORKUSINSKI, IMS, NRC, Canada, A. SARAIVA, IF, UFRJ, Brazil, A. DELGADO, DP, uOttawa, Canada, B. KOILLER, IF, UFRJ, Brazil, P. HAWRYLAK, DP, uOttawa, Canada — The atomic scale circuits in Si are now realized by manipulation of dangling bonds on Si surface or incorporating dopant atoms in Si by STM techniques. We describe the electronic properties of these atomic scale quantum dot circuits (QDC) by the extended Hubbard-Kanamori Hamiltonian (HK), including on site Coulomb repulsion ( $U$ ) and interdot hopping ( $t$ ), direct interaction ( $V$ ) and exchange ( $J$ ) terms. The interdot terms strongly depend on dopant position ( $R_D$ ) in Si lattice—small changes in  $R_D$  strongly impact  $t$ ,  $V$  and  $J$ . We study how disorder in  $R_D$  impacts QDC electronic properties, in particular the interplay of disorder and interactions. With no disorder in  $R_D$  the energy spectrum (ES) of quantum dot chain at half-filling as a function of  $U/t$  ( $V, J = 0$ ) shows a transition from ES dominated by kinetic energy ( $U/t \ll 1$ ) to ES dominated by Coulomb interactions for  $U/t \gg 1$ . The excited states group by single particle energy spacing (Hubbard bands) for weak (strong) interactions. In the weak interaction regime, disorder leads to localization, which strongly affects the electronic properties. We explore the effect of interactions and disorder on HK atomic scale circuits and potential many-body localized phases using Lanczos and Density Matrix Renormalization Group approaches.

**Session A46 GIMS: Advances in Scanning Probe Microscopy I: Novel Approaches and Ultra-sensitive Detection** 311 - Hongwoo Baek, National Magnet Laboratory

**8:00AM A46.00001 AFM cantilever vibration detection with a transmitted electron beam**, TAYLOR WOEHL, RYAN WAGNER, ROBERT KELLER, JASON KILLGORE, Material Measurement Laboratory, National Institute of Standards and Technology — Cantilever oscillations for dynamic atomic force microscopy (AFM) are conventionally measured with an optical lever system. The speed of AFM cantilevers can be increased by decreasing the size of the cantilever; however, the fastest AFM cantilevers are currently nearing the smallest size that can be detected with the current optical lever approach. Here we demonstrate an electron detection scheme in an SEM for detecting AFM cantilever oscillations. An oscillating AFM tip is positioned perpendicular to the propagation direction of a stationary  $\approx 1$  nm diameter electron probe, and the oscillatory change in electron scattering resulting from the changing thickness of the electron irradiated area of the AFM tip is detected with a transmitted electron detector positioned below the AFM tip. We perform frequency sweep and ring-down experiments to determine the first resonant frequency and Q factor of an AFM cantilever.

**8:12AM A46.00002 Innovative SPM Probes for Energy-Storage Science: MWCNT-Nanopipettes to Nanobattery Probes<sup>1</sup>**, JONATHAN LARSON, Dept. of Physics, Univ of Maryland-College Park, ALEC TALIN, Dept. of Mat Physics, Sandia National Labs-Livermore, ALEXANDER PEARSE, Dept. of Mat Sci Eng, Univ of Maryland-College Park, ALEXANDER KOZEN, Dept of Mat Sci Eng, Univ of Maryland-College Park, JANICE REUTT-ROBEY, Dept. of Chem and Biochem, Univ of Maryland-College Park — As energy-storage materials and designs continue to advance, new tools are needed to direct and explore ion insertion/de-insertion at well-defined battery materials interfaces. Scanned probe tips, assembled from actual energy-storage materials, permit SPM measures of local cathode-anode (tip-sample) interactions, including ion transfer. We present examples of “cathode” MWCNT-terminated STM probe tips interacting with Li(s)/Si(111) anode substrates. The MWCNT tip functions as both SPM probe and Li-nanopipette,<sup>[1]</sup> for controlled transport and manipulation of Li. Local field conditions for lithium ionization and transfer are determined and compared to electrostatic models. Additional lithium metallic and oxide tips have been prepared by thin film deposition on conventional W tips, the latter of which effectively functions as a nanobattery. We demonstrate use of these novel probe materials in the local lithiation of low-index Si anode interfaces, probing local barriers for lithium insertion. Prospects and limitations of these novel SPM probes will be discussed. [1] J.M. Larson et al, Small, 2015, DOI: 10.1002/sml.201500999

**8:24AM A46.00003 Carbon nanotube/carbon nanotube composite AFM probes prepared using ion flux molding<sup>1</sup>**, GRACE CHESMORE, Santa Clara University, CARROLLYN ROQUE, Carbon Design Innovations, RICHARD BARBER, Santa Clara University — The performance of carbon nanotube-carbon nanotube composite (CNT/CNT composite) atomic force microscopy (AFM) probes is compared to that of conventional Si probes in AFM tapping mode. The ion flux molding (IFM) process, aiming an ion beam at the CNT probe, aligns the tip to a desired angle. The result is a relatively rigid tip that is oriented to offset the cantilever angle. Scans using these probes reveal an improvement in image accuracy over conventional tips, while allowing higher aspect ratio imaging of 3D surface features. Furthermore, the lifetimes of CNT-CNT composite tips are observed to be longer than both conventional tips and those claimed for other CNT technologies. Novel applications include the imaging of embiid silk.

<sup>1</sup>Supported by the Clare Boothe Luce Research Scholars Award and Carbon Design Innovations

**8:36AM A46.00004 Nanometer-scale scanning magnetometry of spin structures and excitations using Nitrogen-vacancy centers**, YULIYA DOVZHENKO, Department of Physics, Harvard University — The development of increasingly sensitive scanning techniques has led to new insights into the physics of interacting condensed matter systems. Recently, Nitrogen-Vacancy (NV) centers in diamond emerged as a promising scanning magnetic imaging platform capable of operating in a broad range of temperatures and magnetic fields, with sensitivity and resolution capable of imaging a single electron spin with sub-nanometer resolution under ambient conditions [1,2]. In this talk we will review some of the recent developments in this new scanning platform. We will describe our recent progress in using a single NV center in a scanning diamond nano-pillar to study condensed matter magnetism at both room and low temperatures. In particular, we demonstrate the use of scanning NV magnetometry to image stray fields originating from static chiral spin structures, as well as to detect resonant and off-resonant low-energy spin excitations [3]. [1] Grinolds et al., Nature Phys 9, 215 (2013) [2] Grinolds et al., Nature Nanotech. 9, 279 (2014) [3] Van der Sar et al., Nature Comm. 6, 7886 (2015)

**9:12AM A46.00005 Nanoscale imaging of paramagnetic spin labels using a single spin in diamond.**, AMILA ARIYARATNE, BRYAN MYERS, MATTHEW PELLICIONE, ANIA JAYICH, University of California Santa Barbara — Spin-labeling molecules with paramagnetic species is a powerful technique for probing molecular structure. However, current techniques are ensemble measurements, inherently lacking the sensitivity to detect a single spin or the conformational properties of a single biomolecule. In this talk, we demonstrate an imaging technique that has the promise of single-spin imaging and ultimately molecular structure imaging. We present two-dimensional nanoscale imaging of a monolayer of gadolinium (Gd) atomic spin labels at ambient conditions. The sensing element is a single nitrogen-vacancy (NV) center in diamond. A patterned monolayer of Gd atoms self-assembled on a Si atomic force microscopy tip is controllably interacted with and detected by the NV center. The fluctuating magnetic field generated by GHz-scale Gd spin flips relaxes the NV center in a manner that depends strongly on the Gd-NV separation. Using this technique, we demonstrate a Gd-induced reduction of the T1 relaxation time of the NV center with nm spatial resolution. Our results indicate that nanometer-scale imaging of individual electronic spins at ambient conditions is within reach. This will ultimately enable the study of structural and functional studies of single biomolecules in their native, folded state.

**9:24AM A46.00006 ABSTRACT WITHDRAWN —**

**9:36AM A46.00007 How to simultaneously scan connected tips in a dual-tip STM**, WAN-TING LIAO, Univ of Maryland-College Park, MICHAEL DREYER, Laboratory for Physical Sciences, JAMES ANDERSON, CHRISTOPHER LOBB, FREDERICK WELLSTOOD, Univ of Maryland-College Park — Starting with a dual independent-tip scanning tunneling microscope (STM) design [1], we have connected the two tips by a short ( $\sim 3$  mm) flexible Nb foil strip that was patterned by a laser. To enable simultaneous imaging with both tips, we move both tips to within tunneling distance of a surface and modulate one tip's z-piezo at  $\sim 5$  kHz and the other at  $\sim 10$  kHz. The resulting combined tunneling current from the system has modulation at both frequencies, which we detect using two lock-in amplifiers. The two outputs ( $dI/dz_1$  and  $dI/dz_2$ ) are feedback to individual STM electronic controllers to allow simultaneous topographic imaging using both tips. We tested our setup at room temperature using Pt-Ir tips on Au/Mica and HOPG samples. The next step is to operate this dual-tip STM at 30 mK on a superconducting sample so that the device forms a novel type of scanning SQUID. Holding one of the tips fixed as a reference junction, the other tip will be scanned to image the gauge-invariant phase difference of a superconductor at the atomic scale [2]. [1] A. Roychowdhury, et al., Rev. Sci. Inst. 85, 04.706(2014) [2] D. F. Sullivan, et al., J. Appl. Phys. 113, 183905 (2013)

**9:48AM A46.00008 High-resolution imaging of interfacial water by noncontact atomic force microscopy**<sup>1</sup>, JINBO PENG, Peking University, JING GUO, School of Physics, Peking University, PROKOP HAPALA, Institute of Physics, Academy of Sciences of the Czech Republic, DUANYUN CAO, School of Physics, Peking University, PAVEL JELNEK, Institute of Physics, Academy of Sciences of the Czech Republic, LIMEI XU, ENGE WANG, YING JIANG, School of Physics, Peking University, COLLABORATIVE INNOVATION CENTER OF QUANTUM MATTER COLLABORATION — Resolving the hydrogen-bonding configuration of water on the solid surfaces with atomic-scale precision is crucial in water science yet it remains challenging. Recently we have shown the possibility of attacking this problem by STM based on the submolecular orbital imaging of water. However, STM mainly probes the spatial distribution of the density of states near the Fermi level, thus is not sensitive to the chemical structure of molecules. Here we report the ultrahigh resolution imaging of water molecules on a NaCl film by NC-AFM, which enables us to determine the topology of hydrogen-bonding network in unprecedented details. Comparison with the theoretical simulations reveals that the sharp features in the AFM images result from the relaxation of the tip apex mainly due to the electrostatic force between the tip and the water molecules. Our results shed new light on the underlying mechanism of the ultrahigh imaging with NC-AFM and highlight the importance of electrostatics in the imaging of polar molecules such as water.

**10:00AM A46.00009 Tip relaxation in atomic force microscopy imaging simulations to resolve intermolecular bonds**<sup>1</sup>, ALEX LEE, YUKI SAKAI, JIM CHELIKOWSKY, The University of Texas at Austin — Experimental noncontact atomic force microscopy (AFM) studies have reported distinct lines in regions with no electron density for a variety of systems. The appearance of these lines is unexpected because Pauli repulsion is thought to be the dominant factor in the AFM imaging mechanism. These lines have been proposed to represent intermolecular bonding. Recent theoretical studies have shown that accounting for tip probe relaxation can sharpen images and highlight features that make simulations more comparable to experiment. We will apply a similar tip relaxation scheme to our computational method—which uses an *ab initio* real-space pseudopotential formalism with frozen density embedding theory added—to the study of dibenzo[a,h]thianthrene and an 8-hydroxyquinoline dimer to develop our interpretation of imaged intermolecular bonds.

<sup>1</sup>Work is supported by the DOE under DOE/DE-FG02-06ER46286 and by the Welch Foundation under grant F-1837. Computational resources were provided by NERSC and XSEDE.

**10:12AM A46.00010 First-principles AFM image simulation with frozen density embedding theory**<sup>1</sup>, YUKI SAKAI, ALEX J. LEE, JAMES R. CHELIKOWSKY, Univ of Texas, Austin — We present efficient first-principles method of non-contact atomic force microscopy (nc-AFM). Ordinary nc-AFM simulations based on density functional theory (DFT) require exhaustive computational cost because it involves thousands of total energy calculations. Regarding the sample as a fixed external potential can reduce the computational cost, and we adopt frozen density embedding theory (FDET) for this purpose. Simulated nc-AFM images with FDET using a carbon monoxide tip well reproduces the full DFT images of benzene, pentacene, and graphene, although optimized tip-sample distances and interaction energies in FDET are underestimated and overestimated, respectively. The FDET-based simulation method is promising for AFM image simulation of surfaces and two-dimensional materials.

<sup>1</sup>This work was supported by U.S. DOE under grant No. DE-FG02-06ER46286 and award No. DE-SC0008877, and by Welch Foundation under Grant F-1837. Computational resources are provided by NERSC and TACC.

**10:24AM A46.00011 Isotope-Resolved and Charge-Sensitive Force Imaging Using Scanned Single Molecules**, YAN SUN, DOMINIK RASTAWICKI, YANG LIU, WARREN MAR, HARI MANOHARAN, Stanford University, ANNA MIGLIO, SORIN MELINTE, JEAN-CHRISTOPHE CHARLIER, GIAN-MARCO RIGNANESI, Université catholique de Louvain, LIANHUA HE, FANG LIU, AIHUI ZHOU, Chinese Academy of Sciences — Originally conceived as surface imaging instruments, the scanning tunnelling microscope (STM) and the atomic force microscope (AFM) were recently used to probe molecular chemical bonds with exquisite sensitivity. Remarkably, molecule-functionalized scanning tips can also provide direct access to the inelastic electron tunneling spectrum (IETS) of the terminal molecule. Here we report atomic manipulation experiments addressing carbon monoxide (CO) isotopes at low temperatures. The unique and quantifiable dependence of the CO vibrational modes offers insight into tip-controlled force and charge sensing of surface adsorbates, subsurface defects, and quantum nanostructures. The specific behavior of the monitored vibrational modes originates from the interplay of interaction forces between the top electrode—a scanned tip functionalized with a single molecule—and the atomic scale force field surrounding the target atomically-assembled nanostructure. We also present density functional theory (DFT) computations that have been performed in order to scrutinize and visualize the vibrational spectroscopic fingerprints and local force fields.

**10:36AM A46.00012 A cryogen-free variable temperature scanning tunneling microscope capable for inelastic electron tunneling spectroscopy**, SHUAI ZHANG, DI HUANG, SHIWEI WU, Fudan University — While low temperature scanning tunneling microscope (STM) has become an indispensable research tool in surface science, its versatility is yet limited by the shortage or high cost of liquid helium. The makeshifts include the use of alternative cryogen (such as liquid nitrogen) at higher temperature or the development of helium liquefier system usually at departmental or campus wide. The ultimate solution would be the direct integration of a cryogen-free cryocooler based on GM or pulse tube closed cycle in the STM itself. However, the nasty mechanical vibration at low frequency intrinsic to cryocoolers has set the biggest obstacle because of the known challenges in vibration isolation required to high performance of STM. In this talk, we will present the design and performance of our home-built cryogen-free variable temperature STM at Fudan University. This system can obtain atomically sharp STM images and high resolution dI/dV spectra comparable to state-of-the-art low temperature STMs, but with no limitation on running hours. Moreover, we demonstrated the inelastic tunneling spectroscopy (STM-IETS) on a single CO molecule with a cryogen-free STM for the first time.

**10:48AM A46.00013 Cryogen free scanning probe microscope: the solution for atomic scale surface science below 10 Kelvin without liquid helium**, BYOUNG CHOI, MIGUEL VENEGAS, RHK Technology Inc., RHK TEAM — We present a cryogen free low temperature scanning probe microscope (LT-SPM) working at 9K on both tip and sample. The performance of the microscope was validated in various conditions such as noisy environment and modulated temperature as well as the long time elapsed measurements. Building on the stability and consistency of the closed cycle refrigerator, time extended measurements are available with this state-of-the-art LT-SPM. Studies can now be performed without interrupting the critical moment of the tip on the surface while refilling the conventional liquid cryogen tank. We will present the time evolution of the dopant induced topographic and spectroscopic properties of some topological insulators such as Bi<sub>2</sub>Se<sub>3</sub> and Bi<sub>2</sub>Te<sub>3</sub>. The compact and rigid design of the microscope also allows this instrument to work as a practical variable temperature microscope without the hassle of liquid cryogen consumption. We will present temperature dependent STM/STS results on a TiSe<sub>2</sub> surface at the temperature between 10K and 350K. Finally, we will discuss how the cryogen free LT-SPM will make the study of the atomic scale phenomenon at low temperature both economical and easy, opening promising new capabilities to surface scientists and researchers in nanotechnology.

**Monday, March 14, 2016 8:00AM - 11:00AM –**

**Session A47 DCMP: Surface and Thin Film Phase Transitions and Electronic Properties 312 -**

Daniel Dougherty, North Carolina State University

**8:00AM A47.00001 High  $T_{\text{IMT}}$  insulator-to-metal transition of the  $\text{VO}_2$  films on AlN/Si substrate.** , TETIANA SLUSAR, JIN-CHEOL CHO, BONG-JUN KIM, HYUN-TAK KIM, MIT Center in ETRI — Electrical and structural properties of the  $\text{VO}_2$  thin films are strongly affected by growth conditions and underlying substrate providing a flexibility of their functional parameters. We present a new  $\text{VO}_2/\text{AlN}/\text{Si}$  heterostructure, where  $\text{VO}_2$  is characterized by an excellent insulator-to-metal transition (IMT) occurred at a higher temperature  $T_{\text{IMT}}$  than that typical for single crystals. Mentioned characteristics are associated with growth mechanism of the film and its epitaxial alignment with respect to the substrate. In particular, the  $T_{\text{IMT}}$  upshift in  $\text{VO}_2/\text{AlN}/\text{Si}$  is explained by a stable crystallographic configuration in the plane of the  $\text{VO}_2$  film as well as a tensile deformation of a monoclinic  $a$ -axis formed by tilted and dimerized  $\text{V}^{4+}\text{-V}^{4+}$ , responsible for strong electron correlations. Moreover, proposed synergy of  $\text{VO}_2$  and Si is able to make new results for advanced materials fabrication and development of switching devices of new generation.

**8:12AM A47.00002 Ultrafast dynamics of  $\text{VO}_2$  thin films measured in pump-probe configuration**<sup>1</sup>, ELIZABETH RADUE, William and Mary College, SALINPORN KITTIWATANAKUL, JIWEI LU, S. A. WOLF, University of Virginia, ZHENGPING FU, MASASHI YAMAGUCHI, RPI, ENRICO ROSSI, R. A. LUKASZEW, IRINA NOVIKOVA, William and Mary College — The semiconductor-metal transition of  $\text{VO}_2$  continues to be a vigorously studied phenomenon due to complicated interplay between the structural change and the electronic bands. It is also potentially a very useful material, particularly because of its ultrafast transition to the metallic state excited with a femtosecond pulse. We have been exploring the effects of polarization of the pump in relation to the probe affects the sub-picosecond response of  $\text{VO}_2$  thin films, which will be important in designing ultrafast switches. We have also been looking at pumping our  $\text{VO}_2$  films with a THz source that directly pumps the lattice, and have found the film responds optically on a slower scale than when pumped with 800 nm, suggesting that there is an electronic response from disturbing the lattice.

**8:24AM A47.00003 Investigation of the Effect of Crystal Thickness on Free-Standing Vanadium Dioxide Nanocrystals**<sup>1</sup>, SERKAN KASIRGA, MUSTAFA FADLELMULA, Bilkent University- UNAM — The first-order metal-insulator transition (MIT) that vanadium dioxide exhibits at 65 °C has been extensively studied in the last decade thanks to the growth of single crystal nanobeams/plates smaller than characteristic domain size as well as the advances in epitaxial film growth techniques. The effect of crystal thickness has been studied extensively in epitaxially grown  $\text{VO}_2$  films yet not in free-standing nanocrystals[1]. This is mainly due to lack of control over the crystal thickness in physical vapor transport growth of the nanocrystals. Here, we report first observations on the MIT of  $\text{VO}_2$  nanocrystals grown on oxidized silicon substrate thinned using argon-ions. Among these observations AFM measurements reveal an etch rate of 4 nm/min for 1keV Ar-ion energy. Two terminal suspended nanobeam measurements reveal an intriguing phase transition properties below a threshold thickness. [1]Aetukuri, N.B. et al. Nature Phys. 9, 661-666 (2013).

**8:36AM A47.00004 Cryogenic optical nano-imaging of phase coexistence in correlated oxides**, A. S. MCLEOD, University of California San Diego, E. VAN HEUMEN, University of Amsterdam, J. ZHANG, J. G. RAMIREZ, University of California San Diego, Z. HUANG, University of Science and Technology of China, Hefei, S. WANG, T. SAERBECK, S. GUENON, M. GOLDFLAM, L. ANDEREGG, P. KELLY, A. MUELLER, University of California San Diego, M. K. LIU, Stony Brook University, W. B. WU, University of Science and Technology of China, Hefei, R. D. AVERT, I. K. SCHULLER, D. N. BASOV, University of California San Diego — Correlated transition metal oxides exhibit a bevy of textbook electronic phases characterized by richly interacting lattice, spin, and orbital degrees of freedom. A broad array of accessible thermodynamic phases, ranging from Mott insulator to superconductor, enables abrupt transitions in physical and electronic properties under modest external stimuli, accompanied by spontaneous phase coexistence at the nano-scale. We present a novel near-field optical scanning probe capable of resolving the electronic character of such “switched” phases in the coexistent regime, even insulators, at 10 nm resolution and down to liquid helium temperatures. We demonstrate variable-temperature optical, structural, and magnetic imaging functionalities through studies of the insulator-metal transition in two prototypic correlated oxides under epitaxial strain. Structural and electronic attributes of the Mott transition are distinguished in a  $\text{V}_2\text{O}_3$  thin film, whereas metastable electronic and magnetic phase coexistence is revealed across a 200K range in the strained manganite  $\text{La}_{0.67}\text{Ca}_{0.33}\text{MnO}_3$

**8:48AM A47.00005 Collapse of the low temperature insulating state in Cr-doped  $\text{V}_2\text{O}_3$  thin films**, PIA HOMM, LEANDER DILLEMANS, MARIELA MENGHINI, BART VAN BILZEN, PETAR BAKALOV, CHEN-YI SU, RUBEN LIETEN, MICHEL HOUSSA, JIN WON SEO, JEAN-PIERRE LOCQUET, KU Leuven, DAVOUD NASR ESFAHANI, LUCIAN COVANI, FRANCOIS PEETERS, University of Antwerp — We have grown epitaxial Cr-doped  $\text{V}_2\text{O}_3$  thin films with Cr concentrations between 0 and 20% on (0001)- $\text{Al}_2\text{O}_3$  by oxygen-assisted molecular beam epitaxy. For the highly doped samples (> 3%), a regular and monotonous increase of the resistance with decreasing temperature is measured. Strikingly, in the low doping samples (between 1% and 3%), a collapse of the insulating state is observed with a reduction of the low temperature resistivity by up to 5 orders of magnitude. A vacuum annealing at high temperature of the films recovers the low temperature insulating state for doping levels below 3% and increases the room temperature resistivity towards the values of Cr-doped  $\text{V}_2\text{O}_3$  single crystals. It is well known that oxygen excess stabilizes a metallic state in  $\text{V}_2\text{O}_3$  single crystals. Hence, we propose that Cr doping promotes oxygen excess in our films during deposition, leading to the collapse of the low temperature insulating state at low Cr concentrations. These results suggest that slightly Cr-doped  $\text{V}_2\text{O}_3$  films can be interesting candidates for field effect devices.

**9:00AM A47.00006 Modified Young's equation for equilibrium dihedral angles of grain boundary grooves in thin films at the nanoscale**, MING-WEI LIU, SHANG-CHUN LIN, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan, MOGADALAI GURURAJAN, Department of Metallurgical Engineering and Materials Science, Indian Institute of Technology-Bombay, Powai Mumbai, India, KUO-AN WU, Department of Physics, National Tsing Hua University, Hsinchu, Taiwan — We derive the modified Youngs equation for the equilibrium dihedral angle at the triple junction of the grain boundary groove by taking into account the discrete structure of the low angle grain boundary. For low angle grain boundaries, the geometric relation that the misorientation of the bicrystal is inversely proportional to the dislocation spacing naturally gives rise to the variation in the misorientation when the grain boundary length changes (holding the number of dislocations constant). The fact that the grain boundary energy increases as the grain boundary length decreases due to a smaller dislocation spacing leads to a larger dihedral angle compared to that of the classical theory. Two atomistic continuum modelling tools, namely the phase field crystal model and the amplitude equations, are used to simulate the equilibrium dihedral angle. The numerical results are in quantitatively good agreement with the derived modified Youngs equation.

**9:12AM A47.00007 First measurements of bulk and shear mechanical loss in optical thin film materials**, MATTHEW ABERNATHY, Naval Research Lab, GREGORY HARRY, JONATHAN NEWPORT, HANNA FAIR, SAM HICKEY, American University, ANDRI GRETARSSON, Embry-Riddle Aeronautical University, STEVE PENN, Hobart and William Smith Colleges, LIGO COLLABORATION — As advanced gravitational wave detectors come online, and the possibility of the first gravitational wave detection nears, plans for the next generation of gravitational wave detectors are already in the works. These new detectors, and those already planned for the future, are expected to be limited in their most sensitive frequency bands by the Brownian thermal noise generated within the optical thin films used to produce the interferometer mirrors. In order to predict the level of this Brownian noise, it is necessary to know the two independent mechanical moduli (Young modulus and Poisson ratio, Bulk and Shear moduli, etc.) as well as their associated mechanical loss parameters. Traditional measurements of the mechanical loss of thin films has measured only one linear combination of these two loss parameters. Here, we present measurements of the bulk and shear mechanical loss of tantalum pentoxide (tantala) thin films made by taking advantage of the differing ratios of elastic deformation in the various resonant modes of a coated silica disc. These results may have immediate implications for the ultimate sensitivity of currently operated gravitational wave detectors.

**9:24AM A47.00008 Between Crystal and Glass: Thermal Transport in C60 Molecular Crystals<sup>1</sup>**, SIMON LU, SUSHANT KUMAR, ALAN MCGAUGHEY, Department of Mechanical Engineering, Carnegie Mellon University — Molecular crystals of the fullerene C60 and its derivatives [e.g., phenyl-C61-butyric acid methyl ester (PCBM)] are candidate materials for use in photovoltaics and thermoelectrics. In thermoelectrics, their usefulness is due in part to their exceptionally low thermal conductivities (0.4 W/m-K for C60 and 0.05 W/m-K for PCBM) at room temperature. Little is known regarding the microscopic physics underlying these low thermal conductivities. An important question is whether thermal transport in the C60 molecular crystal is (i) crystal-like, where energy is transported as collective vibrations of the centers of mass of the molecules, or (ii) amorphous-like, where energy diffuses from molecule to molecule. We use molecular dynamics (MD) simulations and the Green-Kubo method to probe this question by predicting the relative contributions of crystal-like and amorphous-like transport to the thermal conductivity of the C60 molecular crystal. To isolate crystal-like transport, we perform simulations on C60 crystals where molecular rotations and intra-molecular vibrations are prohibited. To isolate amorphous-like transport, we fix the centers of mass of the molecules. We compare the MD results to predictions from a fully diffusive network resistance model.

**9:36AM A47.00009 C<sub>60</sub>-Induced Devil's Staircase Transformation on Pb/Si(111) Wetting Layer<sup>1</sup>**, LIN-LIN WANG, Ames Lab, DUANE D. JOHNSON, Ames Lab and Department of Materials Science and Engineering, Iowa State University, MICHAEL C. TRINGIDES, Ames Lab and Department of Physics, Iowa State University — Density functional theory is used to study structural energetics of Pb vacancy cluster formation on C<sub>60</sub>/Pb/Si(111) to explain the unusually fast and error-free transformations between the "Devil's Staircase" (DS) phases on the Pb/Si(111) wetting layer at low temperature (~110 K). The formation energies of vacancy clusters are calculated in C<sub>60</sub>/Pb/Si(111) as Pb atoms are progressively ejected from the initial dense Pb wetting layer. Vacancy clusters larger than 5 Pb atoms are found to be stable with 7 being the most stable, while vacancy clusters smaller than 5 are highly unstable, which agrees well with the observed ejection rate of ~5 Pb atoms per C<sub>60</sub>. The high energy cost (~0.8 eV) for the small vacancy clusters to form indicates convincingly that the unusually fast transformation observed experimentally between the DS phases, upon C<sub>60</sub> adsorption at low temperature, cannot be the result of single-atom random walk diffusion but correlated multi-atom processes.

<sup>1</sup>DOE Office of Science, Basic Energy Sciences from the Divisions of MSE (DE-AC02-07CH1135) and Ames Lab LDRD. Ames Laboratory is operated for DOE by Iowa State University under contract DE-AC02-07CH11358.

**9:48AM A47.00010 Competing length scales for the electronic structure of rings of C60**, JERRY TAN, University of Maryland, GARNETT BRYANT, National Institute of Standards and Technology — Recently, rings of C60 have been fabricated. This opens up the possibility of studying the electronic structure of complex nanosystems with competing length scales: here the length scale defined by individual C60 molecules, the length scale defined by moving along the inner edge of the ring of C60s, and the length scale for the outer edge. The effects of such competing length scales could be probed with a magnetic field B. We use a tight-binding model to study these effects theoretically. Noninteracting electrons are considered. B is included with a Peierls transformation. Calculated electronic spectrum for an isolated ring of carbons, here used as a simple model for C60, is compared with spectra for rings of carbon rings. Changes in spectra due to inter-ring hopping are identified. New structure in the density of states is correlated with the spatial distribution of states in rings of rings. A magnetic field is applied to access and couple different length scales. Calculated spectra for rings of full C60 molecules are compared with the model results to highlight the effects of competing length scales in C60 rings. Results are used to suggest possible experiments for rings of C60 molecules.

**10:00AM A47.00011 The Size and Shape dependence of the Surface Free Energy of Nanocrystals**, ESAM ABDUL-HAFIDH, Yanbu University College — Based on many recent reports, it became possible to control the synthesis of nanomaterials with certain sizes and shapes. A theoretical model to investigate the effect of size and shape on the surface free energy of nanocrystals is worked out in this research. The model is applied to a general shape and size nanocrystal designated by a shape factor. The model considers all nanocrystals with different morphologies (but with the same shape factor) to be the same. The results were tested for gold and silver. The surface free energy was found to decrease with size for spherical nanocrystals. On the other hand, the surface free energy is enhanced for non-spherical nanocrystals. These findings are in qualitative agreement with previous experimental and theoretical predictions. The results pave the road to manufacture controlled- mechanical properties materials.

**10:12AM A47.00012 Theory of Space Charge Limited Current in Fractional Dimensional Space**, MUHAMMAD ZUBAIR, L.K. ANG, Engineering Product Development, Singapore University of Technology and Design, East Coast Campus, 8 Somapah Road, Singapore 487372, Singapore — The concept of fractional dimensional space has been effectively applied in many areas of physics to describe the fractional effects on the physical systems. We will present some recent developments of space charge limited (SCL) current in free space and solid in the framework of fractional dimensional space which may account for the effect of imperfectness or roughness of the electrode surface. For SCL current in free space, the governing law is known as the Child-Langmuir (CL) law. Its analogy in a trap-free solid (or dielectric) is known as Mott-Gurney (MG) law. This work extends the one-dimensional CL Law and MG Law for the case of a *D*-dimensional fractional space with  $0 < D \leq 1$ ; where parameter *D* defines the degree of roughness of the electrode surface. Such a fractional dimensional space generalization of SCL current theory can be used to characterize the charge injection by the imperfectness or roughness of the surface in applications related to high current cathode (CL law), and organic electronics (MG law). In terms of operating regime, the model has included the quantum effects when the spacing between the electrodes is small.

**10:24AM A47.00013 Significantly enhanced giant Rashba splitting in a thin film of binary alloy.** , SHU-JUNG TANG, Department of Physics, National Tsing Hua University, WEI-CHUAN CHEN, National Synchrotron Radiation Research Center, Hsinchu, Taiwan, TAY-RONG CHANG, SUN-TING TSAI, JE-MING KUO, Department of Physics, National Tsing Hua University, SH. YAMAMOTO, Institute for Solid State Physics, the University of Tokyo, CHENG-MAW CHENG, KU-DING TSUEI, National Synchrotron Radiation Research Center, Hsinchu, Taiwan , KOICHIRO YAJI, Institute for Solid State Physics, the University of Tokyo, HSIN LIN, Graphene Research Centre and Department of Physics, National University of Singapore, HORNG-TAY JENG, CHUNG-YU MOU, Department of Physics, National Tsing Hua University, IWAO MATSUDA, Institute for Solid State Physics, the University of Tokyo — Dirac cones in a 2D environment have attracted much attention not only because of the massless Dirac fermions but also due to their capability to lock the spin direction with the momentum. Here we demonstrate that the Rashba effect within a single layer of a binary alloy composed of heavy atoms, Pb and Au, can be driven by and even tweaked with the adjacent top and bottom layers to yield cones-like structures and further enhance the Rashba coupling strength. Two cones are observed at the surface zone center  $\bar{\Gamma}$  with giant Rashba parameters 1.53 and 4.45 eV; an anisotropic giant Rashba splitting at the surface zone boundary  $\bar{M}$  has a great value, 6.26 eV, inferring the critical role of  $p$ - $d$  hybridization between Pb and Au. Our results reveal not only an interesting natural phenomenon but also a feasible method of tweaking the Rashba effect of a 2D system.

**10:36AM A47.00014 Photoemission from Shockley surface state on Ag(111)** , SIDDHARTH KARKARE, WEISHI WAN, JUN FENG, HOWARD PADMORE, Lawrence Berkeley National Lab — We present measurements of quantum yield and transverse momentum distributions of electrons emitted from the Shockley surface state on Ag(111) surface using near threshold photons. Our measurements shed light on the validity of the conservation of transverse momentum during photoemission when the kinetic energy of electrons is less than 0.1 eV. We also develop a one-step photoemission model that quantitatively explains photoemission from single crystal metal surfaces. This model accurately calculates the dependence of the electron yield on the angle of incidence and the polarization of incident light (vectorial photoelectric effect). We show excellent agreement between the measured and calculated photoemission properties of the Ag(111) surface. Our measurements show that Ag(111) surface can act as an excellent electron source for several applications like Free Electron Lasers and Ultra-fast Electron Diffraction.

**10:48AM A47.00015 A new approach to measure spatially resolved thermovoltage** , KAI SOTTHEWES, MARTIN SIEKMAN, HAROLD ZANDVLIET, University of Twente — We have recorded spatial maps of the thermovoltage of a Au(111) surface with a scanning tunneling microscope using a novel approach. The novel approach relies a method where we record quasisimultaneously the normal topography as well as the thermovoltage by switching the feedback and sample bias on and off. The thermovoltage, which arises from a temperature difference between scanning tunneling microscope tip and sample, is very sensitive to small variations of the local electronic density of states in vicinity of the Fermi level. Near step edges and defects we have observed well-defined Friedel oscillations.

**Monday, March 14, 2016 8:00AM - 11:00AM —**  
**Session A48 GQI: Quantum Computing and Quantum Simulations with Superconducting Circuits** 349 - David Schuster, University of Chicago

**8:00AM A48.00001 Digitized adiabatic quantum computing with a superconducting circuit, part I: Theory** , L. LAMATA, University of the Basque Country, Spain, R. BARENDT, Google, Santa Barbara, USA , A. SHABANI, Google, Venice, USA , J. KELLY, Google, Santa Barbara, USA, A. MEZZACAPO, U. LAS HERAS, University of the Basque Country, Spain, R. BABUSH, Google, Venice, USA, A. G. FOWLER, Google, Santa Barbara, USA, B. CAMPBELL, University of California, Santa Barbara, USA , YU CHEN, Google, Santa Barbara, USA, Z. CHEN, B. CHIARO, A. DUNSWORTH, University of California, Santa Barbara, USA, E. JEFFREY, E. LUCERO, Google, Santa Barbara, USA, A. MEGRANT, University of California, Santa Barbara, USA, J. Y. MUTUS, M. NEELEY, Google, Santa Barbara, USA, C. NEILL, P. J. J. OMALLEY, C. QUINTANA, University of California, Santa Barbara, USA, P. ROUSHAN, Google, Santa Barbara, USA, E. SOLANO, University of the Basque Country, Spain, and IKERBASQUE, Spain, H. NEVEN, Google, Venice, USA, JOHN M. MARTINIS, Google, Santa Barbara, USA, and University of California, Santa Barbara, USA — Adiabatic quantum computing (AQC) is a general-purpose optimization algorithm that in contrast to circuit-model quantum algorithms can be applied to a large set of computational problems. An analog physical realization of AQC has certain limitations that we propose can be overcome by a gate-model equivalence of the AQC. In this talk we discuss the hardware advantages of digitized AQC in particular arbitrary interactions, precision, and coherence. We could experimentally realize the principles of digitized AQC on a chain of nine qubits, and highlight the physics of adiabatic evolutions as well as the Kibble-Zurek mechanism.

**8:12AM A48.00002 Digitized adiabatic quantum computing with a superconducting circuit, part II: Experiment** , R. BARENDT, A. SHABANI, Google Inc., L. LAMATA, University of the Basque Country, Spain, J. KELLY, Google Inc., A. MEZZACAPO, U. LAS HERAS, University of the Basque Country, Spain, R. BABUSH, A.G. FOWLER, Google Inc., B. CAMPBELL, UC Santa Barbara, Y. CHEN, Z. CHEN, Google Inc., B. CHIARO, A. DUNSWORTH, UC Santa Barbara, E. JEFFREY, E. LUCERO, A. MEGRANT, J. MUTUS, M. NEELEY, Google Inc., C. NEILL, P. O'MALLEY, C. QUINTANA, UC Santa Barbara, P. ROUSHAN, Google Inc., E. SOLANO, University of the Basque Country, Spain, H. NEVEN, J. MARTINIS, Google Inc. — A major challenge in quantum computing is to solve general problems with limited physical hardware. We implement digitized adiabatic quantum computing, combining the generality of the adiabatic algorithm with the universality of the digital approach, using a superconducting circuit with nine qubits. We probe the adiabatic evolutions, explore the scaling of errors with system size, and quantify the success of the algorithm for random spin problems. We find that the system can approximate the solutions to both frustrated Ising problems and non-stoquastic problem Hamiltonians with a performance that is comparable.

**8:24AM A48.00003 Digital quantum simulations with superconducting circuits** , URTZI LAS HERAS, LAURA GARCIA-ALVAREZ, LUCAS LAMATA, University of the Basque Country, Spain, ENRIQUE SOLANO, University of the Basque Country and IKERBASQUE, Spain — Superconducting circuits are a promising quantum technology for the implementation of quantum information protocols. In particular, digital quantum simulations are an efficient method for reproducing dynamics that are not produced naturally in the simulating system. We propose a method for simulating efficiently the dynamics of prototypical spin and fermionic models in circuit quantum electrodynamics architectures with either qubit-qubit pairwise interactions or resonators acting as quantum buses. We show how to implement Ising and Heisenberg spin models, and the Fermi-Hubbard model, making use of the Jordan-Wigner mapping and Mølmer-Sørensen gates.

**8:36AM A48.00004 Quantum simulation of micro and macro frustrated quantum magnetism with superconducting circuits.**<sup>1</sup> , JOYDIP GHOSH, BARRY C. SANDERS, Univ of Calgary — We devise a scalable scheme for simulating a quantum phase transition from paramagnetism to frustrated magnetism in a superconducting flux-qubit network, and show how to characterize this system experimentally both macroscopically and microscopically. The proposed macroscopic characterization of the quantum phase transition is based on the transition of the probability distribution for the spin-network net magnetic moment with this transition quantified by the difference between the Kullback-Leibler divergences of the distributions corresponding to the paramagnetic and frustrated magnetic phases with respect to the probability distribution at a given time during the transition. Microscopic characterization of the quantum phase transition is performed using the standard local-entanglement-witness approach. Simultaneous macro and micro characterizations of quantum phase transitions would serve to verify in two ways a quantum phase transition and provide empirical data for revisiting the foundational emergentist-reductionist debate regarding reconciliation of macroscopic thermodynamics with microscopic statistical mechanics especially in the quantum realm for the classically intractable case of frustrated quantum magnetism.

<sup>1</sup>NSERC, AITF and University of Calgarys Eyes High Fellowship Program

**8:48AM A48.00005 Engineering artificial Hamiltonians with parametric superconducting circuits** , YAO LU, SRIVATSAN CHAKRAM, NELSON LEUNG, RAVI NAIK, NATHAN EARNEST, James Franck Institute and Department of Physics, University of Chicago, PETER GROSZKOWSKI, JENS KOCH, Department of Physics & Astronomy, Northwestern University, ELIOT KAPIT, Department of Physics & Engineering Physics, Tulane University, DAVID SCHUSTER, James Franck Institute and Department of Physics, University of Chicago — One major challenge in building a large scale quantum computer is to generate and manipulate interactions between its many qubits. One promising approach is to use parametric flux or voltage modulation to realize effective interactions between different components of superconducting circuits, generating artificial Hamiltonians that are suitable for various quantum computation tasks, which might be difficult to achieve through other means. We propose a parametric superconducting circuit where transmon qubits and resonators are coupled to a flux-modulated parametric coupler. We show that with this device, arbitrary pairs of qubits or resonators in the circuit can be selectively and simultaneously brought into resonance with each other and swap excitations at a controllable rate. This allows for the creation of various artificial circuit Hamiltonians that are suitable for a number of applications such as single qubit state stabilization, parametric qubit state readout, autonomous error correction and so on.

**9:00AM A48.00006 Strongly interacting photons in a synthetic magnetic field** , PEDRAM ROUSHAN, Google, Inc., C. NEILL, UCSB, A. MEGRANT, Y. CHEN, R. BARENDS, Google, Inc., B. CAMBELL, Z. CHEN, B. CHIARO, A. DUNSWORTH, UCSB, A. FOWLER, E. JEFFREY, J. KELLY, E. LUCERO, J. MUTUS, Google, Inc., P. O'MALLEY, UCSB, M. NEELEY, C. QUINTANA, D. SANK, Google, Inc., A. VAINSENCER, J. WENNER, UCSB, T. WHITE, Google, Inc., E. KAPIT, Tulane University, J. MARTINIS, Google, Inc. — Interacting electrons in the presence of magnetic fields exhibit some of the most fascinating phases in condensed matter systems. Realizing these phases in an engineered platform could provide deeper insight into their. Using three superconducting qubits, we synthesize artificial magnetic fields by modulating the inter-qubit coupling. In the closed loop formed by the qubits, we observe the directional circulation of a microwave photon as well as chiral groundstate currents, the signatures of broken time-reversal symmetry. The existence of strong interactions in our system is seen via the creation of photon vacancies, or "holes", which circulate in the opposite direction from the photons. Our work demonstrates an experimental approach for engineering quantum phases of strongly interacting bosons.

**9:12AM A48.00007 Emulating the 1-Dimensional Fermi-Hubbard Model with Superconducting Qubits** , JAN-MICHAEL REINER, MICHAEL MARTHALER, GERD SCHN, Karlsruhe Institute of Technology — A chain of qubits with both  $ZZ$  and  $XX$  couplings is described by a Hamiltonian which coincides with the Fermi-Hubbard model in one dimension. The qubit system can thus be used to study the quantum properties of this model. We investigate the specific implementation of such an analog quantum simulator by a chain of tunable Transmon qubits, where the  $ZZ$  interaction arises due to an inductive coupling and the  $XX$  interaction due to a capacitive coupling.

**9:24AM A48.00008 Cavity-assisted cooling of Bose-Hubbard model simulator with superconducting circuits** , XIUHAO DENG, School of Natural Sciences, University of California Merced, CHUNJING JIA, Department of Applied Physics, Stanford University; Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator — Interesting progress have been made in using superconducting circuits to simulate Bose-Hubbard model (BHM). However, studying ground state feature of BHM calls for effective cooling process, where the cooling mechanism must preserve total number of simulated bosons and cooling rate has to be much stronger than decay rate. Here, we propose a cooling scheme that satisfies these two conditions by coupling an array of transmission line resonators with an assisted cavity. The quantum simulator we modelled here can be used to study generic BHM, which include both repulsive and attractive on-site interaction and hopping strength. We evaluate the cooling rate in all these regime analytically. And numerical simulation in time domain gives further supports. Our results present a promising cooling scheme for experiments.

**9:36AM A48.00009 Simulating chemical energies to high precision with fully-scalable quantum algorithms on superconducting qubits** , PETER O'MALLEY, UC Santa Barbara, RYAN BABBUSCH, Google Inc., Venice, CA, IAN KIVLICHAN, JHONATHAN ROMERO, Harvard University, JARROD MCCLEAN, Lawrence Berkeley National Lab, ANDREW TRANTER, Tufts University, RAMI BARENDS, JULIAN KELLY, YU CHEN, Google Inc., Santa Barbara, CA, ZIJUN CHEN, UC Santa Barbara, EVAN JEFFREY, AUSTIN FOWLER, Google Inc., Santa Barbara, CA, ANTHONY MEGRANT, UC Santa Barbara, JOSH MUTUS, Google Inc., Santa Barbara, CA, CHARLES NEILL, CHRISTOPHER QUINTANA, UC Santa Barbara, PEDRAM ROUSHAN, DANIEL SANK, Google Inc., Santa Barbara, CA, AMIT VAINSENCER, JAMES WENNER, UC Santa Barbara, THEODORE WHITE, Google Inc., Santa Barbara, CA, PETER LOVE, Tufts University, ALAN ASPURU-GUZIK, Harvard University, HARTMUT NEVEN, Google Inc., Venice, CA, JOHN MARTINIS, UC Santa Barbara and Google Inc. — Quantum simulations of molecules have the potential to calculate industrially-important chemical parameters beyond the reach of classical methods with relatively modest quantum resources. Recent years have seen dramatic progress both superconducting qubits and quantum chemistry algorithms. Here, we present experimental demonstrations of two fully-scalable algorithms for finding the dissociation energy of hydrogen: the variational quantum eigensolver and iterative phase estimation. This represents the first calculation of a dissociation energy to chemical accuracy with a non-precompiled algorithm. These results show the promise of chemistry as the "killer app" for quantum computers, even before the advent of full error-correction.

**9:48AM A48.00010 Hybrid Quantum-Classical Approach to Molecular Excited States On Superconducting Qubits** , JARROD MCCLEAN, Computational Research Division, Lawrence Berkeley National Laboratory, MOLLIE SCHWARTZ, CHRIS MACKLIN, IRFAN SIDDIQI, Quantum Nanoelectronics Laboratory, University of California, Berkeley, JONATHAN CARTER, WIBE DE JONG, Computational Research Division, Lawrence Berkeley National Laboratory — Quantum computers promise to dramatically advance our understanding of correlated quantum systems. Unfortunately, many proposed algorithms have resource requirements not yet suitable for near-term quantum devices. The variational quantum eigensolver (VQE) is a recently proposed hybrid quantum-classical method for solving eigenvalue problems and more generic minimizations on a quantum device leveraging classical resources to minimize coherence time requirements. However, this algorithm has so far focused only on the quantum ground state and has almost exclusively been studied in ideal closed system conditions. We briefly review the original VQE approach and introduce a simple extension requiring no additional coherence time to approximate excited states. Moreover, we show how the same method can be used to mitigate the effects of noise in a real system and how this algorithm can be applied in practice on a superconducting qubit architecture.

**10:00AM A48.00011 Implementation of a Quantum Variational Eigensolver in Superconducting Qubits**, MOLLIE SCHWARTZ, Quantum Nanoelectronics Laboratory, UC Berkeley, JARROD MCCLEAN, Computational Research Division, Lawrence Berkeley National Laboratory, CHRIS MACKLIN, Quantum Nanoelectronics Laboratory, UC Berkeley; Computational Research Division, Lawrence Berkeley National Laboratory, JONATHAN CARTER, WIBE ALBERT DE JONG, Computational Research Division, Lawrence Berkeley National Laboratory, IRFAN SIDDIQI, Quantum Nanoelectronics Laboratory, UC Berkeley; Materials Sciences Division, Lawrence Berkeley National Laboratory — The quantum variational eigensolver (QVE) represents an efficient implementation of quantum simulation that relies on a synergy between classical and quantum computing components. In this approach, a classical computer is used to map the target Hamiltonian onto a fermionic Hilbert space and to perform a variational update of the estimated ground state. This test state is then prepared in the quantum system, enabling an efficient estimation of the expectation value of the Hamiltonian and reducing the requirements for coherent qubit evolution. We present experimental progress toward implementing a QVE in superconducting qubits, capitalizing on the flexibility and scalability of the transmon cQED architecture.

**10:12AM A48.00012 Cavity-assisted dynamical quantum phase transition in superconducting quantum simulators<sup>1</sup>**, LIN TIAN, School of Natural Sciences, University of California, Merced, CA 95343 — Coupling a quantum many-body system to a cavity can create bifurcation points in the phase diagram, where the many-body system switches between different phases. Here I will discuss the dynamical quantum phase transitions at the bifurcation points of a one-dimensional transverse field Ising model coupled to a cavity. The Ising model can be emulated with various types of superconducting qubits connected in a chain. With a time-dependent Bogoliubov method, we show that an infinitesimal quench of the driving field can cause gradual evolution of the transverse field on the Ising spins to pass through the quantum critical point. Our calculation shows that the cavity-induced nonlinearity plays an important role in the dynamics of this system. Quasiparticles can be excited in the Ising chain during this process, which results in the deviation of the system from its adiabatic ground state.

**10:24AM A48.00013 Visualizing singularities of a groundstate landscape using superconducting circuits**, ERIK LUCERO, Google, Inc., A. DUNSWORTH, UCSB, P. ROUSHAN, A. MEGRANT, Google, Inc., C. NEILL, UCSB, T. SOUZA, M. TOMKA, M. KOLODRUBETZ, Boston University, Y. CHEN, R. BARENDT, Google, Inc., B. CAMPBELL, Z. CHEN, B. CHIARO, UCSB, E. JEFFREY, J. KELLY, J. MUTUS, Google, Inc., P. O'MALLEY, C. QUINTANA, UCSB, D. SANK, Google, Inc., J. WENNER, UCSB, T. WHITE, Google, Inc., A. POLKOVNIKOV, Boston University, J. MARTINIS, Google, Inc. — The defining properties of condensed matter phases are set by their groundstate wavefunctions. The adiabatic theorem provides an experimental approach for realizing such states. However, a general protocol for applying this theorem is experimentally unexplored, in particular when the energy gap is small. Using two superconducting qubits, we adiabatically prepare the entire groundstate manifold in a region of the parameter-space where degeneracies are present. We prepare these states by varying the Hamiltonian along 'geodesics' in parameter-space, obtained by minimizing the local non-adiabatic error. From the measured total magnetization of the final state, we compute the Berry curvature, where degeneracies appear as singular points, allowing us to directly visualize the degeneracies in the groundstate landscape.

**10:36AM A48.00014 Observation of the correspondence between Landau-Zener transition and Kibble-Zurek mechanism with a superconducting qubit system<sup>1</sup>**, MING GONG, DONG LAN, YUHAO LIU, XINSHENG TAN, HAIFENG YU, YANG YU, SHILIANG ZHU, School of Physics, Nanjing University, China, GUOZHU SUN, YU ZHOU, YUNYI FAN, PEIHENG WU, School of Electronic Science and Engineering, Nanjing University, China, XUEDA WEN, Department of Physics, University of Illinois at Urbana-Champaign, Urbana, IL 61801, USA, DANWEI ZHANG, Guangdong Provincial Key Laboratory of Quantum Engineering and Quantum Materials, SPTE, South China Normal University, Guangzhou 510006, China, SIYUAN HAN, Department of Physics and Astronomy, University of Kansas, Lawrence, KS 66045, USA — We present a direct experimental observation of the correspondence between Landau-Zener transition and Kibble-Zurek mechanism with a superconducting qubit system. We develop a time resolved approach to study quantum dynamics of the Landau-Zener transition. By using this method, we observe the key features of the correspondence between Landau-Zener transition and Kibble-Zurek mechanism, e.g., the boundary between the adiabatic and impulse regions, the freeze out phenomenon in the impulse region. Remarkably, the scaling behavior of the population in the excited state, an analogical phenomenon originally predicted in Kibble-Zurek mechanism, is also observed in the Landau-Zener transition.

**10:48AM A48.00015 Artificial Quantum Thermal Bath**, ALIREZA SHABANI, HARTMUT NEVEN, Google Quantum AI Lab — In this talk, we present a theory for engineering the temperature of a quantum system different from its ambient temperature, that is basically an analog version of the quantum metropolis algorithm. We define criteria for an engineered quantum bath that, when couples to a quantum system with Hamiltonian  $H$ , drives the system to the equilibrium state  $\frac{e^{-H/T}}{\text{Tr}(e^{-H/T})}$  with a tunable parameter  $T$ . For a system of superconducting qubits, we propose a circuit-QED approximate realization of such an engineered thermal bath consisting of driven lossy resonators. We consider an artificial thermal bath as a simulator for many-body physics or a controllable temperature knob for a hybrid quantum-thermal annealer.

**Monday, March 14, 2016 8:00AM - 11:00AM –**

**Session A51 FIAP: Nanomanufacturing and Optical/Laser/High Frequency Devices** Hilton Baltimore Holiday Ballroom 2 - Nicholas Charipar, Naval Research Lab

**8:00AM A51.00001 Laser printed interconnects for flexible electronics<sup>1</sup>**, ALBERTO PIQUE, IYOEL BENIAM, SCOTT MATHEWS, NICHOLAS CHARIPAR, Naval Research Laboratory — Laser-induced forward transfer (LIFT) can be used to generate microscale 3D structures for interconnect applications non-lithographically. The laser printing of these interconnects takes place through aggregation of voxels of either molten metal or dispersed metallic nanoparticles. However, the resulting 3D structures do not achieve the bulk conductivity of metal interconnects of the same cross-section and length as those formed by wire bonding or tab welding. It is possible, however, to laser transfer entire structures using a LIFT technique known as lase-and-place. Lase-and-place allows whole components and parts to be transferred from a donor substrate onto a desired location with one single laser pulse. This talk will present the use of LIFT to laser print freestanding solid metal interconnects to connect individual devices into functional circuits. Furthermore, the same laser can bend or fold the thin metal foils prior to transfer, thus forming compliant 3D structures able to provide strain relief due to flexing or thermal mismatch. Examples of these laser printed 3D metallic bridges and their role in the development of next generation flexible electronics by additive manufacturing will be presented.

**8:12AM A51.00002 Expanding the Range and Utility of Atomic Calligraphy<sup>1</sup>**, LAWRENCE BARRETT, THOMAS STARK, JEREMY REEVES, RICHARD LALLY, DAVID BISHOP, Boston University — Due to the many potential applications of nanotechnology, there is a drive for new methods of nanomanufacturing. Atomic calligraphy has shown promise, not only as faster and as more economical than conventional methods, but also more precise, potentially being able to place single atoms with nanometer resolution [1]. Atomic calligraphy utilizes nanoscale apertures to define where material is deposited during evaporation. Microelectromechanical systems (MEMS) allow the aperture to be moved with nanometer precision. The technique has been demonstrated, but only over a small range of several microns and structures were written on the same substrate as the MEMS. We have moved from this to a system where structures can be written on any surface over a range of centimeters. To achieve this, first a process for etching through the substrate without damaging the delicate MEMS was developed. Then a scheme for making electrical contact to the MEMS with a low enough profile to still allow the aperture to be brought in contact with the writing surface was devised. Finally, a system of piezo stages was installed to quickly and precisely move the aperture from one area to another. [1] M. Imboden, H. Han, J. Chang, F. Pardo, C. A. Bolle, E. Lowell, and D. J. Bishop, Nano Lett. 13, 3379 (2013).

**8:24AM A51.00003 3D Alignment of nanowriters using fringe capacitance<sup>1</sup>**, RICHARD LALLY, THOMAS STARK, JEREMY REEVES, LAWRENCE BARRETT, DAVID BISHOP, Boston University — With the introduction of atomic calligraphy, high resolution nanoscale structures can be fabricated rapidly over a large surface area [1]. This reliable, chemically stable and cost effective nanoscale writing method can be applied to a number of interesting applications. One specific application of this writing approach is to fabricate metamaterials, a process that requires precise alignment of the MEMS and substrate. Here we present a MEMS based solution coupling the well-studied comb drive capacitance effects [2] with the less predictable close order fringe effects. The combined capacitance allows for precise measurements in the nanometer range. Using two sets of orthogonal static MEMS comb drives, the capacitance is used to discern the x, y, and z spatial displacement from the substrate. The unique SOI wafer is prepared creating a periodic array of silicon pillars. Placement of additional MEMS comb drives at the MEMS device edges will allow stage corrections for tip, tilt and rotational alignment thereby reducing the effects generated by variations in wafer thickness and surface smoothness. **8:36AM A51.00004 Monolayer Tungsten Disulfide Laser**, YU YE, ZI JING WONG, UC Berkeley, XIUFANG LU, University of Science and Technology of China, XINGJIE NI, HANYU ZHU, UC Berkeley, XIANHUI CHEN, University of Science and Technology of China, YUAN WANG, XIANG ZHANG, UC Berkeley — Two-dimensional van der Waals materials have opened a new paradigm for fundamental physics exploration and device applications because of their emerging physical properties. Unlike gapless graphene, monolayer transition-metal dichalcogenides are two-dimensional semiconductors that undergo an indirect-to-direct band gap transition, creating new optical functionalities for next-generation ultra-compact photonics and optoelectronics. Here, we report the realization of a two-dimensional excitonic laser by embedding monolayer tungsten disulfide in a microdisk resonator.

**8:48AM A51.00005 Guided-Wave Plasmon Polariton Modes in High-Index Dielectric Structures**, RACHEL OWEN, JANELLE LEGER, BRAD JOHNSON, Western Washington University — Interest in subwavelength waveguides has increased as the need to interface between optical signals and increasingly small electronic components grows. Surface plasmon polaritons (SPPs) are surface charge density oscillations localized to a metal-dielectric interface that confine energy to a structure that is not diffraction limited. Thus, structures that support SPPs are promising candidates for subwavelength waveguides. However, most of the electric field propagates along the metal interface, causing Ohmic damping to restrict use to short-range applications. Here we present an architecture that supports high index dielectric plasmon polariton modes (HID-PPMs). These structures utilize the metal-dielectric-metal-substrate structure of typical SPP waveguides. However, the core dielectric layer has a higher refractive index than the substrate. This small structural change causes the bulk of the electric field to be concentrated in the dielectric region resulting in a dramatic reduction of damping effects. Here we present experimental evidence of HID-PPMs in a simple trilayer structure. Our results match model predictions with remarkable accuracy using minimal parameter modifications. We discuss these results as well as the potential applications of these devices.

**9:00AM A51.00006 Efficient directional excitation of surface plasmons by a single-element nanoantenna**, WENJIE YAO, SHANG LIU, HUIMIN LIAO, ZHI LI, CHENGWEI SUN, JIANJUN CHEN, QIHUANG GONG, Peking University — Directional light scattering is important in basic research and real applications. This area has been successfully downscaled to wavelength and subwavelength scales with the development of optical antennas, especially single-element nanoantennas. Here we show, by adding an auxiliary resonant structure to a single-element plasmonic nanoantenna, the highly efficient lowest-order antenna mode can be effectively transferred into inactive higher-order modes. Based on this mode conversion, scattered optical fields can be well manipulated by utilizing the interference between different antenna modes. Both broadband directional excitation of surface plasmon polaritons (SPPs) and inversion of SPP launching direction at different wavelengths are experimentally demonstrated as typical examples. The proposed strategy based on mode conversion and mode interference provides new opportunities for the design of nanoscale optical devices, especially directional nanoantennas.

**9:12AM A51.00007 Enhanced performance in SnO<sub>2</sub> thin film UV photodetectors via self-assembled CuO/SnO<sub>2</sub> nanoheterojunctions**, BOTONG QIU, Johns Hopkins Univ, TING XIE, MD HASAN, National Institute of Standards and Technology, EBUKA ARINZE, Johns Hopkins Univ, NHAN NGUYEN, ABHISHEK MOTAYED, National Institute of Standards and Technology, SUSANNA THON, Johns Hopkins Univ, RATAN DEBNATH, National Institute of Standards and Technology — Low-cost visible-blind ultraviolet (UV) photodetectors (PDs) are of interest for versatile applications in digital imaging, optical communications, and biomedical sensing. We report on the use of CuO/SnO<sub>2</sub> *p-n* nanoscale heterojunctions to enhance the performance of SnO<sub>2</sub> thin film UV PDs. Our method produces robust structures that operate at low bias without complex fabrication processes. The nanoheterojunctions are self-assembled by sputtering Cu clusters that oxidize in ambient to form CuO nanoparticles. The chemical identity, morphology and distribution of the nanoparticles are investigated through high-resolution XPS and AFM characterization. Enhanced UV absorption is demonstrated both experimentally and using optical simulations after addition of the CuO/SnO<sub>2</sub> nanoheterojunctions. The device performance improvements are attributed to the strong absorption in the CuO nanoparticles and electron transfer facilitated by the nanoheterojunctions. The PDs show a five-fold increase in peak responsivity at 0.2 V bias. The photoresponse factor, defined as the wavelength-dependent ratio between the photocurrent and dark current, was estimated to be 592 for the CuO-SnO<sub>2</sub> PD under 290 nm illumination.

**9:24AM A51.00008 Influence of cavity optomechanics on Kerr frequency combs**, RYO SUZUKI, AKITOSHI JINNAI, TAKUMA NAGANO, TOMOYA KOBATAKE, TAKUMI KATO, TAKASUMI TANABE, Keio University — The Kerr frequency comb has the potential for applications in, for example, spectroscopy, optical communication, waveform shaping and astronomy. Recently, the mechanism of soliton pulse generation in a microcavity has been studied numerically and experimentally. Silicon nitride ring and magnesium fluoride microcavities are commonly used in experimental research, because of their high nonlinearity, dispersion and other advantageous characteristics. On the other hand, silica toroid microcavities are not much used for Kerr comb research in the time domain (e. g. pulse generation/measurement). This is because toroid microcavities are prone to cavity optomechanical vibration, and the cavity dispersion of the fundamental mode of a small radius microcavity is normal. To fabricate a toroid microcavity with a large radius, we need to use a particular fabrication process. In this research, by controlling the detuning of the resonance and pump laser frequencies, we suppressed the noise of optomechanical vibration and obtained pulses with low background noise using higher order resonance modes. In addition, we observed optical pulses with repetition frequencies of up to 3.7 THz.

**9:36AM A51.00009 Open optical microcavities for CQED experiments and devices**, JASON SMITH, AURELIEN TRICHET, University of Oxford, PHILIP DOLAN, DAVID COLES, LUCAS FLATTEN, SAM JOHNSON, ROBIN PATEL, University of Oxford, UK, STEFAN SCHWARZ, FENG LI, DIMITRII KRIZHANOVSKII, ALEXANDER TARTAKOVSKII, MAURICE SKOLNICK, University of Sheffield, UK, CLAIRE VALLANCE, University of Oxford, DAVID HUNGER, Ludwig Maximilians Universitaet, Germany — Open microcavities have emerged in recent years as flexible tools for quantum optics and engineered light matter coupling. Fabry Perot resonators with concave mirrors on the micrometre scale, highly resonant optical modes can be generated with volumes of order  $1-10\lambda^3$ , along with facile tunability and efficient external coupling. Here we will describe our latest advances in open cavity fabrication using focused ion beam milled templates on which high reflectivity mirrors can be deposited providing measured finesse up to 50,000 with surfaces that deviate by less than 2 nm rms from the design. This degree of control provides opportunities for engineering optical modes to suit a wide variety of applications. We will describe the fabrication of cavities with radius of curvature from  $2\ \mu\text{m}$  to 1 mm, and the realisation of coupled cavities with controlled mode overlap. We will further describe some of the applications of these open cavity devices to particle sensing, exciton-polariton physics with quantum wells and 2D materials, tunable lasers, and spin-photon interfaces using diamond colour centres.

**9:48AM A51.00010 Vanadium dioxide for terahertz devices<sup>1</sup>**, NICHOLAS CHARIPAR, HEUNGSOO KIM, SCOTT MATHEWS, ALBERTO PIQUE, Naval Research Lab — We investigate  $\text{VO}_2$  as a material for ultrafast sub-millimeter wave devices. This material exhibits a semiconductor to metal transition (SMT) at  $\sim 68^\circ\text{C}$  which results in a dramatic increase in carrier density ( $\sim 10^{19} - 10^{23}\text{ cm}^{-3}$ ). The SMT transition can be induced thermally, electrically, or optically enabling strong interactions and unique device operation. This transition has been exploited for numerous microwave/terahertz devices such as tunable filters and modulators. However due to its low carrier mobility ( $\sim 0.1\text{ cm}^2/\text{V-s}$ ) and long recovery times ( $\sim\text{ns}$ ),  $\text{VO}_2$  has been largely ignored as a possible material for millimeter wave and terahertz pulse generation even though the SMT can occur within 100 fs.  $\text{VO}_2$  thin film devices were fabricated and characterized. These devices were capable of generating  $\sim 1\text{ ps}$  electrical pulses. We will present details on the ultrafast switching behaviors of  $\text{VO}_2$  along with the design and fabrication of terahertz emitter based on the SMT of  $\text{VO}_2$ .

**10:00AM A51.00011 Comparative electrochemical studies of a nanostructured vanadium oxide electrode material in aqueous electrolyte<sup>1</sup>**, VICTORIA SOGHOMONIAN, QIFAN YUAN, SHAOLA REN, JULIA ZUKOWSKI, Virginia Tech, Department of Physics — Electrochemical energy storage plays an increasing role in energy solutions. We report on a new hydrothermally synthesized vanadium oxide nanostructured material and study its performance as electrode material for insertion of various ions from aqueous solutions. The as-synthesized product is in the form of nanosheets forming quasi-spherical 3-dimensional objects. Variable temperature resistivity measurements indicate a thermally activated behavior. Electrodes are constructed, and comparative electrochemical insertion reactions of Li, Na, K and  $\text{NH}_4$  cations, over different cycle numbers, investigated. Concomitantly, morphological and microstructural changes are characterized by scanning electron microscopy, providing physical input to the observed electrochemical behavior. Specific charge is calculated. For Li and K, the specific charge decreases as the cycle number increases, while the reverse is observed for Na and  $\text{NH}_4$  cations. The trends are correlated to the morphological changes observed. The specific charge in the case of ammonium reaches 180 mAh/g after 20 cycles and continues increasing, indicating that ammonium cations may be considered as viable charge carriers for electrical energy storage system, and moreover in an aqueous electrolyte.

<sup>1</sup>We acknowledge support from the National Science Foundation, Grant No. DMR- 1206338.

**10:12AM A51.00012 High efficiency on-chip three wave parametric frequency conversion and its applications in both classical and quantum optics**, XIANG GUO, CHANGLING ZOU, CARSTEN SCHUCK, HOJOONG JUNG, RISHENG CHENG, HONG X. TANG, Yale Univ — Second order nonlinearity ( $\chi^{(2)}$ ) is one of the most widely explored properties in photonics. Integrating nonlinear devices on a photonic chip attracts more and more attention due to the devices small foot-print and large scalability. However,  $\chi^{(2)}$  nonlinearity in a scalable platform is normally believed to be weak due to difficulties in finding a suitable material with both high nonlinearity and compatibility with advanced nanofabrication technologies. Aluminum nitride is newly developed as a material combining such two properties: high nonlinearity in low-loss, small foot-print waveguide circuits. In experiment, we fabricate microring resonator devices supporting both telecom and visible modes and achieve exceptionally large second harmonic generation efficiency. High quality photon pair generation is further demonstrated with a generation rate of 3 MHz/mW for degenerate photon pair and 5.8 MHz/mW for non-degenerate photon pair. Furthermore, the strong nonlinearity results in coherent interaction between two spectrally far-away modes which manifest as a nonlinear optic induced transparency and efficient frequency converter. We envision more interesting and important applications in the AlN platform combining its outstanding linear and nonlinear properties.

**10:24AM A51.00013 Highly Stable Nanolattice Structures using Nonlinear Laser Lithography**, OZGUN YAVUZ, ONUR TOKEL, Department of Physics, Bilkent University, 06800 Ankara, Turkey, EMRE ERGECEN, Department of Physics, Massachusetts Institute of Technology, Cambridge Massachusetts MA 02139, IHOR PAVLOV, GHAITH MAKEY, FATIH OMER ILDAY, Department of Physics, Bilkent University, 06800 Ankara, Turkey — Periodic nanopatterning is crucial for multiple technologies, including photovoltaics and display technologies. Conventional optical lithography techniques require complex masks, while e-beam and ion-beam lithography require expensive equipment. With the Nonlinear Laser Lithography (NLL) technique, we had recently shown that various surfaces can be covered with extremely periodic nanopatterns with ultrafast lasers through a single-step, maskless and inexpensive method. Here, we expand NLL nanopatterns to flexible materials, and also present a fully predictive model for the formation of NLL nanostructures as confirmed with experiments. In NLL, a nonlocal positive feedback mechanism (dipole scattering) competes with a rate limiting negative feedback mechanism. Here, we show that judicious use of the laser polarisation can constrain the lattice symmetry, while the nonlinearities regulate periodicity. We experimentally demonstrate that in addition to one dimensional periodic stripes, two dimensional lattices can be produced on surfaces. In particular, hexagonal and square lattices were produced, which are highly desired for display technologies. Notably, with this approach, we can tile flexible substrates, which can find applications in next generation display technologies.

**10:36AM A51.00014 Adaptive quantum well/dot IR photodetector with modulated optical bias**, ANDREI SERGEEV, KIMBERLY SABLON, U.S. Army Research Laboratory, Adelphi, MD 20783, USA — Low doping of optical nanostructures leads to a weak electron coupling to radiation, because the radiation is absorbed due to electron transitions in nanoblocks (quantum wells and dots). High doping levels strongly enhance the absorption, but lead to high dark current and high noise current. This tradeoff is inevitable in traditional detector design and with conventional operating regimes, because the radiation absorption and dark current are both proportional to the number of electrons in nanoblocks. To overcome limitations related to the tradeoff between IR absorption and dark current, we propose and study the “nonequilibrium” IR quantum well or quantum dot photodetectors with modulated optical bias. Here we present design of the detector and results of modelling of key detector characteristics, such as responsivity, operating time, and noise equivalent power.

**10:48AM A51.00015 Multi-terminal Two-color ZnCdSe/ZnCdMgSe Based Quantum-well Infrared Photodetector**, YASIN KAYA, Princeton Univ, ARVIND RAVIKUMAR<sup>1</sup>, GUOPENG CHEN, Department of Electrical Engineering, The City College of New York, NY 10031, USA, MARIA C. TAMARGO, Department of Chemistry, The City College of New York, NY 10031, USA, AIDONG SHEN, Department of Electrical Engineering, The City College of New York, NY 10031, USA, CLAIRE GMACHL, Department of Electrical Engineering, Princeton University, Princeton, NJ 08544, USA — Target recognition and identification applications benefits from two-color infrared (IR) detectors in the mid and long-wavelength IR regions. Currently, InGaAs/AlGaAs and GaAs/AlGaAs multiple quantum wells (QWs) grown on GaAs substrate are the most commonly used two-color QW IR photodetectors (QWIPs). However, the lattice-mismatch and the buildup of strain limit the number of QWs that can be grown, in turn increasing the dark current noise, and limiting the device detectivity.

In this work, we report on two-color QWIPs based on the large conduction band offset ( $\sim 1.12\text{eV}$ ) ZnCdSe/ZnCdMgSe material system lattice matched to InP. QWIPs were designed based on a bound to quasi-bound transition, centered at  $4\text{ }\mu\text{m}$  and  $7\text{ }\mu\text{m}$  and each QW is repeated 50 times to eliminate the high dark current and a contact layer is inserted between the two stacks of QWs for independent electrical contacts. Wafers are processed into two step rectangular mesas by lithography and wet etching. Experiments showed absorption spectra centered at  $4.9\text{ }\mu\text{m}$  and  $7.6\text{ }\mu\text{m}$  at 80 K and the full width at half maximums were  $\Delta\lambda/\lambda = 21\%$  and  $\Delta\lambda/\lambda = 23\%$ , respectively. Current work studies the Johnson and the background noise limited detectivities of these QWIPs.

**8:00AM A53.00001 Oil Induced Spontaneous Flow in Water- Bis(2-ethylhexyl)Sulfosuccinat (AOT) system**, PARVATHALU KALAKONDA, King Abdulla University of Science and Technology — Instability and evaporation rates of oils within the layers of vesicles of a surfactants trigger the spontaneous (second flow) flow. The incorporation of oils into bis(2-ethylhexyl)sulfosuccinat (AOT) system remains incompletely characterized. We show that the second flow has a finite size that show a minimum at a particular concentration (mM) of surfactant solution. As a result, the layers are destabilized lead to explode and create the second flow. The fluorescence emission spectra and evaporation rates show that the oil diffuses into the layers of vesicles of a surfactant. We have characterized evaporation rates of oils on various concentrations (mM) of surfactant solution and observed that oils evaporation rates depend on volume and remain constant as the function of concentration of surfactant. We believe that second flow is new feature and brings a new insight into the fluid flow dynamics.

**8:12AM A53.00002 Joule Heating Effects on Electrokinetic Flow Instabilities in Ferrofluids.**<sup>1</sup>, CHRISTIAN BRUMME, RYAN SHAW, YILONG ZHOU, RAMA PRABHAKARAN, XIANGCHUN XUAN, Clemson University — We have demonstrated in our earlier work that the application of a tangential electric field can draw fluid instabilities at the interface of a ferrofluid/water co-flow. These electrokinetic flow instabilities are produced primarily by the mismatch of electric conductivities of the two fluids. We demonstrate in this talk that the Joule heating induced fluid temperature rises and gradients can significantly suppress the electrokinetic flow instabilities. We also develop a two-dimensional depth-averaged numerical model to predict the fluid temperature, flow and concentration fields in the two-fluid system with the goal to understand the Joule heating effects on electric field-driven ferrofluid flow instabilities.

**8:24AM A53.00003 Wall mode instability driven transition to turbulence in a soft microchannel**<sup>1</sup>, SAGAR SRINIVAS, KUMARAN V, Indian Institute of Science — Transition to turbulence has been triggered due to structure fluid interaction at Reynolds number (Re) much lower than hard wall transition Re, in a soft walled micro channel of dimensions  $40\text{mm} \times 1.5\text{mm} \times 0.16\text{mm}$ . Mixing index analysis indicates high degree of mixing accompanied by lower pressure drop as the channel deforms. Flow after transition velocity statistics has been extensively studied using Particle Imaging Velocimetry (PIV) along streamwise-wallnormal direction. The reduced plots of streamwise mean velocity are shown with the absence of viscous sublayer and presence of logarithmic layer with von Karman constants different from rigid wall channel. The one-point cross correlation between velocity fluctuations is non-zero at the soft surface which is in contrast to flow in hard walled channel. This indicates that the additional fluid stress exerted on the soft surface by the fluid velocity fluctuations result in net energy transfer due to shear work done at the interface. The structure fluid interface acts as a source of energy for the mean turbulent kinetic energy which is typically zero at the interface for hard walled channel. We also detect the onset of wall-oscillations primarily tangential to the surface at the transition Re.

**8:36AM A53.00004 The effect of viscosity variation on the stability of a buoyantly unstable miscible layer in vertical porous media**<sup>1</sup>, SATYAJIT PRAMANIK, TAPAN KUMAR HOTA, MANORANJAN MISHRA, Indian Institute of Technology Ropar, India — We numerically show that in the absence of displacement a buoyantly unstable miscible layer with variable viscosity is less unstable than the constant viscosity layers. With the help of scaling analysis, we proved that the dynamics of variable viscosity layers with stable as well as unstable viscosity contrasts are identical in the absence of displacement. When the heavier fluid displaces the lighter one, the influence of viscosity contrast on the buoyantly unstable miscible layer is analogous to that in neutrally buoyant fluids. These findings of direct numerical simulations (DNS) in the fully nonlinear regime are consistent with the linear stability analysis (LSA). Furthermore, we perform a non-modal stability analysis of the linearized equations, which depicts the qualitative agreement with both LSA and DNS. In addition, the response of the linearized operator to external excitation has been studied through pseudospectra. The present findings are of great importance to understand the hydrodynamic mechanisms involved in geologic carbon sequestration.

**8:48AM A53.00005 Untying vortex knots in fluids and superfluids**, DUSTIN KLECKNER, UC Merced, MARTIN SCHEELER, HRIDESH KEDIA, WILLIAM T. M. IRVINE, University of Chicago — Recent work has demonstrated that vortex knots appear to always untie in fluids and superfluids. Should we expect the same behavior from these two very different systems? I will discuss this unknotting behavior, both quantitatively – through helicity – and qualitatively through the geometry and topology of the vortex lines as they evolve.

**9:00AM A53.00006 Relaxation of Anisotropy in Superfluid Turbulence**, RENA ZIEVE, OWEN DIX, University of California - Davis — We simulate superfluid turbulence on a 3-sphere rather than using the more common periodic boundary conditions. We find that our topology naturally leads to anisotropy in a steady-state vortex tangle. A fundamental assumption in turbulence studies is that any large-scale anisotropy due to a driving velocity can be ignored at small length scales. However, there are practical concerns over how quickly the anisotropy decreases with length scale, and whether isotropic turbulence is attained above the dissipation scale. Here we examine how the anisotropy decreases upon moving from large to small length scales.

**9:12AM A53.00007 Simulating transitional hydrodynamics of the cerebrospinal fluid at extreme scale** , KARTIK JAIN, Simulation Techniques and Scientific Computing, Univ., of Siegen, Germany and Center for Biomedical Computing, Simula Research Lab., Lysaker Norway, SABINE ROLLER, Simulation Techniques and Scientific Computing, University of Siegen, Germany, KENT-ANDRE MARDAL, Center for Biomedical Computing, Simula Research Lab., Lysaker, Norway and Dept., of Mathematics, Univ., of Oslo, Norway — Chiari malformation type I is a disorder characterized by the herniation of cerebellar tonsils into the spinal canal through the foramen magnum resulting in obstruction to cerebrospinal fluid (CSF) outflow. The flow of pulsating bidirectional CSF is of acutely complex nature due to the anatomy of the conduit containing it - the subarachnoid space. We report lattice Boltzmann method based direct numerical simulations on patient specific cases with spatial resolution of  $24\mu\text{m}$  amounting meshes of up to 2 billion cells conducted on 50000 cores of the Hazelhen supercomputer in Stuttgart. The goal is to characterize intricate dynamics of the CSF at resolutions that are of the order of Kolmogorov microscales. Results unfold velocity fluctuations up to  $\sim 10KHz$ , turbulent kinetic energy  $\sim 2$  times of the mean flow energy in Chiari patients whereas the flow remains laminar in a control subject. The fluctuations confine near the cranio-vertebral junction and are commensurate with the extremeness of pathology and the extent of herniation. The results advocate that the manifestation of pathological conditions like Chiari malformation may lead to transitional hydrodynamics of the CSF, and a prudent calibration of numerical approach is necessary to avoid overlook of such phenomena.

**9:24AM A53.00008 Numerical Simulation of Parachutist Generated Turbulence on Parachute Inflation** , XIAOLEI CHEN, XIAOLIN LI, Stony Brook University — Using the front tracking computational platform, we couple parachutists as rigid bodies with the spring-mass model for the parachute system. The rigid body generates turbulent flow which affect the parachute inflation and stability. In this talk, we will present our numerical method to solve the complex system and study the effect of the turbulence at the wake of the parachutist on the canopy opening and parachute descent. Several different turbulence models are used and compared with experiments.

**10:00AM A53.00011 Tailoring boundary geometry to optimize heat transport in turbulent convection** , SRIKANTH TOPPALADODDI, Yale University, University of Oxford, SAURO SUCCI, Istituto per le Applicazioni del Calcolo "Mauro Picone" (C.N.R.), JOHN WETTLAUFER, Yale University, University of Oxford, NORDITA — Turbulent Rayleigh-Bénard convection between planar horizontal boundaries is a classical example of the challenge posed by multiple interacting scales in fluid dynamics. Here, by tailoring the geometry of the upper boundary we manipulate the boundary layer – turbulent interior flow interaction, and study the turbulent transport of heat in two-dimensional Rayleigh-Bénard convection with numerical simulations using the Lattice Boltzmann method. By fixing the roughness amplitude of the upper boundary and varying the wavelength  $\lambda$ , we find that the exponent  $\beta$  in the Nusselt-Rayleigh scaling relation,  $Nu - 1 \propto Ra^\beta$ , is maximized at  $\lambda \equiv \lambda_{max} \approx (2\pi)^{-1}$ , but decays to the planar value in both the large ( $\lambda \gg \lambda_{max}$ ) and small ( $\lambda \ll \lambda_{max}$ ) wavelength limits. The changes in the exponent originate in the nature of the coupling between the boundary layer and the interior flow. We present a simple scaling argument embodying this coupling, which describes the maximal convective heat flux. Results from simulations with both top and bottom rough boundaries showing a further enhancement of heat transport will also be presented.

**10:12AM A53.00012 Tracking Coherent Structures and Source Localization in Geophysical Flows<sup>1</sup>** , ERIC FORGOSTON, Montclair State University, ANI HSIEH, Drexel University, IRA SCHWARTZ, US Naval Research Laboratory, PHILIP YECKO, Cooper Union — There has been a steady increase in the deployment of autonomous underwater and surface vehicles for applications such as ocean monitoring, tracking of marine processes, and forecasting contaminant transport. The underwater environment poses unique challenges since robots must operate in a communication and localization-limited environment where their dynamics are tightly coupled with the environmental dynamics. This work presents current efforts in understanding the impact of geophysical fluid dynamics on underwater vehicle control and autonomy. The focus of the talk is on the use of collaborative vehicles to track Lagrangian coherent structures and to localize contaminant spills.

**10:24AM A53.00013 Neutral equivalent surface stress** , CHERYL KLIPP, US Army Research Laboratory — In laboratory turbulent flows, it has been observed that the eigen axes of the Reynolds stress tensor are oriented 17 deg from the streamwise coordinate system. This has also been observed in atmospheric flows over relatively flat terrain under thermally neutral conditions. The reliability of this relationship is examined, especially for locations very near the surface. The relationship is then used as the basis for a neutral equivalent momentum transport which can be calculated in complex environments, such as urban canyons, where the influence of multiple wall normals makes more conventional measurement of momentum transport problematic.

**8:00AM A54.00001 Detection and characterization of semiconductor thin film domains in non linear nearfield regime<sup>1</sup>** , FARBOD SHAFIEI, The University of Texas at Austin, TOMMASO ORZALI, ALEXEY VERT, SEMATECH, MICHAEL DOWNER, The University of Texas at Austin — High carrier mobility in III-V semiconductor films is attractive for electro-optic devices based on Si substrate. The mismatch between thin film and substrate crystal creates defects that affect electron transport in the film. Optical nonlinear (second harmonic generation) technique has been used in search of domains and boundaries that might have connection to these defects. Fiber based nonlinear nearfield scanning optical microscope (NSOM) was used to detect sub-micron domains at surfaces of the films. This local nearfield optical information was compared with bulk farfield optical information and suppression of the domains was observed and studied by controlling the substrate-film interface. Anti phase boundaries, strain, local charge and cavities in connection with these domains are under study.

**8:12AM A54.00002 Interfacial Stresses and Strains Effect on Band-Gap Emission from Silicon** , SUFIAN ABEDRABBO, The Petroleum Institute and The University of Jordan, ANTHONY FIORY, New Jersey Institute of Technology — Czochralski silicon wafer materials were interfaced with silica films formed by sol-gel deposition and thermal annealing. Under optimal annealing conditions ( $\sim 700^\circ\text{C}$ ), stresses in the silica films induce variations in elastic strains on the order of 1% in the silicon. Concomitantly, emission of band-gap photons at 1.1 eV observed by photoluminescence is increased by two orders of magnitude relative to unperturbed silicon. The enhancement in photon emission is produced by band-gap modulations estimated as  $\sim 0.1$  eV. Elastic reversibility of the strains is inferred from recovery of relatively weak photon emission for annealing above the glass reflow temperature of deposited silica films ( $\sim 950^\circ\text{C}$ ). Films with largest stress variations exhibit enhanced absorption signatures in the infrared and broadening of Si-O-Si stretching vibrations. Examples of Si-based photonics based on the observed effect will be presented.

**8:24AM A54.00003 Electronic Raman Scattering as an Ultra-Sensitive Probe of Strain Effects in Semiconductors.**<sup>1</sup> , ANGELO MASCARENHAS, BRIAN FLUEGEL, DAN BEATON, National Renewable Energy Laboratory — Semiconductor strain engineering has become a critical feature of high-performance electronics due to the significant device performance enhancements it enables. These improvements that emerge from strain induced modifications to the electronic band structure necessitate new ultra-sensitive tools for probing strain in semiconductors. Using electronic Raman scattering, we recently showed that it is possible to measure minute amounts of strain in thin semiconductor epilayers. We applied this strain measurement technique to two different semiconductor alloy systems, using coherently strained epitaxial thin films specifically designed to produce lattice-mismatch strains as small as  $10^{-4}$ . Comparing our strain sensitivity and signal strength in  $\text{Al}_x\text{Ga}_{1-x}\text{As}$  with those obtained using the industry-standard technique of phonon Raman scattering we found a sensitivity improvement of 200, and a signal enhancement of  $4 \times 10^3$  thus obviating key constraints in semiconductor strain metrology. The sensitivity of this approach rivals that of contemporary techniques and opens up a new realm for optically probing strain effects on electronic band structure.

**8:36AM A54.00004 Excitation mechanisms of Er optical centers GaN epilayers** , MATTHEW HAWKINS, Department of Physics, Virginia Tech, Blacksburg, Virginia 24061, HONGXING JIANG, JINGYU LIN, Department of Electrical and Computer Engineering, Texas Tech University, Lubbock, Texas 79409, JOHN ZAVADA, Department of Electrical and Computer Engineering, NYU Polytechnic School of Engineering, Brooklyn, New York 11201, NGUYEN VINH, Department of Physics, Virginia Tech, Blacksburg, Virginia 24061 — We report direct evidence of two mechanisms responsible for the excitation of optically active  $\text{Er}^{3+}$  ions in GaN epilayers grown by metal-organic chemical vapor deposition. These mechanisms, resonant excitation via the higher-lying inner 4f shell transitions and band-to-band excitation of the semiconductor host, lead to narrow emission lines from isolated and the defect-related Er optical centers. However, these centers have different photoluminescence spectra, local defect environments, decay dynamics, and excitation cross sections. The photoluminescence at 1.54 micrometer from the isolated Er optical center which can be excited by either mechanism has the same decay dynamics, but possesses a much higher excitation cross-section under band-to-band excitation. In contrast, the photoluminescence at 1.54 micrometer from the defect-related Er optical center can only be observed through band-to-band excitation but has the largest excitation cross-section. These results explain the difficulty in achieving gain in Er doped GaN and indicate approaches for realization of optical amplification, and possibly lasing, at room temperature.

**8:48AM A54.00005 Spectroscopic characterization of Er optical center in multiple quantum wells  $\text{AlN}/\text{GaN}:\text{Er}$**  , VINH HO, MATTHEW HAWKINS, Department of Physics, Virginia Tech, Blacksburg, Virginia 24061, HONGXING JIANG, JINGYU LIN, Department of Electrical and Computer Engineering, Texas Tech University, Lubbock, Texas 79409, JOHN ZAVADA, Department of Electrical and Computer Engineering, NYU Polytechnic School of Engineering, Brooklyn, New York 11201, NGUYEN VINH, Department of Physics, Virginia Tech, Blacksburg, Virginia 24061 — Er doped GaN material is known to result in the formation of luminescent centers suitable for applications in optoelectronic devices. We report here a significant enhancement of photoluminescence from the Er optical center at 1.5 micrometer in multi-nanolayer structures  $\text{AlN}/\text{GaN}:\text{Er}$  synthesized by metal organic chemical vapor deposition. The enhancement of photoluminescence from Er optical center can be explained via the carrier confinement and strain engineering of multi-nanolayer structures. We study the influence of the quantum wells and barrier width on the photoluminescence at 1.5 micrometer using time-resolved and high-resolution photoluminescence spectroscopy at a large range of temperature. The ability of controlling the carrier confinement in multi-nanolayer structures provides us the possibility of engineering Er doped GaN photonic devices with enhanced optical characteristics at 1.54 micrometer.

**9:00AM A54.00006 Observation of magnetic non-reciprocity for mobile excitons bound to stacking-fault potentials**<sup>1</sup> , KAI-MEI FU, TODD KARIN, XIAYU LINPENG, Univ of Washington, ARNE LUDWIG, ANDREAS WIECK, Ruhr-Universitat Bochum, MIKHAIL GLAZOV, Ioffe Institute — We show that single stacking faults in high-purity GaAs provide the most homogeneous two-dimensional potential for excitons yet reported. The ultra-narrow excitonic transitions enable us to directly observe the microscopic properties of the exciton, including a 0 transverse component of the hole g-factor, which are determined by the  $C_{3v}$  symmetry of the system. A surprising magnetic non-reciprocity effect, in which the energy of the detected excitonic emission depends on the sign of the magnetic field, is also observed. This effect is due to conservation of the exciton two-dimensional momentum in the process of light emission and provides direct evidence that excitons are mobile in this novel potential.

<sup>1</sup>This material is based upon work supported by the NSF under Grant Number 1150647 and the NSF Graduate Research Fellowship under grant number DGE-1256082.

**9:12AM A54.00007 Exploration of exciton delocalization in organic crystalline thin films**<sup>1</sup> , KIM HUA, LANE MANNING, NAVEEN RAWAT, VICTORIA AINSWORTH, MADALINA FURIS, Material Science Program and the Department of Physics, University of Vermont — The electronic properties of organic semiconductors play a crucial role in designing new materials for specific applications. Our group recently found evidence for a rotation of molecular planes in phthalocyanines that is responsible for the disappearance of a delocalized exciton in these systems for  $T > 150\text{K}$ .....<sup>1</sup> In this study, we attempt to tune the exciton delocalization of small organic molecules using strain effects and alloying different molecules in the same family. The exciton behavior is monitored using time- and polarization resolved photoluminescence (PL) spectroscopy as a function of temperature. Specifically, organic crystalline thin films of octabutoxy phthalocyanine ( $\text{H}_2\text{OBPC}$ ), octyloxy phthalocyanines and H-bonded semiconductors such as the quinacridone and indigo derivatives are deposited on flexible substrates (i.e. Kapton and PEN) using an in-house developed pen-writing method.....<sup>2</sup> that results in crystalline films with macroscopic long range order. The room temperature PL studies show redshift and changes in polarization upon bending of the film. Crystalline thin films of alloyed  $\text{H}_2\text{OBPC}$  and octabutoxy naphthalocyanine with ratios ranging from 1:1 to 100:1 fabricated on both sapphire and flexible substrates are also explored using the same PL spectroscopy to elucidate the behaviors of delocalized excitons. .<sup>1</sup>N. Rawat, et al., J Phys Chem Lett **6**, 1834 (2015). <sup>2</sup>R. L. Headrick, et al., Applied Physics Letters **92**, 063302 (2008).

**9:24AM A54.00008 Collective magneto-polariton excitation in a terahertz photonic cavity** , QI ZHANG, MINHAN LOU, XINWEI LI, Rice University, ANDREY CHABANOV, University of Texas at San Antonio, JOHN RENO, WEI PAN, Sandia National Laboratory, JOHN WATSON, MICHAEL MANFRA, Purdue University, JUNICHIRO KONO, Rice University — Collective excitations in solids offer new opportunities for quantum optical studies. Many-body interactions inherent to condensed matter systems can lead to novel phenomena that cannot be achieved in traditional atomic systems. Here, we report collective ultrastrong light-matter coupling in a two-dimensional electron gas in a high- $Q$  terahertz photonic-crystal cavity in a magnetic field. We directly observed time-domain vacuum Rabi oscillations, whose frequency was found to be proportional to the square root of  $N$  (where  $N$  is the carrier density), evidence for the *collective* nature of ultrastrong coupling. In addition, a small but definite blue shift due to the diamagnetic term in the Hamiltonian was observed for the polariton frequencies, which is another signature of ultrastrong light-matter coupling. Furthermore, the high- $Q$  cavity suppressed the superradiant decay of cyclotron resonance, which resulted in unprecedentedly narrow intrinsic cyclotron resonance linewidths ( $\sim 5.6$  GHz at 2 K). Our method is also applicable to many classes of strongly correlated systems with collective many-body excitations in the terahertz range, opening a door to the fascinating physics of terahertz many-body cavity QED.

**9:36AM A54.00009 Multidimensional spectroscopy of exciton polaritons in a microcavity** , BRIAN WILMER, Department of Physics, West Virginia University, FELIX PASSMANN, Experimentelle Physik 2, TU Dortmund, MICHAEL GEHL, GALINA KHITROVA, College of Optical Sciences, The University of Arizona, ALAN BRISTOW, Department of Physics, West Virginia University, WEST VIRGINIA UNIVERSITY COLLABORATION, TU DORTMUND COLLABORATION, UNIVERSITY OF ARIZONA COLLABORATION — Two-dimensional coherent spectra map the anticrossing associated with normal-mode splitting in a semiconductor microcavity [1]. For a 12-meV detuning range near zero detuning, it is observed that there are two diagonal features related to the intra-action of exciton-polariton branches and two off-diagonal features related to coherent interaction between the polaritons. A biexcitonic companion feature is observed, shifted from the exciton feature by the biexciton binding energy. Closer to zero detuning, all features are enhanced and the diagonal intra-action features become nearly equal in amplitude and linewidth. Off-diagonal interaction features are strongly modulated (and invert) at small positive detuning, as the lower polariton branch crosses the bound biexciton energy determined from negatively detuned spectra. This Feshbach type behavior is further evidenced by strong polarization dependence. By exploiting selection rules, the quantum pathways can be more rigorously controlled, allowing the Feshbach coupling to be switched on or off as well as elucidating the role spin and two-quantum states play in the exciton-polariton system.  
[1]. Wilmer et al, Phys. Rev. B 91, 201304(R) (2015)

**9:48AM A54.00010 Indentation-induced structural phase transformations of semiconductor materials and applications**<sup>1</sup> , MAHA KHAYYAT, KACST assignee, NORMA SOSA, IBM assignee, M. MUNAWAR CHAUDHRI, University of Cambridge, CAVENDISH LABORATORY, UNIVERSITY OF CAMBRIDGE TEAM, T. J. WATSON RESEARCH CENTER, IBM COLLABORATION — During hardness indentation materials are subjected to highly localized pressures. These pressures may cause a complete change of the crystal structure of the material within the indented zone. Such structural phase transformations were observed within Vickers indentations made at room temperature in single crystals and amorphous films of Si and Ge. However, when indentations were made at 77 K in Si and Ge, no phase transitions were observed in either. Measurements were also taken from indentations made in silicon single crystals at different temperatures namely 263, 243, 235 and 206 K, and they showed a strong correlation of phase transformation with temperature. It was suggested that during room temperature indentations there is a significant temperature rise approximately to 760 K, which may assist phase transformation. Raman spectroscopy was used as an *ex-situ* tool monitoring phase transformations in semiconductor materials. *In-situ* electrical characterizations of indentation-induced metallization in single crystals of silicon were performed using two- and four-contact measurements. The previous work has led to a technique relates to semiconductor device manufacturing, including solar cells, which is a method for controlling the removal of a surface layer from a base substrate utilizing low-temperature.

<sup>1</sup>KACST is acknowledged for support

**10:00AM A54.00011 Photon correlations through Raman virtual processes**<sup>1</sup> , REINALDO DE MELO E SOUZA, Univ Fed Rio de Janeiro, ANDRE SARAIVA, BELITA KOILLER, UFRJ — In Raman inelastic scattering phonons are either absorbed or created, in what is respectively called an anti-Stokes (aS) or a Stokes (S) process. While these two processes are generally uncorrelated, it is possible that the same phonon generated by S is subsequently absorbed by aS. This two photon process is referred to as SaS. In a standard Raman process, conservation of energy forbids virtual phonons to play a role. However, in a SaS process these virtual phonons may be relevant as long as their lifetimes exceed the interval between the two scatterings. We derive the effective photon-photon interaction mediated by the phonon field. The effective hamiltonian is analogue to the one present in BCS superconductivity. The difference lies in the nature of the particles involved – since photons are bosons, there is no Fermi sea instability and no pair condensation. Still it is possible to obtain an attractive photon-photon interaction. Finally, we propose an experiment to detect the correlated photons emerging from a semiconductor. We pinpoint the material properties that might enhance this effect and discuss the possible technological applications of this idea as a correlated photon source.

<sup>1</sup>This work is part of the Brazilian National Institute for Science and Technology on Quantum Information. We also acknowledge partial support from the Brazilian agencies FAPERJ, CNPq and CAPES.

**10:12AM A54.00012 Calculating Effect of Point Defects on Optical Absorption Spectra of III-V Semiconductor Superlattices Based on (8x8) k-dot-p Band Structures** , DANHONG HUANG, Air Force Rsch Lab-Kirtland, ANDRII IUROV, University of New Mexico, GODFREY GUMBS, Hunter College of the City University of New York, DAVID CARDIMONA, Air Force Rsch Lab-Kirtland, SANJAY KRISHNA, University of New Mexico — For a superlattice which is composed of layered zinc-blende structure III-V semiconductor materials, its realistic anisotropic band structures around the Gamma-point are calculated by using the (8x8)k-dot-p method with the inclusion of the self-consistent Hartree potential and the spin-orbit coupling. By including the many-body screening effect, the obtained band structures are further employed to calculate the optical absorption coefficient which is associated with the interband electron transitions. As a result of a reduced quasiparticle lifetime due to scattering with point defects in the system, the self-consistent vertex correction to the optical response function is also calculated with the help of the second-order Born approximation.

**10:24AM A54.00013 Many-body Effects and the Role of Indirect Excitons in Asymmetric InGaAs/GaAs Double Quantum Wells** , CHRISTOPHER SMALLWOOD, JILA, University of Colorado, NIST, TAKESHI SUZUKI, ROHAN SINGH, Dept. of Physics, University of Michigan, TRAVIS AUTRY, MATTHEW DAY, JILA, University of Colorado, NIST, FAUZIA JABEEN, Laboratory of Quantum Optoelectronics, cole Polytechnique Fdrale de Lausanne (EPFL), STEVEN CUNDIFF, Dept. of Physics, University of Michigan — In semiconductor research, a fundamental question is how excitons in nearby but distinct spatial locations interact and exchange energy. In quantum well heterostructures, these interactions can be conveniently probed via optical coherent multidimensional spectroscopy (CMDS). Recently, it has been shown using CMDS that reducing the GaAs barrier from 30 nm to 10 nm between two asymmetric InGaAs quantum wells results in interactions driven by many-body effects. Here, we use the technique to show that for narrower barrier thicknesses, the interactions are accompanied by an emergence of spatially indirect excitons. Quantitative measurements of the effects are presented, which will be useful in tailoring GaAs heterostructure devices, and may also inform the role that excitonic interactions play in more complicated systems like microcavity polariton structures and/or photosynthetic light harvesting complexes.

**10:36AM A54.00014 Coupled Plasmon Phonon Dynamics in GaP: an indirect gap polar semiconductor.**<sup>1</sup> , AVINASH RUSTAGI, EVAN M. THATCHER, CHRISTOPHER J. STANTON, Univ of Florida - Gainesville, KUNIE ISHIOKA, National Institute for Materials Science, Tsukuba, Japan, KRISTINA BRIXIUS, ULRICH HOFER, Philipps University, Germany, HRVOJE PETEK, Univ of Pittsburgh — Transient Depletion Field Screening (TDFS) is the dominant mechanism behind coupled plasmon-phonon oscillations in polar semiconductors for above gap photoexcitation. Here the surface field distorting the polar lattice is screened by photoexcited plasma initiating coupled oscillations. These oscillations modify the optical property of the material and are observed in reflectivity measurements. We model these oscillations via a set of coupled differential equations in electronic polarization and lattice polarization. We consider the effects of lateral inhomogeneity and diffusion of photoexcited carriers which is crucial to understand the experimental results. The spectrum shows an LO(Longitudinal Optical) phonon peak alongside a LOPC(Longitudinal Optical Plasmon Coupled) peak. Lateral inhomogeneity accounts for the beating phenomenon between these frequencies.

**10:48AM A54.00015 GaAs Refractive Index Dependence On Carrier Density and Optimizing Terahertz Devices**, CHRISTOPHER KIM, DONG HO WU, BENJAMIN GRABER, US Naval Research Laboratory — GaAs is used for various applications, including high speed transistors, high-efficiency photovoltaic cells, electro-optics and terahertz (THz) emitters and detectors. To date, information on the refractive index of GaAs is available only over a limited wave spectrum of 0.2-17 $\mu$ m, where the refractive index varies from 1.3 to 5.0. As detailed information on the refractive index of GaAs at THz frequencies is not available or inadequate for our effort to develop an improved GaAs-based THz emitter, we experimentally investigated the behavior of the refractive index of GaAs for different charge carrier densities, especially with or without the presence of surface plasma. Using a Time Domain THz Spectrometer, which is capable of measuring THz pulses containing a wave spectrum over 100-3000 $\mu$ m with a time accuracy better than 6 femtoseconds, we measured the delay of THz pulses traversing through a GaAs substrate of known thickness while modulating the charge carrier concentration. From the experimental data we estimated the refractive index for THz frequencies to vary from 3.5 to 3.8 for different charge carrier concentrations. We will discuss details of our experiments and implications of our experimental results, especially for our GaAs-based THz devices.

**8:00AM A55.00001 Signaling reactions on membrane surfaces: breaking the law of averages**, JAY T. GROVES, Dept. of Chemistry, UC Berkeley — Most intracellular signal transduction reactions take place on the membrane surface. The membrane provides much more than just a surface environment on which signaling molecules are concentrated. There is a growing realization that multiple physical and chemical mechanisms allow the membrane to actively participate in the signaling reactions. Using a combination of single molecule imaging and spectroscopic techniques, my research seeks to directly resolve the actual mechanics of signaling reactions on membrane surfaces both in reconstituted systems and in living cells. These observations are revealing new insights into cellular signaling processes as well as some unexpected functional behaviors of proteins on the membrane surface.

**8:36AM A55.00002 Physics of building an immunological synapse**, MICHAEL L. DUSTIN, New York University — The adaptive immune response depends upon interaction of T cell antigen receptor (TCR) and peptide-MHC complexes in the nanometer scale (15 nm) gap between the T cell and antigen presenting cells. This immunological synapse is built on a foundation of cell adhesion molecules (CAMs). Short CAM pairs (15 nm) and long CAM pairs (~30 nm) work in parallel to form immunological synapses under control of antigen receptor signaling. The engaged antigen receptor recruits tyrosine kinases to initiate formation of multicomponent signaling complexes that also incorporate F-actin foci. The physical process by which ligand binding to the TCR ligand in the context of the immunological synapse triggers the kinase cascade is not clear. Self-assembly of CAMs to form terraced junctions- with 15 nm and larger spacing between membranes in different positions, may contribute to triggering. We demonstrated segregation of the short and long CAMs in a model synapse in 1998, which was complementary to results from Kupfer demonstrating a bull's eye organization of TCR in the center surrounded by a ring of long CAMs- described as supramolecular activation clusters (SMACs), but corresponding to the predicted terraces. We can directly observe tyrosine kinase recruitment to the TCR complex and the dependence of this recruitment on the strength of interaction of TCR and peptide-MHC. Experimental manipulation of CAM length can predictably alter the effective 2D affinity, lateral mobility and the organization of other associated elements in a size dependent manner. We have developed a general model and will discuss supporting experimental data and implications for immunological synapse assembly in this talk and a related poster.

**9:12AM A55.00003 Lineage-tracking of stem cell differentiation: a neutral model of hematopoiesis in rhesus macaque<sup>1</sup>**, TOM CHOU<sup>2</sup>, Univ of California - Los Angeles — How a potentially diverse population of hematopoietic stem cells (HSCs) differentiates and proliferates to supply more than  $10^{11}$  mature blood cells every day in humans remains a key biological question. We investigated this process by quantitatively analyzing the *clonal* structure of peripheral blood that is generated by a population of transplanted lentivirus-marked HSCs in myeloablated rhesus macaques. Each transplanted HSC generates a clonal lineage of cells in the peripheral blood that is then detected and quantified through deep sequencing of the viral vector integration sites (VIS) common within each lineage. This approach allowed us to observe, over a period of 4-12 years, hundreds of distinct clonal lineages. Surprisingly, while the distinct clone sizes varied by three orders of magnitude, we found that collectively, they form a steady-state clone size-distribution with a distinctive shape. Our concise model shows that slow HSC differentiation followed by fast progenitor growth is responsible for the observed broad clone size-distribution. Although all cells are assumed to be statistically identical, analogous to a neutral theory for the different clone lineages, our mathematical approach captures the intrinsic variability in the times to HSC differentiation after transplantation. Steady-state solutions of our model show that the predicted clone size-distribution is sensitive to only two combinations of parameters. By fitting the measured clone size-distributions to our mechanistic model, we estimate both the effective HSC differentiation rate and the number of active HSCs.

**9:48AM A55.00004 Specificity, cross-talk and adaptation in Interferon signaling**, ANTON ZILMAN, University of Toronto — Innate immune system is the first line of defense of higher organisms against pathogens. It coordinates the behavior of millions of cells of multiple types, achieved through numerous signaling molecules. This talk focuses on the signaling specificity of a major class of signaling molecules - Type I Interferons - which are also used therapeutically in the treatment of a number of diseases, such as Hepatitis C, multiple sclerosis and some cancers. Puzzlingly, different Interferons act through the same cell surface receptor but have different effects on the target cells. They also exhibit a strange pattern of temporal cross-talk resulting in a serious clinical problem - loss of response to Interferon therapy. We combined mathematical modeling with quantitative experiments to develop a quantitative model of specificity and adaptation in the Interferon signaling pathway. The model resolves several outstanding experimental puzzles and directly affects the clinical use of Type I Interferons in treatment of viral hepatitis and other diseases.

**10:24AM A55.00005 Within-host co-evolution of chronic viruses and the adaptive immune system**, ARMITA NOURMOHAMMAD, Princeton University — We normally think of evolution occurring in a population of organisms, in response to their external environment. Rapid evolution of cellular populations also occurs within our bodies, as the adaptive immune system works to eliminate infection. Some pathogens, such as HIV, are able to persist in a host for extended periods of time, during which they also evolve to evade the immune response. In this talk I will introduce an analytical framework for the rapid co-evolution of B-cell and viral populations, based on the molecular interactions between them. Since the co-evolution of antibodies and viruses is perpetually out of equilibrium, I will show how to quantify the amount of adaptation in each of the two populations by analysis of their co-evolutionary history. I will discuss the consequences of competition between lineages of antibodies, and characterize the fate of a given lineage dependent on the state of the antibody and viral populations. In particular, I will discuss the conditions for emergence of highly potent broadly neutralizing antibodies, which are now recognized as critical for designing an effective vaccine against HIV.

**Session A56 APS: Keynote Address: Secretary Moniz** Hilton Baltimore Key Ballroom 5-8 - Homer Neal, University of Michigan APS President

**9:30AM A56.00001 Keynote Address** , ERNEST MONIZ, United States Department of Energy —

**Monday, March 14, 2016 11:15AM - 2:15PM –**

**Session B1 DCMP: Condensed Matter Physics at NSF/DMR and DOE/BES: Challenges and Opportunities** Ballroom I - Tomasz Durakiewicz, Jim Horwitz, NSF/DMR , DOE/BES

**11:15AM B1.00001 Reflections on the past, present and future of condensed matter physics** , ANTHONY LEGGETT, Department of Physics, University of Illinois Urbana Champaign — I consider some of the ways in which the practice and even the definition of "condensed-matter physics" has evolved since its inception in the early twentieth century, with particular reference to its relationship to neighboring and even distant disciplines. I speculate on some possible directions in which the discipline may develop over the next few decades, emphasizing that there are still some very basic questions to which we currently have no satisfactory answers.

**11:51AM B1.00002 The NSF Condensed Matter Physics Program** , PAUL SOKOL, Division of Materials Research, National Science Foundation — The Condensed Matter Physics (CMP) program in the NSF Division of Materials Research (DMR) supports experimental, as well as combined experiment and theory projects investigating the fundamental physics behind phenomena exhibited by condensed matter systems. CMP is the largest Individual Investigator Award program in DMR and supports a broad portfolio of research spanning both hard and soft condensed matter. Representative research areas include: 1) phenomena at the nano- to macro-scale including: transport, magnetic, and optical phenomena; classical and quantum phase transitions; localization; electronic, magnetic, and lattice structure or excitations; superconductivity; topological insulators; and nonlinear dynamics. 2) low-temperature physics: quantum fluids and solids; 1D & 2D electron systems. 3) soft condensed matter: partially ordered fluids, granular and colloid physics, liquid crystals, and 4) understanding the fundamental physics of new states of matter as well as the physical behavior of condensed matter under extreme conditions e.g., low temperatures, high pressures, and high magnetic fields. In this talk I will review the current CMP portfolio and discuss future funding trends for the program. I will also describe recent activities in the program aimed at addressing the challenges facing current and future principal investigators.

**12:27PM B1.00003 DOE/BES Experimental Condensed Matter Physics program** , MICHAEL PECHAN, US Department of Energy — This talk will provide an overview of the Experimental Condensed Matter Physics Program in the Office of Basic Energy Sciences of the US Department of Energy. The role of ECMP within DOE, current priorities, highlights, and challenges will be discussed.

**1:03PM B1.00004 The NSF Condensed Matter and Materials Theory Program** , DARYL HESS, National Science Foundation — The Condensed Matter and Materials Theory (CMMT) Program in the Division of Materials Research is the home of condensed matter theory at the National Science Foundation. CMMT awards reflect a vibrant community with expanding scientific horizons and opportunities. I will present an overview of the CMMT program. Opportunities for theory and computation to open new directions and stimulate emerging frontiers will be discussed. Engaging research across disciplinary boundaries maintains the vitality of the field, leads to an agile next generation of theoretical and computational condensed matter physicists, and advances understanding of the world on the scale of life.

**1:39PM B1.00005 DOE/BES Theoretical Condensed Matter Physics Program** , JAMES DAVENPORT, US Department of Energy — This talk will provide an overview of the Theoretical Condensed Matter Physics Program in the Office of Basic Energy Sciences of the US Department of Energy. The role of theory in DOE, current priorities, highlights, and challenges will be discussed.

**Monday, March 14, 2016 11:15AM - 2:15PM –**

**Session B2 GSOF DPOLY GSNP: The Edwards Statistical Mechanics** Ballroom II - Fyl Pincus, University of California, Santa Barbara

**11:15AM B2.00001 Numerical calculation of granular entropy: counting the uncountable.** , DAAN FRENKEL, U. Cambridge — In 1989, Sir Sam Edwards introduced the concept of 'granular entropy', defined as the logarithm of the number of distinct packings of  $N$  granular particles in a fixed volume  $V$ . The proposal was rather controversial but much of the debate was sterile because the granular entropy could not even be computed for systems as small as 20 particles - hardly a good approximation of the thermodynamic limit. In my talk I will describe how granular entropies of much larger systems can now be computed, using a novel algorithm. Interestingly, it turns out the definition of granular entropy will have to be modified to guarantee that granular entropy is extensive.

**11:51AM B2.00002 Granular statistical mechanics – Building on the legacy of Sir Sam Edwards**<sup>1</sup> , RAPHAEL BLUMENFELD, National University of Defense Technology, Changsha and Imperial College London, UK, Co-Author, Shahar Amitai, Imperial College London, UK — When Sir Sam Edwards laid down the foundations for the statistical mechanics of jammed granular materials he opened a new field in soft condensed matter and many followed. In this presentation we review briefly the Edwards formalism and some of its less discussed consequences. We point out that the formalism is useful for other classes of systems - cellular and porous materials. A certain shortcoming of the original formalism is then discussed and a modification to overcome it is proposed. Finally, a derivation of an equation of state with the new formalism is presented; the equation of state is analogous to the PVT relation for thermal gases, relating the volume, the boundary stress and measures of the structural and stress fluctuations.

<sup>1</sup>NUDT, Changsha, China, Imperial College London, UK, Cambridge University, UK

**12:27PM B2.00003 Unifying Suspensions and Inertial Granular flows near Jamming**, WYART MATTHIEU, Institute of Theoretical Physics, Ecole Polytechnique Federale de Lausanne — Observations support that the fluid to solid transition in granular materials is a continuous transition, with diverging length scales and singular flow curves. I will introduce a framework that predict quantitatively scaling exponents near this transition when particles are frictionless. This framework captures both aerial granular flows and over-damped suspensions, phenomena traditionally studied by two distinct communities.

In this description, the dense fluid phase can be thought as a gas of excitations of the solid phase. Key aspects of the solid entering the description can be obtained by dynamical argument, and imply that the solid is marginally stable. Recent calculations in infinite spatial dimension support however that thermodynamics arguments a la Edwards also capture this marginality.

**1:03PM B2.00004 Soft active matter : a contemporary example of Edwardsian statistical mechanics**<sup>1</sup>, TANNIEMOLA LIVERPOOL, University of Bristol — Colonies of swimming bacteria, algae or spermatozoa are examples of active systems composed of interacting units that consume energy and collectively generate motion and mechanical stresses. Due to the anisotropy of their interactions, these active particles can exhibit orientational order at high concentrations and have been called living liquid crystals<sup>2</sup>. Biology at the cellular and multicellular scale provides numerous examples of these active systems. They provide a novel class of experimentally accessible system far from equilibrium. Their rich collective behaviour includes non-equilibrium phase transitions and pattern formation on mesoscopic scales. Interestingly however, some of the theoretical insights gained from field theories applied to equilibrium soft matter systems can be used to explain aspects of their behaviour, but with a number of surprising new twists. I will describe and summarise recent theoretical results characterising the behaviour of such soft active systems highlighting in particular the effects of their internal dynamics on their macroscopic behaviour.

<sup>1</sup>with support of the EPSRC Grant No. EP/G026440/1

**1:39PM B2.00005 Thinking Outside the Sandbox**, JASNA BRUJIC, New York Univ NYU — Theoretical approaches for inherently out-of-equilibrium systems, from granular to live matter, are at the forefront of soft condensed matter physics. Edwards pioneered a statistical mechanics framework to describe jammed particulate materials, which explains the slow compaction of granular materials towards a given density, the reversibility of such experiments, and the equilibration between shaken powders of different types. During my PhD, Edwards's theoretical work inspired me to develop a transparent emulsion system to test the microscopic distributions underlying granular thermodynamics. I will talk about what it was like to have Sir Sam as a PhD adviser and how he uniquely inspired my curiosity to design and build novel materials, which are not random, but assemble via mobile, multiflavored bonds that respond to environmental queues. I will give an overview of this kind of experimentally guided assembly these results call for new theories of emulsions with programmable architectures.

**Monday, March 14, 2016 11:15AM - 2:15PM —**

**Session B3 DCMF: Symmetry Breaking in Unconventional Superconductors** Ballroom III - Sauls James, Northwestern University

**11:15AM B3.00001 Signatures of time reversal symmetry breaking in multiband superconductors**, SAURABH MAITI, University of Florida — Multiband superconductors serve as natural host to several possible ground states that compete with each other. At the boundaries of such competing phases, the system usually compromises and settles for 'mixed' phases that can show intriguing properties like co-existence of magnetism and superconductivity or even co-existence of different superconducting phases. The latter is particularly interesting as it can lead to non-magnetic ground states that spontaneously break Time-Reversal symmetry. While the experimental verification of such states has proved to be challenging, the theoretical investigations have provided exciting new insights into the nature of the ground state and its excitations all of which have experimental consequences of some sort. These include extrinsic properties like spontaneous currents around impurity sites, and intrinsic properties in the form of collective excitations. These collective modes bear a unique signature and should provide clear evidence for time reversal symmetry broken state. While the results are general, in light of recent Raman scattering experiments, its direct relevance to extremely hole doped  $\text{Ba}_{(1-x)}\text{K}_x(\text{FeAs})_2$  will be presented where a strong competition of  $s$ -wave and  $d$ -wave ground state is expected.

**11:51AM B3.00002 Strain-tuning through a possible van Hove singularity in  $\text{Sr}_2\text{RuO}_4$** , CLIFFORD HICKS, Max Planck Institute for Chemical Physics of Solids — The superconducting transition temperature  $T_c$  of the tetragonal compound  $\text{Sr}_2\text{RuO}_4$  was recently shown to be strongly sensitive to  $\langle 100 \rangle$  orthorhombic distortion:  $T_c$  increases strongly both when  $\text{Sr}_2\text{RuO}_4$  is tensioned and compressed along a  $\langle 100 \rangle$  direction. This sensitivity was tentatively attributed to the proximity of one of its Fermi surface sheets to van Hove singularities (vHS): the sections of this sheet that pass closest to the Brillouin zone boundaries are also those perturbed most strongly by  $\langle 100 \rangle$  orthorhombic distortion. By increasing the applied orthorhombic distortion to 0.5–1.0% — a uniaxial pressure almost certainly above 1 GPa — we have now been able to tune through a sharp peak in both  $T_c$  and the upper critical field,  $H_{c2}$ . At the peak,  $T_c$  more than doubles. The peak is at a strain value consistent with predictions for when the Fermi surface contacts the zone boundary, i.e. the van Hove singularity, although concrete verification will require further measurement. The strength of the enhancement of  $H_{c2}$  may have bearing on the symmetry of the order parameter. The large change in properties at this peak mean that it can almost be considered as a new, unexplored material, opening avenues for future research.

**12:27PM B3.00003 Is  $\text{Sr}_2\text{RuO}_4$  a chiral p-wave superconductor? Insights from edge currents and uniaxial strain**, THOMAS SCAFFIDI, University of Oxford — The prevailing candidate for the superconducting order parameter in  $\text{Sr}_2\text{RuO}_4$  is chiral p-wave and signatures of this phase have been looked for experimentally. In this work, we discuss two of these experiments at the light of theoretical results obtained from a weak coupling RG calculation. First, we show that the most favored chiral superconducting order parameter in  $\text{Sr}_2\text{RuO}_4$  has Chern number  $C=7$  in the weak coupling limit, owing to a dominant longer range pairing. Since it was shown that the edge currents of a  $C=1$  superconductor vanish exactly in the continuum limit, and can be strongly reduced on the lattice, this form of order parameter could help resolve the conflict between experimental observation of time-reversal symmetry breaking and yet the absence of observed edge currents in  $\text{Sr}_2\text{RuO}_4$ . Second, the p-wave order parameter obtained from the RG calculation exhibits a large  $T_c$  enhancement under uniaxial strain along 100. This enhancement is symmetric for tensile and compressive strain, and shows no measurable cusp at zero strain, in agreement with experiments. The absence of such a cusp is therefore not incompatible with a chiral p-wave state. Finally, we make predictions about the evolution of the superconducting state as a Van Hove singularity is crossed at larger strain.

**1:03PM B3.00004 Study of the Topological-insulator-based Topological Superconductors<sup>1</sup>**, DONG QIAN, Shanghai Jiao Tong University — Three-dimensional topological insulators possess nontrivial spin-momentum locked surface states under the protection of time-reversal symmetry. The interplay between topological order and superconductivity can lead to topological superconducting state. In this talk, I will discuss our recent progress in topological-insulator-based topological superconductors. Using molecular beam epitaxy (MBE) method, we succeeded in fabricating very high quality TI/s-wave superconductor heterostructure by growing topological insulator thin films on the conventional superconductor niobium diselenide (NbSe<sub>2</sub>) substrate. Using low temperature scanning tunneling microscopy/spectroscopy (STM/STS) and angle-resolved photoemission spectroscopy (ARPES), we systematically studied its electronic structure and superconducting behavior. Through superconducting proximity effect, coexistence of Cooper pairs and topological surface states on the surface of topological insulator film was realized. By exploring the superconducting vortex core state as the function of film thickness, existing of nontrivial superconducting state on the TI's surface was proposed. Our topological insulator/superconductor heterostructure may host single zero-energy Majorana mode in the vortex core. In addition, I will also discuss STM and ARPES studies on the recently discovered superconducting Sr-doped Bi<sub>2</sub>Se<sub>3</sub> bulk crystals. Our results suggest that Sr-doped Bi<sub>2</sub>Se<sub>3</sub> could be an excellent candidate for exploring topological superconducting states.

**1:39PM B3.00005 Proximity-induced Superconductivity in Topological Insulator/Superconductor Heterostructures<sup>1</sup>**, NITIN SAMARTH, Dept. of Physics, Penn State University, University Park PA 16802 — The exploration of superconductivity in helical Dirac fermions is strongly motivated by scenarios for realizing exotic quantum states in condensed matter. Examples include Majorana modes [1] and supersymmetry [2]. Motivated by such proposals, we are pursuing the development of epitaxially grown heterostructures wherein we attempt to induce superconductivity in the surface states of a three dimensional topological insulator thin film when interfaced with both conventional [3] and unconventional [4] superconductors. This talk will provide an overview of the materials synthesis challenges in this context and discuss the picture of induced superconductivity (or lack thereof) that emerges from angle-resolved photoemission spectroscopy [3,4], point contact Andreev reflection spectroscopy [5] and tunneling spectroscopy. **Session B4 DPOLY: Macromolecular Assemblies: Structure and Dynamics** Ballroom IV - Nitash Balsara, Univ of California - Berkeley

**11:15AM B4.00001 Dynamics of Chain Exchange in Block Copolymer Micelles**, TIMOTHY LODGE, University of Minnesota — Block copolymer micelles are rarely at equilibrium. The primary reason is the large number of repeat units in the insoluble block,  $N_{core}$ , which makes the thermodynamic penalty for extracting a single chain ("unimer exchange") substantial. As a consequence, the critical micelle concentration (CMC) is rarely accessed experimentally; however, in the proximity of a critical micelle temperature (CMT), equilibration is possible. We have been using time-resolved small angle neutron scattering (TR-SANS) to obtain a detailed picture of the mechanisms and time scales for chain exchange, at or near equilibrium. Our model system is poly(styrene)-*block*-poly(ethylene-*alt*-propylene) (PS-PEP), in the PEP-selective solvent squalane (C<sub>30</sub>H<sub>62</sub>). Equivalent micelles with either normal (hPS) or perdeuterated (dPS) cores are initially mixed in a blend of isotopically substituted squalane, designed to contrast-match a 50:50 hPS:dPS core. Samples are then annealed at a target temperature, and chain exchange is revealed quantitatively by the temporal decay in scattered intensity. The rate of exchange as function of concentration, temperature,  $N_{core}$ ,  $N_{corona}$ , and chain architecture (diblock versus triblock) will be discussed.

**11:51AM B4.00002 Assemblies of Cellulose Nanocrystals.**, EUGENIA KUMACHEVA, University of Toronto — The entropically driven coassembly of nanorods (cellulose nanocrystals, CNCs) and different types of nanoparticles (NPs), including dye-labeled latex NPs, carbon dots and plasmonic NPs was experimentally studied in aqueous suspensions and in solid films. In mixed CNC-NP suspensions, phase separation into an isotropic NP-rich and a chiral nematic CNC-rich phase took place; the latter contained a significant amount of NPs. Drying the mixed suspension resulted in CNC-NP films with planar disordered layers of NPs, which alternated with chiral nematic CNC-rich regions. In addition, NPs were embedded in the chiral nematic domains. The stratified morphology of the films, together with a random distribution of NPs in the anisotropic phase, led to the films having close-to-uniform fluorescence, birefringence, and circular dichroism properties.

**12:27PM B4.00003 Mega-supramolecules for safer, cleaner fuel**, JULIE KORNFIELD, Invited Speaker — Guided by the statistical mechanics of ring-chain equilibrium, we designed and synthesized polymers that self-assemble into "mega-supramolecules" ( $\geq 5,000$  kg/mol) at low concentration ( $\leq 0.3\%$ wt) in hydrocarbon liquids. Experimental results accord with model predictions that end-functional polymers, which distribute among cyclic and linear supramolecules, can form a significant population of mega-supramolecules at low total polymer concentration—if, and only if, the backbones are long ( $>400$  kg/mol) and end-association strength is optimal ( $16-18kT$ ). Hydrocarbon liquid fuels are the world's dominant power source (34% of global energy consumption). Transportation relies heavily on such liquids, presenting the risk of explosive post-impact fires. The collapse of the World Trade Center on September 11, 2001 inspired us to revisit polymers for mist control to mitigate post-impact fuel explosions. Rheological and both light and neutron scattering measurements of long end-functional polymers having polycyclooctadiene backbones and acid or amine end groups verify formation of mega-supramolecules. Post-impact flame propagations experiments show that mega-supramolecules control misting. Turbulent flow measurements show that mega-supramolecules reduce drag like ultra-long covalent polymers. With individual building blocks short enough to avoid hydrodynamic chain scission ( $400 < M_w$  [kg/mol]  $\leq 1,000$ ) and reversible linkages that protect covalent bonds, they respond reversibly to flow through pumps and filters without degradation. Mega-supramolecules had no adverse effect on power output, fuel efficiency or emissions in diesel engines. In fact, they gave a 12% reduction in diesel soot. Thus, long end-associative polymers may open the way to fuel additives that reduce pollution and improve transportation safety and security.

**1:03PM B4.00004 Charge Effects on the Self-Assembly of Protein Block Copolymer Nanostructures**, BRADLEY OLSEN, MIT — Self-assembly of globular protein-polymer block copolymers into nanostructured phases provides a simple method for structural control in biomaterials. Electrostatics play a major role in the self-assembly of these structures from aqueous solutions. While the specific distribution of charge on the protein plays a relatively minor role in self-assembly, large changes in the total charge have a large impact on the concentration at which the proteins self-assemble. While for near-neutral proteins salt screening promotes disassembly and suggests that electrostatic interactions are attractive, proteins with a highly asymmetric charge have repulsive interactions that suppress self-assembly. Using a zwitterionic block in the bioconjugate was also explored as a means to promote self-assembly; however, zwitterionic fusions self-assemble over a narrower range of composition than fusions of any of the nonionic polymers explored. This suggests that dipolar attractions in charge-asymmetric protein-polymer materials play a significant role in the driving force for self-assembly. However, the sensitivity of zwitterionic materials to salt conditions in the buffer also provides a powerful handle for tuning polymer solubility, enabling salt to be used as a method to induce self-assembly.

**1:39PM B4.00005 Giant Surfactants based on Precisely Functionalized POSS Nano-atoms: Tuning from Crystals to Frank-Kasper Phases and Quasicrystals<sup>1</sup>**, STEPHEN Z. D. CHENG, University of Akron — In creating new functional materials for advanced technologies, precisely control over functionality and their hierarchical ordered structures are vital for obtaining the desired properties. Giant polyhedra are a class of materials which are designed and constructed via deliberately placing precisely functionalized polyhedral oligomeric silsesquioxane (POSS) and fullerene (C<sub>60</sub>) molecular nano-particles (MNPs) (so-called “nano-atoms”) at the vertices of a polyhedron. Giant surfactants are consisted of polymer tail-tethered “nano-atoms” which are deliberately and precisely functionalized POSS or C<sub>60</sub> molecular nano-particles (MNPs). The “nano-atom” heads and polymer tails thus have drastic chemical differences to impart amphiphilicity. These giant surfactants capture the essential structural features of their small-molecule counterparts in many ways but possess much larger sizes, and therefore, they are recognized as size-amplified versions of small molecule surfactants. Two of the most illustrating examples are a series of novel giant tetrahedra and a series of giant surfactants as building blocks to construct into hierarchical ordered super-lattice structures ranging from crystals, Frank-Kasper phases and quasicrystals in the condensed bulk states, reveals evidently the interconnections between soft matters and hard matters in sharing their common structures and fundamental knowledge.

**Session B5 GMAG DMP: Frustrated Magnetism: Low Dimensional Magnets I** 301 - Oleg Starykh, University of Utah

**11:15AM B5.00001 Magnetic nanopantograph in the in SrCu<sub>2</sub>(BO<sub>3</sub>)<sub>2</sub> Shastry-Sutherland lattice**, ANDRES SAUL, CINaM/CNRS — Magnetostriction experiments of the frustrated spin dimer compound SrCu<sub>2</sub>(BO<sub>3</sub>)<sub>2</sub> have shown that its macroscopic physical dimensions change with the applied magnetic field mimicking the complicated structures, with discreet jumps and plateaus, observed in the magnetization. Using Density Functional based methods we find that the driving force behind the magnetoelastic coupling is the Cu-O-Cu superexchange angle which, thanks to the orthogonal Cu<sup>2+</sup> dimers acting as pantographs, can shrink significantly (0.44%) with minute (0.01%) variations in the lattice parameters. Our calculations show that the consequence is a reduction of the order of ~10% in the antiferromagnetic intra-dimer exchange integral *J*, sufficient to compensate the elastic energy loss in the deformation. This reduction should impact our reading of existing predictions of the magnetization versus field phase diagram and the effect of hydrostatic pressures on the ground state. Finally, our prediction of the dimer shrinking under applied magnetic field should appear as a modification of the optical Raman active modes compatible with the pantograph effect.

**11:51AM B5.00002 Hysteretic magnetoresistance and unconventional anomalous Hall effect in the frustrated magnet TmB<sub>4</sub>**, SAI SWAROOP SUNKU<sup>1</sup>, Div of Physics and Applied Physics, Nanyang Technological University, TAI KONG, Ames Laboratory and Dept of Physics and Astronomy, Iowa State University, TOSHIMITSU ITO, National Institute of Advanced Industrial Science and Technology (AIST), PAUL C. CANFIELD, Ames Laboratory and Dept of Physics and Astronomy, Iowa State University, B. SRIRAM SHASTRY, Physics Dept, University of California, Santa Cruz, PINAKI SENGUPTA, CHRISTOS PANAGOPOULOS, Div of Physics and Applied Physics, Nanyang Technological University — We study TmB<sub>4</sub>, a frustrated magnet on the Archimedean Shastry-Sutherland lattice, through magnetization and transport experiments. The lack of anisotropy in resistivity shows that TmB<sub>4</sub> is an electronically three-dimensional system. The magnetoresistance (MR) is hysteretic at low-temperature even though a corresponding hysteresis in magnetization is absent. The Hall resistivity shows unconventional anomalous Hall effect (AHE) and is linear above saturation despite a large MR. We suggest that both hysteretic MR and AHE arise from the formation of complex non-coplanar structures at magnetic domain walls.

<sup>1</sup>Current address: Department of Applied Physics and Applied Mathematics, Columbia University

**12:03PM B5.00003 Spin-lattice coupling of R<sub>1-x</sub>Lu<sub>x</sub>B<sub>4</sub> revealing anomalous weak ferromagnetism (R=Sm, Gd, Tb, Dy, Ho)**, B.Y. KANG, School of Materials Science and Engineering, Gwangju Institute of Science and Technology (GIST), Korea, SEONGSU LEE, Korea Atomic Energy Research Institute, Korea, SANG-YUN HWANG, SUNGDAE JI, Max Planck POSTECH/Korea Research Initiative, Korea, M.S. SONG, B.K. CHO, Gwangju Institute of Science and Technology (GIST), Korea — RB<sub>4</sub> (R=rare-earth elements) compounds exhibits antiferromagnetic ordering at low temperature and are classified as the Shastry-Sutherland lattice, which is a geometrically frustrated system. In previous study, it was reported that Y substitution in TbB<sub>4</sub> single crystals causes anomalous WF (weak ferromagnetism) even though Y<sup>3+</sup> is non-magnetic. The disturbance of a delicate equilibrium in a frustrated system can lead to new electronic and magnetic states. In this study, single crystals of R<sub>1-x</sub>Lu<sub>x</sub>B<sub>4</sub> (R=Sm, Gd, Tb, Dy, Ho), (x=0 ~0.8) were synthesized. WF is also observed. TbB<sub>4</sub> went through orthorhombic distortion below Néel temperature. To investigate the existence of orthorhombic distortion in TbLu<sub>x</sub>B<sub>4</sub> (x=0.1, 0.35), high resolution single crystal x-ray diffraction was performed at 5 K. It was confirmed that the distortion was vanished with Lu substitution. Interestingly, lattice constant *a* was increased with decreasing temperature below the T<sub>C</sub>. The strong correlation between spin-lattice coupling and WF will be discussed in detail.

**12:15PM B5.00004 Neutron Diffraction on  $\text{NaNi}_2\text{BiO}_6$ : Complex Interactions on a Honeycomb Lattice**<sup>1</sup>, ALLEN SCHEIE, Johns Hopkins University, KATE ROSS, Colorado State University, ELIZABETH SEIBEL, Princeton University, JOSE RODRIGUEZ-RIVERA, NIST, COLLIN BROHOLM, Johns Hopkins University, ROBERT CAVA, Princeton University, INSTITUTE FOR QUANTUM MATTER COLLABORATION — Magnetic crystals with a honeycomb lattice can have a very high degree of frustration when next-nearest neighbor interactions are strong. Such complex interactions can lead to Kitaev model physics, including a proposed spin liquid phase. Using neutron scattering, we studied the magnetic properties of a new spin-1/2 honeycomb compound,  $\text{NaNi}_2\text{BiO}_6$ , which was known to have heat capacity peaks indicative of a phase transition at 5 K. The magnetic order indicates beyond nearest-neighbor exchange as well as significant inter-plane interaction, which allows for a study of rich and complex structure. In this talk I report the magnetic structure of the compound as found with neutron powder diffraction, and discuss the exchanges necessary to lead to such a complex order.

**12:27PM B5.00005 Field-induced dynamical properties of the  $XXZ$  model on a honeycomb lattice**<sup>1</sup>, PAVEL MAKSIMOV, ALEXANDER CHERNYSHEV, Univ of California - Irvine — We present a comprehensive  $1/S$  study of the field-induced dynamical properties of the nearest-neighbor  $XXZ$  antiferromagnet on a honeycomb lattice using the formalism of the nonlinear spin-wave theory developed for this model. External magnetic field controls spin frustration in the system and induces non-collinearity of the spin structure, which is essential for the two-magnon decay processes. Our results include an intriguing field-evolution of the regions of the Brillouin zone where decays of spin excitations are prominent, a thorough analysis of the singularities in the magnon spectra due to coupling to the two-magnon continuum, the asymptotic behavior of the decay rates near high-symmetry points, and inelastic neutron-scattering spin-spin structure factor obtained in the leading  $1/S$  order.

<sup>1</sup>Supported by DOE

**12:39PM B5.00006 Featureless Quantum Insulator on the Honeycomb Lattice**<sup>1</sup>, SHENGHAN JIANG, Boston College, HYUNYONG LEE, PANJIN KIM, JUNG HOON HAN, Sungkyunkwan University, YING RAN, Boston College — We construct fully symmetric, gapped states without topological order on a spin-1/2's honeycomb lattice at half-filling in terms of projected entangled pair states (PEPS) Four distinct classes differing by lattice quantum numbers are found by applying the systematic classification scheme introduced by two of the authors [S. Jiang and Y. Ran, arXiv:1505.03171 (2015)]. Lack of topological degeneracy or other conventional form of symmetry breaking, and the existence of the energy gap in both wave functions are checked by numerical calculation of the entanglement entropy and various correlation functions.

**12:51PM B5.00007 Possible spin liquid behavior in  $\text{Sc}_2\text{Ga}_2\text{CuO}_7$** , A.V. MAHAJAN, R. KUMAR, IIT Bombay, India, P. KHUNTIA, Ames Lab, Iowa State Univ, USA, D. SHEPTYAKOV, PSI, Switzerland, P.G. FREEMAN, H.M. RONNOW, EPFL, Switzerland, B. KOTESWARARAO, IIT Bombay, India, M. BAENITZ, MPICPFS, Germany, Y. FURUKAWA, Ames Lab, Iowa State Univ, USA, M. JEONG, EPFL, Switzerland — The title compound crystallizes in a hexagonal structure (space group  $P6_3/mmc$ ) containing edge-shared triangular planes as also triangular bi-planes. Our work establishes that the single triangular layers mainly have  $S = 0$   $\text{Ga}^{3+}$  (85% Ga, 15% Cu), while the bi-layers contain 43%  $\text{Cu}^{2+}$  and 57%  $\text{Ga}^{3+}$ , as far as the cations are concerned. Our  $\chi(T)$  data shows no spin-freezing or magnetic long-range order (LRO) down to 1.8 K. We infer an effective moment of  $1.79 \mu_B$  and a  $\theta_{CW}$  of about -50 K, suggesting AF interactions. In our specific heat data, no anomalies were found down to 0.35 K, in the field range 0-140 kOe. The magnetic specific heat has a nearly  $T^2$  power-law behavior at low- $T$  (for  $H > 90$  kOe). The  $^{71}\text{Ga}$  nuclear magnetic resonance (NMR) shift  $K(T)$  displays a broad maximum at  $T \sim 50$  K. The  $^{71}\text{Ga}$  spin lattice relaxation rate  $1/T_1$  displays a  $T^{3.2}$  power-law increase from 0.1 K to 2 K, then remains nearly unchanged up to 10 K, and increases thereafter. Once again, down to 100 mK there is no indication of LRO which is usually manifested as an anomaly in the  $T$ -dependence of  $K$  and  $1/T_1$ . Our data suggest the formation of a quantum spin liquid in the  $S = 1/2$  system  $\text{Sc}_2\text{Ga}_2\text{CuO}_7$ .

**1:03PM B5.00008 Phase diagram of weakly coupled Heisenberg spin chains subject to a uniform Dzyaloshinskii-Moriya interaction**<sup>1</sup>, WEN JIN, OLEG STARYKH, University of Utah — Motivated by recent experiments on spin chain materials  $\text{K}_2\text{CuSO}_4\text{Cl}_2$  and  $\text{K}_2\text{CuSO}_4\text{Br}_2$ , we theoretically investigate the problem of weakly coupled spin chains (chain exchange  $J$ , interchain  $J'$ ) subject to a *staggered between chains*, but *uniform* within a given chain, Dzyaloshinskii-Moriya interaction (DMI) of magnitude  $D$ . In the experimentally relevant limit  $J' \ll D \ll J$  of strong DMI the spins on the neighboring chains are forced to rotate in opposite directions, effectively resulting in a cancellation of the interchain interaction between components of spins in the plane normal to the vector  $D$ . This has the effect of promoting two-dimensional collinear spin density wave (SDW) state, which preserves  $U(1)$  symmetry of rotations about the  $D$ -axis. We also investigate response of this interesting system to an external magnetic field  $h$  and obtain the  $h - D$  phase diagrams for the two important configurations,  $h \parallel D$  and  $h \perp D$ . The transitions between various SDW-like phases are found to be of either a commensurate-incommensurate or a spin-flop kind.

**1:15PM B5.00009 Spin Liquid in the Triangular Lattice Heisenberg Model**<sup>1</sup>, IAN MCCULLOCH, SEYED SAADATMAND, University of Queensland — We report the results of a large-scale numerical study of the spin-1/2 Heisenberg model on the triangular lattice, with nearest- and next-nearest neighbor interactions. Using  $SU(2)$ -invariant iDMRG for infinite cylinders, we focus on the YC12 structure (with a circumference of 12 sites), and obtain 4 candidate groundstates, corresponding to even/odd spinon sectors, each with linear and projective representations of the cylinder geometry. The momentum-resolved entanglement spectrum reveals the structure of the low-lying spinon excitations. Contrary to some recent works, we find no evidence for chiral symmetry breaking.

**1:27PM B5.00010 Anisotropic thermal conductivity of proton fluctuation-induced quantum spin liquid  $\kappa\text{-H}_3(\text{Cat-EDT-TTF})_2$** , MASAOKI SHIMOZAWA, YOSHITAKA SUZUKI, KAORI SUGII, AKIRA UEDA, SHOGO YAMADA, YUSUKE IMAI, KIYOSHI TORIZUKA, YOSHIYA UWATOKO, HATSUMI MORI, MINORU YAMASHITA, ISSP, University of Tokyo — We report the thermal transport properties of a quantum spin liquid candidate  $\kappa\text{-H}_3(\text{Cat-EDT-TTF})_2$  (H-CAT) with a two-dimensional nearly isotropic triangular lattice. Above 1.0 K, thermal conductivity of H-CAT is substantially smaller than that of a deuterated non-magnetic sample (D-CAT) despite no spin thermal conductivity in D-CAT. In the zero-temperature limit, a finite  $T$ -linear term of the thermal conductivity of H-CAT is clearly observed when the heat current is parallel to  $c$ -axis, while it is almost zero when the heat current is parallel to  $b$ -axis. These features would be attributed to anisotropic proton fluctuations present in H-CAT.

**1:39PM B5.00011 Theory of triplon dynamics in the quantum magnet  $\text{BiCu}_2\text{PO}_6$** , YONG BAEK KIM, KYUSUNG HWANG, Department of Physics and Centre for Quantum Materials, University of Toronto, Toronto, Ontario M5S 1A7, Canada — We provide a theory of triplon dynamics in the valence bond solid ground state of the coupled spin-ladders modeled for  $\text{BiCu}_2\text{PO}_6$ . Utilizing the recent neutron scattering experimental data as guides and a theory of interacting triplons via the bond operator formulation, we determine a minimal spin Hamiltonian for this system. It is shown that the splitting of the low energy triplon modes and the peculiar magnetic field dependence of the triplon dispersions can be explained by including substantial Dzyaloshinskii-Moriya and symmetric anisotropic spin interactions. Taking into account the interactions between triplons and the decay of the triplons to the two-triplon continuum via anisotropic spin interactions, we provide a theoretical picture that can be used to understand the main features of the recent neutron scattering experimental data.

**1:51PM B5.00012 Multi-Magnon Bound States in J1-J2 Model on a Triangular Lattice**, RINA TAKASHIMA, Kyoto University, HIROAKI ISHIZUKA, LEON BALENTS, KITP, UCSB — Competing exchange interactions in spin systems often give rise to unusual magnetic behavior, such as spiral orders and nematic orders in spin chains. Also, on classical triangular Heisenberg models, recent studies found skyrmion lattice phases in an applied magnetic field. Motivated by these studies, we investigate the magnetic phase diagram of a quantum J1-J2 XXZ model on a triangular lattice. In order to study the quantum phases close to the saturation field, we calculate the low energy excitation spectrum near the saturation field, and find the instability toward condensation of multi-magnon bound states, namely, multipolar order. A similar behavior is confirmed in the exact diagonalization of finite size clusters. We also discuss the relationship between the obtained quantum phases and the skyrmion lattice phase which is found in the classical counterpart of our model.

**2:03PM B5.00013 The  $S=1/2$  J1-J2 Heisenberg Model on the Triangular Lattice**, TSEZAR SEMAN, Northern Illinois University, Argonne National Laboratory, CHENG-CHIEN CHEN, Argonne National Laboratory, RAJIV SINGH, University of California, Davis, MICHEL VAN VEENENDAAL, Northern Illinois University, Argonne National Laboratory — We study the  $S=1/2$  triangular-lattice Heisenberg model using large-scale exact diagonalization. As a function of the next-nearest-neighbor exchange J2, the model shows different long-range magnetically ordered states and a potential quantum spin liquid phase. We compute the spin gap and static structure factors in different regions of the phase diagram. The spin-wave and two-magnon Raman spectra are also explored accordingly.

**Session B6 GMAG DMP FIAP: Dzyaloshinskii-Moriya Interaction** 302 - Emilie Jue, NIST

**11:15AM B6.00001 Proportionality of the interfacial Dzyaloshinskii-Moriya interaction and the Heisenberg exchange**, HANS NEMBACH, JUSTIN SHAW, National Institute of Standards and Technology, MATHIAS WEILER, Walther-Meissner Institut, EMILIE JU, TOM SILVA, National Institute of Standards and Technology — The Dzyaloshinskii-Moriya interaction (DMI) gives rise to chiral magnetic ordering and a shift of spin-wave frequencies, depending on their propagation direction. We employed Brillouin-Light-Scattering spectroscopy to measure this nonreciprocal frequency shift, which allowed us to directly determine the magnitude of the DMI in a series of  $\text{Ni}_{80}\text{Fe}_{20}(\text{t})/\text{Pt}$  thin film bilayers where the thickness t ranged from 1 to 13 nm. It has also been predicted by theory that the DMI is proportional to the Heisenberg exchange for bulk magnetic oxides and metallic spin-glasses. We tested this prediction for our metallic system by independently determining the Heisenberg exchange via fitting the Bloch  $T^{3/2}$ -law to the temperature dependence of the magnetization obtained from SQUID magnetometry. We find that the  $\text{Ni}_{80}\text{Fe}_{20}$  thickness dependence of the DMI and the Heisenberg exchange are identical, which is consistent with the notion that both effects share the same underlying physics. This result will lead us to a deeper understanding of the DMI and related spin-orbitronic effects.-/

**11:27AM B6.00002 Nonreciprocal magnon propagation in a noncentrosymmetric ferromagnet  $\text{LiFe}_5\text{O}_8$** , YUSUKE IGUCHI, SOICHIRO UEMURA, KAZUNORI UENO, YOSHINORI ONOSE, Department of Basic Science, University of Tokyo — In noncentrosymmetric materials, the relativistic effect extensively modifies the energy band of magnons as well as that of electrons. With use of microfabricated microwave antennae, we have demonstrated that the propagation of magnons with large momentum is nonreciprocal in a noncentrosymmetric ferromagnet  $\text{LiFe}_5\text{O}_8$ . The nonreciprocity is clearly explained by the effect of asymmetric magnon band originating from the relativistic Dzyaloshinskii-Moriya interaction. This result may pave a new path to designing magnonic device based on the relativistic band engineering.

**11:39AM B6.00003 A Dzyaloshinskii-Moriya Anisotropy in nanomagnets with in-plane magnetization<sup>1</sup>**, M. CUBUKCU, J. SAMPAIO, Unite Mixte de Physique, CNRS, Thales, Univ. Paris-Sud, Universite Paris-Saclay, Palaiseau, France, A. V. KHVALKOVSKIY, D. APALKOV, Samsung Electronics, Semiconductor RD Center (Grandis), San Jose, USA, V. CROS, N. REYREN, Unite Mixte de Physique, CNRS, Thales, Univ. Paris-Sud, Universite Paris-Saclay, Palaiseau, France — The Dzyaloshinskii-Moriya interaction (DMI) is known to be a direct manifestation of spin-orbit coupling in systems with broken inversion symmetry. We present a new anisotropy for in-plane-magnetized nanomagnets which is due to the interfacial DMI. This new anisotropy depends on the shape of the magnet, and is perpendicular to the demagnetization shape anisotropy [1]. The DMI anisotropy term that we introduce here results from the DMI energy reduction due to an out-of-plane tilt of the spins at the edges that are oriented perpendicular to the magnetization. For large enough DMI, the reduction of the DMI and anisotropy energies takes over the demagnetization energy cost when magnetization lies along the minor axis of a structure. Our experimental, numerical and analytical results demonstrate this prediction in magnets of elongated shape for small enough volume (and thus quasi-uniform magnetization). Our results also provide the first experimental evidence of the interfacial DMI-induced tilt of the spins at the borders. [1] M. Cubukcu *et al.*, *arXiv:1508.02961* (2015).

**11:51AM B6.00004 First principles study of the effective Hamiltonian for Dzyaloshinskii-Moriya interaction**, TAKASHI KORETSUNE, TORU KIKUCHI, RYOTARO ARITA, GEN TATARA, RIKEN CEMS — We propose a new formalism to calculate the Dzyaloshinskii-Moriya (DM) interaction by deriving an effective Hamiltonian for a spin gauge field. By treating the spin gauge field perturbatively, we obtain a physically intuitive result that the spin current density is related to the DM interaction. Using first-principles calculations, we confirm that our approach agrees well with the results using the energies of helical spin structures. We also discuss the relation between band structures and DM interaction for the B20 chiral magnets.

**12:03PM B6.00005 Torque, spin and energy Hall currents in magnets with Dzyaloshinskii-Moriya interactions**, VLADIMIR ZYUZIN, ALEXEY KOVALEV, University of Nebraska — Within a linear response theory, we study nonequilibrium magnonic torques as well as spin and energy Hall currents generated by thermal gradients in ferromagnetic and anti-ferromagnetic systems. We predict a contribution related to Berry curvature which arises in multiband systems with topologically non-trivial magnon bands. We identify symmetries that need to be broken in order to have non-vanishing nonequilibrium magnonic torques. As an example, we study kagome lattice of spins with various symmetries of Dzyaloshinskii-Moriya interactions.

**12:15PM B6.00006 Magnon Chirality Hall Effect in Antiferromagnet<sup>1</sup>**, RAN CHENG, NIKHIL SIVADAS, Carnegie Mellon University, SATOSHI OKAMOTO, Oak Ridge National Laboratory, DI XIAO, Carnegie Mellon University, CARNEGIE MELLON UNIVERSITY TEAM, OAK RIDGE NATIONAL LABORATORY COLLABORATION — In a collinear antiferromagnet with easy-axis anisotropy, symmetry dictates that the spin wave modes must be doubly degenerate with opposite chirality. We show that in the presence of the Dzyaloshinskii-Moriya interaction, there exist a magnon chirality Hall effect, where magnons with opposite chirality flow to opposite transverse edges when an in-plane temperature gradient is applied. Possible material candidates to realize this effect is also discussed.

**12:27PM B6.00007 Soliton-like magnetic domain wall motion induced by the interfacial Dzyaloshinskii-Moriya interaction**, TERUO ONO, Kyoto University — Topological defects such as magnetic solitons, vortices, Bloch lines, and skyrmions start to play an important role in modern magnetism due to their extraordinary stability which can be hailed as future memory devices. Recently, novel type of antisymmetric exchange interaction, namely the Dzyaloshinskii-Moriya interaction (DMI), has been uncovered and found to influence on the formation of topological defects. Exploring how the DMI affects the dynamics of topological defects is therefore an important task. Here we investigate the dynamics of the magnetic domain wall (DW) under a DMI by developing a time-of-flight measurement scheme which allows us to measure the DW velocity for magnetic fields up to 0.3T. For a weak DMI, the trend of DW velocity follows the Walker's model which predicts that the velocity of DW increases with field up to a threshold (Walker field) and decreases abruptly. On the other hand, for a strong DMI, velocity breakdown is completely suppressed and the DW keeps its maximum velocity even far above the Walker field. Such a distinct trend of the DW velocity, which has never been predicted, can be explained in terms of magnetic soliton, of which topology can be protected by the DMI. Importantly, such a soliton-like DW motion is only observed in two dimensional systems, implying that the vertical Bloch lines (VBLs) creating inside of the magnetic domain-wall play a crucial role. This work was partly supported by JSPS KAKENHI Grant Numbers 15H05702, 26870300, 26870304, 26103002, 254251, Collaborative Research Program of the Institute for Chemical Research, Kyoto University, and R & D Project for ICT Key Technology of MEXT from the Japan Society for the Promotion of Science (JSPS).

**1:03PM B6.00008 Magnetoelectric effects in the spin 1/2 XX chain with three spin interactions and Dzyaloshinskii-Moriya interaction<sup>1</sup>**, P DURGANANDINI, Department of Physics, SP Pune University, Pune - 411007, India — We consider the spin 1/2 XX chain with three spin interactions of the XZX+YXY and XZY-YZX types in an external magnetic field and with Dzyaloshinskii-Moriya (D-M) interaction. Interpreting the D-M interaction as a local electric polarization, we study the magnetoelectric effects in the system by using the exact solution of the problem. We obtain the ground state phase diagram by calculating the electric polarization, magnetization and entropies. There are various regimes of magnetic and electric polarization depending on the relative strengths of the three spin interaction as well as that of the external fields. For a certain range of three spin interaction strengths, the system shows the existence of finite magnetization and electric polarization even in the absence of any external fields. The external electric and magnetic fields modify the ground state phases and can be used to tune the various regimes. We also calculate the entropy and analyze the electrocaloric and magnetocaloric effects. We show that the electrocaloric and magnetocaloric effects can be used to obtain information about the magnetoelectric effects in the system.

**1:15PM B6.00009 Large anomalous Hall effect in a non-collinear antiferromagnet Mn<sub>3</sub>Sn at room temperature<sup>1</sup>**, TOMOYA HIGO, NAOKI KIYOHARA, ISSP, University of Tokyo, SATORU NAKATSUJI, ISSP, University of Tokyo and PRESTO, JST — Recent development in theoretical and experimental studies have provided a framework for understanding the anomalous Hall effect using Berry-phase concepts, and this perspective has led to predictions that, under certain conditions, a large anomalous Hall effect may appear in spin liquids and antiferromagnets [1, 2]. In this talk, we will present experimental results showing that the antiferromagnet Mn<sub>3</sub>Sn, which has a non-collinear 120-degree spin order, exhibits a large anomalous Hall effect [3]. The magnitude of the Hall conductivity is  $\sim 20 \Omega^{-1} \text{ cm}^{-1}$  at room temperature and  $> 100 \Omega^{-1} \text{ cm}^{-1}$  at low temperatures. We found that a main component of the Hall signal, which is nearly independent of a magnetic field and magnetization, can change the sign with the reversal of a small applied field, corresponding to the rotation of the staggered moments of the non-collinear antiferromagnetic spin order which carries a very small net moment of a few of  $m\mu_B$ . **1:27PM B6.00010 Nanoscale and proximity effects on low-dimensional helical magnetic structures**, LEONID SANDRATSKII, J. FISHER, S. PARK, S. OUAZI, D. SANDER, J. KIRSCHNER, Max Planck Inst Microstructure — We combine symmetry arguments, first-principles calculations and spin-resolved STS measurements to study a 2D helical magnet of some nm extension in proximity to ferromagnetic Co and vacuum regions. Considering the prototypical helical 2D system, an Fe bilayer with intrinsic helical spin structure (1), we report a non-uniform distortion of the spin helix which depends on the lateral extension of the bilayer and on the proximity to either Co or vacuum. The proximity effect manifests itself in different modifications of the magnetic and electronic structures of Fe in vicinity of the interfaces with Co and vacuum. These nanosize and proximity effects have not been discussed before. We demonstrate that, in contrast to an ideal helix of infinite length, the lack of symmetry of the nm-long distorted Fe spin helix, induces an energy dependence of the direction of the electronic magnetization which is revealed in the measured energy dependence of the spin-asymmetry of the differential tunneling conductance. (1) Phark, S. H.; Fischer, J. A.; Corbetta, M.; Sander, D.; Nakamura, K. & Kirschner, J. Reduced-dimensionality-induced helimagnetism in iron nanoislands Nat Commun **5** (2014) 5183.

**1:39PM B6.00011 Emergence of magnetic order in ultra-thin pyrochlore iridate films<sup>1</sup>**, SURAJ CHEEMA, CLAUDY SERRAO, JULIA MUNDY, SHREYAS PATANKAR, ROBERT BIRGENEAU, JOSEPH ORENSTEIN, SAYEEF SALAHUDDIN, RAMAMOORTHY RAMESH, Univ of California - Berkeley — We report on thickness-dependent magnetotransport in (111) - oriented Pb<sub>2</sub>Ir<sub>2</sub>O<sub>7-x</sub> (Pb227) epitaxial thin films. For thicknesses greater than 4 nm, the magnetoresistance (MR) of metallic Pb227 is positive, linear and non-saturated up to 14 T. Meanwhile at 4 nm, the conduction turns nonmetallic and the MR becomes negative and asymmetric upon field-cooling; such traits are reminiscent of all-in-all-out (AIAO) magnetic order in the insulating pyrochlore iridates. Hysteretic low-field MR dips and trained-untrained resistivity bifurcations suggest the presence of magnetic conducting domain walls within the chiral AIAO spin structure. Beyond just AIAO order, angular-dependent MR indicates a magnetic phase space hosting 2-in-2-out (2I2O) spin ice order. Such anomalous magnetotransport calls for re-evaluation of the pyrochlore iridate phase diagram, as epitaxially strained Pb227 exhibits traits reminiscent of both the insulating magnetic and metallic spin-liquid members. Furthermore, these results open avenues for realizing topological phase predictions in (111) - oriented pyrochlore slabs of kagome-triangular iridate heterostructures.

**1:51PM B6.00012 Modulated magnetic ground state and complex phase diagram in the chiral helimagnet  $\text{Cr}_{1/3}\text{NbS}_2$** , EM CLEMENTS, R DAS, Univ. of South Florida, L LI, Univ. of Tennessee, P LAMPEN-KELLEY, Univ. of Tennessee, Oak Ridge National Lab, MH PHAN, Univ. of South Florida, VEERLE KEPPENS, Univ. of Tennessee, D MANDRUS, Univ. of Tennessee, Oak Ridge National Lab, H SRIKANTH, Univ. of South Florida — The chiral helimagnetic ground state of noncentrosymmetric  $\text{Cr}_{1/3}\text{NbS}_2$  originates from competition between coexisting symmetric ferromagnetic (FM) exchange and the antisymmetric Dzyaloshinskii-Moriya (DM) interaction. Previously, it has been shown via Lorentz microscopy that a field induced chiral soliton lattice (SL) exists followed by an incommensurate-commensurate metamagnetic transition to a FM state. The high crystalline anisotropy as well as magnetic and temperature control of the c-axis oriented spin spiral has generated interest for spintronic applications. Currently, only a preliminary phase diagram has been proposed and details of the phase evolution, specifically from the paramagnetic (PM) to the helicoid HM and SL states, have not yet been determined. In this study, we exploit the magnetocaloric effect (MCE) to construct a phase diagram by determining the magnetic entropy change ( $\Delta S_M$ ) under the influence of applied field and temperature variations. Well below the Curie temperature ( $T_c \sim 131\text{K}$ ) we see the onset of SL formation at  $\sim 1\text{kOe}$  and a FM transition  $\sim 1.2\text{kOe}$ . A negative  $\Delta S_M$  value indicates that the system also shows weak FM behavior in a narrow region just below  $T_c$ , where thermal fluctuations destabilize the weaker DM coupling, before transitioning into the HM phase at lower temperatures.

**11:15AM B7.00001 Calibrating the High Density Magnetic Port within Tissue Expanders to Achieve more Accurate Dose Calculations for Postmastectomy Patients with Immediate Breast Reconstruction<sup>1</sup>**, JASMINE JONES<sup>2</sup>, RUI ZHANG<sup>3</sup>, DAVID HEINS<sup>4</sup>, Louisiana State University, KATHERINE CASTLE, Mary Bird Perkins Cancer Center — In postmastectomy radiotherapy, an increasing number of patients have tissue expanders inserted subpectorally when receiving immediate breast reconstruction. These tissue expanders are composed of silicone and are inflated with saline through an internal metallic port; this serves the purpose of stretching the muscle and skin tissue over time, in order to house a permanent implant. The issue with administering radiation therapy in the presence of a tissue expander is that the port's magnetic core can potentially perturb the dose delivered to the Planning Target Volume, causing significant artifacts in CT images. Several studies have explored this problem, and suggest that density corrections must be accounted for in treatment planning. However, very few studies accurately calibrated commercial TP systems for the high density material used in the port, and no studies employed fusion imaging to yield a more accurate contour of the port in treatment planning. We compared depth dose values in the water phantom between measurement and TPS calculations, and we were able to overcome some of the inhomogeneities presented by the image artifact by fusing the KVCT and MVCT images of the tissue expander together, resulting in a more precise comparison of dose calculations at discrete locations. We expect this method to be pivotal in the quantification of dose distribution in the PTV.

**11:27AM B7.00002 Theoretical Study of NaCl and LiCl Clusters**, BRIDGET ORTIZ, AJIT HIRA, JAMES MCKEOUGH, TED KOETTER, Northern New Mexico College — This research is a Quantum Mechanical study of molecular clusters that examines the chemical properties of small  $\text{Na}_n\text{Cl}_n$  and  $\text{Li}_n\text{Cl}_n$  clusters ( $n = 2 - 20$ ). The potentially important role of these molecular species in biochemical and medicinal processes is well known. This work applies the hybrid ab initio methods to derive the different alkali-halide ( $\text{M}_n\text{H}_n$ ) geometries. Of particular interest is the competition between hexagonal ring geometries and rock salt structures. Electronic energies, rotational constants, dipole moments, and vibrational frequencies for these geometries are calculated. Magic numbers for cluster stability are identified and are related to the property of cluster compactness. Mapping of the singlet, triplet, and quintet, potential energy surfaces is performed. Calculations were performed to examine the interactions of these clusters with some atoms and molecules of biological interest, including O, O<sub>2</sub>, and Fe. Potential design of new medicinal drugs is explored. We will also investigate model and material dependence of the results.

**11:39AM B7.00003 Anisotropic Magnetic Nanostructures For Enhanced Hyperthermia**, D. TORRES, Texas State Univ., R. DAS, J. ALONSO, M.H. PHAN, H. SRIKANTH, Univ. of South Florida — Magnetic nanoparticles assisted hyperthermia is one of the most promising techniques for cancer treatment. By the use of magnetic nanoparticles in an external AC magnetic field, one can target a specific tumor location and deliver toxic doses of heat to the tumor area without damaging the surrounding healthy tissue. Magnetite is typically used in biomedical applications due to its biocompatibility, but the heating efficiency of the commonly used magnetite nanoparticles is not enough to obtain the best results in cancer treatment. Therefore, novel magnetic nanostructures are required in order to improve the heating efficiency. Recently, it has been proposed by different groups that it is possible to increase the heating efficiency of the nanoparticles by tuning their effective anisotropy. Considering this, we have synthesized high aspect ratio magnetic nanorods with increased effective anisotropy. A thorough structural and magnetic characterization has revealed high crystallinity and optimal magnetic properties of these nanorods. The hyperthermia response shows that by increasing the aspect ratio from 5 to 11, their heating efficiency is increased by 150%. In addition, we have observed that a good alignment of the nanorods with the magnetic field ensures the best heating results. Hence, these nanorods appear to be promising candidates for cancer treatment with magnetic hyperthermia.

**11:51AM B7.00004 Layer-by-Layer Assembly Onto Gold Nanoparticles of Various Size**, ANDREW KILROY, SARAH KESSLER, TABBETHA DOBBINS, Rowan University, Dept. of Physics & Astronomy — This research focuses on the potential applications of coated gold nanoparticles in medicine. By coating gold nanoparticles in layers of polyelectrolytes, with a final layer of antibodies which targets chemicals uniquely exhibited by cancer cells, we eventually hope to selectively attach the nanoparticles to the cancer cells. The coated nanoparticles are assembled through layer-by-layer coulombic attraction due to the passive zeta potential of the particle and the charged nature of the polyelectrolytes. This poster will explore the potential usefulness of variously sized nanoparticles with various thickness of polyelectrolyte layers.

**12:03PM B7.00005 Formation and Cytotoxicity of Nanoparticles and Nanocubes Prepared from Gold and Silver Salts**, DANIEL BANKER, SKYLER DORRELL, PRESCOTT IVEY, JOSEPH SCURT, TABBETHA DOBBINS, Rowan University, Dept. of Physics & Astronomy — Photothermal therapy is the use of electromagnetic radiation as the treatment for medical conditions such as cancer. Noble metal nanoparticles and nanocubes are brought to an excited state with laser light and as a result they release vibrational energy in the form of heat, which can be used to kill targeted cancer cells. Wet chemistry gives the basics for the preparation of nanoparticles and nanocubes. Using  $\text{HAuCl}_4$ ,  $\text{AgNO}_3$ , tri-sodium citrate and other chemicals, we were able to successfully create gold and silver nanoparticles and nanocubes. The goal is to make sure that 3T3 cells can survive in a nanoparticle or nanocube doped medium so that we can then observe their reaction to photothermal effects. Cell culture techniques were done to 3T3 cells to keep them alive before the testing of cytotoxicity. Photothermal effect refers to the way that our nanoparticles or nanocubes can be photoexcited to release enough heat to kill the cells. We used a UV-Vis spectrophotometer to ensure that the correct wavelength laser. Assuming that the cells will survive living in the doped medium, a medium that has had nanomaterials introduced into it, we will use a high powered laser to observe what the excitation does to the cells since the photothermal effect should result in dead cells.

**12:15PM B7.00006 Implementation of Multiple Spectroscopic Techniques to Simultaneously Observe Native and Mutated Protein Unfolding**, BRENNAN CULL, KELTY BEN, JUSTIN LINK, Xavier University, Cincinnati, OH — A protein's natural, correctly folded structure can determine the protein's ability to carry out its function. If the unfolding process of proteins can be observed, then the relative stability can be better understood between native and mutated proteins. A global picture of the unfolding process may be completed through the studies of strategically mutated proteins using tryptophan as a probe. Horse heart cytochrome c, a thoroughly studied, model protein was used in our investigation to explore this idea. Various spectroscopic techniques such as circular dichroism (CD), absorbance, and fluorescence were simultaneously applied while slowly unfolding our protein by increasing the concentration of a chemical denaturant, guanidine hydrochloride. This provided us information about the thermodynamic properties of the protein and several mutants which can then be interpreted to gain relative stability information among mutations. Efforts to utilize these techniques on native and mutated proteins in comparison to current scientific unfolding theories will be presented in this session.

**12:27PM B7.00007 Transport of Motor Proteins along Microtubules: A Study by Optical Trapping Method and Analysis of Data<sup>1</sup>**, ANGELIQUE MCFARLANE, Seton Hall University — The cellular transportation is fundamental for cell function. Under this transportation, organelles bind to motor proteins. These proteins, then move along cellular microfilaments such as microtubules. The optical trapping technique is a method that allows us to monitor the movement of molecular motors along their tracks. In this method, motor proteins are absorbed by micro-sized beads. The beads are captured by the laser and placed close to the microfilaments. Consequently, the motor proteins bind to the track and move along them. This motion can be recorded and analyzed. In this work, we have analyzed many produced trajectories resulted from the motion of a single kinesin along microtubules. We present the design of the experiment, the method of recording and extracting data, as well as the factors that need to be considered to obtain accurate results. Finally, we calculated some of the physical properties resulted from kinesin movement in our experiment. Our outcomes are compatible with previously reported results.

<sup>1</sup>I acknowledge the support of NJSGC 2016 during this project. This work was conducted under the supervision of Dr. Mitra Feizabadi.

**12:39PM B7.00008 Olive Oil and its Potential Effects on Alzheimer's Disease**, SHAN ANTONY, Indiana State Univ, G.P. ZHANG, Indiana State University — Alzheimer's disease is a neuro-degenerative brain disease that is responsible for affecting the lives of hundreds of thousands of people every year. There has been no evidence to suggest a cure for the disease and the only existing treatments have very low rates of success in trial patients. This is largely due to the fact that the brain is one of the most undiscovered parts of the human body. Brain chemistry is highly complex and responds to its environment in random and radical ways. My research includes testing the reactionary outcomes of combining compounds of olive oil with the 20 basic amino acids. Regions around the world with olive oil based diets show a direct correlation to lower rates of Alzheimer's. Testing few compounds of olive oil with chemicals already found in the brain may yield to a better understanding as to why that is. I took the compounds tyrosol, hydroxytyrosol, and oleocanthal, and combined them with the 20 basic amino acids and calculated the total energy of the new molecule. The molecules produced with acceptably low energy values will be the center of further research. These molecules could lead to truly understanding olive oil's effect on the brain, and ultimately, the cure or prevention of Alzheimer's disease.

**12:51PM B7.00009 Optimization of Fe<sub>3</sub>O<sub>4</sub> Nanoparticle Synthesis**, E VILA, Baker University, K STOJAK REPA, H SRIKANTH, MH PHAN, University of South Florida — Magnetic nanoparticles have been of great interest for the past several decades due to the increasing demands of technology as a direct result of device miniaturization. Additionally, they are interesting for biomedical applications, such as magnetic hyperthermia, because of their controllable size and shape, which can make them compatible with biological entities such as cells or viruses. In this study, iron oxide nanoparticles were synthesized through a thermal decomposition process. The original recipe was altered by changing the type and amounts of reagents used; the reaction time was also changed. Specifically, the amount of surfactants and solvent were altered, and the typical co-surfactant, 1,2-hexadecanediol was substituted by 1,2-tetradecanediol. Finally, a systematic reflux time study was conducted to determine the importance of reaction time to the synthetic process. Each sample was analyzed structurally via XRD to confirm the Fe<sub>3</sub>O<sub>4</sub> phase and TEM to confirm their size. Several samples were also measured in a standard magnetometer to observe changes in their magnetic properties. Results from the systematic study will be presented here.

**1:03PM B7.00010 Study of gold nanoparticle synthesis by synchrotron x-ray diffraction and fluorescence<sup>1</sup>**, ZHONGYING YAN, XIAO WANG, LE YU, Bryn Mawr College, SINA MOEENDARBARI, YAOWU HAO, University of Texas at Arlington, ZHONGHOU CAI, Argonne National Laboratory, XUEMEI CHENG, Bryn Mawr College — Gold nanoparticles have a wide range of potential applications, including therapeutic agent delivery, catalysis, and electronics. Recently a new process of hollow nanoparticle synthesis was reported, the mechanism of which was hypothesized to involve electroless deposition around electrochemically evolved hydrogen bubbles. However, the growth mechanism still needs experimental evidence. We report investigation of this synthesis process using synchrotron x-ray diffraction and fluorescence measurements performed at beamline 2-ID-D of the Advanced Photon Source (APS). A series of gold nanoparticle samples with different synthesis time (50-1200 seconds) were deposited using a mixture electrolyte solution of Na<sub>3</sub>Au(SO<sub>3</sub>)<sub>2</sub> and H<sub>4</sub>N<sub>2</sub>NiO<sub>6</sub>S<sub>2</sub> on anodic aluminum oxide (AAO) membranes. The 2D mapping of fluorescence intensity and comparison of x-ray diffraction peaks of the samples have provided valuable information on the growth mechanism.

<sup>1</sup>Work at Bryn Mawr College and University of Texas at Arlington is supported by NSF grants (1207085 and 1207377) and use of the APS at Argonne National Laboratory is supported by the U. S. Department of Energy under Contract No. DE-AC02-06CH11357.

**1:15PM B7.00011 Softening and Hardening of a Micro-electro-mechanical systems (MEMS) Oscillator in a Nonlinear Regime**, SARAH JOHNSON, Hillsdale College, TERENCE EDMONDS, University of Florida — Micro-electro-mechanical systems or MEMS are used in a variety of today's technology and can be modeled using equations for nonlinear damped harmonic oscillators. Mathematical expressions have been formulated to determine resonance frequency shifts as a result of hardening and softening effects in MEMS devices. In this work we experimentally test the previous theoretical analysis of MEMS resonance frequency shifts in the nonlinear regime. Devices were put under low pressure at room temperature and swept through a range of frequencies with varying AC and DC excitation voltages to detect shifts in the resonant frequency. The MEMS device studied in this work exhibits a dominating spring softening effect due to the device's physical make-up. The softening effect becomes very dominant as the AC excitation is increased and the frequency shift of the resonance peak becomes quite significant at these larger excitations. Hardening effects are heavily dependent on mechanical factors that make up the MEMS devices. But they are not present in these MEMS devices. I will present our results along with the theoretical analysis of the Duffing oscillator model. This work was supported by NSF grant DMR-1461019 (REU) and DMR-1205891 (YL).

**1:27PM B7.00012 A Simple Memristor Model for Circuit Simulations**, FARRAH-AMOY FULLERTON, AALEYAH JOE, NADINE GERGEL-HACKETT, Mary Baldwin College, DEPARTMENT OF CHEMISTRY AND PHYSICS TEAM — This work describes the development of a model for the memristor, a novel nanoelectronic technology. The model was designed to replicate the real-world electrical characteristics of previously fabricated memristor devices, but was constructed with basic circuit elements using a free widely available circuit simulator, LT Spice. The modeled memristors were then used to construct a circuit that performs material implication. Material implication is a digital logic that can be used to perform all of the same basic functions as traditional CMOS gates, but with fewer nanoelectronic devices. This memristor-based digital logic could enable memristors' use in new paradigms of computer architecture with advantages in size, speed, and power over traditional computing circuits. Additionally, the ability to model the real-world electrical characteristics of memristors in a free circuit simulator using its standard library of elements could enable not only the development of memristor material implication, but also the development of a virtually unlimited array of other memristor-based circuits.

**1:39PM B7.00013 Cosmic Reionization: An Analysis of Various Contributable Cosmological Factors.** , ADAM BRYAN, MARCO FATUZZO, Xavier University, Cincinnati, OH — According to the most accepted model of cosmology, the  $\Lambda$ -CDM model, the intergalactic medium (IGM) slowly becomes ionized after the period of recombination. This span of ionization, deemed the epoch of reionization, has proven to be a pertinent chapter to the narrative of our evolving universe. Star-forming galaxies have been accredited as the driving force behind reionization, however, recent results suggest that they cannot be the only cause of reionization. The purpose behind this work was to incorporate other cosmological phenomena to reduce the amount of radiation needed from star-forming galaxies, while still meeting the observational criteria of reionization.

**1:51PM B7.00014 Alfvén Wave Propagation in Young Stellar Systems** , RAY HUMIENNY, MARCO FATUZZO, Xavier University, Cincinnati, OH — Young stellar systems have disks that are threaded by magnetic field lines with an hourglass geometry. These fields funnel ionizing cosmic rays (CRs) into the system. However, the effect is offset by magnetic mirroring. An previous analysis considered how the presence of magnetic turbulence moving outward from the disk would effect the propagation of cosmic-rays, and in turn, change the cosmic-ray ionization fraction occurring within the disk. This work indicated that turbulence reduces the overall flux of cosmic-rays at the disk, which has important consequences for both chemical processes and planet formation that occur within these environments. However, the analysis assumed ideal MHD condition in which the gas is perfectly coupled to the magnetic field. We explore here the validity of this assumption by solving the full equations governing the motion of both ions and neutral within the system.

**2:03PM B7.00015 Theoretically Investigating the Nature of Spacetime- A grand definition of what clocks measure<sup>1</sup>** , MERU EGIE<sup>2</sup>, None — Einstein's special theory of relativity established time as a dimension of reality, explaining physically the mathematical stipulations of Lorentz transformation equations that are required to keep the validity of Maxwell's equations of light and explain the null result of Michelson-Morley experiment. Our current understanding of time is relativistic, that is time is not absolute but runs differently depending on the frame of reference, yet this description uncovers so little about the fundamental reality of time. Using mathematical arguments derived from a simple thought experiment, both Lorentz transformation equations and Einstein's far reaching conclusions of his 1905 paper on the electrodynamics of moving bodies are obtained with arguments that suggest no prior knowledge of both Einstein and Lorentz works. This work attempts uncovering the fundamental nature of what clocks measure and a major implication of this is that the fourth dimension could just be a persistent illusion caused by the existence of space.

<sup>1</sup>gratitude to Mr. Jon Egie for his support and Aghogo Rita for her listening ears

<sup>2</sup>change permits all structures forms & proportion, whether cosmic or individual, organic or inorganic, optics or acoustics, it is evident with what clocks measure, leaving an undermine beauty in the clocks while noting their position and movement through space.

**Monday, March 14, 2016 11:15AM - 2:15PM —**

**Session B11 DMP: Superconductivity in Monolayer FeSe/SrTiO<sub>3</sub>** 307 - Douglas Scalapino, UCSB

**11:15AM B11.00001 ARPES of single layer iron pnictide on STO.** , ZHI-XUN SHEN, Stanford University — Quantum systems in confined geometries have been a very rich ground for discoveries. In this talk, I will discuss recent progresses in uncovering novel physics at ultra-thin limit, with focus on mono-unit-cell (UC) superconductor FeSe grown on SrTiO<sub>3</sub>, where the Cooper pairing temperature is reported to have dramatically enhanced from its bulk value of 8K to ~60K. Of interest are the cause of the enhanced pairing strength, and the nature of the superconducting state. We show angle-resolved photoemission spectroscopy (ARPES) data that provide clear evidence for strong cross-interface electron-phonon coupling in single UC limit, suggesting that pairing is significantly enhanced by the strong interface mode coupling. We will also show other results on the nature of the superconducting state in this system. [References: JJ Lee et al., Nature 515, 245 (2014)].

**11:51AM B11.00002 Enhanced superconductivity due to forward scattering in FeSe thin films on SrTiO<sub>3</sub> substrates** , STEVEN JOHNSTON, Univ of Tennessee, Knoxville, LOUK RADEMAKER, Kavli Institute for Theoretical Physics, University of California Santa Barbara, YAN WANG, Univ of Tennessee, Knoxville, TOM BERLIJN, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory — We examine the consequences of an electron-phonon (*e-ph*) interaction that is strongly peaked in the forward scattering ( $\mathbf{q} = 0$ ) direction in a two-dimensional superconductor. We find that strong forward scattering results in an enhanced  $T_c$  that is linearly proportional to the strength of the dimensionless *e-ph* coupling constant  $\lambda_m$  in the weak coupling limit. This is in stark contrast to the exponential dependence commonly derived in conventional BCS theory. This interaction also produces distinct replica bands in the single-particle spectral function, similar to those observed in recent angle-resolved photoemission experiments on FeSe monolayers on SrTiO<sub>3</sub> and BaTiO<sub>3</sub> substrates. By comparing our model to photoemission experiments, we infer an *e-ph* coupling strength that can provide a significant portion of the observed high  $T_c$  in these systems. [Reference: arXiv:1507.03967]

**12:03PM B11.00003 Electron-Phonon Couplings of the Interfacial Mode in FeSe Thin Films on SrTiO<sub>3</sub> and BaTiO<sub>3</sub>** , YAN WANG, Department of Physics and Astronomy, University of Tennessee, Knoxville, TOM BERLIJN, Oak Ridge National Laboratory, LOUK RADEMAKER, Kavli Institute for Theoretical Physics, University of California Santa Barbara, STEVE JOHNSTON, Department of Physics and Astronomy, University of Tennessee, Knoxville — Monolayers FeSe on SrTiO<sub>3</sub> or BaTiO<sub>3</sub> substrates possess highest superconducting transition temperatures in Fe-based superconductors with  $T_c \sim 70$  K measured by angle-resolved photoemission spectroscopy (ARPES) and other experiments. Furthermore, the high  $T_c$ 's concur with exact replica bands in ARPES spectra. A forward scattering mechanism with small momentum transfer through the electron-phonon interaction has been proposed to explain the high  $T_c$ 's and the replica bands.[1] We apply *ab initio* techniques to study such coupling in monolayer and bilayer FeSe thin films on SrTiO<sub>3</sub>, BaTiO<sub>3</sub>, and oxygen-vacant SrTiO<sub>3</sub> substrates. Our results confirm the forward scattering nature of electron-phonon coupling of the oxygen polar mode whose energy coincides with the off-set energy of the replica bands. [1]L. Rademaker, et al., arXiv:1507.03967.

**12:15PM B11.00004 Oxygen vacancy induced flat phonon mode at FeSe/STO interface.** , YUN XIE, HAI-YUAN CAO, YANG ZHOU, Fudan Univ, SHIYOU CHEN, East China Normal University, HONGJUN XIANG, XINGAO GONG, Fudan Univ, FUDAN UNIVERSITY TEAM — A high-frequency optical phonon mode of SrTiO<sub>3</sub>(STO) was found to assist the high-temperature superconductivity observed recently at the interface between monolayer FeSe and STO substrate. However, the origin of this mode is not clear. Through first-principles calculations, we find that there is a novel polar phonon mode on the surface layers of the STO substrate, which does not exist in the STO crystals. The oxygen vacancies near the FeSe/STO interface drives the dispersion of this phonon mode to be flat and lowers its energy, whereas the charge transfer between STO substrate and FeSe monolayer further reduces its energy to 81 meV. This energy is in good agreement with the experimental value fitted by Lee et al. for the phonon mode responsible for the observed replica band separations and the increased superconducting gap. The oxygen-vacancy-induced flat and polar phonon mode provides clues for understanding the origin of high  $T_c$  superconductivity at the FeSe/ STO interface.

**12:27PM B11.00005 ARPES Studies on the substrate effect on monolayer FeSe**, SLAVKO REBEC, Stanford, SIMES, TAO JIA, JAMES LEE, WEI LI, CHAOFAN ZHANG, SIMES, Stanford, ROBERT MOORE, SSRL, SIMES, Z.X. SHEN, SIMES, Stanford — For 2D films, interface interactions can play a critical role in determining the prevailing physics of the system. In the case of FeSe on SrTiO<sub>3</sub>, reducing the FeSe thickness to 1 monolayer (ML) from bulk leads to a significantly increased superconducting transition temperature (T<sub>c</sub>). To fully utilize and maximize this approach to increasing T<sub>c</sub> in FeSe and potentially apply it to other superconducting materials, the role which the substrate plays in this system must be understood. Here we present recent in-situ angle-resolved photo emission studies of the substrate effect on MBE grown 1 ML FeSe films.

**12:39PM B11.00006 The role of the  $\sqrt{13} \times \sqrt{13} - R33.7^\circ$  surface reconstruction on superconducting FeSe/SrTiO<sub>3</sub>**, STEPHEN D. ALBRIGHT, Department of Physics and Center for Research on Interface Structures and Phenomena (CRISP), Yale University, K. ZOU, SUBHASISH MANDAL, DIVINE KUMAR, Department of Applied Physics and CRISP, Yale University, OMUR DAGDEVIREN, G.H. SIMON, UDO SCHWARZ, Department of Mechanical Engineering & Materials Science and CRISP, Yale University, ERIC ALTMAN, Department of Chemical & Environmental Engineering and CRISP, Yale University, MYUNG-GEUN HAN, YIMEI ZHU, Condensed Matter Physics & Materials Science Department, Brookhaven National Laboratory, SOHRAB ISMAIL-BEIGI, F.J. WALKER, C.H. AHN, Department of Applied Physics and CRISP, Yale University — The creation of specific oxide surface structures is important to nucleating epitaxial growth. Here we show that the reconstructions of the SrTiO<sub>3</sub> (STO) surface impact the properties of monolayer FeSe grown on STO. We achieve high-quality epitaxial growth of FeSe on surfaces that feature a double TiO<sub>2</sub> termination, such as the  $\sqrt{13} \times \sqrt{13} - R33.7^\circ$  reconstructed STO surface prepared by high-temperature annealing in oxygen. Diffraction patterns characteristic of the reconstruction are observed with electron and synchrotron x-ray diffraction. The detailed structure of the FeSe/ $\sqrt{13} \times \sqrt{13} - R33.7^\circ$  interface is determined using crystal truncation rod analysis, and the double TiO<sub>2</sub> termination observed is consistent with previous transmission electron microscopy studies. We further demonstrate the significance of this particular interface structure on epitaxial growth and its implications for the resulting electronic structure using first principles theory.

**12:51PM B11.00007 Role of double TiO<sub>2</sub> layers at the FeSe/SrTiO<sub>3</sub> superconducting interface: A Density functional study<sup>1</sup>**, S. MANDAL, Department of Applied Physics, Yale University, R. PENG, Y. PU, D. FENG, Department of Physics and Advanced Materials Laboratory, Fudan University, X. HE, I. BOZOVIC, Brookhaven National Laboratory, K. ZOU, S. ALBRIGHT, G. SIMON, O. E. DAGDEVIREN, U. D. SCHWARZ, E. I. ALTMAN, D. KUMAR, F. J. WALKER, C. H. AHN, S. ISMAIL-BEIGI, Center for Research on Interface Structures and Phenomena (CRISP), Yale University — The recent discovery of high temperature superconductivity in monolayer FeSe on SrTiO<sub>3</sub> (STO) has drawn much attention. Since there is a strong enhancement of superconductivity compared to bulk FeSe, understanding the interfacial interactions between FeSe and STO is important. To date, density functional theory (DFT) studies have had difficulties explaining a key feature in the observed Fermi surface topology: namely the absence of a “hole pocket” about the  $\Gamma$  point in the Brillouin zone of the heterostructure. By combining DFT and experiment, we find that the STO surface termination is not the primitive  $1 \times 1$  single-layer TiO<sub>2</sub> assumed in most works but instead is a more complex double-layered TiO<sub>2</sub> structure. We find that the double layer facilitates epitaxial growth of monolayer FeSe. Our DFT calculations show that the hole pocket can be eliminated by the enhanced tendency of the double layer (compared to the single layer) termination to donate electrons to the FeSe when oxygen vacancies are present at the STO surface.

**1:03PM B11.00008 STM investigation of FeSe/STO binding<sup>1</sup>**, TATIANA A. WEBB, University of British Columbia, Harvard University, DENNIS HUANG, Harvard University, HARRIS PIRIE, JASON HOFFMAN, University of British Columbia, Harvard University, MOHAMMAD H. HAMIDIAN, Harvard University, Cornell University, CAN-LI SONG, Tsinghua University, CUI-ZU CHANG, JAGADEESH S. MOODERA, Massachusetts Institute of Technology, JENNIFER E. HOFFMAN, University of British Columbia, Harvard University — The electronic properties of monolayer FeSe grown on a SrTiO<sub>3</sub> (STO) substrate differ dramatically from bulk FeSe, with the superconducting transition temperature (T<sub>c</sub>) enhanced by an order of magnitude. This change in T<sub>c</sub> is accompanied by suppressed nematicity, electron doping, and possible coupling to substrate phonons. The first monolayer on the STO surface appears to be unique, and its electronic structure is tunable via sample preparation. We investigate the FeSe/STO binding and growth mechanism via scanning tunneling microscopy and spectroscopy, in order to understand the crucial role of the STO surface in modifying the electronic structure of FeSe.

<sup>1</sup>Work supported by the National Science Foundation DMR-1231319 (STC CIQM), and the Gordon & Betty Moore Foundation EPiQS GBMF4536.

**1:15PM B11.00009 Defects in Thin-Film FeSe/SrTiO<sub>3</sub>: STM and DFT Investigations<sup>1</sup>**, DENNIS HUANG, Harvard University, TATIANA A. WEBB, University of British Columbia, Harvard University, CAN-LI SONG, Tsinghua University, CUI-ZU CHANG, JAGADEESH S. MOODERA, Massachusetts Institute of Technology, EFTHIMIOS KAXIRAS, Harvard University, JENNIFER E. HOFFMAN, University of British Columbia, Harvard University — A single-layer of FeSe deposited on SrTiO<sub>3</sub> exhibits an order-of-magnitude enhancement of its superconducting transition temperature compared to bulk FeSe. This dramatic effect is curiously absent in a second layer of FeSe deposited on the heterostructure, leading to many questions concerning the role of the interface structure, electron doping and phonon coupling. Here, we approach these questions by using STM to characterize and compare native defects that appear in multi-layer and single-layer FeSe/SrTiO<sub>3</sub> grown by MBE under excess Se flux. We use DFT to explore candidate defect configurations, formation energies and diffusion barriers, in order to gain atomic-scale insights into the growth and structure of these film heterostructures.

<sup>1</sup>Work supported by NSF DMR-1231319 (STC CIQM) and Moore Foundation EPiQS GBMF4536. Computations run on Harvard RC Odyssey.

**1:27PM B11.00010 Impact of impurities on superconducting states of FeSe films on SrTiO<sub>3</sub><sup>1</sup>**, ZHUOZHI GE, DUSHYANT TOMER, SHIVANI RAJPUT, LIAN LI, Univ of Wisconsin, Milwaukee — Monolayer and bilayer FeSe films are grown on SrTiO<sub>3</sub> substrates by molecular beam epitaxy, and their surface atomic structure and electronic properties are studied using scanning tunneling microscopy/spectroscopy. Tunneling spectroscopy carried out at 6K reveals a superconducting gap of 20 meV for monolayer FeSe, while bilayer FeSe is found to be mostly semiconducting. However, a gap of 16 meV is observed within 1nm of impurity sites for the bilayer FeSe, indicating a superconducting state. This observation suggests that controlled doping can significantly change the electronic property of FeSe films on SrTiO<sub>3</sub>, which can even open a large superconducting gap. This research was supported by NSF DMR-1335215.

<sup>1</sup>This research was supported by NSF DMR-1335215.

**1:39PM B11.00011 Controlling superconductivity at the FeSe/SrTiO<sub>3</sub> interface by interfacial electron density<sup>1</sup>**, WEIWEI ZHAO, Pennsylvania State University, CUI-ZU CHANG, MIT, JUE JIANG, Pennsylvania State University, JAGADEESH MOODERA, MIT, MOSES CHAN, Pennsylvania State University — Single layer iron selenide (FeSe) on SrTiO<sub>3</sub> substrate with a possible superconducting transition temperature ( $T_c$ ) above 100K has attracted a great deal of attention recently. An important outstanding puzzle in this system is the inconsistency in  $T_c$  as measured by different techniques. Here we systematically study the dependence of  $T_c$  on the electron carrier density in this system and found that  $T_c$  can be most effectively enhanced by increasing the density of electron carriers directly at the FeSe/SrTiO<sub>3</sub> interface. We believe that our result resolves some of the puzzles in previous experiments, and open the possibility for further enhancement of  $T_c$  in this system even when taken outside the UHV chamber.

<sup>1</sup>This research is supported by the NSF grants (DMR-1420620, Penn State MRSEC; in MIT by DMR-1207469 and the STC Center for Integrated Quantum Materials under NSF grant DMR-1231319) and by ONR Grant N00014-13-1-0301.

**1:51PM B11.00012 Charge transfer effect of FeSe thin films on SrTiO<sub>3</sub><sup>1</sup>**, YUANJUN ZHOU, ANDREW MILLIS, Columbia University — Monolayer FeSe grown on SrTiO<sub>3</sub> substrate has shown a significant enhancement in the superconducting transition temperature ( $T_c$ ) relative to the bulk material. Monolayers of FeSe are electron doped relative to bulk; we propose that the doping comes from work-function-mismatch driven charge transfer from SrTiO<sub>3</sub> impurity bands, modified by out-of-plane polar distortions of the SrTiO<sub>3</sub>. We present a modified Schottky model combined with density functional calculations substantiating this picture for monolayer FeSe films on Nb doped SrTiO<sub>3</sub>. Physically relevant levels of Nb doping are shown to lead to doping of the FeSe compatible with observation. Adding polar fluctuations to the model leads to an electron-phonon interaction whose effect on the transition temperature is investigated.

<sup>1</sup>YZ is supported by National Science Foundation under grant No. DMR-1120296. AJM is supported by the Department of Energy under No. DOE-ER-046169.

**2:03PM B11.00013 Observation of Dirac cone band dispersions in FeSe thin films by photoemission spectroscopy.**, SHIYONG TAN, YUN FANG, DONGHUA XIE, WEI FENG, Institute of Materials, China Academy of Engineering Physics, CHENHAOPING WEN, QI SONG, Fudan university, QIYUN CHEN, WEN ZHANG, YUN ZHANG, LIUZHU LUO, Institute of Materials, China Academy of Engineering Physics, BINPING XIE, Fudan university, XINCHUN LAI, Institute of Materials, China Academy of Engineering Physics, DONGLAI FENG, Fudan university, FENG GROUP TEAM, LAI GROUP TEAM — The search for novel materials with Dirac cone band dispersion is one of the most challenging and important works for both fundamental physics and technological applications. Here, we studied the electronic structure of FeSe thin films grown on SrTiO<sub>3</sub> substrates by angle-resolved photoemission spectroscopy (ARPES). We reveal the existence of Dirac cone band dispersions in FeSe thin films thicker than 1 Unit Cell below the nematic transition temperature, whose apexes are located -10 meV below Fermi energy. The evolution of electronic structures for FeSe thin films as function of temperature, thickness and cobalt doping are systematically studied. The Dirac cones are found to be coexisted with the nematicity in FeSe, disappear when nematicity is suppressed. Our results provide useful guidelines for understanding the novel electronic structure, nematicity and superconductivity in FeSe system..

Session B13 GQI: Adiabatic Quantum Computation and Quantum Annealing 309 - Tameem Albash, Univ of Southern California

### 11:15AM B13.00001 Simulated annealing versus quantum annealing , MATTHIAS TROYER, ETH Zurich —

Based on simulated classical annealing and simulated quantum annealing using quantum Monte Carlo (QMC) simulations I will explore the question where physical or simulated quantum annealers may outperform classical optimization algorithms. Although the stochastic dynamics of QMC simulations is not the same as the unitary dynamics of a quantum system, I will first show that for the problem of quantum tunneling between two local minima both QMC simulations and a physical system exhibit the same scaling of tunneling times with barrier height. The scaling in both cases is  $O(\Delta^2)$ , where  $\Delta$  is the tunneling splitting. An important consequence is that QMC simulations can be used to predict the performance of a quantum annealer for tunneling through a barrier. Furthermore, by using open instead of periodic boundary conditions in imaginary time, equivalent to a projector QMC algorithm, one obtains a quadratic speedup for QMC, and achieve linear scaling in  $\Delta$  [1]. I will then address the apparent contradiction between experiments on a D-Wave 2 system that failed to see evidence of quantum speedup [2] and previous QMC results [3] that indicated an advantage of quantum annealing over classical annealing for spin glasses. We find that this contradiction is resolved by taking the continuous time limit in the QMC simulations which then agree with the experimentally observed behavior and show no speedup for 2D spin glasses. However, QMC simulations with large time steps gain further advantage: they “cheat by ignoring what happens during a (large) time step, and can thus outperform both simulated quantum annealers and classical annealers [4]. I will then address the question how to optimally run a simulated or physical quantum annealer. Investigating the behavior of the tails of the distribution of runtimes for very hard instances we find that adiabatically slow annealing is far from optimal. On the contrary, many repeated relatively fast annealing runs can be orders of magnitude faster for hard spin glass problems. The intuitive explanation is that hard instances, which are stuck in the wrong minimum can be solved faster by perturbing them [5]. I will finally discuss the consequences of these findings for designing better quantum annealers. [1] S.V. Isakov, G. Mazzola, V.N. Smelyanskiy, Z. Jiang, S. Boixo, H. Neven, and M. Troyer, arXiv:1510.08057. [2] T.F. Rønnow, Z. Wang, J. Job, S. Boixo, S.V. Isakov, D. Wecker, J.M. Martinis, D.A. Lidar, M. Troyer, Science **345**, 420 (2014). [3] G.E. Santoro, R. Martonak, E. ### 11:51AM B13.00002 Mean-field analysis of quantum annealing with XX-type terms , HIDETOSHI NISHIMORI, Tokyo Institute of Technology —

I analyze the role of XX-type terms in quantum annealing for a few mean-field systems including the Ising ferromagnet and the Hopfield model, both with many-body interactions. The XX-type terms are shown to be effective to remove first-order quantum phase transitions, which exist in the conventional implementation of quantum annealing using only transverse fields. This means an exponential increase in efficiency, and is suggestive for the design of quantum annealers. I will discuss how and why this phenomenon emerges and what may happen on realistic finite-dimensional lattices.

### 12:27PM B13.00003 Error suppression and correction for quantum annealing , DANIEL LIDAR, Univ of Southern California —

While adiabatic quantum computing and quantum annealing enjoy a certain degree of inherent robustness against excitations and control errors, there is no escaping the need for error correction or suppression. In this talk I will give an overview of our work on the development of such error correction and suppression methods. We have experimentally tested one such method combining encoding, energy penalties and decoding, on a D-Wave Two processor, with encouraging results. Mean field theory shows that this can be explained in terms of a softening of the closing of the gap due to the energy penalty, resulting in protection against excitations that occur near the quantum critical point. Decoding recovers population from excited states and enhances the success probability of quantum annealing. Moreover, we have demonstrated that using repetition codes with increasing code distance can lower the effective temperature of the annealer.

### 1:03PM B13.00004 Precision and the approach to optimality in quantum annealing processors , MARK W JOHNSON, D-Wave Systems Inc —

The last few years have seen both a significant technological advance towards the practical application of, and a growing scientific interest in the underlying behaviour of quantum annealing (QA) algorithms [1]. A series of commercially available QA processors, most recently the D-Wave 2X™ 1000 qubit processor, have provided a valuable platform for empirical study of QA at a non-trivial scale. From this it has become clear that misspecification of Hamiltonian parameters is an important performance consideration, both for the goal of studying the underlying physics of QA, as well as that of building a practical and useful QA processor. The empirical study of the physics of QA requires a way to look beyond Hamiltonian misspecification.

Recently, a solver metric called ‘time-to-target’ was proposed [2] as a way to compare quantum annealing processors to classical heuristic algorithms. This approach puts emphasis on analyzing a solver’s short time approach to the ground state. In this presentation I will review the processor technology, based on superconducting flux qubits, and some of the known sources of error in Hamiltonian specification. I will then discuss recent advances in reducing Hamiltonian specification error, as well as review the time-to-target metric and empirical results analyzed in this way.

### 1:39PM B13.00005 Universal fault-tolerant adiabatic quantum computing with quantum dots or donors , ANDREW LANDAHL, Sandia National Laboratories —

I will present a conceptual design for an adiabatic quantum computer that can achieve arbitrarily accurate universal fault-tolerant quantum computations with a constant energy gap and nearest-neighbor interactions. This machine can run any quantum algorithm known today or discovered in the future, in principle. The key theoretical idea is adiabatic deformation of degenerate ground spaces formed by topological quantum error-correcting codes. An open problem with the design is making the four-body interactions and measurements it uses more technologically accessible. I will present some partial solutions, including one in which interactions between quantum dots or donors in a two-dimensional array can emulate the desired interactions in second-order perturbation theory. I will conclude with some open problems, including the challenge of reformulating Kitaev’s gadget perturbation theory technique so that it preserves fault tolerance. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy’s National Nuclear Security Administration under contract DE-AC04-94AL85000.

Session B14 FHP: The History of Electrical Science 310 - Amy Fisher, University of Puget Sound

**11:15AM B14.00001 Electrical Enlightenment: Joseph Priestley's Historical and Experimental Studies of Electricity** , VICTOR BOANTZA, University of Minnesota — Joseph Priestley (1733–1804) was one of the most controversial public figures of the eighteenth century. A true Enlightenment polymath, he wrote more than two hundred books, pamphlets, sermons, and essays on subjects ranging from science to politics and from metaphysics to theology. He was a religious dissenter, political radical, vocal supporter of the French Revolution, and lifelong defender of the losing side in the Chemical Revolution. Priestley is best known for having "discovered" oxygen in the 1770s and for his lasting contributions to pneumatic chemistry. Yet his first scientific fascination, while teaching at Warrington Academy, was electricity—one of the greatest scientific fads of the Enlightenment. Priestley's work on electricity, both historical and experimental, culminated in his *History and Present State of Electricity* (1767), which became a standard textbook on the subject for nearly a century, and went through numerous editions and translations. Situating Priestley's electrical investigations against the background of eighteenth-century ideals of scientific theory and practice, especially concerning physics, experimental philosophy, and natural history, illuminates the relations between science, society, and epistemology in the Enlightenment.

**11:51AM B14.00002 Lomonosov's Electrical Experiments** , ROBERT CREASE, State Univ of NY- Stony Brook — No abstract available.

**12:27PM B14.00003 Priestley's Shadow and Lavoisier's Influence: Electricity and Heat in the Late Eighteenth and Early Nineteenth Centuries** , AMY FISHER, University of Puget Sound — In the late eighteenth century, Joseph Priestley argued that any complete theory of heat also had to explain electrical phenomena, which manifested many similar effects to heat. For example, sparking or heating a sample of trapped air caused a reduction in the volume of air and made the gas toxic to living organisms. Because of the complexity of electrical and thermal phenomena, Antoine Lavoisier did not address electrical action in his published works. Rather, he focused on those effects produced by heating alone. With the success of Lavoisier's caloric theory of heat, natural philosophers and chemists continued to debate the relationship between heat and electricity. In this presentation, I compare and contrast the fate of caloric in early-nineteenth-century electrical studies via the work of two scientists: Humphry Davy in Britain and Robert Hare in America.

**1:03PM B14.00004 Broken Circuits? International Scientific Communication on Galvanic Electricity During the Napoleonic Wars** , IAIN WATTS, University of Puget Sound — No abstract available.

**1:39PM B14.00005 The Bottom Line: Cable Telegraphy and the Rise of Field Theory in the Victorian British Empire** , BRUCE HUNT, Univ of Texas, Austin — The networks of telegraph wires and undersea cables that began to spread across the world in the 1840s and 1850s had far-reaching effects on commerce and the dissemination of news. They also had deep effects on electrical science. In this paper, I will argue that what might at first appear to be a prime example of pure science—the development of electromagnetic field theory in Britain in the middle decades of the 19th century—was in fact driven in important ways by developments in the telegraph industry, particularly British scientists' and engineers' encounters with puzzling new phenomenon of the 'retardation' of signals that turned up on underground wires and undersea cables in the early 1850s.

**Monday, March 14, 2016 11:15AM - 2:15PM —**

**Session B15 DCMP DMP: Graphene: Magnetotransport** 314 - Aubrey Hanbicki, Naval Research Laboratory

**11:15AM B15.00001 ABSTRACT WITHDRAWN —**

**11:27AM B15.00002 Magnetoresistance and Anti-Ferromagnetic Coupling in FM-Graphene-FM Trilayers** , ENRIQUE D. COBAS, OLAF M. J. VAN 'T ERVE, SHU-FAN CHENG, BEREND T. JONKER, US Naval Research Laboratory — Both high-magnetoresistance(MR) minority spin filtering[1] and anti-ferromagnetic (AFM) coupling[2-3] have been predicted for FM|Graphene|FM vertical heterostructures. Our previous experiments[4-5] demonstrated ordinary magnetoresistance in NiFe-Graphene-Co heterostructures and no evident AFM coupling. Here we present experimental results that confirm both MR minority spin filtering and AFM coupling in high-quality FM|Graphene|FM heterostructures. The heterostructures were fabricated by a combination of sputtering, chemical vapor deposition and electron beam evaporation. The stack was patterned into symmetric cross-bar structures using Ar ion milling. Measurements show negative magnetoresistance in excess of 10 percent, confirming spin-filtering, and weak anti-ferromagnetic coupling throughout the temperature range 15K to 300K. The temperature dependence of the MR was studied and found consistent with thermal excitation of spin waves in the ferromagnetic electrodes. Junction resistance-area products are in the range of  $10 \Omega\text{cm}^2$ . These heterostructures provide a fast and low-power magnetic field sensor in the sub-100 Oe range and are a step towards high-MR low RA-product MRAM junctions. [1] Karpan, et al. Phys. Rev. Lett 99, 176602, 2007. [2] Li et al., App. Phys. Lett 98 (13), 133111, 2011. [3] Kim, D. et al., App. Phys. Lett 102 (11), 112403, 2013 [4] Cobas et al., Nano Lett. 12, 3000, 2012. [5] Cobas et al., IEEE Trans. Mag., 49 (7), 4343, 2013.

**11:39AM B15.00003 Magneto Transport in Three Dimensional Carbon Nanostructures** , TIMIR DATTA, LEI WANG, University of South Carolina, JAN JAROSZYNSKI, National High Magnetic Field Lab, MING YIN, Benedict College, DHEYAA ALAMERI, University of South Carolina — Electrical properties of self-assembled three dimensional nanostructures are interesting topic. Here we report temperature dependence of magneto transport in such carbon nanostructures with periodic spherical voids. Specimens with different void diameters in the temperature range from 200 mK to 20 K were studied. Above 2 K, magnetoresistance,  $MR = [R(B) - R(0)] / R(0)$ , crosses over from quadratic to a linear dependence with the increase of magnetic field [Wang et al, APL 2015; DOI:10.1063/1.4926606]. We observe MR to be non-saturating even up to 18 Tesla. Furthermore, MR demonstrates universality because all experimental data can be collapsed on to a single curve, as a universal function of B/T. Below 2 K, magnetoresistance saturates with increasing field. Quantum Hall like steps are also observed in this low temperature regime. Remarkably, MR of our sample displays orientation independence, an attractive feature for technological applications.

**11:51AM B15.00004 Study on anisotropic quantum transport in graphene sheets by ESR** , LIQIN YAN, YOUNG SUN, JIAO HUANG, XIAOLONG CHEN, Beijing National Laboratory for Condensed Matter Physics, Institute of Physics, Chinese Academy of Sciences, P.O. Box 603, Beijing 100190, China — Quantum transport in graphene has attracted much attention due to its excellent thermal conductivity and high room-temperature electron mobility.[1] Using the electron spin resonance (ESR) spectrometer for studying weak localization (WL) and weak antilocalization (WAL) effects, except for having the obvious advantage of no need for electrical contacts, differs from the electric transport measurement technique also in the dominant signal from the surface of the layer not from the bulk substrate. [2] Here we have studied an experimental anisotropic quantum transport performed on an assemblage of vertical aligned graphene sheets from 5 to 300 K by a Bruker X-band (9.3 GHz). An anisotropic quantum transport is observed between b with WL and c with WAL axes at 5 - 50 K. With increasing temperature, the transport mechanism is changed along b and c axes. We use WL theory to fit all the spectra and obtain the coherence length  $L_\phi$ , long range scattering length  $L_{l\tau}$ , intervalley scattering length  $L_i$  and analyze the data. Our results indicate that ESR is a robust platform to study the intrinsic physical properties of graphene. [1] Y. Zhang, et al, Nature (London) 438, 201 (2005). [2] A. Drabinska, et al, Phys. Rev. B 86, 045421 (2012).

## 12:03PM B15.00005 Study of magnetotransport across the neutrality point in CVD graphene<sup>1</sup>

, RAMESH G. MANI, Georgia State University, Atlanta, GA 30303 — Hall effect compensation and a residual resistivity  $\rho_{xx} \approx h/4e^2$  are experimentally examined over the p $\leftrightarrow$ n transition about the nominal Dirac point in CVD graphene. The observed characteristics are reproduced in a model with a parabolic distribution  $f(V_N)$  of neutrality potentials,  $V_N$ , and simultaneous electron- and hole- conduction. The results suggest that, broadly about the gate-induced n  $\leftrightarrow$  p transition, charge transport is characterized by domain confined ambipolar currents, which leads to compensation in the global Hall effect and the observed residual resistivity.

## 12:15PM B15.00006 Magnetotransport measurements in graphene/ferromagnetic insulator heterostructures

, AARON SHARPE, Stanford University, WENMIN YANG, Institute of Physics, Chinese Academy of Science, MENYOUNG LEE, DAVID GOLDBERGER-GORDON, Stanford University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute of Material Science, Japan, ROBERT CAVA, Princeton University — Through proximity effects, it is possible for two-dimensional graphene sheets to inherit order parameters from another two-dimensional substrate. Specifically, graphene has been seen to exhibit ferromagnetism when placed on a ferromagnetic insulator. Ferromagnetic graphene is a very promising platform for devices potentially useful for spintronics applications. We present here magnetotransport measurements of graphene/ferromagnetic insulator heterostructures.

## 12:27PM B15.00007 Magnetotransport in Graphene on the Nano Scale measured by Scanning Tunneling Potentiometry<sup>1</sup>

, PHILIP WILLKE, THOMAS DRUGA, THOMAS KOTZOTT, RAINER ULBRICH, Univ Goettingen, ALEXANDER SCHNEIDER, Univ Erlangen-Nuernberg, MARTIN WENDEROTH, Univ Goettingen — The method of scanning tunneling potentiometry (STP) has been introduced by Muralt and Pohl [1] as a technique for mapping the electrochemical potential locally. Here we present a new home-built low-temperature STP setup with applicable magnetic field of up to 6T to study the spatial evolution of the voltage drop at extended defects in graphene with high-resolution.[2] We show that the voltage drop at a monolayer-bilayer boundary in graphene clearly extends spatially up to a few nanometers into the bilayer and hence is not located strictly at the structural defect. Moreover, different scattering mechanisms can be disentangled. Besides, we perform magnetotransport STP measurements mapping the local electrochemical potential as a function of the applied magnetic field. This allows us to identify localized and delocalized contributions to the magnetoresistance in epitaxial-grown graphene and to reveal the contribution of defects. [1] P. Muralt, D. W. Pohl, Scanning tunneling potentiometry, Appl. Phys. Lett., 48, 514 (1986) [2] P. Willke, et al. Spatial Extent of a Landauer Residual-Resistivity Dipole in Graphene quantified by Scanning Tunneling Potentiometry, Nature Commun. 6, 6399 (2015)

## 12:39PM B15.00008 Universality of Effective Medium and Random Resistor Network models for disorder-induced linear unsaturating magnetoresistance<sup>1</sup>

, SILVIA LARA, YING TONG LAI, CAMERON LOVE, Yale-NUS College, NAVNEETH RAMAKRISHNAN, Department of Physics and Centre for Advanced 2D Materials, National University of Singapore, SHAFIQUE ADAM, Yale-NUS College — In recent years, the Effective Medium Theory (EMT) [1] and the Random Resistor Network (RRN) [2] have been separately used to explain disorder induced magnetoresistance that is quadratic at low fields and linear at high fields. We demonstrate that the quadratic and linear coefficients of the magnetoresistance and the transition point from the quadratic to the linear regime depend only on the inhomogeneous carrier density profile. We use this to find a mapping between the two models using dimensionless parameters that determine the magnetoresistance and show numerically that they belong to the same universality class. [1] J. Ping, I. Yudhistira, N. Ramakrishnan, S. Cho, S. Adam, and M. S. Fuhrer, Phys. Rev. Lett. 113, 047206 (2014). [2] M. Parish and P. Littlewood, Nature 426, 162 (2003)

## 12:51PM B15.00009 Linear unsaturating magnetoresistance in disordered systems<sup>1</sup>

, YING TONG LAI, SILVIA LARA, CAMERON LOVE, Yale-NUS College, NAVNEETH RAMAKRISHNAN, Centre for Advanced 2D Materials, SHAFIQUE ADAM, Yale-NUS College — Theoretical works [1, 2] have shown that disordered systems exhibit classical magnetoresistance (MR). In this talk, we examine a variety of experimental systems that observe linear MR at high magnetic fields, including silver chalcogenides, graphene, graphite and Weyl semimetals. We show that a careful analysis of the magnitude of the MR, as well as the field strength at which the MR changes from quadratic to linear, reveal important properties of the system, such as the ratio of the root-mean-square fluctuations in the carrier density and the average carrier density. By looking at other properties such as the zero-field mobility, we show that this carrier density inhomogeneity is consistent with what is known about the microscopic impurities in these experiments. The application of this disorder-induced MR to a variety of different experimental scenarios underline the universality of these theoretical models. J. Ping, I. Yudhistira, N. Ramakrishnan, S. Cho, S. Adam, and M. S. Fuhrer, Phys. Rev. Lett. 113, 047206 (2014). M. Parish and P. Littlewood, Nature 426, 162 (2003)

<sup>1</sup>This work is supported by the Singapore National Research Foundation (NRF-NRFF2012-01) and the Singapore Ministry of Education and Yale-NUS College through grant number R-607-265-01312.

## 1:03PM B15.00010 Valley-symmetry-preserved transport in ballistic graphene layers with gate-defined carrier guiding

, MINSOO KIM, JI-HAE CHOI, SANG-HOON LEE, Department of Physics, Pohang University of Science and Technology, Korea, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, SEUNG-HOON JHI, HU-JONG LEE, Department of Physics, Pohang University of Science and Technology, Korea — Zigzag graphene nanoribbons are predicted to exhibit interesting electronic properties stemming from its Dirac band structure. However, to date, investigation of them is highly limited because of the defects and the roughness at the edges, which mix different valley properties of graphene. Here, we report the signature of conservation of valley symmetry in two types of quasi-1D ballistic graphene transport devices; one is a quantum point contact (QPC) and another is an Aharonov-Bohm (AB) interferometer. In measurements, charge carriers were confined in a potential well formed by the dual gates operation and the four-terminal magnetoconductance (MC) was measured with varying the carrier density, dc bias, and temperature. It exhibits the conductance quantization in steps of  $\Delta G = 4e^2/h$  starting from  $G = (2, 6), 10 \times e^2/h$  in a constricted conducting channel of QPC-type devices. This behavior is similar to the one observed in zigzag graphene nanoribbons having edge localized channels. Our tight-binding calculation shows that quasi-1D charge flow on a graphene plane acts a zigzag-type nanoribbon, unless it is perfectly aligned along the armchair direction. In the AB interferometry, we observed  $h/e$  periodic modulation of MC and the zero-field conductance minimum with a negative MC background.

**1:15PM B15.00011 Visualization of phase-coherent electron interference in a ballistic graphene Josephson junction**, MONICA ALLEN, Harvard University, OLES SHTANKO, MIT, ION COSMA FULGA, Weizmann Institute, JOEL WANG, MIT, DANIYAR NURGALIEV, Harvard University, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, ANTON AKHMEROV, TU Delft, PABLO JARILLO-HERRERO, LEONID LEVITOV, MIT, AMIR YACOBY, Harvard University — Graphene provides an appealing platform to explore electronic analogs of optics-like effects due to the nonclassical nature of ballistic charge transport. By coupling superconductors to a ballistic graphene sheet, we explore a new regime of superconducting transport in which phase-coherent interference of electron waves is a dominant feature. We employ Fraunhofer interferometry to achieve spatial imaging of cavity modes in a graphene Fabry-Perot resonator, embedded between two superconductors to form a Josephson junction. By visualizing current flow using Fourier methods, our measurements provide evidence of separate interference conditions for bulk and edge currents and elucidate the microscopic nature of interference at the crystal boundaries. We also observe modulation of the multiple Andreev reflection amplitude on and off resonance, a direct measure of cavity transparency. These results constitute a strong departure from conventional Josephson behavior and motivate further exploration of new effects at the intersection of superconductivity and electron-optics.

**1:27PM B15.00012 Magnetostrain-driven quantum engine on a grapheme flake<sup>1</sup>**, ENRIQUE MUNOZ, Pontificia Universidad Catolica de Chile, FRANCISCO PENA, Pontificia Universidad Catolica de Valparaiso — The concept of a quantum heat engine (QHE) has been discussed [1-3] as an alternative to efficiently recover, on a nanoscale device, thermal energy in the form of useful work. In a QHEN the working substance is in a mixed quantum state determined by a density matrix. Interesting examples of this concept are constituted by photosynthesis in plants as well as human-designed photocells [4]. In this work [1], we propose a graphene-based quantum engine, driven by a superposition of mechanical strain and an external magnetic field. Engineering of strain in a nanoscale graphene flake creates a gauge field with an associated uniform pseudo-magnetic field. The combination leads to the emergence of discrete relativistic Landau levels [1]. The inter-level distance and hence their statistical population can be modulated by quasi-statically tuning the imposed magnetic field along a sequence of reversible transformations that constitute a quantum mechanical analog of the classical Otto cycle. **1:39PM B15.00013 Magnetotransport of Epitaxial Graphene on Hexagonal SiC Surface Grown with Metal Plate Capping<sup>1</sup>**, KIBOG PARK, HAN BYUL JIN, SUNGCHUL JUNG, JUNHYOUNG KIM, Ulsan Natl Inst of Sci & Tech, DONG-HUN CHAE, WAN-SEOP KIM, JAESUNG PARK, Korea Research Institute of Standards and Science — High quality epitaxial graphene (EG) was grown on a Si-face hexagonal SiC substrate by capping the surface with a metal plate (Molybdenum, Tungsten) during UHV annealing. The growth temperature was  $\sim 950$  degree C, significantly lower than the conventional UHV annealing. The crystallinity of EG film was examined with Raman spectrum measurements. Almost no D-peak and a large narrow 2D-peak ensure that a thin (mono- or bi-layer) EG film was grown with a negligible number of defects. The electrical properties of EG film were also characterized by performing magnetotransport measurements with Hall-bar structures. The carrier type was found to be n-type, the sheet carrier density be  $(3.6-9.2) \times 10^{12} / \text{cm}^2$ , and the Hall mobility be  $\sim 2100 \text{ cm}^2/\text{Vs}$ . Due to the relatively high carrier density, the Quantum Hall Effect was observed only for high filling factors up to 14 T. However, clear Shubnikov-de-Hass oscillations were observed, indicating that the random carrier scattering due to impurities or defects is minimal in the EG film grown with metal plate capping.

<sup>1</sup>Supported by NRF in South Korea (2014M2B2A9031944)

**1:51PM B15.00014 Thermal Smearing of the Magneto-Kohn Anomaly for Dirac materials and comparison with the Two-dimensional electron Liquid**, DIPENDRA DAHAL, Department of Physics and Astronomy, Graduate Center and Hunter College of the City University of New York, 695 Park Avenue, New York, NY 10065, ANTONIOS BALASSIS, Department of Physics, Fordham University, NY, USA, GODFREY GUMBS, Department of Physics and Astronomy, Hunter College of the City University of New York, 695 Park Avenue, New York, NY 10065, M. L. GLASSER, Department of Physics, Clarkson University, Potsdam, New York 13699-5820, USA, GRAPHENE PROJECTS COLLABORATION — We compute and compare the effects due to a uniform perpendicular magnetic field and the temperature on the static polarization functions for monolayer graphene (MLG) associated with the Dirac point with that for the two-dimensional electron liquid (2DEL). Previous results for the 2DEL are discussed and we point out a flaw in reported analytic derivation to exhibit the smearing of the Fermi surface for 2DEL. The relevance of our study to the Kohn anomaly in low-dimensional structures and the Friedel oscillations for the screening of the potential for a dilute distribution of impurities is reported.

**2:03PM B15.00015 Hofstadter butterfly and quantum transport in graphene on hexagonal boron nitride from multiscale lattice simulations**, NICOLAS LECONTE, University of Texas at Austin, US - Department of Physics, University of Seoul, Seoul 130-742, Korea, RAFAEL MARTINEZ-GORDILLO, Centre Interdisciplinaire de Nanoscience de Marseille, CINAM, CNRS and Aix Marseille University, Campus de Luminy, Case 913, 13288 Marseille Cedex 9, ALLAN MACDONALD, University of Texas at Austin, US, JEIL JUNG, Department of Physics, University of Seoul, Seoul 130-742, Korea — Clear signatures of the Hofstadter butterfly have been experimentally observed in graphene on hexagonal boron nitride (G/BN), thanks to an appropriate balance between the length scale and the quality of the moiré superlattices. During this talk, I will present a methodology to map the continuum moiré pattern of incommensurable G/BN crystals obtained from ab initio calculations onto supercell lattice tight-binding Hamiltonians. Using efficient Lanczos recursion techniques for simulating large scale systems containing millions of atoms, the density of states and the dc conductivity are obtained as a function of energy or carrier density and magnetic field. The calculated Hofstadter butterflies and Landau fan diagrams show that the site potential variations, the mass, and substantial virtual strain contributions that appear even in the absence of real strains in the band Hamiltonian sensitively affect the electron-hole asymmetry, the gaps at the secondary Dirac points, as well as the tertiary features that appear at high-carrier densities.

**Monday, March 14, 2016 11:15AM - 2:15PM –**  
**Session B16 DMP: 2D Devices: Plasmonics and Optoelectronics** 315 - Paola Barbara, Georgetown University

**11:15AM B16.00001 GRAPHENE PLASMONICS** , SHIN MOU, DON ABEYSINGHE, Air Force Research Laboratory, Materials & Manufacturing Directorate, Wright-Patterson AFB, OH, USA, NIMA NADER, JOSHUA HENDRICKSON, JUSTIN CLEARY, Air Force Research Laboratory, Sensors Directorate, Wright-Patterson AFB, OH, USA, SAID ELHAMRI, Department of Physics, University of Dayton, Dayton, OH, USA — Plasmon, the collective free charge carrier oscillation, has been a popular research theme recently mostly associated with surface plasmon in metal nanoparticles. After the discovery of graphene, researchers soon began to study plasmonic effects with or within graphene, for instance, decorating graphene with metal nanoparticles to enhance optical processes via plasmonic field enhancement. Following that, people also gained interests in studying the intrinsic plasmon of graphene. Graphene, a tunable semimetal under field effect, demonstrates tunable plasmon resonances at room temperature, which enables new capabilities beyond those of metal-nanoparticle surface plasmons. In this project, we would like to show intrinsic graphene plasmon resonances in that we experimentally demonstrated polarization dependent and gate-bias tunable plasmon-resonance absorption in the mid-infrared regime of 5-14  $\mu\text{m}$  by utilizing an array of graphene nanoribbon resonators. By scaling nanoribbon width and charge densities, we probed graphene plasmons with plasmon resonance energy as high as 0.26 meV ( $2100\text{ cm}^{-1}$ ) for 40 nm wide nanoresonators. The result reveals the intriguing nature of graphene plasmon in graphene nanoribbons where the nanoribbon edge plays critical roles by introducing extra doping and damping the graphene plasmon resonance.

**11:27AM B16.00002 Optical and Electronic Properties of 2D Graphitic Carbon-Nitride and Carbon Enriched Alloys** , JOEL THERRIEN, YANCEN LI, DANIEL SCHMIDT, MICHAEL MASAKI, ABDULMANNAN SYED, U. Massachusetts Lowell — The two-dimensional form of graphitic carbon-nitride (gCN) has been successfully synthesized using a simple CVD process. In its pure form, the carbon to nitrogen ratio is 0.75. By adding a carbon bearing gas to the growth environment, the C/N ratio can be increased, ultimately reaching the pure carbon form: graphene. Unlike attempts at making a 2D alloy system out of BCN, the CN system does not suffer from phase segregation and thus forms a homogeneous alloy. The synthesis approach and electronic and optical properties will be presented for the pure gCN and a selection of alloy compositions.

**11:39AM B16.00003 Infrared two-wave mixing technique for characterization of graphene THz plasmonic devices<sup>1</sup>** , DENNIS DREW, MOHAMMAD JADIDI, ANDREI SUSHKOV, XINGHAN CAI, RYAN SUESS, MARTIN MITTENDORFF, THOMAS MURPHY, University of Maryland, College Park, MD 20742, MICHAEL FUHRER, Monash University, Australia, KEVIN DANIELS, KURT GASKILL, U.S. Naval Research Laboratory, Washington, DC 20375 — We have studied the heterodyne mixing of two beams from infrared lasers on graphene plasmonic devices and detectors. The nonlinear thermal response of graphene allows us to measure a DC photovoltage that depends on the heterodyne difference frequency and gate voltage. The inversion symmetry of the graphene device is broken by using dissimilar metal contacts to allow a net photo-thermoelectric signal. The power, frequency, and temperature dependence of the photoresponse are used to probe the graphene hot-electron cooling rates and mechanisms. We will discuss the use of photothermal effects in graphene to excite surface plasmons at the difference frequency. The high mobility of the free carriers in graphene is important for this experiment. We have measured exfoliated graphene on SiO<sub>2</sub>/Si substrate detector and we are working on BN graphene and intercalated SiC graphene devices.

<sup>1</sup>This work was sponsored by the U.S. ONR (N000141310865) and the U.S. NSF (ECCS 1309750).

**11:51AM B16.00004 THz Plasmonics of Quasi-freestanding Bilayer Epitaxial Graphene via H-intercalation** , KEVIN DANIELS, NRC postdoc residing at US Naval Research Laboratory, ANTHONY BOYD, ASEE postdoc residing at US Naval Research Laboratory, ANINDYA NATH, U.S. Naval Research Laboratory, MOHAMMAD JADIDI, ANDREI SUSHKOV, DENNIS DREW, University of Maryland, RACHAEL MYERS-WARD, KURT GASKILL, U.S. Naval Research Laboratory — Graphene plasmonics has attracted attention as a suitable platform for tunable THz optoelectronics. THz plasmonic resonances in conventional large-area graphene, however, suffer from low quality factor (Q) because of high carrier scattering rate. This low Q is attributed to charge carrier induced scattering and lower carrier mobility caused by the partially covalent bonding between the silicon carbide (SiC) substrate and the  $6\sqrt{3}$  buffer layer between the substrate and EG. Improving the Q of plasmons makes stronger THz resonance effects and also enable THz optoelectronics with fine tunability in frequency via gating. EG on Si-face, semi-insulating 6H-SiC was intercalated in-situ by hydrogen (H<sub>2</sub>), releasing the buffer layer from SiC forming quasi-freestanding bilayer graphene. H-intercalation time was varied from 0 – 75 minutes and structural, electrical and optical properties were explored, revealing at long H-intercalation durations high carrier mobility ( $3000\text{-}4000\text{ cm}^2/\text{Vs}$ ) and high sheet carrier concentration ( $1\text{E}13\text{ cm}^{-2}$ ) independent of carrier mobility. Far IR simultaneous transmission/reflection measurements revealed a narrow frequency response with line widths ( $\gamma$ ) smaller in H-intercalated EG ( $30\text{cm}^{-1}$ ) than observed in pristine EG ( $>100\text{cm}^{-1}$ ) consistent with the improved mobility.

**12:03PM B16.00005 Graphene Josephson Junction Single Photon Detector** , EVAN D WALSH, Massachusetts Institute of Technology, Harvard University, Raytheon BBN Technologies, GIL-HO LEE, Harvard University, DMITRI K EFETOV, MIKKEL HEUCK, Massachusetts Institute of Technology, JESSE CROSSNO, Harvard University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Japan, THOMAS A OHKI, Raytheon BBN Technologies, PHILIP KIM, Harvard University, DIRK ENGLUND, Massachusetts Institute of Technology, KIN CHUNG FONG, Raytheon BBN Technologies — Single photon detectors (SPDs) have found use across a wide array of applications depending on the wavelength to which they are sensitive. Graphene, because of its linear, gapless dispersion near the Dirac point, has a flat, wide bandwidth absorption that can be enhanced to nearly 100% through the use of resonant structures making it a promising candidate for broadband SPDs. Upon absorbing a photon in the optical to mid-infrared range, a small ( $\sim 10\text{ }\mu\text{m}^2$ ) sheet of graphene at cryogenic temperatures can experience a significant increase in electronic temperature due to its extremely low heat capacity. At 1550 nm, for example, calculations show that the temperature could rise by as much as 500%. This temperature increase could be detected with near perfect quantum efficiency by making the graphene the weak link in a Josephson junction (JJ). We present a theoretical model demonstrating that such a graphene JJ SPD could operate at the readily achievable temperature of 3 K with near zero dark count, sub-50 ps timing jitter, and sub-5 ns dead time and report on the progress toward experimentally realizing the device.

**12:15PM B16.00006 Imaging height fluctuations in free-standing graphene membranes** , KYLE DORSEY, MARC MISKIN, ARTHUR BARNARD, PETER ROSE, ITAI COHEN, PAUL MCEUEN, Cornell University — We present a technique based on multi-wavelength interference microscopy to measure the heights of observed ripples in free-standing graphene membranes. Graphene membranes released from a transparent substrate produce interference fringes when viewed in the reflection mode of an inverted microscope (Blees et. al. Nature 524 (7564): 204-207 (2015)). The fringes correspond to corrugation of the membrane as it floats near an interface. A single set of fringes is insufficient to uniquely determine the height profile, as a given fringe spacing can correspond to an increase or decrease in height by  $\lambda/2$ . Imaging at multiple wavelengths resolves the ambiguities in phase, and enables unique determination of the height profile of the membrane (Schilling et. al. Phys. Rev. E, 69:021901, 2004). We utilize this technique to map out the height fluctuations in free-standing graphene membranes to answer questions about fundamental mechanical properties of two-dimensional materials.

**12:27PM B16.00007 Metal Ion Intercalated graphitic as Transparent Electrodes** , JIAYU WAN, Univ of Maryland-College Park, WENZHONG BAO, Fudan University, FENG GU, Univ of Maryland-College Park, MICHAEL FUHRER, Monash University, LIANGBIN HU, University of Maryland, UMD TEAM — To best utilize the performance of graphene based transparent electrodes, we novelized Li-ion intercalation in graphene, and achieved highest performance of carbon based transparent electrodes. Transmission as high as 91.7% with a sheet resistance of 3.0 ohm/sq is achieved for 19-layer LiC<sub>6</sub>, significantly higher than any other continuous transparent electrodes. The unconventional modification of ultrathin graphite optoelectronic properties is explained by the suppression of interband optical transitions and a small intraband Drude conductivity near the interband edge. To achieve low cost, large scale graphene-based transparent electrodes, we further developed Na-ion intercalated printed reduced graphene oxide (RGO) film. The larger layer-layer distance of RGO allows Na-ion intercalation, leading to simultaneously much higher DC conductivity and higher optical transmittance. Typical increase of transmittance from 36% to 79% and decrease of sheet resistance from 83 kohms/sq to 311 ohms/sq in the printed network was observed. This study demonstrated the great potential of metal-ion intercalation to improve the performance of graphene-based materials for transparent conductor applications.

**12:39PM B16.00008 Tunable Broadband Printed Carbon Transparent Conductor** , YUE XU, JIAYU WAN, Univ of Maryland-College Park — Transparent conductors have been widely applied in solar cells, transparent smart skins, and sensing/imaging antennas, etc. Carbon-based transparent conductor has attracted great attention for its low cost and broad range transparency. Ion intercalation has been known to highly dope graphitic materials, thereby tuning materials' optoelectronic properties. For the first time, we successfully tune the optical transmittance of a reduced graphene oxide (RGO)/CNT network from mid-IR range to visible range by means of Li-ion intercalation/deintercalation. We also observed a simultaneous increase of the electrical conductivity with the Li-ion intercalation. This printed carbon hybrid thin film was prepared through all solution processes and was easily scalable. This study demonstrates the possibility of using ion intercalation for low cost, tunable broadband transparent conductors.

**12:51PM B16.00009 Design Two-dimensional Materials with Superb Electronic and Optoelectronic Properties: The case of SiS** , SU-HUAI WEI, Beijing Computational Science Research Center, JI-HUI YANG, National Renewable Energy Laboratory, YUEYU ZHANG, Fudan University, WAN-JIAN YIN, Soochow University, X. G. GONG, Fudan University, BORIS I. YAKOBSON, Rice University — Two-dimensional (2D) semiconductors have many unique electronic and optoelectronic properties that is suitable for novel device applications. Most of the current study are focused on group IV or transition metal chalcogenides. In this study, using atomic transmutation and global optimization methods, we identified two group IV-VI 2D materials, Pma2-SiS and silicene sulfide that can overcome shortcomings encountered in conventional 2D semiconductor. Pma2-SiS is found to be both chemically, energetically, and thermally stable. Most importantly, Pma2-SiS has unique electronic and optoelectronic properties, including direct bandgaps suitable for solar cells, good mobility for nanoelectronics, good flexibility of property tuning by layer thickness and strain appliance, and good air stability as well. Therefore, Pma2-SiS is expected to be a very promising 2D material in the field of 2D electronics and optoelectronics. Silicene sulfide also shows similar properties. We believe that the designing principles and approaches used to identify these materials have great potential to accelerate future finding of new functional materials within the 2D families.

**1:03PM B16.00010 Tunable ambipolar polarization-sensitive photodetectors based on high anisotropy ReSe<sub>2</sub>** , ENZE ZHANG, Fudan University, PENG WANG, Shanghai Institute of Technical Physics, ZHE LI, CE HUANG, KAITAI ZHANG, SHIHENG LU, WEIYI WANG, SHANSHAN LIU, Fudan University, HEHAI FANG, XIAOHAO ZHOU, WEIDA HU, Shanghai Institute of Technical Physics, PENG ZHOU, FAXIAN XIU, Fudan University — Atomically-thin 2D layered transition metal dichalcogenides (TMDs) have been extensively studied recently because of their intriguing physical properties and promising applications in nanoelectronic devices. Among them, ReSe<sub>2</sub> is a material that exhibits a stable distorted 1T phase and strong in-plane anisotropy. Here, the anisotropic nature of ReSe<sub>2</sub> is revealed by Raman scattering under linearly polarized excitations. Utilizing high-quality ReSe<sub>2</sub> nanosheets, we are able to build top-gate ReSe<sub>2</sub> field-effect transistors which show an excellent on/off current ratio exceeding 10<sup>7</sup> and a well-developed current saturation at room temperature. Importantly, the successful synthesis of ReSe<sub>2</sub> directly onto hexagonal boron nitride substrates has effectively improved the electron motility over 100 times and the hole mobility over 50 times at low temperatures. Remarkably, the ReSe<sub>2</sub> based photodetectors show a polarization-sensitive photo-responsivity due to the intrinsic linear dichroism originated from high in-plane optical anisotropy. With a back gate the linear dichroism photodetection can be unambiguously tuned both in the electron and hole regime. The appealing physical properties of ReSe<sub>2</sub> demonstrated in this study identify it as an emerging candidate for electronic and optoelectronic applications.

**1:15PM B16.00011 Silicon-nitride photonic circuits interfaced with monolayer MoS<sub>2</sub>**<sup>1</sup> , TEODOR K. STANEV, GUOHUA WEI, NATHANIEL P. STERN, Department of Physics and Astronomy, Northwestern University, DAVID A. CZAPLEWSKI, IL WOONG JUNG, Center for Nanoscale Materials, Argonne National Laboratory — Monolayers of transition metal dichalcogenides exhibit interesting low-dimensional opto-electronic phenomena and large optical interactions. Harnessing these features for modulating light requires interfacing these monolayer semiconductors with photonic devices. Here, we show the integration of monolayer molybdenum disulphide (MoS<sub>2</sub>) with silicon nitride ring microresonators using a visco-elastic layer transfer<sup>2</sup>. Cavity transmission is used to measure the coupling of the monolayer evanescently coupled to the ring resonator. A linear absorption coefficient of 850 dB/cm is observed in this geometry, which is larger than that of graphene and black phosphorus with the same thickness. These assembly methods can be applied to a diverse catalog of monolayer materials for assembling hybrid optoelectronic devices over a wide spectral range.

**1:27PM B16.00012 Plasmonic Hot Electron Induced Photocurrent Response at MoS<sub>2</sub>-Metal Junctions** , TU HONG, Vanderbilt University, BHIM CHAMLAGAIN, Wayne State University, SHUREN HU, SHARON WEISS, Vanderbilt University, ZHIXIAN ZHOU, Wayne State University, YAQIONG XU, Vanderbilt University — We investigate the photocurrent generation mechanisms at few-layer MoS<sub>2</sub>-metal junctions through wavelength- and polarization-dependent scanning photocurrent measurements. When laser energy is above the direct bandgap of MoS<sub>2</sub>, the maximum photocurrent response is observed when incident laser polarization direction is parallel to the metal electrode due to photovoltaic effect. On the contrary, when illuminated by laser with energy below the direct bandgap of MoS<sub>2</sub>, the strongest photocurrent response occurs when incident laser is polarized perpendicular to the metal electrode. Further studies demonstrate that light absorption by the plasmonic metal electrode is polarization-dependent, which creates hot electron-hole pairs and subsequently inject into MoS<sub>2</sub>. These studies shed light on future design rules of two-dimensional material based optoelectronic devices through surface plasmon resonances.

**1:39PM B16.00013 Spin-Polarized Transport on Photo-Assisted Bilayer Graphene Ribbons<sup>1</sup>**, DAVID ZAMBRANO, LUIS ROSALES, PEDRO ORELLANA, Departamento de Física, Universidad Técnica Federico Santa María, Casilla 110-V, Valparaíso, Chile, ANDREA LATGÉ, Instituto de Física, Universidade Federal Fluminense, 24210-340 Niterói-RJ, Brazil — We show how both transmission and spin polarization [1,2] behave in bilayer graphene ribbons in contact with a ferromagnetic insulator while a laser is applied to the ribbon. Using a  $\pi$ -orbital tight-binding model as a low energy approximation [1] and the Tien-Gordon [3] formalism we explore how these systems behave when the ribbon is photo-assisted with a laser. For particular values of the laser parameters, the Fano antiresonance are removed enhancing the transmission while for others spin-polarized transport will arise.

**1:51PM B16.00014 Graphene/MoS<sub>2</sub> heterostructures for optoelectronics applications<sup>1</sup>**, P HAN, Department of Physics, Georgetown University, Q WONG, Physics Department, University of Central Florida, A EL FATIMY, Department of Physics, Georgetown University, M ISHIGAMI, Physics Department and Nanoscience Technology Center, University of Central Florida, Orlando, FL 32816, P BARBARA, Department of Physics, Georgetown University, Washington DC, 20057 — Graphene and other atomically thin materials can be combined to make novel ultra-thin devices that are suitable for flexible substrates. However, fabricating these heterostructures is a challenge. Most previous work was done by stacking monolayers exfoliated from bulk materials [1], which is a very time-consuming, low-yield method. Large-area monolayer can also be grown by CVD and stacked, as demonstrated by the successful transfer of graphene on as-grown MoS<sub>2</sub> [2], yet the optical properties of some materials like MoS<sub>2</sub> may be degraded by the processing required to detach them from the growth substrate, thereby limiting options in device architecture. Here we develop a method to transfer, align and stack large flakes and films of MoS<sub>2</sub> and graphene after transferring both from the growth substrate onto an arbitrary substrate. The Raman and photoluminescence measurements show that the optical properties of the stacked monolayers are not degraded, making this method viable for fabrication of optoelectronics devices. **2:03PM B16.00015 Controlled growth, growth mechanism, and device applications of two-dimensional WSe<sub>2</sub>**, BILU LIU, CHONGWU ZHOU, University of Southern California — Atomically thin 2D transition metal dichalcogenides have attracted lots of attention recently. Here we will present our progress on the controlled growth of 2D WSe<sub>2</sub>. Vapor phase methods for the growth of large single crystalline WSe<sub>2</sub> with lateral sizes up to tens of micrometers will be discussed. Substrate atomic-step-guided nucleation and growth of aligned WSe<sub>2</sub> on single crystalline sapphire substrate will also be presented. In addition, by reducing the supply of source materials, we observed a novel screw-dislocation-driven growth of 2D few layer and pyramid-like WSe<sub>2</sub> flakes. Then, we will discuss device applications of CVD WSe<sub>2</sub>. We show that the device characteristics of CVD WSe<sub>2</sub> can be tuned into either p-type or ambipolar behavior, by changing the types of contact metals. We further developed an efficient method to convert as-grown semiconducting 2H-phase WSe<sub>2</sub> into metallic 1T-phase WSe<sub>2</sub>, by controlled reacting with n-butyl lithium (n-BuLi). By using metallic WSe<sub>2</sub> as contact regimes and intact semiconducting WSe<sub>2</sub> as channel regimes, we successfully made ohmic contacted WSe<sub>2</sub> transistors and achieved a hole mobility of 66 cm<sup>2</sup>/V.s and on/off ratio of 10<sup>7</sup> for monolayer CVD WSe<sub>2</sub>.

**Session B17 DMP: Graphene: Synthesis, Properties, and Defects** 316 - Saptarshi Das, Pennsylvania State University

**11:15AM B17.00001 Synthesis and Properties of 2D Atomic Layers: from Graphene to 2D-GaN**, JOSHUA ROBINSON, The Pennsylvania State University — Beyond graphene, there is a huge variety of layered materials that range in properties from insulating to superconducting. Furthermore, heterogeneous stacking of 2D materials also allows for additional “dimensionality” for band structure engineering. In this talk, I will discuss recent breakthroughs in two-dimensional atomic layer synthesis and properties, including novel 2D heterostructures and novel 2D nitrides. Our recent works include development of an understanding of substrate impact on 2D layer growth and properties, doping of 2D materials with magnetic elements, selective area synthesis of 2D materials, and the first demonstration of 2D gallium nitride (2D-GaN). Our work and the work of our collaborators has lead to a better understanding of how substrate not only impacts 2D crystal quality, but also doping efficiency in 2D materials, and stabilization of nitrides at their quantum limit.

**11:51AM B17.00002 Line defects in Graphene: How doping cures the electronic and mechanical properties**, DANIEL BERGER, CHRISTIAN RATSCH, Department of Mathematics, UCLA — Graphene and carbon nanotubes have extraordinary mechanical properties. Intrinsic line defects such as local non-hexagonal reconstructions or grain boundaries, however, significantly reduce the tensile strength and destroy its unique electronic properties. Here, we address the properties of line defects in graphene from first-principles on the level of full-potential density functional theory, and assess doping as one strategy to strengthen such materials. We carefully disentangle the global and local effect of doping by comparing results from the virtual crystal approximation with those from local substitution of chemical species, in order to gain a detailed understanding of the breaking and stabilization mechanisms. We find that n-type doping or local substitution with electron rich species increases the ultimate tensile strength significantly. In particular, it can stabilize the defects beyond the ultimate tensile strength of the pristine material. We therefore propose that this should be a key strategy to strengthen graphenic materials. We find that doping can furthermore lead to semi-conducting behaviour along line defects, ultimately restoring the unique electronic properties of graphene.

**12:03PM B17.00003 Polycyclic carbon molecules with zigzag edges as sources of defects in graphene on a metal**, ALEXANDRE ARTAUD, CEA Grenoble, F-38000 Grenoble, France, LAURENCE MAGAUD, CNRS, Institut Néel, F-38000 Grenoble, France, KITTI RATTER, CNRS, SIMAP, F-38000 Grenoble, France, VALÉRIE GUISET, PHILIPPE DAVID, CNRS, Institut Néel, F-38000 Grenoble, France, BRUNO GILLES, CNRS, SIMAP, F-38000 Grenoble, France, JOHANN CORAUX, CNRS, Institut Néel, F-38000 Grenoble, France, CLAUDE CHAPÉLIER, CEA Grenoble, F-38000 Grenoble, France — Unlike the armchair edge, the zigzag edge of graphene breaks the equivalence of its two constituting carbon sub-lattices. Uncompensated magnetic moments are thus expected for such edges. For the same reason, dense polycyclic molecules (PCMs) terminated by zigzag edges are predicted to host net magnetic moments. Unfortunately, their synthesis is challenging. One approach relies on the pyrolysis of hydrocarbons, catalyzed by a transition metal. Here we investigate this little-explored approach, and put in evidence the formation of a series of highly symmetric zigzag edge PCMs onto Re(0001), among which phenalene, coronene and sumanene. We also address the relationship between the preparation of such molecules and graphene, which both form following hydrocarbon pyrolysis. We establish that the PCMs are unexpected obstacles towards high quality graphene.

**12:15PM B17.00004 Electronic Transport through linear strain defects in Graphene**, YONG WU, BIN CHENG, CHENG PAN, MARC BOCKRATH, University of California, Riverside — Strain-induced pseudo magnetic fields in Graphene have been studied by STM [1] as well as theoretically.[2] Such pseudo magnetic fields can confine electrons by the presence of magnetic barriers [3] or by the formation of closed cyclotron orbits. Here we report transport measurements through a nanometer-scale width, but micron-scale length linear strain defect in a graphene sheet. The transport data exhibits Coulomb blockade features, indicating the presence of a quantum dot. The charging energy and level spacing are consistent with the defect forming a one-dimensional quantum wire, similar to a carbon nanotube. This suggests the possibility that such defects can be used to confine or guide electrons in graphene. Our latest results will be discussed. [1].Strain? Induced PseudoMagnetic Fields Greater Than 300 Tesla in Graphene Nanobubbles ,N. Levy ,M. F. Crommie etc, Science [2].?Energy gaps and a zero? field quantum Hall effect in graphene by strain engineering, F. Guinea, A.Geim , Nature Physics [3].Magnetic Confinement of Massless Dirac Fermions in Graphene,A. De Martino, L. Dell'Anna, and R. Egger, Physical Review Letters

**12:27PM B17.00005 ABSTRACT WITHDRAWN —**

**12:39PM B17.00006 The Effect of Defects on Mechanical Properties and Failure Mechanisms of Graphene**, JONATHAN WILLMAN, JOSEPH GONZALEZ, University of South Florida, ROMAIN PERRIOT, Los Alamos National Laboratory, IVAN OLEYNIK, University of South Florida — Recent experiments involving nanoindentation of graphene have demonstrated counterintuitive increasing of Young's modulus with increasing concentrations of point defects in graphene. To fully resolve this controversy we perform large-scale molecular dynamics simulations of graphene nanoindentation. The reliable description of interatomic interactions is achieved by using recently developed screened environment-dependent bond order (SED-REBO) potential. The elastic properties of the defective graphene, the breaking strength and the mechanisms of fracture under indenter are investigated as a function of defect concentration and other factors specific to Atomic Force Microscopy (AFM) nanoindentation experiments.

**12:51PM B17.00007 Mechanical Behavior of Graphene Nanomeshes**, MENGXI CHEN, LIN HU, ASHWIN RAMASUBRAMANIAM, DIMITRIOS MAROUDAS, Univ of Mass - Amherst — Graphene nanomeshes (GNMs) are ordered, defect-engineered graphene nanostructures consisting of periodic arrays of nanopores in the graphene lattice with neck widths less than 10 nm. The electronic, transport, and mechanical properties of GNMs can be tuned by varying the structural, chemical, and architectural parameters of the nanomeshes, namely, their porosity, as well their pore lattice structure, pore morphology, and pore edge passivation. Here, we study the mechanical response of GNMs to uniaxial tensile straining and determine their mechanical properties based on molecular-dynamics simulations of dynamic deformation tests according to a reliable bond-order interatomic potential. We establish the dependences of the elastic modulus, fracture strain, ultimate tensile strength, and toughness on the nanomesh porosity and derive scaling laws for GNM modulus-density and strength-density relations. We also establish the dependence of the above properties on pore morphology, for GNMs with circular and elliptical pores over a range of aspect ratios, and on pore edge hydrogen passivation that causes elastic stiffening and strength reduction. The underlying mechanisms of crack initiation and propagation and nanomesh failure also are characterized.

**1:03PM B17.00008 Fe-catalyzed etching of graphene layers**, GUANGJUN CHENG, IRENE CALIZO, ANGELA HIGHT WALKER, NIST, PML, NIST TEAM — We investigate the Fe-catalyzed etching of graphene layers in forming gas. Fe thin films are deposited by sputtering onto mechanically exfoliated graphene, few-layer graphene (FLG), and graphite flakes on a Si/SiO<sub>2</sub> substrate. When the sample is rapidly annealed in forming gas, particles are produced due to the dewetting of the Fe thin film and those particles catalyze the etching of graphene layers. Monolayer graphene and FLG regions are severely damaged and that the particles catalytically etch channels in graphite. No etching is observed on graphite for the Fe thin film annealed in nitrogen. The critical role of hydrogen indicates that this graphite etching process is catalyzed by Fe particles through the carbon hydrogenation reaction. By comparing with the etched monolayer and FLG observed for the Fe film annealed in nitrogen, our Raman spectroscopy measurements identify that, in forming gas, the catalytic etching of monolayer and FLG is through carbon hydrogenation. During this process, Fe particles are catalytically active in the dissociation of hydrogen into hydrogen atoms and in the production of hydrogenated amorphous carbon through hydrogen spillover.

**1:15PM B17.00009 The Production of Graphene Coated Surface by PVD and Investigation of Its Electrical and Optical Properties**, MEHMET YUMAK, Bogazici University Lifescie Center, FATMA SIMSEK, OZGUR KOCATURK, Bogazici University Department of Biomedical Engineering — Graphene is used for a broad range of applications with unique properties such as lightweight, flexibility, mechanical strength, best electrical and thermal conductivity in industrial processes like electronics,medicine,energy,sensors, and other areas related with material usage variations. There are a few common methods to produce graphene. In this study PVD method was used to produce graphene. Many challenging issue was handled in this method like production temperature, growth surface, and mechanical effects. Produced graphene was studied by XRD, scanning electron microscopy (SEM), Raman spectroscopy, and AFM.

**1:27PM B17.00010 Defects, Strain, Incommensurability and Polymorphism in Graphene on Metals**, MICHAEL ALTMAN, KA MAN YU, FEIFEI WANG, Hong Kong University of Science and Technology — The prevalence of defects in large-area graphene fabricated on metal substrates may undermine the unique properties that are vital to its use in technological applications. Although efforts to mitigate these imperfections have met with some success, they may alternatively be harnessed to tailor graphene's properties or alter its functionality. We have studied the growth/defect structure of graphene/metals using low energy electron microscopy (LEEM) and micro-low energy electron diffraction ( $\mu$ -LEED). These investigations reveal the proliferation of small-angle lattice orientational disorder and small angle grain boundaries in graphene/Ru(0001) prepared by conventional ethylene CVD at high temperature. Although orientationally uniform graphene could be produced by a hybrid CVD/segregation method, this layer exhibits significant incommensurability and polymorphism, i.e. several commensurate structures. Two-dimensional strain mapping in graphene/Ir(111) obtained from scanning  $\mu$ -LEED measurements using a 250nm probe beam reveals inhomogeneous strain relaxation by wrinkles. This suggests that it may be possible to strain engineer the properties of graphene if wrinkling can be controlled to form desirable wrinkle networks. Coupling of lattice rotation and strain is also observed by the same approach in graphene on other metal substrates.

**1:39PM B17.00011 A single-step growth process of graphane using hydrogen plasma and observation of an induced bandgap.** , M.L. TEAGUE, D.A. BOYD, W.-S. TENG, C.-C. HSU, N.-C. YEH, Dept. of Physics, Caltech, Pasadena, CA 91125, M. GHARIB, Dept. of Aeronautics, Caltech, Pasadena, CA 91125 — There has been considerable interest in reliably opening up a bandgap in graphene for electronic applications. One promising method is the hydrogenation of graphene into graphane. We present Raman spectroscopy, scanning tunneling microscopy/spectroscopy (STM/STS) and x-ray photoemission spectroscopy (XPS) studies of hydrogenated multilayer graphene on Cu as a function of hydrogen exposure time ( $t$ ). Our growth process for hydrogenated graphene involved *in-situ* exposure of PECVD-grown graphene on Cu to hydrogen plasma. Raman measurements revealed an increase in intensity of a pronounced and narrow D-band with  $t$  when compared to pristine graphene. FTIR studies revealed the presence of C-H bonds on the surface of our samples post hydrogenation. STM topographic studies revealed a nanoscale Moiré pattern resulting from the hydrogenated graphene. For  $t = 120$ s, STS studies revealed an average gap of  $\Delta \sim (0.2750.050)$  eV, which increased to average value of  $\Delta \sim (0.3150.050)$  eV for  $t = 600$ s. Topographic and spectroscopic studies showed approximate hydrogen coverage of 20%, 50% and 80% for  $t = 30$ s, 60s and 120s, respectively. XPS studies of the C-1s state revealed an energy shift from the C-C peak (284.6 nm) towards a C-H peak (285.8 nm), consistent with the formation of carbon-hydrogen bonds. Our results have demonstrated the existence of a bandgap opening in graphene, induced by the adsorption of atomic hydrogen onto graphene.

**1:51PM B17.00012 Ion irradiation of graphene on Ir(111): From trapping to blistering** , CHARLOTTE HERBIG, Universität zu Köln, E. HARRIET ÅHLGREN, University of Helsinki, PHILIPP VALERIUS, ULRIKE A. SCHRÖDER, ANTONIO J. MARTÍNEZ-GALERA, Universität zu Köln, MOHAMMAD A. ARMAN, Lund University, JANI KOTAKOSKI, University of Vienna, JAN KNUDSEN, Lund University, ARKADY V. KRASHENINNIKOV, Aalto University and Helmholtz-Zentrum Dresden-Rossendorf, THOMAS MICHELY, Universität zu Köln — Graphene grown epitaxially on Ir(111) is irradiated with low energy noble gas ions and the processes induced by atomic collision and subsequent annealing are analyzed using scanning tunneling microscopy, low energy electron diffraction, X-ray photoelectron diffraction and thermal desorption spectroscopy. Upon room temperature ion irradiation graphene amorphizes and recovers its crystalline structure during annealing. The energetic noble gas projectiles are trapped with surprisingly high efficiency under the graphene cover up to extremely high temperatures beyond 1300K. The energy, angle, and ion species dependence of trapping are quantified. At elevated temperatures the trapped gas forms well developed and highly pressurized blisters under the graphene cover [1-3]. We use molecular dynamics simulations and ab initio calculations to elucidate the trapping mechanism and its thermal robustness. Similar trapping and blistering are observed after ion irradiation of a single layer of hexagonal boron nitride on Ir(111) and we speculate on the generality of the observed phenomena. [1] C. Herbig et al., ACS Nano 8, 12208 (2014). [2] C. Herbig et al., ACS Nano 9, 4664 (2015). [3] C. Herbig et al., PRB 92, 085429 (2015).

**2:03PM B17.00013 Visualizing Klein tunneling in graphene at the atomic limit** , CHRISTOPHER GUTIERREZ, Columbia University, LOLA BROWN, EDWARD B. LOCHOCKI, CHEOL-JOO KIM, KYLE M. SHEN, JIWOONG PARK, Cornell University, ABHAY N. PASUPATHY, Columbia University — Graphene has attracted much attention from both the solid-state and high-energy scientific communities because its elementary excitations mimic relativistic chiral fermions. This has allowed graphene to act as a table-top testbed for verifying certain longstanding theoretical predictions dating back to the very first formulation of relativistic quantum mechanics. One such prediction is Klein tunneling, the ability of chiral electrons to transmit perfectly through arbitrarily high potential barriers. Previous transport and point-spectroscopic studies confirmed Klein behavior of graphene electrons but lacked real-space resolution. Here we use scanning tunneling microscopy and spectroscopy (STM/STS) measurements to present the first real-space atomic images of Klein tunneling in graphene. In these CVD-grown samples, quasi-circular regions of the copper substrate underneath graphene act as potential barriers that can scatter and transmit electrons. At certain energies, the relativistic chiral fermions that Klein scatter from these barriers are shown to fulfill resonance conditions such that the transmitted electrons become trapped and form standing waves. These resonant modes are visualized with detailed spectroscopic images with atomic resolution that agree well with theoretical calculations. The trapping time is shown to depend critically on both the angular momenta quantum number of the resonant state and the radius of the trapping potential.

Session B18 GMAG DCMP FIAP: Spin-orbit and Superconductivity: Majorana Modes 317 - Alex Matos-Abiague, University at Buffalo

**11:15AM B18.00001 Quantized Conductance in InSb nanowires at zero magnetic field** , JAKOB KAMMhuber, MAJA CASSIDY, HAO ZHANG, ÖNDER GÜL, FEI PEI, MICHIEL DE MOOR, Delft University of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, DIANA CAR, ERIK BAKKERS, Eindhoven University of Technology, LEO KOUWENHOVEN, Delft University of Technology — We present measurements of InSb nanowires in the ballistic transport regime. In 1D materials such as nanowires, electron scattering has an increased chance of back-reflection, obscuring the observation of quantized conductance at low magnetic fields. By improving the contacts to the nanowire as well as its dielectric environment backscattering events are minimized and conductance quantization is observable at zero magnetic field with high device yield. We study the evolution of individual sub-bands in an external magnetic field, observing a degeneracy between the 2<sup>nd</sup> and 3<sup>rd</sup> sub-band when the magnetic field is orientated perpendicular to the nanowire axis.

**11:27AM B18.00002 Majorana fermions in charge carrier hole quantum wires<sup>1</sup>** , JINGCHENG LIANG, YULI LYANDA-GELLER, Purdue Univ — In order to realize Majorana fermions in a hybrid semiconductor- superconductor structure, spin helical order is needed, which prevents fermion doubling. A natural proposal for Majorana fermion setting is to utilize charge carrier hole systems, which have strong spin orbit couplings that can result in a spin helix. In this work, we demonstrate that transformation of heavy holes into light holes and vice versa upon reflection from the heterostructure boundaries crucially affects Luttinger hole spectrum in low dimensions, and most importantly, spin-orbit interactions in the ground sub-band of a hole quantum wire. Spin orbit interactions are dominated by several terms linear in the hole momentum. We show that the criterion for realizing proximity-induced topologically non-trivial superconducting phase and zero Majorana modes in a hole wire is similar to that for electrons, but an extra constraint should be satisfied. Due to their stronger spin-orbit coupling, the hole systems can be promising settings to study Majorana fermions experimentally.

**11:39AM B18.00003 Majorana modes in InSb nanowires (II): resolving the topological phase diagram**, HAO ZHANG, ÖNDER GÜL, MICHIEL DE MOOR, FOKKO DE VRIES, JASPER VAN VEEN, DAVID VAN WOERKOM, KUN ZUO, VINCENT MOURIK, MAJA CASSIDY, ATTILA GERESDI, Delft Univ. of Tech, DIANA CAR, Eindhoven Univ. of Tech, ERIK BAKKERS, Delft Univ. of Tech, Eindhoven Univ. of Tech, SRIJIT GOSWAMI, Delft Univ. of Tech, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, Japan, LEO KOUWENHOVEN, Delft Univ. of Tech — Majorana modes in hybrid superconductor-semiconductor nanowire devices can be probed via tunnelling spectroscopy which shows a zero bias peak (ZBP) in differential conductance (1). Majoranas are formed when the Zeeman energy  $E_Z$  and the chemical potential  $\mu$  satisfy the condition  $E_Z > \sqrt{\Delta^2 + \mu^2}$ , with  $\Delta$  the superconducting gap. This Majorana condition outlines the topologically non-trivial phase and predicts a particular dependence of ZBPs on the gate voltage and the external magnetic field. In this talk we show that the magnetic field range of ZBPs can be tuned by gate voltage and vice versa, consistent with these Majorana predictions. Supported by measurements in different external magnetic field orientations, these observations pave the way for exploring the topological phase diagram of spin-orbit coupled semiconductor nanowires with induced superconductivity.

**11:51AM B18.00004 Majorana modes in InSb nanowires (I): zero bias peaks in hybrid devices with low-disorder and hard induced superconducting gap**, Ö. GÜL, H. ZHANG, M.W.A. DE MOOR, F. DE VRIES, J. VAN VEEN, D.J. VAN WOERKOM, K. ZUO, V. MOURIK, M. CASSIDY, A. GERESDI, Delft Univ. of Tech., D. CAR, Eindhoven Univ. of Tech., E.P.A.M. BAKKERS, Delft Univ. of Tech., Eindhoven Univ. of Tech., S. GOSWAMI, Delft Univ. of Tech., K. WATANABE, T. TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, Japan, L.P. KOUWENHOVEN, Delft Univ. of Tech. — Majorana modes in hybrid superconductor-semiconductor nanowire devices can be probed via tunnelling spectroscopy which shows a zero bias peak (ZBP) in differential conductance (1). However, alternative mechanisms such as disorder or formation of quantum dots can also give rise to ZBPs, and obscure experimental studies of Majoranas. Further, a soft induced superconducting gap commonly observed in experiments presents an outstanding challenge for the demonstration of their topological protection. In this talk we show that with device improvements, we reach low-disorder transport regime with clear quantized conductance plateaus and Andreev enhancement approaching the theoretical limit. Tunnelling spectroscopy shows a hard induced superconducting gap and no formation of quantum dots. Together with extremely stable ZBPs observed in large gate voltage and magnetic field ranges, we exclude various alternative theories besides the formation of localized Majorana modes for our observations.

**12:03PM B18.00005 Investigation of semiconductor nanowires with shadow-evaporated epitaxial superconducting shells**, JOHN WATSON, MAJA CASSIDY, JAKOB KAMMHUBER, MICHIEL DE MOOR, LEO KOUWENHOVEN, Delft Technical University, PETER KROGSTROP, MINGTANG DENG, THOMAS JESPERSEN, JESPER NYGARD, CHARLES MARCUS, University of Copenhagen — We report progress on epitaxially grown InAs/Al core/shell nanowire heterostructures by molecular beam epitaxy with junctions in the Al shells formed in-situ by a crossed wire shadowing method during growth. Such wires allow the creation of superconductor-normal-superconductor (SNS) junctions with high quality superconductor-semiconductor interfaces without introducing damage in the junction by etching the Al. Shadowing is accomplished by a two-step growth process in which the nanowire growth direction is changed resulting in crossed networks of nanowires which shadow one another from the Al flux. We observe hard superconducting gaps and supercurrents in excess of 50 nA with in-plane critical fields above 1 T. We compare our results with shadowed devices to previous data from SNS junctions with wet-etched shells. Our experiments indicate that this crossed wire shadowing technique provides an interesting route to investigating induced superconductivity in semiconductor nanowires.

**12:15PM B18.00006 Wireless Majorana Fermions: From Magnetic Tunability to Braiding<sup>1</sup>**, GEOFFREY FATIN, ALEX MATOS-ABIAGUE, BENEDIKT SCHARF, IGOR ZUTIC, University at Buffalo - SUNY — We propose a versatile platform to investigate the existence of zero-energy Majorana fermions (MFs) and their non-Abelian statistics through braiding [1]. This implementation combines a two-dimensional electron gas formed in a semiconductor quantum well grown on the surface of an *s*-wave superconductor, with a nearby array of magnetic tunnel junctions (MTJs). The underlying magnetic textures produced by MTJs provide highly-controllable topological phase transitions to confine and transport MFs in two dimensions, overcoming the requirement for a network of wires.

**12:27PM B18.00007 Spin-Orbit Coupling in Hybrid Semiconductor Structures: From Majorana Fermions to Topological Insulators**, BENEDIKT SCHARF, State Univ of NY - Buffalo — Hybrid semiconductor structures with strong spin-orbit coupling are responsible for many fascinating phenomena. Topological states in systems of reduced dimensionality, in particular, offer many intriguing possibilities, both for fundamental research as well as for potential applications. In this talk, we describe the importance of the interplay of spin-orbit coupling (SOC) and the sample geometry in realizing exotic Majorana fermions (MFs) in quantum dots and rings and discuss several schemes to detect MFs [1]. An effective SOC from the magnetic textures provided by magnetic tunnel junctions could enable a versatile control of MFs and their adiabatic exchange [2]. We show that in 2D topological insulators (TIs), such as inverted HgTe/CdTe QWs, helical quantum spin Hall (QSH) states persist even at finite magnetic fields below a critical magnetic field above which only quantum Hall (QH) states can be found [3]. We propose magneto-optical absorption measurements to probe the magnetic-field induced transition between the QSH and QH regimes. This measurement scheme is robust against perturbations such as additional SOC due to bulk or structure-inversion asymmetry [4]. Finally, tunnel junctions based on the surfaces of 3D TIs are presented. These junctions can exhibit giant tunneling anomalous Hall (TAH) currents and negative differential TAH conductance, which makes them an attractive and versatile system for spintronic applications [5]. **1:03PM B18.00008 Wavefunction oscillations and fermion parity crossings in disordered Majorana wire**, SURAJ HEGDE, SMITHA VISHVESHVARA, Univ of Illinois - Urbana — We study aspects of decay and oscillations of Majorana wavefunctions in one dimensional topological superconducting chains, by employing Majorana transfer matrix technique. The phase transition separating the trivial phase and the topological phase associated with the Majorana end modes can be traced to the cancellation of the two parts (superconducting and normal) of the Lyapunov exponent of the transfer matrix. We find that the Majorana oscillations and related fermion parity flips can be completely determined by an underlying non-superconducting tight-binding model. Using this observation we pinpoint the behavior of Majorana mode oscillations within the topological phase diagram. For a disordered wire, these band oscillations are completely washed out, leading to a second localization length for the Majorana mode. The remnant oscillations are however manifested and completely randomized by disorder effects. As a result, the associated fermion parity flips depend heavily on the average of the disorder distribution and the number of lattice sites of the chain. We show that the transfer matrix technique offers a simple way of understanding the known log-normal distribution of mid-gap Majorana states.

**1:15PM B18.00009 Interfacial spin-orbit fields in ferromagnet/normal metal (FN) and ferromagnet/superconductor (FS) systems<sup>1</sup>**, PETRA HOEGL, University of Regensburg, ALEX MATOS-ABIAGUE, IGOR ZUTIC, University at Buffalo - SUNY, JAROSLAV FABIAN, University of Regensburg — Breaking of space-inversion symmetry at interfaces induces spin-orbit fields as an emergent phenomenon. Interfacial spin-orbit fields are believed to enable a wealth of new phenomena, not existent or fragile in the bulk, such as the tunneling anisotropic magnetoresistance (TAMR), interfacial spin-orbit torques, Skyrmions, or possible realization of topological superconductors. We theoretically investigate spin-polarized transport in FN and FS junctions in the presence of Rashba and Dresselhaus interfacial spin-orbit fields. The interplay of magnetism and spin-orbit fields leads to a marked magnetoanisotropy of the conductances. Remarkably, the anisotropy in FS systems—magnetoanisotropic Andreev reflection (MAAR)—is giant compared to TAMR, its normal-state counterpart in FN junctions [1]. We further report on the dependence of spin-flip probability currents on characteristic system parameters [2].

**1:27PM B18.00010 An exactly solvable model for a strongly spin-orbit-coupled nanowire quantum dot<sup>1</sup>**, RUI LI, Beijing Computational Science Research Center, LIAN-AO WU, University of the Basque Country, XUEDONG HU, University at Buffalo, SUNY, J.Q. YOU, Beijing Computational Science Research Center — In the presence of spin-orbit coupling, quantum models for semiconductor materials are generally not exactly solvable. As a result, understanding of the strong spin-orbit coupling effects in these systems remains incomplete. Here we develop a method to solve exactly the one-dimensional hard-wall quantum dot problem for a single electron in the presence of a strong spin-orbit coupling and a finite magnetic field. This method allows us to obtain the exact eigenenergies and eigenstates for the single electron. With the help of this solution, we demonstrate unique effects from the strong spin-orbit coupling in a semiconductor quantum dot, in particular the anisotropy of the electron g-factor and its tunability.

**1:39PM B18.00011 Charge instability in double quantum dots in Ge/Si core/shell nanowires**, AZARIN ZARASSI, ZHAOEN SU, University of Pittsburgh, JENS SCHWENDERLING, RWTH Aachen University, SERGEY M. FROLOV, University of Pittsburgh, MORA HOCEVAR, Institutel Nel CNRS, BINH-MINH NGUYEN, HRL Labs, JINKYOUNG YOO, Los Alamos National Laboratory, SHADI A. DAYEH, University of California San Diego — Controlling dephasing times are of great challenge in the studies of spin qubit. Reported long spin coherence time and predicted strong spin-orbit interaction of holes in Ge/Si core/shell nanowires, as well as their weak coupling to very few nuclear spins of these group IV semiconductors, persuade electrical spin control. We have established Pauli spin blockade in gate-tunable quantum dots formed in these nanowires. The g-factor has been measured and evidence of spin-orbit interaction has been observed in the presence of magnetic field. However, electrical control of spins requires considerable stability in the double dot configuration, and imperfectly these dots suffer from poor stability. We report on fabrication modifications on Ge/Si core/shell nanowires, as well as measurement techniques to suppress the charge instabilities and ease the way to study spin-orbit coupling and resolve electric dipole spin resonance.

**1:51PM B18.00012 Electrically driven hole spin resonance in MOSFET nanowires**, DHARMRAJ KOTEKAR PATIL, ROMAIN MAURAND, ANDREA CORNA, XAVIER JEHL, CEA-INAC and Universit Grenoble Alpes, 17 Rue des Martyrs, 38054 Grenoble, France, ALEXEI ORLOV, Department of Electrical Engineering, University of Notre Dame, Notre Dame, IN 46556, USA, ROMAIN LAVIVILLE, SYLVAIN BARRAUD, LOUIS HUTIN, CEA-LETI and Universit Grenoble Alpes, 17 rue des Martyrs, 38054 Grenoble, France, MARC SANQUER, SILVANO DE FRANCESCHI, CEA-INAC and Universit Grenoble Alpes, 17 Rue des Martyrs, 38054 Grenoble, France — Hole spins in silicon represent a promising direction for solid-state quantum computation, possibly combining fast qubits with limited hyperfine interaction yielding long coherence times. Here we report on hole double quantum dots defined in dual-gate, p-type silicon nanowire MOSFETs. Devices are fabricated on 300-mm silicon-on-insulator wafers using an industry-standard CMOS platform. We show that a microwave frequency signal applied to one gate of the transistor can induce hole spin resonance leading to an enhanced electrical current through the device. The origin of the observed spin resonance is discussed. From the power dependence of the spin resonance signal we deduce Rabi frequencies as high as ~100 MHz. Our experiments suggest hole quantum dots in silicon as promising candidates for electrically controlled spin qubits.

**2:03PM B18.00013 Spin transistor based on pure nonlocal Andreev reflection in EuO-graphene/superconductor/EuO-graphene nanostructure**, YEE SIN ANG, LAY KEE ANG, Singapore University of Technology and Design, CHAO ZHANG, University of Wollongong, ZHONGSHUI MA, Peking University — In graphene-magnetic-insulator hybrid structure such as graphene-Europium-oxide, proximity induced exchange interaction opens up a spin-dependent bandgap and spin splitting in the Dirac band. We show that such band topology allows pure crossed Andreev reflection to be generated exclusively without the parasitic local Andreev reflection and elastic cotunnelling over a wide range of bias and Fermi levels. We model the charge transport in an EuO-graphene/superconductor/EuO-graphene three-terminal device and found that the pure non-local conductance exhibits rapid on/off switching characteristic with a minimal subthreshold swing of ~20 mV. Non-local conductance oscillation is observed when the Fermi levels in the superconducting lead is varied. The oscillatory behavior is directly related to the quasiparticle propagation in the superconducting lead and hence can be used as a tool to probe the subgap quasiparticle mode in superconducting graphene. The non-local current is 100% spin-polarized and is highly tunable in our proposed device. This opens up the possibility of highly tunable graphene-based spin transistor that operates purely in the non-local transport regime.

**Monday, March 14, 2016 11:15AM - 2:15PM—**

**Session B19 GMAG DMP: Magnetic Devices and Production Level Scaling** 318 - Joe Davies

**11:15AM B19.00001 Development of 22 T VSM System using Novel Improvements in HTS Conductor**, JEREMY GOOD, DARKO BRACANOVIC, Cryogenic Ltd — Current research has identified a need for greater magnetising fields during vibrating sample magnetometer (VSM) measurements and other measurement options. We present here the methodology involved in our development of a VSM system with 22 T superconducting magnet, a unique system and the highest field combined with a VSM anywhere in the world. Recent developments in HTS conductors have allowed greater reliability than previous coils made from YBCO and BISCO and thus facilitate the consistent achievement of higher magnetising fields at the sample with operation at 4.2 K rather than 2.2 K. Cryogenic Ltd wind HTS coils in both solenoid and pancake forms with an emphasis on solenoids, since they have been found to give a more reliable performance with less thermal transfer to the surrounding liquid helium. The 22T VSM system has been developed using 2G YBCO coated and BSSCO tape which exhibit critical currents up to 5 times greater than those seen in YBCO and BISCO at 4.2 K.

**11:27AM B19.00002 Write operation in MRAM with voltage controlled magnetic anisotropy**, KAMARAM MUNIRA, SUMEET PANDEY, GURTEJ SANDHU, Micron Technology, Inc. — In non-volatile Magnetic RAM, information is saved in the bistable configuration of the free layer in a magnetic tunnel junction (MTJ). New information can be written to the free layer through magnetic induction (Toggle MRAM) or manipulation of magnetization using electric currents (Spin Transfer Torque MRAM or STT-MRAM). Both of the writing methods suffer from a shortcoming in terms of energy efficiency. This limitation on energy performance is brought about by the need for driving relatively large electrical charge currents through the devices for switching. In STT-MRAM, the nonzero voltage drop across the resistive MTJ leads to significant power dissipation. An energy efficient way to write may be with the assistance of voltage controlled magnetic anisotropy (VCMA), where voltage applied across the MTJ creates an electric field that modulates the interfacial anisotropy between the insulator and free layer. However, VCMA cannot switch the free layer completely by 180 degree rotation of magnetization. It can lower the barrier between the two stable configurations or at best, cancel the barrier, allowing 90 degree rotation. A second mechanism, spin torque or magnetic field, is needed to direct the final switching destination.

**11:39AM B19.00003 Tunable Magnetic Resonance via Interlayer Exchange Interaction**, YUNPENG CHEN, University of Delaware, XIN FAN, University of Denver, YUNSONG XIE, University of Delaware, JEFFREY WILSON, RAINEE SIMONS, Electron and Opto-Electronic Devices Branch, NASA Glenn Research Center, SUI-TAT CHUI, JOHN XIAO, University of Delaware — Magnetic resonance is a critical property of magnetic materials for the applications in microwave devices and novel spintronics devices. The resonance frequency is commonly controlled with an external magnetic field generated by an energy-inefficient and bulky electromagnet. The search for tuning the resonance frequency without electromagnets has attracted tremendous attention. The voltage control of resonance frequency has been demonstrated in multiferroic heterostructures through magnetoelastic effect. However, the frequency tunable range is limited. We propose a paradigm to tune the magnetic resonance frequency by recognizing the huge interlayer exchange field and the existence of the high-frequency modes in coupled oscillators. We demonstrate the optical mode in exchange coupled magnetic layers which occurred at much higher frequencies than coherent ferromagnetic resonance. We further demonstrated a large resonance frequency tunable range from 11GHz to 21 GHz in a spin valve device by in-situ manipulating of the exchange interaction. The technique developed here is far more efficient than the conventional methods of using electromagnets and multiferroics. This new scheme will have an immediate impact on applications based on magnetic resonance.

**11:51AM B19.00004 Amplification effect of low-field magnetoresistance in silicon dual  $p-n$  junctions**, DEZHENG YANG, TAO WANG, MINGSU SI, FANGCONG WANG, Key Laboratory for Magnetism and Magnetic materials of Ministry of Education, Lanzhou University, Lanzhou 730000, China, SHIMING ZHOU, Department of physics, Tongji University, Shanghai 200092, China, DESHENG XUE, Key Laboratory for Magnetism and Magnetic materials of Ministry of Education, Lanzhou University, Lanzhou 730000, China — Nonmagnetic semiconductors with large magnetoresistance are identified as promising feature for the development of magnetoelectronics. However, to manipulate the magnetoresistance require the magnetic field of several Tesla. In this work, we realized an amplification effect of low-field magnetoresistance based on an elementary electronic building block: dual  $p-n$  junction. Analogous to the electrical amplification effect of transistor  $p-n-p$  junction, where the coupling current between  $p-n$  and  $n-p$  junctions is tuned by base current, in a silicon  $p+-n-n+$  device we demonstrate that the coupling strength of  $p+-n$  and  $n-n+$  junctions can be tuned by magnetic field. Owing to the amplification effect of magnetic-field-manipulated coupling, at a small magnetic field from 0 to 0.1 T the device is directly switched from conducting state "on" (10000 ohms) to blocking state "off" (5 megohm), yielding an magnetoresistance of 50,000 per cent and magnetic field sensitivity as high as 50 per cent  $\text{Oe}^{-1}$ . Such a combination of magnetoresistance and high sensitivity not only makes the semiconductor device available in the magnetic field sensing industry, but also permits a new kind of magnetic-field-manipulated semiconductor electronics.

**12:03PM B19.00005 Towards Atomic-Scale Data Storage in Topologically Protected Spin Structures**, RALPH SKOMSKI, BALA BALAMURUGAN, PRIYANKA MANCHANDA, University of Nebraska, GEORGE C HADJIPANAYIS, University of Delaware, D J SELLMYER, University of Nebraska — Model calculations are used to investigate prospects for atomic-scale data storage in topologically protected spin structures. The approach relies exclusively on exchange interactions, as contrasted to storage based on spin-orbit coupling. The latter category includes magnetocrystalline anisotropy, as in present-day ultrahigh-density recording media, and skyrmions involving Dzyaloshinski-Moriya (DM) interactions. Since spin-orbit coupling is a higher-order relativistic correction to the leading electrostatic terms, including exchange, the corresponding bit sizes are limited to about 5 nm at room temperature. Smaller bit sizes are possible at low temperatures, but cooling is not a practicable solution for most data-storage applications. Our mechanism relies on competing but not necessarily frustrated exchange interactions that realize topological protection through spin angles. The approach can also be considered a magnetic analog to cis-trans isomerism in chemistry and polymer science. The corresponding length scale is of the order of 1 nm, corresponding to an areal-density increase by a factor of order 25 compared to data storage based on spin-orbit coupling. Experimental realizations may involve elements in the middle of the iron transition-metal series, such as Cr, Mn, and Fe. - This research is supported by DOE (DE-FG02-04ER46152), ARO (W911NF-10-2-0099), and NCMN.

**12:15PM B19.00006 Stability of single skyrmionic bits.**<sup>1</sup>, OLENA VEDMEDENKO, JULIAN HAGEMEISTER, NIKLAS ROMMING, KIRSTEN VON BERGMANN, ROLAND WIESENDANGER, University of Hamburg — The switching between topologically distinct skyrmionic and ferromagnetic states has been proposed as a bit operation for information storage. While long lifetimes of the bits are required for data storage devices, the lifetimes of skyrmions have not been addressed so far. Here we show by means of atomistic Monte Carlo simulations that the field-dependent mean lifetimes of the skyrmionic and ferromagnetic states have a high asymmetry with respect to the critical magnetic field, at which these lifetimes are identical. According to our calculations, the main reason for the enhanced stability of skyrmions is a different field dependence of skyrmionic and ferromagnetic activation energies and a lower attempt frequency of skyrmions rather than the height of energy barriers. We use this knowledge to propose a procedure for the determination of effective material parameters and the quantification of the Monte Carlo timescale from the comparison of theoretical and experimental data [1]. [1] Nature Comms. 6, 8455 (2015)

<sup>1</sup>Financial support from the DFG in the framework of the SFB668 is acknowledged

**12:27PM B19.00007 Perpendicular reading of single confined magnetic skyrmions**<sup>1</sup>, DAX M. CRUM, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA, and The University of Texas at Austin, MOHAMMED BOUHASSOUNE, JUBA BOUAZIZ, BENEDIKT SCHWEFLINGHAUS, STEFAN BLÜGEL, SAMIR LOUNIS, Peter Grünberg Institut and Institute for Advanced Simulation, Forschungszentrum Jülich and JARA — We present the first fully self-consistent first-principles investigation of single chiral magnetic skyrmions as entire entities based on density functional theory. The work is tied to skyrmions with sub-5nm diameters embedded within thin ferromagnetic films stabilized through interfacial Dzyaloshinskii-Moriya interactions. We found that the non-collinearity of the magnetic texture inside the skyrmions leads to spin-mixing of the electronic structure, which can be probed as site-dependent tunneling spin-mixing magnetoresistance (TXMR). The conduction inhomogeneity can reach values up to 20% in Pd/Fe/Ir(111) samples [1]. The non-collinear component of the TXMR has been experimentally verified [2], validating our theoretical calculations and showing the capability of the TXMR to resolve complex nanoscale spin-textures. The work is carried out with the newly developed Jülich relativistic Korringa-Kohn Rostoker Green function method [3]. [1] Crum, D.M. et al. Perpendicular reading of single confined magnetic skyrmions. Nat. Commun. 6 8541 (2015). [2] Hanneken, C. et al. **12:39PM B19.00008 Reconfigurable magnetic logic combined with non-volatile memory in silicon.** , ZHAOCHU LUO, XIAOZHONG ZHANG, Tsinghua Univ — Silicon-based complementary metal-oxide-semiconductor (CMOS) transistors have achieved great success and become the mainstream of integrated logic circuits. However, the traditional pathway to enhance computational performance and decrease cost by continuous miniaturization is approaching its fundamental limits. The recent emergence of magnetic logic devices, especially magnetic-field-based semiconductor logic devices, shows promise for surpassing the development limits of CMOS logic and arouses profound attentions. Based on our Si based magnetoresistance (MR) device [1], we proposed a Si based reconfigurable magnetic logic device by coupling nonlinear transport effect and Hall effect in Si [2], which could do all four basic Boolean logic operations including AND, OR, NOR and NAND combined with non-volatile memory. Further, we developed a Si based current-mode magnetic logic device, which allowed direct communication between different logic devices by current-induced magnetization switch effect without external intermediate magnetic-electric converters. This may result in a memory-logic integrated system leading to a non von Neumann computer. [1] CH Wan, et al, Nature 477, 304, (2011). [2] ZC Luo et al. Adv. Funct. Mater. 25, 158, (2015)..

**12:51PM B19.00009 Toward spin-based Magneto Logic Gate in Graphene** , HUA WEN, Dept of Physics and Astronomy, Univ. of California, Riverside, HANAN DERY, Dept. of Electrical and Computer Engineering, University of Rochester, WALID AMAMOU, Dept. of Physics and Astronomy, University of California, Riverside, TIANCONG ZHU, Dept. of Physics, The Ohio State University, ZHISHENG LIN, Deptt. of Physics and Astronomy, University of California, Riverside, JING SHI, Dept. of Physics and Astronomy, University of California, Riverside, IGOR ZUTIC, Dept. of Physics, University at Buffalo, State University of New York, ILYA KRIVOROTOV, Dept. of Physics and Astronomy, University of California, Irvine, LU SHAM, Dept. of Physics, University of California, San Diego, ROLAND KAWAKAMI, Dept. of Physics, The Ohio State University — Graphene has emerged as a leading candidate for spintronic applications due to its long spin diffusion length at room temperature. A universal magnetologic gate (MLG) based on spin transport in graphene has been recently proposed as the building block of a logic circuit which could replace the current CMOS technology. This MLG has five ferromagnetic electrodes contacting a graphene channel and can be considered as two three-terminal XOR logic gates. Here we demonstrate this XOR logic gate operation in such a device. This was achieved by systematically tuning the injection current bias to balance the spin polarization efficiency of the two inputs, and offset voltage in the detection circuit to obtain binary outputs. The output is a current which corresponds to different logic states: zero current is logic '0', and nonzero current is logic '1'. We find improved performance could be achieved by reducing device size and optimizing the contacts.

**1:03PM B19.00010 Low Drift in Resistance of Plasma Oxidized, Cobalt Confined AlOx Tunnel Barriers** , Z. S. BARCIKOWSKI, Y. HONG, J. M. POMEROY, National Institute of Standards and Technology — Co/AlOx/Co tunnel junctions show <15% drift in resistance measured over the first three months. This long term stability is achieved using plasma oxidation and sandwiching the AlOx tunnel barrier between cobalt layers. Plasma oxidation of aluminum, when compared to thermal oxidation, has been shown to produce a more homogeneous and stoichiometric oxide. The confinement of the oxide between Co layers, which have higher oxide enthalpies of formation, is thought to provide a barrier against oxygen diffusion. Junction resistance and current-voltage (I-V) measurements are taken over a period of approximately 9 months. Barrier width (s) and asymmetric barrier heights ( $\varphi_1$ ,  $\varphi_2$ ) are extracted using Simmons/Chow transport model. Bottom barrier height ( $\varphi_2$ ) and barrier width (s) show near constant values in contrast to a rise in top barrier height ( $\varphi_1$ ) in time.

**1:15PM B19.00011 A Study of Morphology and Magnetic Properties of Doped Barium Ferrite Films Formed by Aerosol Deposition** , SCOTTER JOHNSON, Naval Research Laboratory, CHRISTOPHER GONZALEZ, California State University Long Beach, ZACHARY ROBINSON, College at Brockport SUNY, DAVID ELLSWORTH, MINGZHONG WU, Colorado State University — Aerosol deposition is a room-temperature thick film deposition technique that produces polycrystalline films that have > 95% of theoretical density and are up to several hundred microns thick. In addition to depositing films at room temperature another distinct advantage of aerosol deposition is the ability to produce films with the same resulting stoichiometry as the starting material. For this work, we deposited a proprietary doped barium ferrite (BaFe<sub>12</sub>O<sub>19</sub>) film from powder produced by *Temex Ceramics*. This material is designed for microwave absorption near 18 GHz via ferromagnetic resonance. We compare the structural and magnetic properties of the as-deposited film, bulk material, and starting powder. For this purpose, we employed scanning electron microscopy, x-ray photoemission spectroscopy, x-ray diffraction, vibrating sample magnetometry, and broad-band ferromagnetic resonance characterization techniques.

**1:27PM B19.00012 Large-area patterned substrates for micromagnetic actuation of superparamagnetic microbeads** , MINAE OUK, GEOFFREY S.D. BEACH, Massachusetts Inst of Tech-MIT — Superparamagnetic microbeads (SBs) have been used to capture and manipulate biological entities in a fluid environment. Chip-based magnetic actuation provides a means to transport SBs in lab-on-a-chip technologies. This is accomplished using the stray field from patterned magnetic microstructures [1], or domain walls in magnetic nanowires [2]. Recently many studies have focused on the submicron-size antidot array of magnetic materials because non-magnetic holes affect the micromagnetic properties. Here, we use photolithographic patterning to create periodic anti-dot arrays in Co thin films, show the transport of SBs across large distance by a rotating field. We describe the dynamics of bead motion, highlighting the key factors to control bead transport. We show there is a critical threshold for both in-plane and out-of-plane components that must be exceeded for bead motion to occur. The threshold values are different depending on direction, which allows for directionally-anisotropic transport across the chip surface. Hence the periodic magnetically-patterned substrates can be used to digitally separate magnetic beads and augment microfluidic actuation for long distance transport.[1]B. Yellen, et al., Lab Chip, 7, 1681 (2007) [2]E. Rapoport and G. S. D. Beach, APL 100, 082401 (2012)

**1:39PM B19.00013 Measurement of Nanoparticle Magnetic Hyperthermia Using Fluorescent Microthermal Imaging** , XIAOWAN ZHENG, EDWARD VAN KEUREN, Georgetown Univ — Nanoparticle magnetic hyperthermia uses the application of an AC magnetic field to ferromagnetic nanoparticles to elevate the temperature of cancer cells. The principle of hyperthermia as a true cell-specific therapy is that tumor cells are more sensitive to high temperature, so it is of great importance to control the locality and magnitude of the temperature differences. One technique to measure temperature variations on microscopic length scales is fluorescent microthermal imaging (FMI). Since it is the local temperature that is measured in FMI, effects such as heating due to nearby field coils can be accounted for. A dye, the rare earth chelate europium thenoyltrifluoroacetate (Eu:TTA), with a strong temperature-dependent fluorescence emission has been incorporated into magnetic nanoparticles dispersed in a polymer films. FMI experiments were carried out on these samples under an applied high frequency magnetic field. Preliminary results show that FMI is a promising technique for characterizing the local generation of heat in nanoparticle magnetic hyperthermia.

**1:51PM B19.00014 Optimization of magnetic refrigerators by tuning the heat transfer medium and operating conditions.** , MOHAMMADREZA GHAHREMANI, AMIR ASLANI, LAWRENCE BENNETT, EDWARD DELLA TORRE, George Washington University — A new reciprocating Active Magnetic Regenerator (AMR) experimental device has been designed, built and tested to evaluate the effect of the system's parameters on a reciprocating Active Magnetic Regenerator (AMR) near room temperature. Gadolinium turnings were used as the refrigerant, silicon oil as the heat transfer medium, and a magnetic field of 1.3 T was cycled. This study focuses on the methodology of single stage AMR operation conditions to get a higher temperature span near room temperature. Herein, the main objective is not to report the absolute maximum attainable temperature span seen in an AMR system, but rather to find the system's optimal operating conditions to reach that maximum span. The results of this work show that there is an optimal operating frequency, heat transfer fluid flow rate, flow duration, and displaced volume ratio in an AMR system. It is expected that such optimization and the results provided herein will permit the future design and development of more efficient room-temperature magnetic refrigeration systems.

**2:03PM B19.00015 Impact of DC Joule anneal treatment on the high-frequency magnetoimpedance response of Fe-rich FeCo ribbons with varying glass former content**, TATIANA EGGER, Department of Physics, University of South Florida, Tampa, FL, ALEX LEARY, MICHAEL MCHENRY, Materials Science and Engineering, Carnegie-Mellon University, Pittsburgh, PA, IVAN SKORVANEK, Institute of Experimental Physics, Slovak Academy of Sciences, Kosice, Slovakia, HARIHARAN SRIKANTH, MANH-HUONG PHAN, Department of Physics, University of South Florida, Tampa, FL — The Magnetoimpedance (MI) effect in 2 mm wide  $(\text{Fe}_{65}\text{Co}_{35})_{83.5-x}\text{B}_{13}\text{Nb}_x\text{Si}_2\text{Cu}_{1.5}$  rapidly quenched ribbons with varying glass former content ( $x = 0$  and  $x = 4$ ) has been studied in the frequency range of 1-1000 MHz. Two measurement techniques were used: auto-balancing bridge method in the frequency range of 1-110 MHz and transmission line technique for 20-1000 MHz. The impact of DC Joule heating treatments of varying current amplitude and annealing time on the MI effect of the amorphous ribbons was evaluated by examining the field and frequency dependence on the resistive and reactive components of the MI. To interpret the MI behavior, the domain structure of the ribbons in their as-quenched state and after heating treatment was imaged by magneto-optical Kerr effect microscopy. A significant improvement in the MI response from the as-quenched state was found for both compositions of ribbon with a 3 hour-500 mA Joule anneal treatment. The improvement is attributed to the development of a low anisotropy domain structure longitudinally and at an oblique angle between the longitudinal and transverse directions for the 0% and 4% Nb content, respectively.

**Session B20 DCOMP: Electronic Structure Methods I** 319 - Oliver Albertini, Georgetown University

**11:15AM B20.00001 An Accurate Density Functional from Exchange-Correlation Hole<sup>1</sup>**, JIANMIN TAO, YUXIANG MO, Temple Univ — The exchange-correlation hole is most fundamentally important in the development and understanding of density functional theory (DFT). However, due to the nonlocal nature of the exchange-correlation hole, development of DFT from the underlying hole presents a great challenge, and the works along this direction are limited. Here I will discuss a novel nonempirical DFT based on a semilocal hole, which is obtained from the density matrix expansion. Extensive tests on molecules and solids show that this functional can achieve remarkable accuracy for wide-ranging properties in condensed matter physics and quantum chemistry.

<sup>1</sup>This work was supported by NSF under Grant No. CHE-1261918.

**11:27AM B20.00002 Assessment of a New Semilocal Density Functional on Molecules and Solids<sup>1</sup>**, YUXIANG MO, JIANMIN TAO, Temple Univ — We have recently developed a new semilocal density functional based on the exchange hole (localized under a general coordinate transformation) from density matrix expansion, instead of imposing energy constraints to the functional or fitting it to a training set of properties. This functional is comprehensively evaluated on diverse properties of molecules and solids, including atomization energies for G2/97 (148 molecules), enthalpies of formation for G3-3 (75 molecules), ionization potentials for G3/99 (86 species), electron affinities for G3/99 (58 species), proton affinities (8 molecules), bond lengths for T-96R (96 molecules), vibrational frequencies for T-82F (82 molecules), 10 hydrogen bonded complexes, as well as lattice constants, bulk moduli, and cohesive energies for solids. Our tests show that the functional is remarkably accurate for these wide-ranging properties.

<sup>1</sup>This work was supported by NSF under Grant No. CHE-1261918.

**11:39AM B20.00003 Benchmarking Post-SCF Treatments of Spin-Orbit Coupling in Electronic Structure Theory**, WILLIAM PAUL HUHN, VOLKER BLUM, MEMS Department, Duke University, Durham, NC 27708 — Spin-orbit coupling (SOC) is an essential aspect of the electron band structures for all but the lightest-element materials. SOC is often incorporated into density-functional theory (DFT) calculations in a second-order variational approach, applying the SOC correction based on the orbitals from a scalar-relativistic self-consistent calculation. This talk compares the quality of non-self-consistent and self-consistent SOC corrections for a test set of over 100 different materials spanning the periodic table. We quantitatively compare entire DFT band structures from two benchmark-quality full-potential all-electron codes, i.e., the numeric atom-centered orbital code FHI-aims and the linearized augmented plane-wave code WIEN2k, based on the semilocal PBE functional. Few-meV agreement between non-self-consistent and self-consistent SOC is shown for elements up to row 4 of the periodic table, with agreement on the order of 10 meV for row 5 elements and differences exceeding 100 meV emerging for row 6 elements. We find little difference in SOC splittings between the PBE functional and the hybrid HSE06 functional.

**11:51AM B20.00004 Dielectric-dependent Density Functionals for Accurate Electronic Structure Calculations of Molecules and Solids<sup>1</sup>**, JONATHAN SKONE, Institute for Molecular Engineering, University of Chicago, MARCO GOVONI, GIULIA GALLI, Institute for Molecular Engineering, University of Chicago & Argonne National Laboratory — Dielectric-dependent hybrid [DDH] functionals [1] have recently been shown to yield highly accurate energy gaps and dielectric constants for a wide variety of solids, at a computational cost considerably less than standard GW calculations. The fraction of exact exchange included in the definition of DDH functionals depends (self-consistently) on the dielectric constant of the material. In the present talk we introduce a range-separated (RS) version of DDH functionals [2] where short and long-range components are matched using material dependent, non-empirical parameters. Comparing with state of the art GW [3] calculations and experiment, we show that such RS hybrids yield accurate electronic properties of both molecules and solids, including energy gaps, photoelectron spectra and absolute ionization potentials. [1] See, e.g. Skone et. al. PRB 89 195112 (2014) [2] Skone et. al. PRB (to be submitted) [3] Govoni and Galli JCTC 11 2680 (2015)

**12:03PM B20.00005 Quest for a semi-empirical MGGA functional with tight bound**, BERNARD DELLEY, Paul Scherrer Inst — A numerically robust parametrization for a meta-GGA exchange functional approximation has been obtained by optimization of bond energies in a database of 303 species. The variables, density, gradient and kinetic energy density, are useful to differentiate efficiently among the wide variety of bonding types in the database. The resulting MGGA rivals the thermochemistry accuracy of composite quantum chemistry approaches when applied to a wider data set of 592 species. Noticeable improvements over GGA's are also obtained for solid state properties. The present functional shows some similarities with the recently presented SCAN functional of Sun, Ruscinszky and Perdew. With the easily available semi-nonlocality through gradients and a kinetic energy density, this MGGA is widely applicable for molecular- as well as for extended systems and surface models.

**12:15PM B20.00006 Modeling Spin Fluctuations and Magnetic Excitations from Time-Dependent Density Functional Theory**, TOMMASO GORNI, IURI TIMROV, ANDREA DAL CORSO, STEFANO BARONI, SISSA, Trieste — Harnessing spin fluctuations and magnetic excitations in materials is key in many fields of technology, spanning from memory devices to information transfer and processing, to name but a few. A proper understanding of the interplay between collective and single-particle spin excitations is still lacking, and it is expected that first-principle simulations based on TDDFT may shed light on this interplay, as well as on the role of important effects such as relativistic ones and related magnetic anisotropies. All the numerical approaches proposed so far to tackle this problem are based on the computationally demanding solution of the Sternheimer equations for the response orbitals or the even more demanding solution of coupled Dyson equations for the spin and charge susceptibilities. The Liouville-Lanczos approach to TDDFT has already proven to be a valuable alternative, the most striking of its features being the avoidance of sums over unoccupied single-particle states and the frequency-independence of the main numerical bottleneck. In this work we present an extension of this methodology to magnetic systems and its implementation in the QUANTUM ESPRESSO distribution, together with a few preliminary results on the magnon dispersions in bulk Fe.

**12:27PM B20.00007 Symmetry-adapted Wannier Functions from  $L_1$  regularized Sparse Optimization**, JIATONG CHEN, KE YIN, YI XIA, VIDVUDS OZOLINS, STANLEY OSHER, RUSSEL CAFLISCH, Univ of California - Los Angeles — Wannier functions are widely used as real space representation of periodic solids in electronic structure calculation. We present a new approach to calculate symmetry-adapted Wannier functions which are directly obtained from variational principle of total energy plus an  $L_1$  regularization term,  $\frac{1}{\mu} \int |\psi| dr$ . The obtained compressed Wannier functions are only nonzero within a finite region. With the help of induced group representation theory, we only need to calculate Bloch functions (in Wannier gauge) within irreducible Brillouin zone, while point group symmetry is strictly enforced. Implementation in plane waves-pseudopotential codes and application to real material system will be demonstrated.

**12:39PM B20.00008 Free energy from stationary implementation of the DFT+EDMFT functional**, TURAN BIROL, KRISTJAN HAULE, Rutgers University — The workhorse of first principles calculations on crystalline solids is the Density Functional Theory at the level of Local Density Approximation (LDA). Despite its various successes, LDA is prone to an overbinding problem, which introduces an error in optimized lattice constants and other structural parameters. Various Generalized Gradient Approximations are introduced to correct for this problem, but they often fail to systematically correct it, in particular in correlated electron materials. We developed a stationary and functional derivable Embedded Dynamical Mean Field Theory combined with the DFT (EDMFT+DFT) to calculate the free energy and to optimize the structural parameters in correlated electron compounds. In our stationary formalism, the first order error in the density leads to a much smaller, second order error in the free energy. We consider the correlated metal  $\text{SrVO}_3$ , Mott insulating  $\text{FeO}$ , elemental Ce, and iron chalcogenide  $\text{FeSe}$  as examples to show that EDMFT predicts the lattice constants with high accuracy.

**12:51PM B20.00009 Relativistic Green's Functions in Full-Potential Multiple-Scattering Theory**, XIANGLIN LIU, Department of Physics, Carnegie Mellon University, YANG WANG, Pittsburgh Supercomputing Center, Carnegie Mellon University, MARKUS EISENBACH, G.MALCOLM STOCKS, Materials Science and Technology Division, Oak Ridge National Laboratory — The Greens functions play a central role in MST based KKR method. Obtaining the Greens functions by solving the Dirac equation is appealing since it naturally incorporated the electron spin and the spin-orbit coupling effects. Here we implemented the full-potential relativistic KKR method using a technique called the sine and cosine matrices formalism. The charge density and the density of states of some pure element crystals have been calculated. Different expressions of the Greens functions have been investigated for numerical benefits.

**1:03PM B20.00010 Understanding the Relativistic Generalization of Density Functional Theory (DFT) and Completing it in Practice.**, DIOLA BAGAYOKO, Department of Mathematics, Physics, and Science and Mathematics Education (MP-SMED) Southern University and AM College, Baton Rouge, LA 70813, USA — In 2014, 50 years following the introduction of density functional theory (DFT), a rigorous understanding of it was published [AIP Advances, 4, 127104 (2014)]. This understanding included necessary steps ab initio electronic structure calculations have to take if their results are to possess the full physical content of DFT. These steps guarantee the fulfillment of conditions of validity of DFT; not surprisingly, they have led to accurate descriptions of several dozens of semiconductors, from first principle, without invoking derivative discontinuity or self-interaction correction. This presentation shows the mathematically and physically rigorous understanding of the relativistic extension of DFT by Rajagopal and Callaway [Phys. Rev. B 7, 1912 (1973)]. As in the non-relativistic case, the attainment of the absolute minima of the occupied energies is a necessary condition for the corresponding current density to be that of the ground state of the system and for computational results to agree with corresponding, experimental ones. Acknowledgments: This work was funded in part by the US National Science Foundation [NSF, Award Nos. EPS-1003897, NSF (2010-2015)-RII-SUBR, and HRD-1002541], the US Department of Energy, National Nuclear Security Administration (NNSA, Award No. DE-NA0002630), LaSPACE, and LONI-SUBR.

**1:15PM B20.00011 Enhancing inter-tube conductivity in carbon nanotube networks<sup>1</sup>**, ARASH MOSTOFI, Departments of Materials and Physics and the Thomas Young Centre, Imperial College London, UK, ROBERT BELL, MIKE PAYNE, Cavendish Laboratory, University of Cambridge, UK — Retaining the remarkable electronic transport properties of individual carbon nanotubes (CNTs) when scaling up to macroscopic CNT networks for use in devices remains a significant challenge. As no single tube spans the device, electrons must travel between CNTs to contribute to the conductivity. Conductivity between CNTs of different chirality is suppressed due to the requirement of momentum conservation. Using a combination of analytic theory and tight-binding, I will show that this limitation can be overcome by supplying a weak perturbation to the system, resulting in order of magnitude increases of conductivity<sup>2</sup>. I will present practical realizations of such perturbations, which I will demonstrate using Landauer-Buttiker transport simulations based on large-scale density-functional theory calculations<sup>3</sup>.

**1:27PM B20.00012 Data compression algorithms for electronic wave functions**, WILLIAM DAWSON, FRANCOIS GYGI, Univ of California - Davis — Large scale, First-Principles Molecular Dynamics (FPMD) simulations require an large amount of computational effort. Unfortunately, the size of the data they generate and the overhead cost of saving it result in the overwhelming majority of this potentially valuable data being lost. The rising gap between CPU and file I/O performance will restrict even further the amount of data saved during future FPMD simulations. The Recursive Subspace Bisection method for generating localized wavefunctions has recently been utilized to reduce the cost of computing Hartree-Fock exchange with controlled accuracy. We show that a variation of this method can be used to compress FPMD simulation data. Furthermore, we show that this method has controlled and predictable accuracy, and can be applied without concern for specific system properties. We demonstrate this method by compressing data from the simulation of liquid water, melting silicon, and other representative systems. Supported by: DE-SC0008938.

**1:39PM B20.00013 Nonorthogonal generalized hybrid Wannier functions for large-scale DFT simulations<sup>1</sup>**, ANDREA GRECO, Imperial College London, JOHN W. FREELAND, Argonne National Laboratory, ARASH A. MOSTOFI, Imperial College London — Semiconductor-based thin-films have applications in microelectronics, from transistors to nanocapacitors. Many properties of such devices strongly depend on the details of the interface between a metallic electrode and the thin-film semiconductor/insulator. Hybrid Wannier Functions (WFs), extended in the surface plane, but localized along the direction normal to the surface/interface, have been successfully used to explore the properties of such heterostructures layered along a given direction, and are a natural way to study systems that are at the same time a 2D conductor (in plane) and a 1D insulator (out of plane). Current state-of-the-art implementations of Hybrid WF's rely on first performing a traditional cubic-scaling density-functional theory (DFT) calculation. This unfavourable scaling precludes the applicability of this method to the large length scales typically associated with processes in realistic structures. To overcome this limitation we extend the concept of Hybrid WF's to nonorthogonal orbitals that are directly optimized in situ in the electronic structure calculation. We implement this method in the ONETEP large-scale DFT code and we apply it to realistic heterostructure systems, showing it is able to provide plane-wave accuracy but at reduced computational cost.

**2:03PM B20.00015 Effective on-site Coulomb interaction and electron configurations in transition-metal complexes from constraint density functional theory**, KENJI NAWA, KOHJI NAKAMURA, TORU AKIYAMA, TOMONORI ITO, Mie University, MICHAEL WEINERT, University of Wisconsin-Milwaukee — Effective on-site Coulomb interactions ( $U_{\text{eff}}$ ) and electron configurations in the localized  $d$  and  $f$  orbitals of metal complexes in transition-metal oxides and organometallic molecules, play a key role in the first-principles search for the true ground-state. However, wide ranges of values in the  $U_{\text{eff}}$  parameter of a material, even in the same ionic state, are often reported. Here, we revisit this issue from constraint density functional theory (DFT) by using the full-potential linearized augmented plane wave method. The  $U_{\text{eff}}$  parameters for prototypical transition-metal oxides, TMO (TM=Mn, Fe, Co, Ni), were calculated by the second derivative of the total energy functional with respect to the  $d$  occupation numbers inside the muffin-tin (MT) spheres as a function of the sphere radius. We find that the calculated  $U_{\text{eff}}$  values depend significantly on the MT radius, with a variation of more than 3 eV when the MT radius changes from 2.0 to 2.7 a.u., but importantly an identical valence band structure can be produced in all the cases, with an approximate scaling of  $U_{\text{eff}}$ . This indicates that a simple transferability of the  $U_{\text{eff}}$  value among different calculation methods is not allowed. We further extend the constraint DFT to treat various electron configurations of the localized  $d$ -orbitals in organometallic molecules, TMCp<sub>2</sub> (TM=Cr, Mn, Fe, Co, Ni), and find that the calculated  $U_{\text{eff}}$  values can reproduce the experimentally determined ground-state electron configurations.

Session B21 GMAG DMP: Single Molecule Magnets 320 - Janathan Friedman, Amherst College

**11:15AM B21.00001 Decoherence mechanisms in Mn3 single-molecule magnet<sup>1</sup>**, C ABEYWARDANA, Department of Chemistry, University of Southern California, Los Angeles CA 90089, USA, A. M. MOWSON, G. CHRISTOU, Department of Chemistry, University of Florida, Gainesville FL 32611, USA, S TAKAHASHI, Department of Chemistry, Department of Physics, University of Southern California, Los Angeles CA 90089, USA — In spite of wide interest in the quantum nature of SMMs, decoherence effects that ultimately limit such behavior have yet to be fully understood. Recent investigations have shown that there are three main decoherence mechanisms present in SMMs: spins can couple locally (i) to phonons (phonon decoherence); (ii) to many nuclear spins (nuclear decoherence); and (iii) to each other via dipolar interactions (dipolar decoherence)[1]. We have recently uncovered quantum coherence in a Mn3 SMM by quenching decoherence due to dipole interaction between SMMs using a high frequency electron paramagnetic resonance and low temperature [2]. In this presentation, we will discuss temperature dependence of spin relaxation times and the decoherence mechanisms in the Mn3 SMM. [1] S. Takahashi et al., Nature 476, 76 (2011). [2] C. Abeywardana et al. (2015), submitted.

**11:27AM B21.00002 Controlling electronic access to the spin excitations of a single molecule in a tunnel junction**, CYRUS F. HIRJIBEHEDIN, BEN WARNER, FADI EL HALLAK, HENNING PRUESER, AFOLABI AJIBADE, TOBIAS G. GILL, ANDREW J. FISHER, UCL, MATS PERSSON, U. Liverpool and Chalmers University of Technology — Spintronic phenomena can be utilized to create new devices with applications in data storage and sensing. Scaling these down to the single molecule level requires controlling the properties of the current-carrying orbitals to enable access to spin states through phenomena such as inelastic electron tunneling. Here we show that the spintronic properties of a tunnel junction containing a single molecule can be controlled by their coupling to the local environment. For tunneling through iron phthalocyanine (FePc) on an insulating copper nitride (Cu<sub>2</sub>N) monolayer above Cu(001), we find that spin transitions may be strongly excited depending on the binding site of the central Fe atom. Different interactions between the Fe and the underlying Cu or N atoms shift the Fe  $d$ -orbitals with respect to the Fermi energy, and control the relative strength of the spin excitations, an effect that can be described in a simple co-tunneling model. This work demonstrates the importance of the atomic-scale environment in the development of single molecule spintronic devices.

**11:39AM B21.00003 Inelastic Neutron Scattering and Magnetisation Investigation of an Exchange-Coupled Dy<sub>2</sub> SMM<sup>1</sup>**, MICHAEL L. BAKER, City College of New York, CUNY and New York University, QING ZHANG, MYRIAM P. SARACHIK, City College of New York, CUNY, ANDREW D. KENT, YIZHANG CHEN, New York University, NICHOLAS BUTCH, NIST, EUFEMIO M. PINEDA, ERIC MCINNES, University of Manchester — The strong spin orbit coupling and weak crystal field energies of simple exchange-coupled rare earth SMMs makes the precise evaluation of their magnetic properties nontrivial. Here we report a detailed investigation of the single molecule magnet hqH<sub>2</sub>Dy<sub>2</sub>(hq)<sub>4</sub>(NO<sub>3</sub>)<sub>3</sub>MeOH. Inelastic neutron scattering is used to obtain direct access to several low energy crystal field excitations. The INS results display several features that are not found in earlier FIR absorption experiments [1], while other features found in the latter are absent. Based on the effective point charge model, numerical calculations are currently underway to resolve these apparent discrepancies using complementary magnetisation measurements to resolve the exchange between Dy ions. **11:51AM B21.00004 Mechanisms of relaxation and spin decoherence in nanomagnets**, JOHAN VAN TOL, Florida State University, National High Magnetic Field Laboratory, Tallahassee, FL 32310 — Relaxation in spin systems is of great interest with respect to various possible applications like quantum information processing and storage, spintronics, and dynamic nuclear polarization (DNP). The implementation of high frequencies and fields is crucial in the study of systems with large zero-field splitting or large interactions, as for example molecular magnets and low dimensional magnetic materials. Here we will focus on the implementation of pulsed Electron Paramagnetic Resonance (ERP) at multiple frequencies of 10, 95, 120, 240, and 336 GHz, and the relaxation and decoherence processes as a function of magnetic field and temperature. Firstly, at higher frequencies the direct single-phonon spin-lattice relaxation (SLR) is considerably enhanced, and will more often than not be the dominant relaxation mechanism at low temperatures, and can be much faster than at lower fields and frequencies. In principle the measurement of the SLR rates as a function of the frequency provides a means to map the phonon density of states. Secondly, the high electron spin polarization at high fields has a strong influence on the spin fluctuations in relatively concentrated spin systems, and the contribution of the electron-electron dipolar interactions to the coherence rate can be partially quenched at low temperatures [1]. This not only allows the study of relatively concentrated spin systems by pulsed EPR (as for example magnetic nanoparticles and molecular magnets), it enables the separation of the contribution of the fluctuations of the electron spin system from other decoherence mechanisms. Besides choice of temperature and field, several strategies in sample design, pulse sequences, or clock transitions can be employed to extend the coherence time in nanomagnets. A review will be given of the decoherence mechanisms with an attempt at a quantitative comparison of experimental rates with theory. **12:27PM B21.00005 Evaluation of the exchange interaction and crystal fields in a prototype Dy<sub>2</sub> SMM**<sup>1</sup>, QING ZHANG, MYRIAM SARACHIK, City College of New York, CUNY, MICHAEL BAKER, Stanford University, YIZHANG CHEN, ANDREW KENT, New York University, EUFEMIO PINEDA, ERIC MCINNES, The University of Manchester — In order to gain an understanding of the INS and magnetization data obtained for Dy<sub>2</sub>, the simplest member of a newly synthesized family of dysprosium-based molecular magnets [1], we report on calculations of the magnetic behavior of a Dy<sub>2</sub> cluster with the formula [h<sub>2</sub>Q<sub>2</sub>][Dy<sub>2</sub>(h<sub>2</sub>)<sub>4</sub>(NO<sub>3</sub>)<sub>3</sub>]MeOH. The molecular complex contains one high symmetry Dy(III) ion and one low symmetry Dy(III) ion. Our calculations suggest that exchange coupling between the two ions controls the behavior of the magnetization at low temperature, while the crystal field of the low symmetry Dy(III) ion controls the behavior at higher temperature. A point charge electrostatic model, based on crystallographic coordinates, provides a starting point for the determination of the crystal field [2]. Parameters in these calculations are adjusted to provide best fits to inelastic neutron scattering data (INS) and low temperature magnetometry [3]: the INS measurements access crystal field energies and low temperature magnetization probes the Dy-Dy exchange interaction. **12:39PM B21.00006 The first single atom magnet**, FABIO DONATI, STEFANO RUSPONI, CHRISTIAN WÄCKERLIN, APARAJITA SINGHA, ROMANA BALTIC, KATHARINA DILLER, FRANÇOIS PATTHEY, EDGAR FERNANDES, HARALD BRUNE, Ecole Polytechnique Fédérale de Lausanne, JAN DREISER, Paul Scherrer Institute, ZELJKO SLJIVANCANIN, Vinča Institute of Nuclear Sciences, KURT KUMMER, European Synchrotron Radiation Facility, SEBASTIAN STEPANOW, LUCA PERSICHETTI, CORNELIU NISTOR, PIETRO GAMBARELLA, ETH Zürich — The prime feature of a magnet is to retain a significant fraction of its saturation magnetization in the absence of an external magnetic field. Realizing magnetic remanence in a single atom would allow storing and processing information in the smallest unit of matter. Here we show that individual rare-earth atoms on ultrathin insulating layers grown on non-magnetic metal substrates exhibit magnetic remanence and, therefore, are the first magnets formed by a single surface adsorbed atom. These magnets have a magnetic lifetime of 1500 s and a coercive field of 3.7 T at 10 K. In addition, their hysteresis loop remains open up to 30 K. This first example of a single atom magnet shows bistability at a temperature which is significantly higher than the best single molecule magnets reported so far. Its extraordinary stability is achieved by a suitable combination of magnetic ground state and adsorption site symmetry, and by decoupling the 4f spin from the underlying metal by a tunnel barrier.

**12:51PM B21.00007 Giant exchange interaction in mixed lanthanides**, NAOYA IWAHARA, VEACHESLAV VIERU, LIVIU UNGUR, LIVIU CHIBOTARU, Theory of Nanomaterials Group, Katholieke Universiteit Leuven — Combining strong magnetic anisotropy with strong exchange interaction is a long standing goal in the design of quantum magnets. The lanthanide complexes, while exhibiting a very strong ionic anisotropy, usually display a weak exchange coupling, amounting to only few wavenumbers. Recently, an isostructural series of mixed Ln-R-Ln complexes with R the N<sub>2</sub><sup>3-</sup> radical have been reported, in which the exchange splitting is estimated to reach hundreds wavenumbers [1,2]. Here we apply a new methodology allowing to establish on the basis of DFT and *ab initio* calculations the microscopic mechanism governing the unusual exchange interaction in these compounds [3]. We find it to be basically kinetic and highly complex, involving non-negligible contributions up to seventh power of total momentum  $\vec{J}$  of each Ln site. The performed analysis also elucidates the origin of magnetization blocking in these compounds. Contrary to general expectations the latter is not always favored by strong exchange interaction. Iwahara, L. Ungur, and L. F. Chibotaru, arXiv:1509.02206.

**1:03PM B21.00008 Visualizing Improved Spin Coupling in Large Magnetic Molecules**, JUDITH DONNER, Institute for Molecules and Materials, Radboud University Nijmegen, JAN-PHILIPP BROCHINSKI, BASTIAN FELDSCHE, THORSTEN GLASER, Faculty of Chemistry, University of Bielefeld, ALEXANDER AKO KHAJETOORIAN, DANIEL WEGNER, Institute for Molecules and Materials, Radboud University Nijmegen — In an attempt to combine a high spin ground state and a large magnetic anisotropy in one molecule, tripesalen-based complexes are promising building blocks for a new generation of single molecule magnets (SMMs). The spin coupling in these molecules is based on the spin polarization effect, which requires a delocalized aromatic  $\pi$ -system in the central carbon ring of the complex. Unfortunately, chemical analysis indicates that this ring can change its configuration to [6]radialene, therefore causing a loss of aromaticity and weakening the magnetic coupling. We have employed a combination of scanning tunneling microscopy (STM) and spectroscopy (STS) to investigate single Cu<sub>3</sub>-tripesalen and Cu<sub>3</sub>-tripesalen molecules, the latter being designed to show an enhanced intramolecular spin coupling. The large molecules were deposited in situ using the unconventional techniques pulse injection and rapid heating. A thorough structural and spectroscopic analysis allows us to discuss the electronic properties of the two complexes, with a special focus on the state of the central carbon ring. We find that even small changes in the ligand structure have a drastic influence on the intramolecular spin coupling, which opens the way for an improved rational design of future SMMs.

**1:15PM B21.00009 Exchange coupling and anisotropy effects on the low temperature magnetization dynamics in rare-earth dioxolene complexes**, ASMA AMJAD, GIORDANO PONETI, SILVIA SOTTINI, ANDREA DEI, LORENZO SORACE, INSTM, Università di Firenze — The prelude of relevant magnetic coupling in f-element based complexes is actively pursued to improve the single-molecule magnetic features. However, a quantitative analysis of magnetic properties of exchange-coupled anisotropic rare-earth based complexes is often hampered owing to the comparable magnitude of the crystal field with the magnetic coupling. In this study, we investigated the properties of complexes containing different ligands with comparable molecular structures and ligand field strengths. Comparative low-temperature magnetic and EPR study of homologous Ln<sup>III</sup>Semiquinonate (LnSQ) and Ln<sup>III</sup>Tropolonate (LnTrp) complexes, where Ln = Dy, Tb is investigated. Single-crystal EPR revealed that the direct exchange coupling in DySQ resulted in a highly anisotropic pseudo-triplet state. An out-of-phase susceptibility signal was observed for TbTrp only in the presence of an external magnetic field. Furthermore, the dynamics revealed slow relaxation of magnetization in the DySQ at low temperature which upon comparative study with the dynamics of the related DyTrp revealed a not so simple dependence on the crystal field effects of the coordination sphere of the lanthanide.

**1:27PM B21.00010 Anomalous power dependence in the zero-field resonance for the molecular nanomagnet  $\text{Cr}_7\text{Mn}$** <sup>1</sup>, C.A. COLLETT, Department of Physics, Amherst College, Amherst, MA, USA, G.A. TIMCO, R.E.P. WINPENNY, School of Chemistry, The University of Manchester, Manchester, UK, J.R. FRIEDMAN, Department of Physics, Amherst College, Amherst, MA, USA — We report electron-spin resonance studies of the paramagnetic ring  $[(\text{CH}_3)_2\text{NH}_2][\text{Cr}_7\text{MnF}_8((\text{CH}_3)_3\text{CCOO})_{16}]$  (" $\text{Cr}_7\text{Mn}$ "), a spin  $S=1$  molecular nanomagnet with a large zero-field ground-state tunnel splitting of  $\sim 4$  GHz. We perform parallel-mode electron-spin-resonance (ESR) spectroscopy with loop-gap resonators (LGRs) with resonance frequencies of 4-6 GHz. A crystal of  $\text{Cr}_7\text{Mn}$  is placed on the loop of the LGR with the sample's easy axis parallel to the field. We observe an ESR peak at zero dc field. With increasing radiation power, a pronounced dip develops in the center of the resonance peak, indicating a decoupling of the sample from the resonator with increased power. The onset of this decoupling depends on both the temperature and the applied power, with greater power required to observe the dip at higher temperatures. By pulsing the radiation, we can rule out that the dip is related to sample heating or saturation of the resonance. Power, temperature, and frequency dependence of the decoupling will be presented, and possible explanations will be discussed.

**1:39PM B21.00011 Time-resolved Measurements of Spontaneous Magnetic Deflagration of  $\text{Mn}_{12}\text{tBuAc}$** <sup>1</sup>, YIZHANG CHEN, A. D. KENT, New York Univ NYU, QING ZHANG, M. P. SARACHIK, City College of New York CUNY, M. L. BAKER, City College of New York CUNY and New York University NYU, D. A. GARANIN, Lehman College of CUNY, NAJAH MHESN, CHRISTOS LAMPROPOULOS, University of North Florida — Magnetic deflagration in molecular magnets has been triggered by heat pulses [1,2] and acoustic waves [3,4]. In this work we report spontaneous magnetic deflagration (i.e. deflagration that occurs without an external trigger) in the axially symmetric single molecule magnet  $\text{Mn}_{12}\text{tBuAc}$ . Magnetic hysteresis measurements show steps due to resonant quantum tunneling (RQT) below 1K, confirming the spin-Hamiltonian parameters for this material and previous results. Deflagration speeds measured with a newly constructed higher bandwidth (2MHz) setup will be presented as a function of transverse and longitudinal fields  $H_x \otimes H_z$  both on and off resonance. A large increase in front velocity near RQT steps is observed in experiments with swept transverse fields and will be discussed in light of models of deflagration. [1] S. McHugh *et al.* PRB **76**, 172410 (2007); [2] P. Subedi *et al.*, PRL **110**, 207203 (2013). [3] A. Hernández-Mínguez *et al.*, PRL **95**, 217205 (2005).

**1:51PM B21.00012 ELECTRO-NUCLEAR CLOCK TRANSITIONS IN A  $\text{Ho(III)}$  MOLECULAR NANOMAGNET**<sup>1</sup>, DORSA KOMIJANI, M. SHIDDIQ, Department of Physics, Florida State University (NHMFL), FL, Y. DUAN, A. GAITA-ARINO, E. CORONADO, Instituto de Ciencia Molecular (ICMol), Universidad de Valencia, Spain, S. HILL, Department of Physics, Florida State University (NHMFL), FL — One of the challenges in the field of quantum information processing involves protecting qubits against decoherence. The primary source of decoherence in spin qubits at low temperatures is the dipolar interaction, which can be minimized using so-called clock transitions [1]. Here, we report pulsed EPR studies of the Holmium Polyoxometalate,  $[\text{Na}]_9[\text{Ho}_x\text{Y}_{1-x}(\text{W}_5\text{O}_{18})_2]$ , where we observe electro-nuclear clock transitions that involve coupled dynamics of the electron and nuclear spins ( $\Delta m_J = \pm 8$  and  $\Delta m_I = \pm 1$ ). These transitions are formally forbidden in EPR. However, the symmetry of this molecule generates admixtures of the ground doublet ( $m_J = \pm 4$ ) through second order perturbation, and application of a transverse magnetic field mixes  $m_I$  and  $m_I \pm 1$  states, allowing such transitions to occur in the vicinity of avoided level crossings. Pulsed EPR measurements on an  $x = 0.1$  sample, were carried out at a temperature of 5 K at X-band. These experiments suggest an enhancement in the coherence time at these electro-nuclear clock transitions which is significant for applications in hybrid magnetic qubits, where manipulation of the nuclear spin is controlled by EPR pulses. **2:03PM B21.00013 A Crystal Field Approach to Orbitally Degenerate SMMs: Beyond the Spin-Only Hamiltonian**<sup>1</sup>, LAKSHMI BHASKARAN, Department of Physics and NHMFL, Florida State University, Tallahassee, USA, KATIE MARRIOTT, MARK MURRIE, WestCHEM, School of Chemistry, University of Glasgow, Glasgow, UK, STEPHEN HILL, Department of Physics and NHMFL, Florida State University, Tallahassee, USA — Single-Molecule Magnets (SMMs) with large magnetization reversal barriers are promising candidates for high-density information storage. Recently, a large uniaxial magnetic anisotropy was observed for a mononuclear trigonal bipyramidal (TBP)  $[\text{Ni}^{\text{II}}\text{Cl}_3(\text{Me-abco})_2]$  SMM [1]. High-field EPR studies analyzed on the basis of a spin-only Hamiltonian give  $D > 400 \text{ cm}^{-1}$ , which is close to the spin-orbit coupling parameter  $\lambda = 668 \text{ cm}^{-1}$  for  $\text{Ni}^{\text{II}}$ , suggesting an orbitally degenerate ground state. The spin-only description is ineffective in this limit, necessitating the development of a model that includes the orbital moment. Here we describe a phenomenological approach that takes into account a full description of crystal field, electron-electron repulsion and spin-orbit coupling effects on the ground state of a  $\text{Ni}^{\text{II}}$  ion in a TBP coordination geometry. The model is in good agreement with the high-field EPR experiments, validating its use for spectroscopic studies of orbitally degenerate molecular nanomagnets. [1] K. E. Marriott *et al.*, Chem Sci (published Online)

**11:15AM B22.00001 Hole localization, water dissociation mechanisms, and band alignment at aqueous-titania interfaces<sup>1</sup>**, JOHN L. LYONS, Brookhaven National Laboratory — Photocatalytic water splitting is a promising method for generating clean energy, but materials that can efficiently act as photocatalysts are scarce. This is in part due to the fact that exposure to water can strongly alter semiconductor surfaces and therefore photocatalyst performance. Many materials are not stable in aqueous environments; in other cases, local changes in structure may occur, affecting energy-level alignment. Even in the simplest case, dynamic fluctuations modify the organization of interface water. Accounting for such effects requires knowledge of the dominant local structural motifs and also accurate semiconductor band-edge positions, making quantitative prediction of energy-level alignments computationally challenging. Here we employ a combined theoretical approach to study the structure, energy alignment, and hole localization at aqueous-titania interfaces. We calculate the explicit aqueous-semiconductor interface using ab initio molecular dynamics, which provides the fluctuating atomic structure, the extent of water dissociation, and the resulting electrostatic potential. For both anatase and rutile TiO<sub>2</sub> we observe spontaneous water dissociation and re-association events that occur via distinct mechanisms. We also find a higher-density water layer occurring on anatase. In both cases, we find that the second monolayer of water plays a crucial role in controlling the extent of water dissociation. Using hybrid functional calculations, we then investigate the propensity for dissociated waters to stabilize photo-excited carriers, and compare the results of rutile and anatase aqueous interfaces. Finally, we use the GW approach from many-body perturbation theory to obtain the position of semiconductor band edges relative to the occupied 1b<sub>1</sub> level and thus the redox levels of water, and examine how local structural modifications affect these offsets.

**11:51AM B22.00002 Role of excited states in Shockley-Read-Hall recombination in wide band-gap semiconductors**, AUDRIUS ALKAUSKAS, Center for Physical Sciences and Technology, Lithuania, CYRUS E. DREYER, JOHN L. LYONS, CHRIS G. VAN DE WALLE, University of California Santa Barbara — Defect-assisted recombination is an important limitation on efficiency of optoelectronic devices. However, since nonradiative capture rates decrease exponentially with energy of the transition, the mechanisms by which such recombination can take place in wide-band-gap materials are unclear. We investigate the role of electronic excited states in the recombination process, focusing on group-III nitrides, for which accumulating experimental evidence indicates that defect-assisted recombination is an important limiting factor in efficiency. Based on first-principles electronic structure calculations, we show that excited states of gallium vacancy complexes make these defects very efficient recombination centers. Our work provides new insights into the physics of nonradiative recombination. The mechanism discussed in this work is suggested to be very critical and ubiquitous in wide-band-gap semiconductors. This work was supported by DOE and the European Union.

**12:03PM B22.00003 Auger recombination in InN from first principles<sup>1</sup>**, ANDREW MCALLISTER, EMMANOUIL KIOUPAKIS, Univ of Michigan - Ann Arbor — Group-III Nitride materials are used in numerous electronic and optoelectronic devices including solid-state lighting, energy conversion, sensor technologies, and high-power electronics. Indium nitride in particular is interesting for fast electronics and optoelectronics in the infrared. Auger recombination is a non-radiative carrier recombination process that would limit the efficiency of these devices. The small band gap (0.7 eV) and the high intrinsic free-electron concentrations in InN possibly make Auger recombination particularly important in this material. We used first-principles computational methods to determine the Auger recombination rates in InN. Our results suggest that direct Auger recombination is dominant in this material and that phonon-assisted Auger processes are not as important as in wider-gap nitrides such as GaN.

<sup>1</sup>This research was supported by the National Science Foundation CAREER award through Grant No. DMR-1254314. Computational resources were provided by the DOE NERSC facility.

**12:15PM B22.00004 Electronic coherence and the kinetics of energy transfer in light-harvesting systems**, PENGFEI HUO, University of Rochester, DAVID COKER, Boston University, THOMAS MILLER, Caltech — Recent 2D-spectroscopy experiments have observed transient electronic coherence in natural and artificial light harvesting systems, which raises questions about the role of electronic coherence in facilitating excitation energy transfer (EET) processes. In this talk, we introduce the recently developed partial linearized path-integral (PLPI) method, which can accurately simulate exciton transfer dynamics across multiple reaction regimes, as well as reliably describe the electronic coherence among excitonic states. Further, we develop a strategy that enables the analysis of the relative impact of static and dynamic electronic coherence. With PLPI simulations, we find that energy transfer dynamics are almost entirely dominated by static coherence effects; dynamic coherence is found to cause only minor effects. These conclusions are consistent with the historical view that emphasizes the importance of energy-level alignment for efficient incoherent energy transfer, while suggesting a less important role for more exotic electronic coherence effects that have been recently emphasized.

**12:27PM B22.00005 The Optical Spectrum of LaAlO<sub>3</sub>: Quasiparticle Energies and the Effect of Lattice Screening**, XIAO ZHANG, ANDRE SCHLEIFE, University of Illinois, Urbana — Lanthanum aluminate (LaAlO<sub>3</sub>) is a commonly used high- $\kappa$  dielectric material but its exact optical properties are not well understood. By solving the Bethe-Salpeter Equation for the optical polarization function, which describes the interaction between electrons and holes, a precise prediction of the dielectric function can be obtained. However, for LaAlO<sub>3</sub>, there are two major problems limiting the computational study: The first problem is that due to the complicated conduction band structure, the quasiparticle effect needs to be taken into account, which makes the calculations costly. We resolved this problem by interpolating accurate eigenenergies computed using a hybrid exchange-correlation functional to a dense k-point grid. Another problem is that for such high- $\kappa$  materials, the lattice contribution to the dielectric screening may be important. We investigated this by computing the optical spectrum using electronic constant, static dielectric constant and the average of both and found that taking lattice contribution into account significantly reduces excitonic effects. All results are compared to available experiments.

**12:39PM B22.00006 Electronic and optical properties of Ga<sub>2</sub>O<sub>3</sub> from first principles**, KELSEY MENGLE, EMMANOUIL KIOUPAKIS, University of Michigan — Wide band-gap semiconductors such as Ga<sub>2</sub>O<sub>3</sub> are used in numerous applications including high voltage/temperature electronics, deep-UV emission, and transparent contacts. We have investigated the electronic and optical properties of Ga<sub>2</sub>O<sub>3</sub> with first-principles calculations based on density functional theory. The electronic and optical properties are calculated with many-body perturbation theory using the GW and Bethe-Salpeter equation methods. The semicore states of Ga are treated as valence electrons to accurately determine the band gap and band structure. We will present results for the structural, electronic, and optical properties of the various Ga<sub>2</sub>O<sub>3</sub> polymorphs, including  $\beta$ -Ga<sub>2</sub>O<sub>3</sub>. This research was supported by the National Science Foundation through Grant No. DMR- 1534221. Computational resources were provided by the DOE NERSC facility.

**12:51PM B22.00007 Substrate Screening Induced Renormalization of Excited-States in 2D Materials**, NEERAV KHARCHI, VINCENT MEUNIER, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, Troy, NY 12180 — Two-dimensional (2D) materials offer an emerging platform for exploring novel electronic phenomena in reduced dimensionality systems. However, because of their atomic scale thickness, their excitation energy levels in 2D materials are strongly renormalized due to the screening by the surrounding environment. This effect is expected to have strong impact when the materials are integrated into functional devices. For example, the presently available GW calculations significantly overestimate the band gaps in graphene nanoribbons (GNRs) by as much as one eV compared to experiment. Here, we outline an integrated computational approach combining DFT, the GW approximation, and a classical image charge model to include substrate screening effects in a computationally tractable manner. We investigate the band gaps and defect charge transition levels (CTLs) in a prototypical 2D material, hexagonal boron nitride (hBN) and a prototypical 1D nanostructure, GNR. The band gaps and defect CTLs are strongly renormalized by several tenths of an eV in the substrate-supported versus the free-standing configurations. In the case of GNRs, the predicted band gaps are in an excellent agreement with recent STS experiments.

**1:03PM B22.00008 Electronic structure, transport properties, and excited states in CoTiSb, CoZrSb, and CoHfSb half-Heusler compounds**<sup>1</sup>, ANDERSON JANOTTI, ZHIGANG GUI, University of Delaware, Department of Materials Science and Engineering, JASON KAWASAKI, Kavli Institute at Cornell for Nanoscale Science, Cornell University, CHRIS PALMSTROM, Materials Department, University of California, Santa Barbara, BURAK HIMMETOGLU, Center for Scientific Computing, University of California, Santa Barbara — CoTiSb is a member of a large family of half-Heusler compounds with 18 valence electrons. CoTiSb is semiconductor material with a band gap a little over 1 eV, and it has been considered promising for thermoelectric applications. It can be grown on conventional III-V semiconductors, and could potentially be integrated in III-V devices. Here we present results of first-principles calculations of electronic structure, transport properties, and excited states in CoTiSb, as well as CoZrSb and CoHfSb. Electronic structures are studied using density functional theory within the local density approximation, hybrid functional and quasiparticle GW methods. Both room-temperature Seebeck coefficient and carrier mobility are calculated from first-principles. We also determine the band alignments to III-V semiconductors, and all the results are presented and discussed in the light of available experimental data.

<sup>1</sup>This work was supported by the DOE.

**1:15PM B22.00009 Ab Initio Calculations of Excited Carrier Dynamics in Gallium Nitride**, VATSAL JHALANI, MARCO BERNARDI, California Institute of Technology — Bulk wurtzite GaN is the primary material for blue light-emission technology. The radiative processes in GaN are regulated by the dynamics of excited (or so-called hot) carriers, through microscopic processes not yet completely understood. We present ab initio calculations of electron-phonon (e-ph) scattering rates for hot carriers in GaN. Our work combines density functional theory to compute the electronic states, and density functional perturbation theory to obtain the phonon dispersions and e-ph coupling matrix elements. These quantities are interpolated on fine Brillouin zone grids with maximally localized Wannier functions, to converge the e-ph scattering rates within 5 eV of the band edges. We resolve the contribution of the different phonon modes to the total scattering rate, and study the impact on the relaxation times of the long-range Fröhlich interaction due to the longitudinal-optical phonon modes.

**1:27PM B22.00010 Time Evolution of Charge Carriers & Phonons after Photo-Excitation by an Ultra-Short Light Pulse in Bulk Germanium**<sup>1</sup>, STEPHEN FAHY, University College Cork, FELIPE MURPHY-ARMANDO, Tyndall National Institute, Cork, Ireland, MARIANO TRIGO, Stanford Institute for Materials and Energy Science, SLAC National Accelerator Laboratory, IVANA SAVIC, EAMONN MURRAY, Tyndall National Institute, Cork, Ireland, DAVID REIS, Stanford Institute for Materials and Energy Science, SLAC National Accelerator Laboratory — We have calculated the time-evolution of carriers and generated phonons in Ge after ultrafast photo-excitation above the direct band-gap. The relevant electron-phonon and anharmonic phonon scattering rates are obtained from first-principles electronic structure calculations. Measurements of the x-ray diffuse scattering after excitation near the L point in the Brillouin zone find a relatively slow (5 ps, compared to the typical electron-phonon energy relaxation of the Gamma-L phonon) increase of the phonon population. We find this is due to emission caused by the scattering of electrons between the Delta and L valleys, after the initial depopulation of the Gamma valley. The relative slowness of this process is due to a combination of causes: (i) the finite time for the initial depopulation of the conduction Gamma valley; (ii) the associated electron-phonon coupling is relatively weaker (compared to Gamma-L, Gamma-Delta and Delta-Delta couplings); (iii) the TA associated phonon has a long lifetime and (iv) the depopulation of the Delta valley suppresses the phonon emission.

**1:39PM B22.00011 Constrained Density Functional Theory by Imaginary Time-Step Method**, DANIEL KIDD, Vanderbilt University — Constrained Density Functional Theory (CDFT) has been a popular choice within the last decade for sidestepping the self interaction problem within long-range charge transfer calculations.<sup>1</sup> Typically an inner constraint loop is added within the self-consistent field iterations of DFT in order to enforce this charge transfer state by means of a Lagrange multiplier method.<sup>2</sup> In this work, an alternate implementation of CDFT is introduced, that of the imaginary time-step method, which lends itself more readily to real space calculations in the ability to solve numerically for 3D local external potentials which enforce arbitrary given densities. This method has been shown to reproduce the proper  $1/R$  dependence of charge transfer systems in real space calculations as well as the ability to generate useful constraint potentials. As an example application, this method is shown to be capable of describing defects within periodic systems using finite calculations by constraining the 3D density to that of the periodically calculated perfect system at the boundaries.

**1:51PM B22.00012 Density functional study on a light-harvesting carotenoid-porphyrin-C<sub>60</sub> molecular triad in explicit solvent**, CARLOS DIAZ, TUNNA BARUAH, RAJENDRA ZOPE, University of Texas at El Paso — We investigate the effect of solvent on the electronic structure of a biomimetic molecular triad that shows photoinduced charge transfer in laboratory. The supramolecular triad contains three different units - C<sub>60</sub>, porphyrin, and beta-carotenoid. We have performed classical molecular dynamics simulation of the triad surrounded by 15000 water molecules using NAMD for 20 nanoseconds. Subsequently, we performed an all-electron density functional calculations (DFT) using large basis sets on the 50 snap-shots taken from the molecular dynamics simulation. The solvent effects in the DFT calculations are treated using both the explicit water molecules as well as using the point charge representation of water. The excitation energies and absorption spectra show that the polar solvent induces significant changes in the electronic structure of the triad.

**2:03PM B22.00013 Ab-Initio Computations of Electronic and Related Properties of cubic Lithium Selenide ( $\text{Li}_2\text{Se}$ )**, ABDOULAYE GOITA, Department of Electrical Engineering, Southern University and AM College, Baton Rouge, IFEANYI H. NWIGBOJI, Department of Computational Science, University of Texas at El Paso, El-Paso, TX 79968 USA, YURIY MALOZOVSKY, DIOLA BAGAYOKO, Department of Physics, Southern University and AM College, Baton Rouge, LA 70813, USA — We present theoretical predictions, from ab-initio, self-consistent calculations, of electronic and related properties of cubic lithium selenide ( $\text{Li}_2\text{Se}$ ). We employed a local density approximation (LDA) potential and the linear combination of atomic orbitals (LCAO). We performed the computations following the Bagayoko, Zhao, and Williams (BZW) method, as enhanced by Ekuma and Franklin (BZW-EF). Our results include electronic energies, total and partial densities of states, effective masses, and the bulk modulus. The theoretical equilibrium lattice constant is 5.882 Å. We found cubic  $\text{Li}_2\text{Se}$  to have a direct band gap of 4.363 eV (prediction), at  $\Gamma$ . This gap is 4.065 eV for a room temperature lattice constant of 6.017 Å. The calculated bulk modulus is 31.377 GPa. Acknowledgments: This work was funded in part by the National Science Foundation (NSF) and the Louisiana Board of Regents, through LASiGMA [Award Nos. EPS- 1003897, NSF (2010-15)-RII-SUBR] and NSF HRD-1002541, the US Department of Energy – National, Nuclear Security Administration (NNSA) (Award No. DE- NA0002630), LaSPACE, and LONI-SUBR.

**11:15AM B23.00001 Materials by design: methodological developments in the calculation of excited-state properties<sup>1</sup>**, MARCO GOVONI, Institute for Molecular Engineering, University of Chicago and Argonne National Laboratory — Density functional theory (DFT) is one of the main tools used in first principle simulations of materials; however several of the current approximations of exchange and correlation functionals do not provide the level of accuracy required for predictive calculations of excited state properties. The application to heterogeneous systems of more accurate post-DFT approaches such as Many-Body Perturbation Theory (MBPT) – for example to nanostructured, disordered, and defective materials – has been hindered by high computational costs. In this talk recent methodological developments in MBPT calculations will be discussed, as recently implemented in the open source code WEST [1], which efficiently exploits HPC architectures. Results using a formulation that does not require the explicit calculation of virtual states, nor the storage and inversion of large dielectric matrices will be presented; these results include quasi particle energies for systems with thousands of electrons and encompass the electronic structure of aqueous solutions, spin defects in insulators, and benchmarks for molecules and solids containing heavy elements. Simplifications of MBPT calculations based on the use of static response properties, such as dielectric-dependent hybrid functionals [2], will also be discussed.

**11:51AM B23.00002 An Automated Ab Initio Approach for Identifying Small Band Gap Ferroelectric**, TESS SMIDT, SEBASTIAN REYES-LILLO, Physics Department, UC Berkeley; Molecular Foundry, Lawrence Berkeley National Lab, JEFFREY NEATON, Physics Department, UC Berkeley; Molecular Foundry, Lawrence Berkeley National Lab; Kavli Energy NanoSciences Institute at Berkeley — Small band gap ferroelectrics are scarce and yet hold promise for optoelectronics applications. In this work, we leverage the electronic and symmetry requirements that give rise to ferroelectricity to search for new small band gap ferroelectrics using the Materials Project and Inorganic Crystal Structure Database. We create an automated workflow that combines database queries, symmetry tools and high-throughput DFT to identify candidate classes of ferroelectrics. Using density functional theory and beyond, we reveal accurate band gap trends for new and previously synthesized compounds. The effect of chemical doping on the polarization and energy barrier is discussed for select cases.

**12:03PM B23.00003 Ab initio parametrization of bond-polarizability model for Raman spectroscopy of complex Si materials**, DAVID A. STRUBBE, JEFFREY C. GROSSMAN, Department of Materials Science and Engineering, Massachusetts Institute of Technology — Classical inter-atomic potentials can be successful at predicting the vibrations of materials at system sizes intractable by quantum methods. However, to predict Raman spectra, electrons must be re-introduced, for example via a bond-polarizability model which attributes the polarizability to cylindrically symmetrical inter-atomic bonds. Parameters in assumed functional forms are fit to experimental spectra, and then a Raman intensity can be computed for each mode. In the case of amorphous silicon, the existing models do not show satisfactory agreement with experimental spectra. To generate a more accurate and transferable bond-polarizability model, we have instead begun with ab initio calculated Raman tensors for a set of a-Si:H structures [DA Strubbe et al., arXiv:1511.01139]. This atomistic data set allows us to obtain parameters and functional forms for a general model, without confounding errors from the potentials. This Raman model can be used to study large structural models with relevance for photovoltaics, such as medium- and long-range order in a-Si:H, nanocrystalline Si, amorphous/crystalline interfaces, or a-Si:H nanowires, at sizes that would be inaccessible for ab initio calculations. We analyze the applicability of this approach to other materials systems.

**12:15PM B23.00004 Self-consistent perturbation theory for two dimensional twisted bilayers**, SHARMILA N. SHIRODKAR, GEORGIOS A. TRITSARIS, EFTHIMIOS KAXIRAS<sup>1</sup>, John A. Paulson School of Engineering and Applied Sciences, Harvard University, Cambridge, Massachusetts 02138, USA — Theoretical modeling and ab-initio simulations of two dimensional heterostructures with arbitrary angles of rotation between layers involve unrealistically large and expensive calculations. To overcome this shortcoming, we develop a methodology for weakly interacting heterostructures that treats the effect of one layer on the other as perturbation, and restricts the calculations to their primitive cells<sup>2</sup>. Thus, avoiding computationally expensive supercells. We start by approximating the interaction potential between the twisted bilayers to that of a hypothetical configuration (viz. ideally stacked untwisted layers), which produces band structures in reasonable agreement with full-scale ab-initio calculations for commensurate and twisted bilayers of graphene (Gr) and Gr/hexagonal boron nitride (h-BN) heterostructures. We then self-consistently calculate the charge density and hence, interaction potential of the heterostructures. In this work, we test our model for bilayers of various combinations of Gr, h-BN and transition metal dichalcogenides, and discuss the advantages and shortcomings of the self-consistently calculated interaction potential.

**12:27PM B23.00005 Simplified Quantum Transport Theory for Finite Bias and Temperature<sup>1</sup>**, XIAOQUANG ZHANG, YUNING WU, Univ of Florida - Gainesville, SOKRATES PANTELIDES, Vanderbilt University — We reformulate the Landauer-Buttiker formula for quantum transport by explicitly accounting for the energy and bias voltage dependence of the transmission probability. Under the assumption of a constant electric field, a simple formula for the differential conductance under a finite bias and at a finite temperature is derived that does not require a nonequilibrium self-consistent calculation. Calculation for the tunneling current through Au-Benzendithiol-Au molecular junction shows excellent agreement with the nonequilibrium Green's function (NEGF) method at zero temperature. Temperature dependent I-V curves for a number of devices are demonstrated.

**12:39PM B23.00006 High-throughput determination of Hubbard U for cubic perovskites using the ACBN0 functional.**, LAALITHA LIYANAGE, University of North Texas, ANDREW SUPKA, PRIYA GOPAL, Central Michigan University, LUIS AGAPITO, University of North Texas, GUS HART, Brigham Young University, MARCO FORNARI, Central Michigan University, STEFANO CURTAROLO, Duke University, MARCO BUONGIORNO NARDELLI, University of North Texas — High-throughput (HT) density functional theory (DFT) computations are the method of choice for rapid screening of materials properties and materials development. However, traditional DFT is not adequate for the investigation of all systems. For materials containing transition metal elements, methods such as DFT+U or hybrid functionals are needed for an accurate prediction of the electronic structure. As an efficient and accurate alternative we have recently introduced the ACBN0 functional for DFT as a new pseudo-hybrid Hubbard density functional that is a parameter-free extension of traditional DFT+U that has been proved to correct both the band gap and the relative position of the different bands in transition metal compounds. We implemented ACBN0 in a Medium-Throughput Framework (MTFrame) designed to automate DFT calculations for systems that share a single reference crystal structure. Using the MTFrame, we have determined the effective U values for 3969 cubic perovskites (ABO<sub>3</sub>) built by permutating 63 different elements in the A and B sites. Analysis of resulting data reveals the effects of Hubbard U on the electronic properties and crystal structure. Finally, machine learning algorithms are used to find correlations in the extracted data and the U values.

**12:51PM B23.00007 A tool for accelerating material calculations through the generation of highly efficient *k*-point grids**, TIM MUELLER, PANDU WISESA, Johns Hopkins University — The calculation of many material properties requires the evaluation of an integral over the Brillouin zone, which is commonly approximated by sampling a regular grid of points, known as *k*-points, in reciprocal space. We have developed an automated tool for generating *k*-point grids that significantly accelerates the calculation of material properties compared to commonly used methods. Our tool, which is being made freely available to the public, is capable of generating highly efficient *k*-point grids in a fraction of a second for any crystalline material. We present an overview of our method, benchmark results, and a discussion of how it can be integrated into a high-throughput computing environment.

**1:03PM B23.00008 Advancing Efficient All-Electron Electronic Structure Methods Based on Numeric Atom-Centered Orbitals for Energy Related Materials<sup>1</sup>**, VOLKER BLUM, MEMS Department, Duke University, Durham, NC 27708 — This talk describes recent advances of a general, efficient, accurate all-electron electronic theory approach based on numeric atom-centered orbitals; emphasis is placed on developments related to materials for energy conversion and their discovery. For total energies and electron band structures, we show that the overall accuracy is on par with the best benchmark quality codes for materials, but scalable to large system sizes (1,000s of atoms) and amenable to both periodic and non-periodic simulations. A recent localized resolution-of-identity approach for the Coulomb operator enables  $O(N)$  hybrid functional based descriptions of the electronic structure of non-periodic and periodic systems, shown for supercell sizes up to 1,000 atoms; the same approach yields accurate results for many-body perturbation theory as well. For molecular systems, we also show how many-body perturbation theory for charged and neutral quasiparticle excitation energies can be efficiently yet accurately applied using basis sets of computationally manageable size. Finally, the talk highlights applications to the electronic structure of hybrid organic-inorganic perovskite materials, as well as to graphene-based substrates for possible future transition metal compound based electrocatalyst materials.

<sup>1</sup>All methods described here are part of the FHI-aims code. VB gratefully acknowledges contributions by numerous collaborators at Duke University, Fritz Haber Institute Berlin, TU Munich, USTC Hefei, Aalto University, and many others around the globe.

**1:39PM B23.00009 Simple Rules for Solid-state Design: From Bulk to Interface**, KEITH BUTLER, ARON WALSH, ADAM JACKSON, DAN DAVIES, University of Bath, FUMIYASU OBA, YU KUMAGAI, Tokyo Institute of Technology, WALSH MATERIALS DESIGN TEAM, JSPS COLLABORATION — High-throughput screening enterprises such as Materials Project and the QCMD are well suited to the application of density functional theory for assessing the merits of known bulk materials. The blind exploration of the new combinations and permutations of the periodic table is a daunting task, to paraphrase Samuel Beckett we feel *lost before the confusion of innumerable prospects*. Centuries of research have provided us with myriad rules for assessing the feasibility of a given stoichiometry and the likelihood of particular crystal arrangements. We explore the ways in which chemical knowledge and state-of-the-art computational physics can be combined to accelerate materials design. We present the SMOCT (Semiconducting Materials by Analogy and Chemical Theory) package, which combines these rules with searching of chemical space to predict plausible and heretofore unknown compounds. I will then provide some illustrative examples of materials' design focusing on several important issues: (i) designing new photovoltaic materials [1], (ii) the role of surfaces and polymorphism in controlling electronic properties [2,3], and (iii) the design of porous materials [4]. Butler, et al., *J. Am. Chem. Soc.*, **2014**, 136, 2703

**1:51PM B23.00010 ACBN0-tool for accelerated materials discovery.**, PRIYA GOPAL, Central Michigan University, LAALITHA LIYANAGE, LUIS AGAPITO, University of North Texas, SEUNGHUN LEE, ICHIRO TAKEUCHI, University of Maryland, GUS HART, Brigham Young University, STEFANO CURTAROLO, Duke University, MARCO FORNARI, Central Michigan University, MARCO BUONGIORNO NARDELLI, University of North Texas — High-Throughput QM computation of material properties by abinitio methods has become the foundation of an effective approach to materials design. One of the major challenges in mapping the materials genome is in developing efficient computational tools that are cost-effective and accurate at the same time. In this talk, we discuss the newly developed ACBN0 pseudo-hybrid Hubbard density functional where the Hubbard energy within the DFT + U formulation is calculated self consistently. The U depends on the electron density and depends both on the geometry and chemical environment of the system. We show that ACBN0 improves the description of both the structural and electronic properties in a range of complex materials from Zn/Cd based chalcogenides to the TMOs. The magnetic properties are better described compared to the LDA/GGA functionals. We will also discuss the application of the ACBN0 approach to surfaces, doped and multi-valent systems where it is possible to evaluate U for different sites and chemical bonding. For all the complex materials studied here, we find that the electronic properties are significantly improved over the DFT values and the accuracy is at par with the HSE values at a fraction of the computational cost.

**Session B24 DMP: Optical Effects Near Metallic Nanostructures** 323 - Latha Venkataraman, Columbia University

**11:15AM B24.00001 Optical functionality of plasmon-exciton nanomaterials in the strong coupling regime**, MAXIM SUKHAREV, Arizona State University — Understanding optical plasmon-exciton interaction in hybrid plasmonic nanostructures is important for tuning the optical response, e.g. for applications in nonlinear optics, organic solar cells, or organic light-emitting diodes. In developing such nanostructures, the strong coupling phenomena play crucial role allowing to efficiently transfer energy between plasmons and molecular excitons on a femtosecond time scale. In this talk I will discuss modeling aspects of various optical phenomena at plasmonic interfaces using Maxwell-Bloch equations in three dimensions. Various plasmonic systems including periodic V-grooves, bowtie antennas, nanowires, periodic hole arrays, and others will be considered. In particular, I will demonstrate that one can design hybrid nanomaterials with highly pronounced Fano resonances using femtosecond lasers. I will show that it is possible to use ultra-short laser pulses to materials with desired properties and functionality. Electromagnetic energy transport in systems composed of closely spaced nanowires in a presence of molecular excitons will also be discussed.

**11:51AM B24.00002 Surface Enhance Infrared Absorption in nanogap structures**, YAJING LI, PAVLO ZOLOTAVIN, DOUGLAS NATELSON, Rice University — Understanding the energy dissipation at the interface of molecules and metal nanostructures is of interest. We fabricate self-aligned gold nanostructures with nanometer-scale interelectrode spacing. Those gold nanostructures support highly hybridized plasmon modes with great enhanced local electric field. Previous studies have proven those structures to be suitable substrates for surface-enhanced Raman spectroscopy with single-molecule sensitivity, which enables the study of molecular vibrational and electronic physics. We propose those structures as possible probes of the energy dissipation at the nanometer gap. By measuring the absorption spectrum of molecules assembled in the junction, we can estimate the local field intensity at the gap and discuss the plasmonic responses of these self-aligned structures under infrared excitation.

**12:03PM B24.00003 Optically induced changes to the tunneling properties of molecular junctions.**<sup>1</sup>, PAVLO ZOLOTAVIN, CHARLOTTE EVANS, DOUGLAS NATELSON, Department of Physics & Astronomy, Rice University — We report increased conductance under laser illumination in plasmonically active atomic scale gold junction in a cryogenic environment (substrate temperatures down to 4 K). Additionally, we observe changes in the bias dependence of differential conductance, which we attribute to local heating due to the illumination. We differentiate between plasmon and direct gold absorption by investigating the polarization dependence of the observed temperature change. The effect is quantified by measuring optically induced changes in the resistance of the metal nanowire and by the change in the magnitude of simultaneously measured Johnson-Nyquist noise. A combination of these techniques provides independent measurements of effective lattice and electronic temperatures. Unlike previous experiments at room temperature and 80 K, we report a substantially larger light-driven temperature increase of 80-120K for devices fabricated on SiO<sub>2</sub>/Si substrates held at substrate temperatures as low as 4 K. The implications of the observed behavior for electronic transport in single molecular junctions with plasmonically active nanowire leads will be discussed.

**12:15PM B24.00004 Propagating plasmon excitation of molecular junctions for spectroscopy**<sup>1</sup>, CHARLOTTE EVANS, PAVLO ZOLOTAVIN, DOUGLAS NATELSON, Rice University Department of Physics and Astronomy — Electronic transport and simultaneous optical measurements on molecule-containing junctions can provide critical information about the dissipation of energy through inelastic processes. Gold bowtie nanostructures have been used for electronic transport and as plasmonically active substrates for surface-enhanced Raman scattering (SERS), conventionally with exciting light incident directly on the molecular junction. Electromigrating these devices created interelectrode nanogaps with single-molecule sensitivity in which the Raman scattering rate is dominated by plasmonically enhanced electromagnetic fields due to the presence of the metal nanojunction near the molecules of interest. Direct optical excitation of the junction region, however, can cause heating of the metal, molecular instability via conformational and chemical changes, and breakdown over time. Adding metallic gratings to the electrode design enables the excitation of propagating plasmon modes that can couple into the junction region without direct excitation by far-field radiation. We will present preliminary data on how the addition of these gratings affects single-molecule SERS and the electrical properties of the molecules in these junctions.

<sup>1</sup>This research was funded by NSF Graduate Research Fellowships Program DGE-1450681 and ARO award W911 NF-13-1-0476.

**12:27PM B24.00005 Enhancement of Resonant Energy Transfer Due to Evanescent-wave from the Metal**, AMRIT POUDEL, Northwestern University, XIN CHEN, Xi'an Jiaotong University, MARK RATNER, Northwestern University — The high density of evanescent modes in the vicinity of a metal leads to enhancement of the near-field Forster resonant energy transfer (FRET) rate. We present a mathematical formulation based on classical electromagnetic theory using the dyadic Greens function and investigate the effect of metallic environment using material permittivity in local and nonlocal limits, which provides better estimates of the transfer rate at small separations from the metal. Furthermore, we present a general formula of FRET rate for multiple donors and acceptors in the presence of arbitrary dielectric environment and discuss the path interference effect on FRET rate.

**12:39PM B24.00006 Two-photon up-conversion affected by inter-molecule correlations near metallic nanostructure**<sup>1</sup>, YOSHIKI OSAKA, NOBUHIKO YOKOSHI, HAJIME ISHIHARA, Osaka Prefecture University — Optical antennas, which consist of metallic nanostructures, concentrate free-propagating light into localized surface plasmons (LSP). Such a localized field enables effective interactions between light and molecules nearby the metal surfaces. However, as the light intensity decreases to single-photon level, large dissipation in the metals always inhibits the effective photon-molecule interaction via LSP. We have theoretically elucidated that controlling quantum interference in an antenna-molecule coupled system strongly suppresses the photon-dissipations, and leads to efficient two-photon processes in the molecule. However, it is difficult to prepare only one molecule nearby the metal. Therefore, as a beachhead into a multi-molecule system, we will consider the case that two photons couple with two molecules under one LSP. In rapid intuition, the appearance of the second molecule seemingly damages the up-conversion process. In the presentation, we reveal that controlling the inter-molecule interaction could resolve the difficulty, and lead to the efficient up-conversion through the quantum interference among three-bodies, i.e., LSP and two molecules.

## **12:51PM B24.00007 Finite-Difference Time-Domain (FDTD) Modeling of Gold Core-Shell Structures with Different Shell Morphology for Surface-Enhanced Raman Spectroscopy (SERS)<sup>1</sup>**

, ZOHRE GORUNMEZ, DEBRINA JANA, JIE HE, LAURA SAGLE, THOMAS BECK, University of Cincinnati — Core-shell (CS) nanostructures have received attention in recent years due to their usefulness in applications ranging from catalysis to cancer treatment. SERS has been shown to be one of the most sensitive techniques for molecular detection, achieving single molecule detection. It has been established that the electromagnetic mechanism (EM) provides the main contribution to SERS enhancement due to the normal Raman spectroscopy arising from coupling of both the incident and re-emitted fields. The FDTD technique has been developed to provide numerical solutions to Maxwell's time-dependent curl equations in order to promise modeling capabilities for EM enhancement of SERS. Herein, we apply this method to the study of three morphologically different gold core-shell nanoparticles to investigate their contributions to SERS. In these structures, the dye/probe molecule resides in between the shell and the core and only the shell morphology is altered. The data shows that the surface plasmon resonances (PRs) influencing the SERS of the probe molecules, due to the coupling of the core and shell, are tunable by changing the shell morphologies and CS structures with sharp features on their surfaces highlight larger enhancements due to stronger localized surface PRs.

## **1:03PM B24.00008 Block copolymer based design of highly sensitive substrates for detecting single molecules by surface enhanced Raman scattering**

, ATIKUR RAHMAN, CHARLES BLACK, Brookhaven National Lab — Surface enhanced Raman spectroscopy (SERS) relies on substrates with nanometer-scale curvature in order to concentrate and amplify the incident electromagnetic field to increase the spectroscopic signature of Raman scattering. The localization and amplification of incident light is maximum between two plasmonic nanostructures called as "hot spot". Here, we report a new, scalable method for fabricating high-performance SERS substrates based on self-assembly of nanostructured block copolymer thin films. Due to the high spatial density and extremely high field strengths of substrate hot spots, these substrate are capable of enhancing Raman scattering signals from target molecules by more than 10 billion times. We will describe the process of fabricating these remarkable diagnostic tools, which are  $\sim \text{cm}^2$  area substrates composed of an extremely high density ( $\sim 10^{11} / \text{cm}^2$ ) of hexagonally-arranged Au or Ag nanoparticles positioned atop  $\sim 70\text{nm}$  tall silicon nanopillars. Key to the substrate performance is the sub-5 nm separation between particles, which we control with nm level precision. By systematically varying the gap between nanoparticles, we demonstrate that both the high hotspot density and sub 5nm hot spot gap are necessary to achieve the highest degree of enhancement of the Raman signal. The enormous enhancements provided by these substrates make possible the detection of single molecules.

## **1:15PM B24.00009 Single-step, high yield synthesis of gold nanoworms and their surface enhanced Raman scattering properties**

, WAQQAR AHMED, COMSATS Institute of Information Technology, JAN M. VAN RUITENBEEK, Kamerlingh Onnes Laboratory, Niels Bohrweg 2, Leiden University — Rod-shaped gold nanoparticles have attracted enormous attention owing to their interesting optical properties arising from the surface plasmon resonances. Slight deviation from the rod morphology can markedly change the optical properties. For example, worm-shaped gold nanoparticles can have more than two plasmon peaks. Furthermore, they show much higher local field enhancements as compared to their rod-shaped counterparts. We have devised a simple seedless, high-yield protocol for the synthesis of gold nanoworms (NWs). NWs were grown simply by reducing  $\text{HAuCl}_4$  with ascorbic acid in a high pH reaction medium, and in the presence of growth directional agents, cetyltrimethylammonium bromide and  $\text{AgNO}_3$ . In contrast to the seed-mediated growth of gold nanorods where a seed grows into a rod, NWs grow by oriental attachment of nanoparticles. By varying different reaction parameters we were able to control the length of NWs from a few nanometers to micrometers. Furthermore, the aspect ratio can also be tuned over a wide range. Gold NWs show excellent surface enhanced Raman scattering (SERS) properties. Ultra-low concentrations of various target molecules were detected using NWs based SERS substrates.

## **1:27PM B24.00010 A condensed matter field theory for quantum plasmonics**

, FOUAD BALLOUT, ORTWIN HESS, Imperial College London — In recent years plasmonics has advanced to ever decreasing length scales reaching dimensions comparable to the de Broglie wavelength of an electron, which has a manifest influence on the plasmon dispersion relation. The associated phenomenology lies beyond the reach of the classical drude free electron theory or its nonlocal extension and adequate models are needed to address the quantum matter aspects of light-matter interaction that are responsible for plasmonic quantum size effects. We present on the basis of the jellium model a quantum field theory of surface-plasmon polaritons in which they emerge as extended objects as a result of an inhomogeneous condensation of bosons around a topological singularity describing the surface. The benefit of this approach lies in relating the electromagnetic fields belonging to such a macroscopic quantum state with the surface topology and nonlocal response function (expressed in terms of the retarded photon self-energy) of the delimited electron gas sustaining that state.

## **1:39PM B24.00011 Combining magneto-optics with plasmonics in gold-nickel nanoparticle arrays**

, MIKKO KATAJA, SARA POURJAMAL, NanoSpin, Aalto University, NICOLÓ MACCAFERRI, PAOLO VAVASSORI, CIC NanoGUNE, TOMMI HAKALA, MIKKO HUTTUNEN, PÄIVI TÖRMÄ, COMP, Aalto University, SEBASTIAAN VAN DIJKEN, NanoSpin, Aalto University — Periodic arrays of metallic nanoantennas support intense surface lattice resonances (SLRs) with very narrow linewidths that arise from radiative coupling between the surface plasmon polaritons of the individual nanoparticles. Combining plasmonic systems with active components such as magneto-optical materials opens up new possibilities for active optical devices. Here, we present a new versatile method of integrating ferromagnetic and noble metal plasmonic nanostructures leading to strong magneto-optical responses in conjunction with drastically enhanced optical reflectivity. The structures under study consist of nickel and gold nanoparticles that are ordered into periodic checkerboard arrays. The gold constituent of these hybrid arrays guarantees intense optical reflectivity. Yet, compared to pure nickel arrays, the magneto-optical signal is practically retained. Local analyses of the radiation fields indicate that the nickel and gold nanoparticles both actively contribute to the magneto-optical activity of the hybrid lattice via radiative coupling. The results also demonstrate that the size of the noble metal nanoparticles can be used to tailor magneto-optical spectra, providing a new tool for designer magneto-optical materials.

## **1:51PM B24.00012 Surface lattice resonances and magneto-optical response in magnetic nanoparticle arrays**

, TOMMI HAKALA, MIKKO KATAJA, ALEKSI JULKU, MIKKO HUTTUNEN, SEBASTIAAN VAN DIJKEN, PÄIVI TORMA, Aalto University — We show that periodic rectangular arrays of magnetic nanoparticles display collective surface plasmon modes which are coupled by the radiation fields from each particle. The two directions of the lattice are coupled by the magnetic-field-controllable spin-orbit coupling in the nanoparticles. When breaking the symmetry of the lattice, we find that the optical response shows Fano-type surface lattice resonances whose frequency is determined by the periodicity orthogonal to the polarization of the incident field. In striking contrast, the magneto-optical Kerr response is controlled by the period in the parallel direction. The spectral separation of the response for longitudinal and orthogonal excitations provides versatile tuning of narrow and intense magneto-optical resonances.

**Monday, March 14, 2016 11:15AM - 2:03PM —**

**Session B25 DCMF: Superconducting Materials: Growth, Structure, and Properties** 324 - Joseph Prestigiacomo, Naval Research Laboratory

**11:15AM B25.00001 Superconductivity Study of  $\text{LaO}_{0.5}\text{F}_{0.5}\text{BiS}_2$  using Nuclear Magnetic Resonance**<sup>1</sup>, SHRISHTI YADAV, OSCAR BERNAL, California State University, Los Angeles, LEI SHU, JIAN ZHANG, Fudan University, Shanghai, DUYGU YAZICI, KEVIN HUANG, M. B. MAPLE, University of California, San Diego, La Jolla, CA, CALIFORNIA STATE UNIVERSITY TEAM, FUDAN UNIVERSITY TEAM —  $\text{LaO}_{0.5}\text{F}_{0.5}\text{BiS}_2$  is a member of the recently discovered class of  $\text{BiS}_2$ -layered superconductors. It has a superconducting temperature  $T_c$  close to 3 K when prepared under normal conditions. Pressure makes  $T_c$  as high as 10 K.  $T_c$  is also close to 10 K at ambient pressure for samples synthesized under pressure (2 GPa). We are conducting a  $^{19}\text{F}$ -NMR study in a polycrystalline powder of  $\text{LaO}_{0.5}\text{F}_{0.5}\text{BiS}_2$  ( $T_c \sim 3$  K). We report static and dynamic NMR parameters as functions of temperature, between 1.8 and 300 K. Our data show changes of sample behavior on cooling below both 10 and 3 K, and a modulation on the spin-echo-amplitude decay, which we discuss in some detail.

<sup>1</sup>NSF/DMR-1105380 (Cal State LA) and the NSF of China, grant 1147060 (Fudan U)

**11:27AM B25.00002 Ferrodistoritive lattice modes and polytypism in  $\text{LaO}_{1-x}\text{F}_x\text{BiS}_2$  superconductor**, ANUSHIKA ATHAUDA, DESPINA LOUCA, Univ of Virginia, CHRISTINA HOFFMAN, Oak Ridge National Laboratory, YANG REN, Argonne National Laboratory, XIANGDE ZHU, SAICHARAN ASWARTHAM, JASMINKA TERZIC, GANG CAO, Univ of Kentucky —  $\text{LaO}_{1-x}\text{F}_x\text{BiS}_2$  is a disordered, non-magnetic superconductor with a transition temperature of 10.8 K at  $x = 0.5$ . The crystal structure of  $\text{LaO}_{1-x}\text{F}_x\text{BiS}_2$  is investigated using synchrotron X-ray and neutron diffraction experiments. The Bragg pattern obtained in  $hk0$  plane could not be reproduced by either the long-presumed nominal symmetry  $P4/nmm$  or other theoretically suggested symmetries and indicated the possibility that the symmetry is lower than expected. The Bragg structure can be reproduced by a model involving coordinated ferrodistoritive in-plane displacements of sulfur. Several possibilities of sulfur displacement arrangements can reproduce the data equally well leading to the possibility of domains. When several domains are averaged together the fitting results improve. Therefore, the structure most likely consists of polytypes stacked along the  $c$ -axis. In the superconducting planes, the structure needs to be uniform, otherwise domain walls are created due to antiferrodistoritive arrangements, giving rise to additional peaks not present in the data.

**11:39AM B25.00003 Rattling induced superconductivity in  $\text{RV}_2\text{Al}_{20}$  (R = Sc, Lu, Y) aluminides — an experimental and theoretical study**<sup>1</sup>, MICHAL WINIARSKI, Gdansk University of Technology, BARTLOMIEJ WIENDLOCHA, AGH University of Science and Technology, MALGORZATA STERNIK, Institute of Nuclear Physics, Polish Academy of Sciences, PIOTR WISNIEWSKI, DARIUSZ KACZOROWSKI, Institute for Low Temperatures and Structure Research, Polish Academy of Sciences, TOMASZ KLIMCZUK, Gdansk University of Technology — Polycrystalline samples of four ternary intermetallics  $\text{RV}_2\text{Al}_{20}$  (R = Sc, Y, La, and Lu) were synthesized. Structural studies carried out using powder x-ray diffraction and Rietveld analysis show that all compounds crystallize in  $\text{CeCr}_2\text{Al}_{20}$ -type structure composed of icosahedral Al-R cages. Results of physical properties measurements reveal that  $\text{ScV}_2\text{Al}_{20}$ ,  $\text{YV}_2\text{Al}_{20}$ , and  $\text{LuV}_2\text{Al}_{20}$  are weakly-coupled BCS superconductors with critical temperatures  $T_c = 1.0, 0.57$ , and  $0.60$  K, respectively. Electronic and phonon structure calculations reveal the key role of low-frequency anharmonic vibrations of R atoms (rattling effect) for the appearance of superconductivity. A correlation between phonon and crystal structures was observed, allowing to search for new  $\text{RV}_2\text{Al}_{20}$  superconductors.

<sup>1</sup>Project was financially supported by the National Science Centre (Poland) grant (DEC-2012/07/E/ST3/00584).

**11:51AM B25.00004 Influence of ZnO and  $\text{Dy}_2\text{O}_3$  on  $\text{MgB}_2$  Bulks Fabricated by High Temperature and Pressure Reaction**, MIKE SUMPTION, YUAN YANG, MSE, The Ohio State University — ZnO and  $\text{Dy}_2\text{O}_3$  have been considered as dopants for the improvement of superconducting properties in  $\text{MgB}_2$  bulks. However, the effect of these dopants is still unclear: some studies reported these metal oxides worked as new pinning centers and others was attributed the effects to Mg site substitution. In addition, low temperature reactions may explore limited solubility regimes for these dopants. In order to study the intrinsic effect of ZnO and  $\text{Dy}_2\text{O}_3$  in  $\text{MgB}_2$ , a high temperature solid state sintering method has been used to fabricate dense and homogeneous  $\text{MgB}_2$  bulks. Even higher temperature excursions above the peritectic allow us to explore the solubility limits. To do this we used an induction furnace built inside of a high pressure vessel which allowed us to reach  $1700^\circ\text{C}$  and 1500 Psi. A slow cooling rate ( $2^\circ\text{C}/\text{min}$ ) was used in an attempt to obtain a homogeneous nucleation and phase distribution. A series of  $\text{MgB}_2$  bulk samples with ZnO and  $\text{Dy}_2\text{O}_3$  additives were synthesized through this high pressure and temperature procedures. The resulting microstructures of these bulk samples were revealed by SEM and TEM. Atomic substitution were evaluated by high resolution XRD. The upper critical field  $B_{c2}$ , irreversible field  $B_{irr}$ , and  $T_c$  were obtained from both magnetic and resistivity measurements. The roles of substitution vs precipitate induced strain on  $B_{c2}$  enhancements with adding ZnO and  $\text{Dy}_2\text{O}_3$  were discussed.

**12:03PM B25.00005  $\text{Mo}_5\text{PB}_2$ : a new superconductor in the  $\text{Cr}_5\text{B}_3$  structure type with  $T_c = 9.2$  K**<sup>1</sup>, MICHAEL MCGUIRE, DAVID PARKER, Oak Ridge National Laboratory — Superconductivity has been reported recently in several ternary silicide-borides adopting the tetragonal  $\text{Cr}_5\text{B}_3$  structure type, including  $\text{Nb}_5\text{Si}_{3-x}\text{B}_x$ ,  $\text{Mo}_5\text{SiB}_2$ , and  $\text{W}_5\text{SiB}_2$ , with critical temperatures ranging from 5.8-7.8 K. Here we report superconductivity with  $T_c$  exceeding 9 K in the phosphorus-containing analogue  $\text{Mo}_5\text{PB}_2$ . We have synthesized polycrystalline samples of the compound, made measurements of electrical resistivity, magnetic susceptibility, and heat capacity, and performed first principles electronic structure calculations. The highest  $T_c$  values occur in slightly phosphorus rich samples, with composition near  $\text{Mo}_5\text{P}_{1.1}\text{B}_{1.9}$ . Together with the measured properties, the calculations suggest the superconductivity in these materials may be multi-band.

**12:15PM B25.00006 Superconductivity and ferromagnetism in Pd doped  $\text{Y}_9\text{Co}_7$** <sup>1</sup>, TOMASZ KLIMCZUK, JUDYTA STRYCHALSKA, Gdansk University of Technology, JOE THOMPSON, Los Alamos National Laboratory, ROBERT CAVA, Princeton University — The ferromagnetic superconductor  $\text{Y}_9\text{Co}_7$  was chemically doped with Pd in an attempt to form  $\text{Y}_9\text{Co}_{7-x}\text{Pd}_x$  for  $0 < x < 0.4$ . The lattice parameter  $a$  does not depend on  $x$ ; whereas,  $c$  increases with increasing Pd content up to  $x = 0.2$ , which turned out to be the palladium solubility limit. Superconductivity ( $T_{sc} = 2.4$  K) and ferromagnetism ( $T_C = 4.5$  K) were observed only for the parent  $\text{Y}_9\text{Co}_7$  compound. For the lowest tested Pd doping level ( $x=0.05$ ), strong enhancement of ferromagnetism is observed ( $T_C = 9.35$  K), but superconductivity is not seen above 1.8K. The Curie temperature rapidly increases from 4.5 K to about 10 K for a Pd concentration  $x=0.1$  and remains almost unchanged for  $\text{Y}_9\text{Co}_{6.8}\text{Pd}_{0.2}$ .

<sup>1</sup>Project was financially supported by the National Science Centre (Poland) grant (DEC-2012/07/E/ST3/00584).

**12:27PM B25.00007 Quench-condensing superconducting thin films using the Fab on a Chip approach<sup>1</sup>**, HAN HAN, Boston Univ, MATTHIAS IMBODEN, cole Polytechnique Fdrale de Lausanne, PABLO DEL CORRO, Bajas Temperaturas, Instituto Balseiro, THOMAS STARK, RICHARD LALLY, Boston Univ, FLAVIO PARDO, CRISTIAN BOLLE, SLIM Line, Bell Labs, Alcatel-Lucent, DAVID BISHOP, Boston Univ — Micro-electromechanical systems (MEMS) being manufactured in a macroscopic fab inspires the idea of getting the process further down to fabricate even smaller structures, namely nano-structures, using MEMS. The Fab on a Chip concept was proposed based on such ideas. By implementing the final-step, additive fabrication approach, manufacturing, characterization and experiments of nano-structures are integrated *in-situ*. Due to the miniature size of MEMS, the thickness precision is significantly improved while the power consumption is significantly depressed, making the quench-condensation of very thin films well controlled and easily achievable. Among various types of nano-structures, quench-condensed superconducting thin films are of great interest for physicists. Here we present such experiments done on superconducting thin films quench-condensed using the Fab on a Chip. We show that we are able to fabricate very thin films with its thickness precisely controlled, and the base temperature kept under ~3K during the process. The resistivity data demonstrates the high purity and uniformity of the film, as well as the annealing effect when cycling to higher temperatures. Based on the tremendous results obtained from the superconducting thin films, more complex nano-circuits can be fabricated and investigated using the Fab on a Chip, enabling a new approach for novel condensed matter physics experiments. This research is funded by the NSF through their CMMI division.

**12:39PM B25.00008 Application of metamaterial nanoengineering to triple the superconducting critical temperature of bulk aluminum<sup>1</sup>**, VERA SMOLYANINOVA, KATHRYN ZANDER, THOMAS GRESOCK, CHRISTOPHER JENSEN, WILLIAM ZIMMERMAN, Towson University, JOSEPH PRESTIGIACOMO, MICHAEL OSOFSKY, Naval Research Laboratory, ZHEN XING, MUMTAZ QAZILBASH, College of William and Mary, IGOR SMOLYANINOV, University of Maryland — Recent experiments have shown the viability of the metamaterial approach to dielectric response engineering for enhancing the transition temperature,  $T_c$ , of a superconductor [1]. In this report, we demonstrate the use of Al<sub>2</sub>O<sub>3</sub>-coated aluminium nanoparticles to form the recently proposed epsilon near zero (ENZ) core-shell metamaterial superconductor [2] with a  $T_c$  that is three times that of pure aluminium [3]. IR reflectivity measurements confirm the predicted metamaterial modification of the dielectric function thus demonstrating the efficacy of the ENZ metamaterial approach to  $T_c$  engineering. The developed approach advances potentials for efficient nanofabrication of bulk aluminium-based metamaterial superconductors. These results open up numerous new possibilities of considerable  $T_c$  increase in other simple superconductors. [1]. V. N. Smolyaninova et al., Scientific Reports 4, 7321 (2014) [2] I. I. Smolyaninov and V. N. Smolyaninova, Phys. Rev. B 91, 094501 (2015). [3] V. N. Smolyaninova et al., Scientific Reports 5, 15777 (2015)

**12:51PM B25.00009 ABSTRACT WITHDRAWN —**

**1:03PM B25.00010 Interplay of superconductivity and magnetism in oxy-chalcogen cuprates YBaSrCu<sub>3</sub>O<sub>x</sub>Se<sub>y</sub><sup>1</sup>**, ARMEN GULIAN, VAHAN NIKOGHOSYAN<sup>2</sup>, Chapman University, VADIM GRINENKO, Leibniz-Institute IFW-Dresden, PF 270116, Dresden D-01171, Germany — In YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7</sub> superconductors we substituted one atom of Sr for Ba, and simultaneously doped the composition by Se. The resulting substance demonstrates two superconducting transitions: at 34K and 12K. Moreover, at 18K it reveals the Wohleben effect, jumping from a diamagnetic to paramagnetic response, while keeping the resistance zero. At about 4K, a ferromagnetic state sets up yielding a re-entrance effect, noticeable as an upturn in magnetic susceptibility and, in some samples, in resistivity. This substance behaves very differently from the reported YBaSrCu<sub>3</sub>O<sub>7</sub> or YBa<sub>2</sub>Cu<sub>3</sub>O<sub>x</sub>Se<sub>y</sub>: simultaneous presence of Se- and Sr-ions yields magnetic moments in the lattice. We present data on DC and AC magnetization, on heat capacity and resistivity in magnetic fields, on crystalline phases, as well as on composition. We also discuss possible mechanisms responsible for the observed effects.

**1:15PM B25.00011 Novel Superoxygenated Phases in Superconducting Cuprate Thin Films<sup>1</sup>**, C. ZHANG, H. ZHANG, University of Toronto, N. GAUQUELIN, G. A. BOTTON, Canadian Centre for Electron Microscopy & Brockhouse Institute for Materials Research, C. MCMAHON, D. G. HAWTHORN, University of Waterloo, J. Y. T. WEI, University of Toronto & Canadian Institute for Advanced Research — The superconducting critical temperature ( $T_c$ ) of hole-doped cuprates tends to increase with their lattice complexity, which is generally correlated with higher states of oxidation. For YBa<sub>2</sub>Cu<sub>3</sub>O<sub>7- $\delta$</sub>  (YBCO-123), it is known that solid-state reaction in high-pressure oxygen can induce the formation of more complex and oxidized phases such as Y<sub>2</sub>Ba<sub>4</sub>Cu<sub>7</sub>O<sub>15- $\delta$</sub>  (YBCO-247) and Y<sub>2</sub>Ba<sub>4</sub>Cu<sub>8</sub>O<sub>16</sub> (YBCO-248). In this work, we apply this superoxygenation concept of material synthesis to nanoscale thin films which, owing to their large surface-to-volume ratio, are more thermodynamically reactive than bulk samples. Epitaxial thin films of YBCO-123 were grown by pulsed laser deposition on (La,Sr)(Al,Ta)O<sub>3</sub> substrates, and post-annealed in up to 500 atm of oxygen at 800C. Our post-annealed films show robust superconducting transitions with  $T_c$  ranging from 80 to 93K. Transmission electron microscopy and X-ray absorption spectroscopy were used to probe the lattice structure and oxygen stoichiometry. Our measurements show clear evidence of conversion to YBCO-247 and YBCO-248 in the superoxygenated films, as well as YBCO-125, a novel YBCO phase that has three CuO chains per unit cell and potentially higher  $T_c$ .

**1:27PM B25.00012 Quasi-One Dimensional Analogues of BiS<sub>2</sub>-Based Superconductors<sup>1</sup>**, JESSICA PANELLA, JUAN CHAMORRO, TYREL MCQUEEN, Johns Hopkins Univ — Many recently-reported superconductors have layered structures consisting of superconducting planes separated by insulating charge reservoir layers. Studies linking the width of the blocking layer to the critical temperature of the superconductivity onset draw a direct connection from the superconducting properties to the structure. We report three new compounds (Sr<sub>2</sub>O<sub>2</sub>Bi<sub>2</sub>Se<sub>3</sub>, Ba<sub>2</sub>O<sub>2</sub>Bi<sub>2</sub>Se<sub>3</sub>, and Sr<sub>2</sub>O<sub>2</sub>Sb<sub>2</sub>Se<sub>3</sub>) which are quasi-one dimensional analogues of the bismuth sulfide and bismuth selenide superconductors, providing a unique opportunity to study the role of dimensionality on superconductivity. The physical properties of the compounds were studied via magnetic susceptibility, thermal transport, resistivity, and heat capacity.

## **1:39PM B25.00013 Vertical Magnetic Levitation Force Measurement on Single Crystal YBaCuO Bulk at Different Temperatures**

, SUKRU CELIK, Department of Energy Systems Engineering, Faculty of Engineering and Architecture, Sinop University, 57000, Sinop, TURKEY, SAIT BARIS GUNER, Department of Physics, Faculty of Arts and Sciences, Recep Tayyip Erdogan University, 53100 Rize, TURKEY, KEMAL OZTURK, Department of Physics, Faculty of Arts and Sciences, Karadeniz Technical University, 61100 Trabzon, TURKEY, OZGUR OZTURK, Department of Physics, Faculty of Arts and Sciences, Kastamonu University, 37100 Kastamonu, TURKEY — Magnetic levitation force measurements of HTS samples are performed with the use of liquid nitrogen. It is both convenient and cheap. However, the temperature of the sample cannot be changed (77 K) and there is problem of frost. So, it is necessary to build another type of system to measure the levitation force high  $T_c$  superconductor at different temperatures. In this study, we fabricated YBaCuO superconducting by top-seeding-melting-growth (TSMG) technique and measured vertical forces of them at FC (Field Cooling) and ZFC (Zero Field Cooling) regimes by using our new designed magnetic levitation force measurement system. It was used to investigate the three-dimensional levitation force and lateral force in the levitation system consisting of a cylindrical magnet and a permanent cylindrical superconductor at different temperatures (37, 47, 57, 67 and 77 K).

## **1:51PM B25.00014 Low Temperature Properties and Quantum Criticality of CrAs<sub>1-x</sub>P<sub>x</sub> single crystal.**

, JIANLIN LUO, Institute of Physics, Chinese Academy of Sciences, INSTITUTE OF PHYSICS, CHINESE ACADEMY OF SCIENCES TEAM — We report a systematically study of resistivity and specific heat on phosphorus doped CrAs<sub>1-x</sub>P<sub>x</sub> single crystals with  $x=0$  to 0.2. With the increasing of phosphorus doping concentration  $x$ , the magnetic and structural transition temperature  $T_N$  is suppressed. Non-fermi liquid behavior and quantum criticality phenomenon are observed from low temperature resistivity around critical doping with  $x_c \sim 0.05$  where the long-range antiferromagnetic ordering is completely suppressed. The low temperature specific heat of CrAs<sub>1-x</sub>P<sub>x</sub> is contributed by the thermal excitation of phonons and electrons. The electronic specific heat coefficient  $\gamma$ , which reflects the effective mass of quasi-particles, shows maximum around  $x_c \sim 0.05$ , also indicating the existence of quantum critical phenomenon around the critical doping. The value of Kadowaki-Woods ratio of CrAs<sub>1-x</sub>P<sub>x</sub> shows no significant different from that of CrAs. Work is done in collaboration with Fukun Lin, Wei Wu, Ping Zheng, Guozhi Fan, Jinguang Cheng.

## **11:15AM B26.00001 High-frequency current oscillations in graphene-boron nitride resonant tunnel diodes<sup>1</sup>**

, MARK GREENAWAY, JENN GASKELL, LAURENCE EAVES, University of Nottingham, KOSTYA NOVOSELOV, ARTEM MISHCHENKO, ANDRE GEIM, University of Manchester, MARK FROMHOLD, University of Nottingham — The successful realisation of multilayer graphene-hBN-graphene resonant tunnelling diodes (graphene-RTDs) with negative differential conductance (NDC) and MHz current oscillations offers the exciting possibility of exploiting them as high-frequency oscillators and mixers [1, 2]. In this paper, we examine their potential for generating higher frequencies by simulating the oscillations in the tunnel current and charge that arise when the device is biased in the NDC region and placed in a resonant circuit. Using the Bardeen transfer Hamiltonian method, we examine the effect on the device characteristics of the twist angle,  $\theta$ , between the two graphene electrodes, the hBN barrier thickness and of the carrier density in the graphene electrodes, which can be adjusted by chemical doping or by an applied bias voltage. The simulations accurately reproduce our recently-reported measurements on these RTDs (Fig. 4, [2]). The results of simulations show that frequencies of tens of GHz are achievable by optimising the device parameters [3]. References: [1] L. Britnell et al., Nature Communications 4, 1794 (2013). ## **11:27AM B26.00002 Band structure engineering of graphene by a local gate defined periodic potential**

, CARLOS FORSYTHE, PATRICK MAHER, DIEGO SCARABELLI, CORY DEAN, Columbia University, PHILIP KIM, Harvard University — Recent improvements in 2-dimensional (2D) material layering have resulted in enhanced device quality and created pathways for new device architectures. We fabricate periodic arrays from a patterned local back gate and a uniform top gate on hBN encapsulated graphene channels. The symmetry and lattice size of the periodic potential can be determined by state-of-art electron beam lithography and etching, achieving a lattice constant of 35 nm. The strength of the electric potential modulation can be controlled through applied voltage on the patterned gate. We observe signatures of superlattice modulation near the main Dirac peak in the density dependent resistance measurement at zero magnetic field. Current studies focus on the exploration of Hofstadter fractal band structures under magnetic fields. Our nano-patterned engineered superlattices on graphene hold great promise for wider applications.

## **11:39AM B26.00003 Layer resolved capacitive probing of graphene bilayers**

, ALEXANDER ZIBROV, Department of Physics, UC Santa Barbara, Santa Barbara, CA 93106, USA, FRANOIS PARMENTIER, Service de Physique de l'Etat Condense, DSM/IRAMIS/SPEC, CNRS UMR 3680, CEA Saclay, 91191 Gif sur Yvette cedex, France, JIA LI, Department of Physics, Columbia University, New York, NY 10027, USA, LEI WANG, Department of Electrical Engineering, Columbia University, New York, NY 10027, USA, BENJAMIN HUNT, Physics Department, Carnegie Mellon University, Pittsburgh, PA 15213, CORY DEAN, Department of Physics, Columbia University, New York, NY 10027, USA, JAMES HONE, Department of Mechanical Engineering, Columbia University, New York, NY 10027, USA, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, 1-1 Namiki, Tsukuba, Japan, ANDREA YOUNG, Department of Physics, UC Santa Barbara, Santa Barbara, CA 93106, USA — Compared to single layer graphene, graphene bilayers have an additional which-layer degree of freedom that can be controlled by an external electric field in a dual-gated device geometry. We describe capacitance measurements capable of directly probing this degree of freedom. By performing top gate, bottom gate, and penetration field capacitance measurements, we directly extract layer polarization of both Bernal and twisted bilayers. We will present measurements of hBN encapsulated bilayers at both zero and high magnetic field, focusing on the physics of the highly degenerate zero-energy Landau level in the high magnetic field limit where spin, valley, and layer degeneracy are all lifted by electronic interactions.

## **11:51AM B26.00004 Topologically-driven valley polarization in twisted graphene/hexagonal boron nitride heterostructures**

, LEONARDO BASILE, Escuela Politécnica Nacional, JUAN CARLOS IDROBO, Oak Ridge National Laboratory — Valley polarization, that is, selective electronic localization in a momentum valley, has been proposed on materials presenting either a strong spin-orbit coupling (SOC) or with a weak SOC but in the presence of electric and magnetic fields. In this talk, we identify a non-centro symmetric system which can also present valley polarization purely by topological means without the necessity of SOC. We find that twisted bilayers of graphene/hexagonal boron nitride heterostructures have different absorption for right- and left- circular polarized light, indicating valley polarization. This induced polarization occurs due to band folding of the electronic bands, i.e., it has a topological origin.

**12:03PM B26.00005 Bandgap opening in bilayer graphene at metal contacts** , RYO NOUCHI, Osaka Prefecture University — A bandgap is opened in bilayer graphene (BLG) by introducing a potential difference between the two graphene layers, raising expectations for its application to a transistor channel. The potential difference can be introduced, for example by charge transfer from surface adsorbates. Thus, a finite bandgap is expected to be opened also at a metal contact, an inevitable component of transistors, where interfacial charge transfer occurs to align the Fermi levels of the metallic electrode and the underlying BLG. The bandgap at the metal-BLG interface can be detected by the superlinear current-voltage characteristics in back-gate field-effect transistors, caused by carriers propagating through the bandgap, i.e., by the band-to-band transport [1]. The superlinearity was higher in the positively-gated region, attributed to hole doping from the Cr/Au electrodes. The control experiments using single-layer graphene (SLG) did not have a superlinearity, which is consistent with the fact that a sizeable bandgap is not expected at the metal-SLG interface. The current transport through the bandgap should be an additional source of electrode-contact resistance. [1] R. Nouchi, Appl. Phys. Lett. 105, 223106 (2014).

**12:15PM B26.00006 Anomalous conductivity noise in gapped bilayer graphene heterostructure** , MOHAMMED ALI AAMIR, PARITOSH KARNATAK, T. PHANINDRA SAI, ARINDAM GHOSH, Department of Physics, Indian Institute of Science, Bangalore - 560012, India — Bilayer graphene has unique electronic properties it has a tunable band gap and also, valley symmetry and pseudospin degree of freedom like its single layer counterpart. In this work, we present a study of conductance fluctuations in dual gated bilayer graphene heterostructures by varying the Fermi energy and the band gap independently. At a fixed band gap, we find that the conductance fluctuations obtained by Fermi energy ensemble sampling increase rapidly as the Fermi energy is tuned to charge neutrality point (CNP) whereas the time-dependent conductance fluctuations diminish rapidly. This discrepancy is completely absent at higher number densities, where the transport is expected to be through the 2D bulk of the bilayer system. This observation indicates that near the CNP, electrical transport is highly sensitive to Fermi energy, but becomes progressively immune to time-varying disorder. A possible explanation may involve transport via edge states which becomes the dominant conduction mechanism when the bilayer graphene is gapped and Fermi energy is situated close to the CNP, thereby causing a dimensional crossover from 2D to 1D transport. Our experiment outlines a possible experimental protocol to probe intrinsic topological states in gapped bilayer graphene.

**12:27PM B26.00007 Tuning the Band Gap of Bilayer Graphene by Sandwich-Like Stacking<sup>1</sup>** , ZHENPENG HU, Nankai University — As far as we know, graphene has been taken as a potential host material for next-generation electric devices. However, this attractive prospect has been blocked by the metallic character of graphene. Although many methods have been proposed to get a moderate energy gap, such as hydrogenated graphene (graphane), but all the intrinsic advantages (carrier's mobility, etc...) of graphene have been destroyed. Here, we report that a large energy gap of graphene bilayer can be opened without breaking its natural characters by sandwiching it between functionalized BN substrates. Also, we show that the band gap of graphene bilayer can be tuned from 0.35 eV to 0.50 eV, depending on the substrates. The gap value is much larger than any other methods, and the structure of graphene bilayer is perfectly kept. And the energy gap is robust, namely, once the sandwiched substrates are selected, the relative position of substrates and graphene bilayer hardly changes the energy gap. Since the proposed way is easy to be realized in experiments, our results will hopefully accelerate the application of graphene in semiconductor devices and promote the development of the graphene technology.

**12:39PM B26.00008 Anomalous Coulomb drag in bilayer graphene double layers** , XIAOMENG LIU, Harvard University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Material Science, PHILIP KIM, Harvard University — Bilayer graphene double-layer structure consists of two layers of bilayer graphene separated by atomically thin hexagonal boron nitride (hBN). With a perfect Fermi surface nesting and strong electron-electron interaction ( $E_{Coulomb} > E_{kinetic}$ ), such systems offer exciting platforms to study interaction driven phenomena, such as Coulomb drag and exciton condensation. We fabricate ultra-clean encapsulated bilayer graphene double layers with dry pick-up method. Room temperature drag measurement on our devices shows the sign of drag agree with the typical Fermi liquid behavior. However, at lower temperatures, the sign of drag reversed, indicating a new drag mechanism emerges and dominates. We measure this with different geometry, temperature, bias and gating to investigate the origin of such effect and discuss the implication of the drag sign changes.

**12:51PM B26.00009 Coulomb Drag Measurements in Bilayer-Bilayer Graphene Device** , JIA LI, CORY DEAN, Columbia University — We report Coulomb drag measurements on bilayer-bilayer graphene devices assembled using the Van De Waals transfer technique. The two bilayer graphene flakes are encapsulated and separated by hBN. High temperature measurements reveal positive drag response when the carrier types are different in two graphene layers, and negative when carrier types are the same, a result that is similar to previous measurements reported in monolayer graphene devices. However, upon cooling to low temperature, novel drag response is observed in the low density region. We also report a new device set-up which improves measurement quality for Coulomb drag measurements at low temperature.

**1:03PM B26.00010 Planar Tunneling Spectroscopy of Graphene Nanodevices** , JOEL I-JAN WANG, LANDRY BRETHERAU, Massachusetts Institute of Technology, USA, RICCARDO PISONI, Massachusetts Institute of Technology, USA/Politecnico di Milano, Italy, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science (NIMS), Japan, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology, USA — 2-D Van-der-Waals mesoscopic physics have seen a rapid development in the last 10 years, with new materials each year added to the toolbox. Stacking them like Lego enables the combination of their individual electronic properties. In particular, hexagonal boron nitride, which is an insulator, gives the possibility to perform planar (2-D to 2-D) tunneling spectroscopy within this type of heterostructures. Unlike standard transport measurements, tunneling spectroscopy enables to probe the electronic properties in the energy domain. Moreover, since planar tunneling probes a large area of the system, global quantum features such as quantum Hall effect, superconducting proximity effect or quantum confinement can be investigated. In this talk, we will present implementation of heterostructures consisting of graphene, hexagonal boron nitride, and graphite, fabricated for planar tunneling spectroscopy. In order to reveal the intrinsic properties of materials, the fabrication scheme aims at preserving the pristine nature of the 2-DEGS as well as minimizing the doping introduced by external probes. As a demonstration, measurements of these devices in normal states, high magnetic field environment, and induced superconducting state will be presented.

**1:15PM B26.00011 Observation of Large Intrinsic Gap in Rhombohedral-Stacked Tetralayer Graphene** , KEVIN MYHRO, SHI CHE, YANMENG SHI, YONGJIN LEE, KEVIN THILAHAR, University of California, Riverside, DMITRY SMIRNOV, National High Magnetic Field Laboratory, Tallahassee, FL, CHUN NING LAU, University of California, Riverside — Few-layer graphene has attracted attention in the scientific community as a novel 2D material due to its observed quantum hall effect, high electronic mobility, high transparency and tensile strength, among other properties. In rhombohedral-stacked few-layer graphene, the very flat band near the charge neutrality point is unstable to electronic interactions, and gives rise to states with spontaneous broken symmetries. Intrinsic gaps of ~2 meV and 40 meV are observed in bilayer and trilayer graphene, respectively. Here, we report the observation of an even larger gap in suspended rhombohedral-stacked tetralayer graphene (r-4LG) samples. We will present the latest data of the evolution of the gapped state with temperature and external fields, and compare with theoretical models.

**1:27PM B26.00012 Observation of Hysteresis in Rhombohedral-Stacked Trilayer Graphene**, SHI CHE, YONGJIN LEE, YANMENG SHI, KEVIN MYHRO, TIMOTHY ESPIRITU, DAVID TRAN, JAIRO VELASCO, YAFIS BARLAS, CHUN NING (JEANIE) LAU, University of California, Riverside — Few-layer graphene is an attractive platform for exploration of physical processes confined to two dimensions. Diverging density of states in rhombohedral-stacked trilayer graphene (r-TLG) leads to strong electronic correlation. Recently an intrinsic insulating phase with 40 meV gap has been observed at charge neutrality point (CNP) in r-TLG, which is consistent with an layer antiferromagnetic state. By using dual-gated suspended r-TLG device, we observe hysteresis loops in conductance in the vicinity of CNP, which suggests the possible evidence of spontaneous spin polarization or presence of domains with different anomalous Hall conductivities.

**1:39PM B26.00013 Experimental realization of gate controlled topological conducting channels in bilayer graphene**, J. LI, K. J. MCFAY, Z. ZERN, J. ZHU, Department of Physics, Penn State University, University Park, USA, K. WANG, Y. F. REN, Z. H. QIAO, ICQD, USTC, Hefei, China, K. WATANABE, T. TANIGUCHI, National Institute for Material Science, 1-1 Namiki, Tsukuba, Japan — Manipulating the valley degree of freedom in two-dimensional honeycomb lattices can potentially lead to a new type of electronics called valleytronics. In electrically gapped bilayer graphene, the broken inversion symmetry leads to non-zero and asymmetric Berry curvature  $\Omega$  in the K and K' valleys of the Brillouin zone. Reversing the sign of  $\Omega$  at the internal line junction of two oppositely gated bilayer graphene is predicted to yield counter-propagating edge modes, the so-called kink states, with quantized conductance of  $4e^2/h$  in the absence of valley mixing. We have overcome fabrication challenges to implement high-quality hBN encapsulated, dual-split-gates structures necessary to observe the kink states. Here I present experimental evidences of the kink states. In the absence of a magnetic field, the kink states have a mean free path of a few hundred nm. Ballistic conductance of  $4e^2/h$  is achieved in a perpendicular magnetic field. We discuss the potential valley-mixing mechanisms and the role of the magnetic field. Experimental results are supported by numerical studies. We will also discuss ongoing efforts in realizing valley-controlled transmission and guiding of the kink states, which is a significant step towards the development of valleytronics.

**1:51PM B26.00014 Topological valley transport at bilayer graphene domain walls**, LONG JU, ZHIWEN SHI, NITYAN NAIR, YINCHUAN LV, CHENHAO JIN, JAIRO VELASCO JR., CLAUDIA OJEDA-ARISTIZABAL, Univ of California - Berkeley, HANS BECHTEL, MICHAEL MARTIN, Lawrence Berkeley National Lab, ALEX ZETTL, JAMES ANALYTIS, Univ of California - Berkeley, PAUL MCEUEN, Cornell University, FENG WANG, Univ of California - Berkeley — Electron valley, a degree of freedom that is analogous to spin, can lead to novel topological phases in bilayer graphene. An external electric field can induce a tunable bandgap in bilayer graphene, and domain walls between AB- and BA-stacked bilayer graphene can support protected chiral edge states of quantum valley Hall insulators. In this talk, I will present our efforts on revealing the topologically protected edge states at AB-BA domain walls by combining near field infrared nanoscopy with electrical transport measurement. These one-dimensional valley-polarized conducting channels feature a ballistic length of about 400 nanometres at 4 kelvin.

**2:03PM B26.00015 Electronic excitation spectrum of ABC-stacked multilayer graphene**, Y. HENNI, K. NOGAJEWSKI, Laboratoire National des Champs Magnétiques Intenses, CNRS, H. P. OJEDA COLLADO, G. USAJ, C. A. BALSEIRO, Centro Atómico Bariloche and Instituto Balseiro, Comisión Nacional de Energía Atómica, M. POTESKI, C. FAUGERAS, Laboratoire National des Champs Magnétiques Intenses, CNRS — The electronic properties of ABC graphene trilayers has attracted lot of attention recently due to their potential applications in engineering carbon-based devices with gate tunable electrical conductivity. Moreover, ABC-stacked thin layers of graphite are predicted to host peculiar surface electronic states, with a flat dispersion over most of the Brillouin zone. The associated high density of states is likely to favour the emergence of exotic electronic phases, such as charge density waves or even superconductivity. We present a micro-magneto-Raman scattering study of a thin graphite flake produced by exfoliation of natural graphite, composed of  $\sim 15$  graphene layers, and including a large ABC-stacked domain. Exploring the low temperature Raman scattering spectrum of this domain up to  $B=29T$ , we identify inter Landau level electronic excitations within the surface flat bands, together with electronic excitations involving the gapped states in the bulk. This interband electronic excitation at  $B=0T$  can be observed, up to room temperature, directly in the Raman scattering spectrum as a broad ( $\sim 180\text{cm}^{-1}$ ) feature. Because the energy gap strongly depends on the number of layers, this electronic excitation can be used to identify and characterize ABC-stacked graphite thin layers.

**Monday, March 14, 2016 11:15AM - 2:15PM –**

**Session B27 DCMP: Strongly Correlated Physics in d-electron Systems** 326 - Christianne Beekman, Florida State University

**11:15AM B27.00001  $\mu$ SR study of the stoichiometric  $\text{NbFe}_2$** , DANIEL MARGINEDA, SEAN GIBLIN, School of Physics and Astronomy Cardiff University, UK, ROSS STEWART, ISIS Facility, Rutherford Appleton Laboratory, UK, JON DUFFY, Department of Physics, University of Warwick, UK, STEPHEN DUGDALE, HH Wills Physics Laboratory, Department of Physics, Bristol, UK, JON TAYLOR, European Spallation Source ERIC, Lund, Sweden — Quantum critical points (QCP) are important as understanding how fluctuating ground states can be lifted by novel correlated electron states such as unconventional superconductivity is not clear.  $\text{Nb}_{1-y}\text{Fe}_{2+y}$  is a good candidate to investigate such criticality as it displays a rich magnetic phase diagram and quantum criticality in a d-band metal. We investigate the magnetic ground state of stoichiometric  $\text{NbFe}_2$  by bulk magnetisation and muon spin relaxation. Local magnetism clearly emerges below the critical temperature  $T_N = 10.3K$  and is dominated by quasi-static moments with an even distribution of magnetic fields  $\Delta_{eff}$  ranging from 0 to  $\sim 140G$ . A small moment of  $M \sim 0.02\mu_B/Fe$  is estimated, which is small because of the delocalised electronic distribution. In this work a stronger Curie-Weiss enhancement and an increased critical field suggests sample sensitivity to site mixing effects during the sample growth. Similar results are explained by a Spin Density Wave (SDW) with a large correlation length but the absence of oscillations cannot confirm this scenario: magnetic phase controlled by short-range interactions driven by Nb/Fe site mixing or an incommensurate helical SDW phase could both explain the field random orientation.

<sup>1</sup>Supported by EPSRC of UK

**11:27AM B27.00002 The Possibility of a Structural Quantum Critical Point in  $\text{LaCu}_{6-x}\text{Au}_x$** , L. POUDEL, Univ of Tennessee, Knoxville and Oak Ridge National Laboratory, A. F. MAY, Oak Ridge National Laboratory, M. KOEHLER, Univ of Tennessee, Knoxville, C. DE LA CRUZ, M. A. MCGUIRE, S. CALDER, Oak Ridge National Laboratory, V. KEPPENS, Univ of Tennessee, Knoxville, D. MANDRUS, A. D. CHRISTIANSON, Univ of Tennessee, Knoxville and Oak Ridge National Laboratory — Understanding the critical phenomena near a quantum critical point (QCP) has attracted a substantial interest from the condensed matter physics community. Despite this interest, QCPs involving the zero temperature termination of a continuous structural phase transition remain largely unexplored. Here, we study the structural properties of the  $\text{LaCu}_{6-x}\text{Au}_x$  series, which appears to be an ideal candidate to exhibit a SQCP. The orthorhombic-monoclinic transition temperatures in  $\text{LaCu}_{6-x}\text{Au}_x$  decrease with Au-composition until a complete suppression of the monoclinic phase occurs at the SQCP,  $x = 0.3$ . The lattice component of the low-temperature heat capacity exhibits a maximum at the critical concentration, providing a further indication of the presence of a SQCP in the  $\text{LaCu}_{6-x}\text{Au}_x$  series.

**11:39AM B27.00003 Evolution of Quantum Critical Behavior In A Concentrated Ternary Solid Solution: NiCoCr<sub>x</sub>**, BRIAN SALES, KE JIN, HONGBIN BEI, MALCOLM STOCKS, GERMAN SAMOLYUK, ANDREW MAY, MICHAEL MCGUIRE, Oak Ridge National Laboratory — The face centered cubic (fcc) alloy NiCoCr<sub>x</sub> with x near 1 is found to be close to the Cr concentration where the ferromagnetic transition temperature, T<sub>c</sub> goes to 0. Near this composition these alloys exhibit a resistivity linear in temperature to 2 K, a perfectly linear magnetoresistance, and an excess -TlnT contribution to the low temperature heat capacity. As the Cr concentration is decreased from 1, the Curie temperature and the saturation magnetization, M<sub>0</sub>, both increase exponentially with x. For x = 0.5, T<sub>c</sub> ≈ 217 K, but M<sub>0</sub> is only 0.26 Bohr magnetons/atom, indicating highly itinerant ferromagnets for 0.5 < x < 0.8. All of the low temperature electrical, magnetic and thermodynamic properties of the alloys with compositions near x=1 are not typical of a Fermi liquid and suggest strong magnetic fluctuations associated with a quantum critical region. This new class of concentrated solid solution fcc alloys are ideal model systems to study the effects of chemical disorder on emergent properties near a quantum critical point. Research supported by the DOE Office of Science, Materials Science and Engineering Division, and the Energy Dissipation to Defect Evolution EFRC.

**11:51AM B27.00004 Finite mass enhancement across bandwidth controlled Mott transition in NiS<sub>2-x</sub>Se<sub>x</sub><sup>1</sup>**, GARAM HAN, Center for Correlated Electron Systems, Institute for Basic Science (IBS), Seoul 151-742, Korea, W. S. KYUNG, Institute of Physics and Applied Physics, Yonsei University, Seoul 120-749, Korea, Y. K. KIM, Center for Correlated Electron Systems, Institute for Basic Science (IBS), Seoul 151-742, Korea, C. M. CHENG, K. D. TSUEI, National Synchrotron Radiation Research Center, Hsinchu 30076, Taiwan, K. D. LEE, N. HUR, Department of Physics, Inha University, Incheon 402-751, Korea, H.-D. KIM, C. KIM, Center for Correlated Electron Systems, Institute for Basic Science (IBS), Seoul 151-742, Korea — One of the most important and still debated issues in the strongly correlated electron systems is on the metal insulator transition (MIT) mechanism. In the bandwidth controlled Mott transition (BCMT) scenario, which Mott originally proposed, MIT occurs through a mass divergence in which the effective mass of the quasi-particle (QP) diverges approaching the MIT. The interpretation is supported by dynamic mean field theory (DMFT) model calculations. However, few direct observations have been made yet due to various experimental restrictions. In this talk, I present systematic angle resolved photoemission studies on the MIT in NiS<sub>2-x</sub>Se<sub>x</sub>, which is a well-known BCMT material. We observed not only the bandwidth shrinkage but also the coherent quasi-particle peak (QP) which is not of the surface origin. In addition, we experimentally showed the mass of the QP remains finite approaching the MIT.

**12:03PM B27.00005 Revealing the electronic ground state of ReNiO<sub>3</sub> combining Ni-L<sub>3</sub> x-ray absorption and resonant inelastic x-ray scattering**, VALENTINA BISOGNI, Brookhaven National Laboratory, New York, SARA CATALANO, University of Geneva, Switzerland, ROBERT GREEN, University of British Columbia, Canada, MARTA GIBERT, RAOUL SCHERWITZL, University of Geneva, Switzerland, YAOBO HUANG, Paul Scherrer Institute, Switzerland, SHADI BALANDESH, University of British Columbia, Canada, VLADIMIR N. STROCOV, Paul Scherrer Institute, Switzerland, PAVLO ZUBKO, University of Geneva, Switzerland, GEORGE SAWATZKY, University of British Columbia, Canada, JEAN-MARC TRISONE, University of Geneva, Switzerland, THORSTEN SCHMITT, Paul Scherrer Institute, Switzerland — Rare-earth nickelates ReNiO<sub>3</sub> attract a lot of interest thanks to their intriguing physical properties like sharp metal to insulator transition, unusual magnetic order and expected superconductivity in nickelate-based heterostructures. Full understanding of these materials, however, is hampered by the difficulties in describing their electronic ground state (GS). Taking a NdNiO<sub>3</sub> thin film as a representative example, we reveal with x-ray absorption and resonant inelastic x-ray scattering unusual coexistence of bound and continuum excitations, providing strong evidence for abundant O 2p holes in the GS of these materials. Using an Anderson impurity model interpretation, we show that these distinct spectral signatures arise from a Ni 3d<sup>8</sup> configuration along with holes in the O 2p valence band, confirming suggestions that these materials exhibit a negative charge-transfer energy, with O 2p states extending across the Fermi level.

**12:15PM B27.00006 Polyanion Driven Antiferromagnetic and Insulating Ground State of Olivine Phosphates: LiMPO<sub>4</sub><sup>1</sup>**, AJIT KUMAR JENA, B. R. K. NANDA, Indian Inst of Tech-Madras, CONDENSED MATTER THEORY & COMPUTATION TEAM — Through density functional calculations we have investigated the electronic and magnetic properties of LiMPO<sub>4</sub>, where M is a 3d transition metal element. We find that contrary to many transition metal oxides, in these Olivine phosphates the band gap is originated due to crystal field anisotropy as well as weak O-p – M-d covalent interaction. Both of them are attributed to the presence of PO<sub>4</sub><sup>3-</sup> polyanion. The anisotropic crystal field, in the absence of covalent interactions, creates atomically localized non-degenerate M-d states and therefore the gap is a natural outcome. Onsite repulsion, due to strong correlation effect, further enhances the gap. These localized d states favor high-spin configuration which leads to antiferromagnetic ordering due to Hund's coupling. Experimentally observed low Neel temperature of this family of compounds is explained from the DFT obtained spin exchange interaction parameters.

**12:27PM B27.00007 *Ab initio* quantum Monte Carlo calculations of ground-state properties of manganese's oxides<sup>1</sup>**, VINIT SHARMA, JARON T. KROGEL, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA, P.R.C. KENT, Center for Nanophase Materials Sciences and Computer Science and Mathematics Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, FERNANDO A. REBOREDO, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA — One of the critical scientific challenges of contemporary research is to obtain an accurate theoretical description of the electronic properties of strongly correlated systems such as transition metal oxides and rare-earth compounds, since state-of-art ab-initio methods based on approximate density functionals are not always sufficiently accurate. Quantum Monte Carlo (QMC) methods, which use statistical sampling to evaluate many-body wave functions, have the potential to answer this challenge. Owing to the few fundamental approximations made and the direct treatment of electron correlation, QMC methods are among the most accurate electronic structure methods available to date. We assess the accuracy of the diffusion Monte Carlo method in the case of rocksalt manganese oxide (MnO). We study the electronic properties of this strongly-correlated oxide, which has been identified as a suitable candidate for many applications ranging from catalysts to electronic devices. "This work was supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division."

<sup>1</sup>Ab initio quantum Monte Carlo calculations of ground-state properties of manganese oxides

**12:39PM B27.00008 Angle resolved photoemission spectroscopy and X-ray diffraction study on IrTe<sub>1.6</sub>Se<sub>0.4</sub>**, D.-H. KIM, K.-T. KO, KYOO KIM, J.-H. PARK, Pohang Univ of Sci & Tech, B.-G. PARK, T.-Y. KOO, Pohang Accelerator Laboratory, J.-J. YANG, S.-W. CHEONG, Dept. Physics and Astronomy, Rutgers University, USA — IrTe<sub>2</sub> shows an interesting phase transition accompanying q = (1/5, 0, 1/5) lattice distortion, Ir valence fluctuation, and J<sub>eff</sub> = 1/2 dimer formation. In order to study the role of anion doping, we investigated IrTe<sub>1.6</sub>Se<sub>0.4</sub> which is known to exhibit q = (1/6, 0, 1/6) lattice distortion and higher transition temperature, about 370 K. The electronic structure of IrTe<sub>1.6</sub>Se<sub>0.4</sub> single crystal was investigated by using angle resolved photoemission spectroscopy before and after the dimerization transition, which displays abrupt changes. Ir valence, investigated by corelevel X-ray photoemission, varies continuously from a pure Ir<sup>3+</sup> state to Ir<sup>4+</sup>:Ir<sup>3+</sup> ≈ 1 : 1 state, while x-ray diffraction measurement reveals a first order structure transition. In this talk, we will discuss an implication of our observations.

**12:51PM B27.00009 Consequences of breaking time reversal symmetry in LaSb: a resistivity plateau and extreme magnetoresistance**, FAZEL TAFTI, QUINN GIBSON, SATYA KUSHWAHA, NEEL HALDOLAARACHCHIGE, ROBERT CAVA, Princeton University, CAVA LAB TEAM — Time reversal symmetry protects the metallic surface modes of topological insulators (TIs). The transport signature of robust metallic surface modes of TIs is a plateau that arrests the exponential divergence of the insulating bulk with decreasing temperature. This universal behavior is observed in all TI candidates ranging from  $\text{Bi}_2\text{Te}_2\text{Se}$  to  $\text{SmB}_6$ . Recently, several topological semimetals (TSMs) have been found that exhibit extreme magnetoresistance (XMR) and TI universal resistivity behavior revealed only when breaking TRS, a regime where TIs theoretically cease to exist. Amongst these new materials, TaAs and NbP are nominated for Weyl semimetal due to their lack of inversion symmetry,  $\text{Cd}_3\text{As}_2$  is nominated for Dirac semimetal due to linear band crossing, and  $\text{WTe}_2$  is nominated for resonant compensated semimetal due to perfect electron-hole symmetry. Here we introduce LaSb, a simple rock-salt structure material without broken inversion symmetry, without perfect linear band crossing, and without perfect electron-hole symmetry. Yet LaSb portrays all the exotic field induced behaviors of the aforementioned semimetals. It shows the universal TI resistivity with a plateau at 15 K, revealed by a magnetic field, ultrahigh mobility of carriers, quantum oscillations with 2D Fermi surface, and XMR of about one million percent. Due to its dramatic simplicity, LaSb is the ideal model system to formulate a theoretical understanding of the exotic consequences of breaking TRS in TSMs.

**1:03PM B27.00010 Low-energy Electrodynamics of non-Drude Transport in the Strongly Correlated Ferromagnetic Metal  $\text{SrRuO}_3$** , YOUNG WANG, G. BOSSE, Y. LUBASHEVSKY, J. P. SHECKELTON, The Institute for Quantum Matter, Johns Hopkins Univ., D. E. SHAI, Laboratory of Atomic and Solid State Physics, Dept. of Physics, Cornell Univ., C. ADAMO, Dept. of Materials Science and Engineering, Cornell Univ., D.G. SCHLÖM, Dept. of Materials Science and Engineering, Kavli Institute at Cornell for Nanoscale Science, Cornell Univ., K. M. SHEN, Laboratory of Atomic and Solid State Physics, Dept. of Physics, Kavli Institute at Cornell for Nanoscale Science, Cornell Univ., N. P. ARMITAGE, The Institute for Quantum Matter, Johns Hopkins Univ. — While the highly correlated complex oxide perovskite ferromagnet  $\text{SrRuO}_3$  has been studied for decades, interest remains in its unusual transport properties. Here we report time-domain THz conductivity measurements taken from room temperature down to 1.5 K on a low disorder film of  $\text{SrRuO}_3$ . Previous optical measurements have shown a deviation from Drude-like transport in this material. We investigate these deviations using an extended Drude model analysis and find evidence for an effective non-Fermi liquid-like behavior in the frequency dependence of the scattering rate. The high quality of our film, reflected in its large residual resistivity ratio, allows us to better isolate the inelastic scattering channels. We have also extended these experiments down to the microwave regime and in this context investigate possible origins of this non-Drude transport, including the possibility of very low frequency interband transitions that are caused by small octahedral rotations and tilting that are inherent in the class of materials.

**1:15PM B27.00011 Surface Broken Symmetry on Orthorhombic Double-layer  $\text{Sr}_3(\text{Ru}_{1-x}\text{Mn}_x)_2\text{O}_{7-1}$** , CHEN CHEN, Louisiana State University, V. B. NASCIMENTO, Departamento de Física, ICEX-UFMG, ZHENYU DIAO, JIANDI ZHANG, RONGYING JIN, E. W. PLUMMER, Louisiana State University — The surface of double-layered ruthenate  $\text{Sr}_3\text{Ru}_2\text{O}_7$  exhibits octahedra tilt distortion and an enhanced rotational distortion caused by the broken symmetry. Previous LEED IV calculation reveals that the tilt angle is  $(2.51.7)^\circ$  at 80 K (B. Hu *et al.*, Physical Review B 81, 184104 (2010)). A glide symmetry and a mirror symmetry along this direction are both broken. Results from LEED IV simulations show that both broken symmetries originate from the emergence of surface tilt. The degree of broken symmetry is more sensitive to the tilt angle, thus producing a smaller error than from conventional LEED IV calculation. When Mn doping is induced into the compound, the tilt is removed and the symmetry of the LEED pattern returns to what is expected for rotation, two glide planes and four-fold symmetry.

**1:27PM B27.00012 Band dependent magneto thermoelectric measurements on  $\text{Ca}_3\text{Ru}_2\text{O}_7$** , HUI XING, Shanghai Jiao Tong University, CHENYI SHEN, Zhejiang University, LIBIN WEN, JIAMING HE, SHUN WANG, Shanghai Jiao Tong University, JIN PENG, JIANJIAN GE, Tulane University, YOUNG ZOU, MINGLIANG TIAN, High Magnetic Field Laboratory, Chinese Academy of Sciences, ZHUAN XU, Zhejiang University, ZHIQIANG MAO, Tulane University, YING LIU, Pennsylvania State University, Shanghai Jiao Tong University —  $\text{Ca}_3\text{Ru}_2\text{O}_7$  features a Neel transition at 56 K followed by a structure and metal-insulator transition at 48 K as the temperature is lowered, suggesting a complex structure-property relationship driven by electron correlated effects. However, the electronic states of  $\text{Ca}_3\text{Ru}_2\text{O}_7$  are not understood. ARPES measurements revealed the presence of an electron Fermi arc, while the expected hole Fermi arc is missing. Quantum oscillations showed the existence of a small Fermi surface, but the details of the Fermi surface, including whether the hole Fermi arc is present, are not determined. We performed band-dependent thermoelectric measurement with the temperature gradient directed to a specific crystalline axis. Magneto thermopower along crystalline a and b axes,  $S_a$  and  $S_b$ , both of which are negative in sign and nearly identical at high temperatures, were found to behave markedly differently below the metal-insulator transition, with  $S_b$  changing its sign from being negative to positive. Our analysis suggests that  $S_a$  and  $S_b$  in  $\text{Ca}_3\text{Ru}_2\text{O}_7$  are dominated by the electron and hole Fermi arcs, respectively. The implications of our data on the physics of  $\text{Ca}_3\text{Ru}_2\text{O}_7$  will be discussed.

**1:39PM B27.00013 Quasi-continuum excitation in Co-doped  $\text{CaRuO}_3$** <sup>1</sup>, JAGATH GUNASEKERA, ASHUTOSH DAHAL, Univ of Missouri - Columbia, JOSE RODRIGUEZ, LELAND HARRIGER, NIST Center for Neutron Research, TOM HEITMANN, Missouri University Research Reactor, DEEPAK SINGH, Univ of Missouri - Columbia — Spin-1/2 systems provide a unique platform to study the interplay between magnetism and quantum mechanics that often depict novel properties, such as quantum spin liquid or singlet-to-triplet transition. In this presentation, we report an interesting observation of singlet-to-triplet transition in Co-doped  $\text{CaRuO}_3$ , even though none of the magnetic atoms (Co or Ru) exhibit spin-1/2 properties. What we have found that as Co atom gradually replaces Ru in  $\text{CaRuO}_3$ , the system tends to develop a localized excitation around  $Q=1 \text{ \AA}^{-1}$  at 5.9 meV at low temperature. At roughly 20% doping percentage of Co, the inelastic excitation is well described by singlet-to-triplet transition of  $S=1/2$ . As the measurement temperature increases, the localized excitation fades into a sort of Q-independent background that becomes stronger as a function of temperature. This behavior is also well manifested by ac susceptibility measurements where the dynamic susceptibility tends to get stronger as the temperature increases. Our analysis suggests that Co-doping in  $\text{CaRuO}_3$  locally creates  $3d^7$  electronic configuration, which can be described by  $S=1/2$  in this disordered system.

<sup>1</sup>U.S. Department of Energy, Office of Basic Energy Sciences under Grant No. DE-SC0014461

**1:51PM B27.00014 Electronic correlation effects in  $\text{SrRuO}_3$  ultra-thin films**, LIANG SI, Institute of Solid State Physics, Vienna University of Technology, ZHICHENG ZHONG, Max Planck Institute for Solid State Research, OLEG JANSON, GANG LI, JAN TOMCZAK, KARSTEN HELD, Institute of Solid State Physics, Vienna University of Technology, COMPUTATIONAL MATERIALS SCIENCE TEAM, ELECTRONIC STRUCTURE OF CORRELATED MATERIALS TEAM —  $\text{SrRuO}_3$  (SRO) is a ferromagnetic metal with an appreciably high Curie-temperature of 160 K and a ferromagnetic moment of 0.8-1.6  $\mu_B/\text{Ru}$ . Recent experimental studies on SRO thin films show that both electronic and magnetic ground states drastically depend on the nature of the surface. Ultra-thin (001)-oriented films are insulating and lack ferromagnetism, while in (111)-oriented films ferromagnetic moments and  $T_c$  are enhanced compared with bulk. Here we investigate SRO films by density functional theory (DFT)+U and DFT+dynamical mean-field theory (DMFT). In agreement with the experiments, we find that metallic ferromagnetism in SRO (001)-oriented films vanishes below a certain critical layer thickness. We propose a new route for tuning the properties of these thin films and show that room temperature ferromagnetism can be attained by electron doping. For the SRO (111)-oriented thin films, we find that the enhanced  $T_c$  is facilitated by electronic correlation effects and the geometric confinement. The experimentally observed enhancement of ferromagnetic moments in SRO(111)-oriented thin films is addressed by considering the stability of the high-spin Ru state in the presence of oxygen vacancies. Finally, the topological properties of SRO (111)-oriented bilayers will be discussed.

**2:03PM B27.00015 Ambipolar transport in the field-suppressed superconducting state of quasi-one-dimensional  $\text{Li}_{0.9}\text{Mo}_6\text{O}_{17}$** <sup>1</sup>, JOSHUA L. COHN, University of Miami, CARLOS A. M. DOS SANTOS, Escola de Engenharia de Lorena - USP, Brazil, JOHN J. NEUMEIER, Montana State University — We present resistivity, Hall, Seebeck, and Nernst coefficient measurements in the range  $0.4\text{ K} \leq T \leq 20\text{ K}$  on single crystals of the quasi-one-dimensional (Q1D) metal,  $\text{Li}_{0.9}\text{Mo}_6\text{O}_{17}$  with current along the Q1D metallic chains. At temperatures below the nominal superconducting transition temperature ( $T_c = 2\text{ K}$ ), a transition from hole-like ( $\mu_0 H < 1\text{ T}$ ) to electron-like ( $\mu_0 H \geq 2\text{ T}$ ) behavior is evidenced in the magnetotransport coefficients. Possible insights from these results into the nature of the mysterious density-wave order<sup>a,b</sup> responsible for the upturn in resistivity below  $\sim 25\text{ K}$  will be discussed.

## Monday, March 14, 2016 11:15AM - 2:03PM —

Session B28 DMP: Topological Kondo Insulators 327 - Natalia Drichko, The Johns Hopkins University

**11:15AM B28.00001 Surface conductance and one-dimensional edge state transport in topological Kondo insulator  $\text{SmB}_6$** <sup>1</sup>, JOHNPIERRE PAGLIONE, University of Maryland — The Kondo insulator compound  $\text{SmB}_6$ , with hybridization between itinerant conduction electrons and localized *f*-electrons driving an insulating gap and metallic surface states at low temperatures, is an ideal candidate for realizing the topological Kondo insulator state. By exploiting the presence of a time reversal symmetry breaking surface ferromagnetic state, we investigate the topological nature of metallic surface states, finding evidence of one-dimensional surface transport with conductance values approaching the quantized value of  $e^2/h$  and originating from the chiral edge channels of ferromagnetic domain walls. We will review our milliKelvin magnetotransport measurements of the edge state transport phenomenon in  $\text{SmB}_6$ , as well as thickness and surface gating studies that conclusively prove the surface nature of low temperature conductance.

<sup>1</sup>This research was supported by AFOSR (FA9550-14-1-0332) and NSF (DMR-0952716).

**11:51AM B28.00002 Effect of Sm valence variation on hybridization gap and in-gap excitons in  $\text{SmB}_6$  studied by Raman spectroscopy**<sup>1</sup>, MICHAEL VALENTINE, SEYED KOOPAYEH, WILLIAM A. PHELAN, TYREL MCQUEEN, NATALIA DRICHKO, Institute for Quantum Matter, Johns Hopkins University, PRISCILA ROSA, ZACHARY FISK, University of California, Irvine —  $\text{SmB}_6$  is a proposed topological Kondo insulator where the presence of topological nontriviality can be tuned by variations in the Sm valence. A range of samples where Sm valence was varied by increasing numbers of Sm vacancies was investigated using Raman spectroscopy over a temperature range of 10 to 300 K. We show a possibility to characterize the presence of Sm vacancies on the order of 1

<sup>1</sup>The work at IQM was supported by the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Material Sciences and Engineering, under Grant No. DEFG02-08ER46544

**12:03PM B28.00003 Origin of bulk quantum oscillations in the bulk Kondo insulating ground state of  $\text{SmB}_6$** , SUCHITRA SEBASTIAN, B. S. TAN, Y.-T. HSU, University of Cambridge, B. ZENG, NHMFL, M. CIOMAGA HATNEAN, University of Warwick, N. HARRISON, Z. ZHU, LANL, M. HARTSTEIN, M. KIOURLAPPOU, M. SRIVASTAVA, University of Cambridge, M. D. JOHANNES, Naval Research Laboratory, T. P. MURPHY, J.-H. PARK, L. BALICAS, NHMFL, N. SHITSEVALOVA, National Academy of Sciences of Ukraine, G. G. LONZARICH, University of Cambridge, G. BALAKRISHNAN, University of Warwick — I will discuss our recent observation of quantum oscillations corresponding to a bulk Fermi surface in the Kondo insulator  $\text{SmB}_6$ , and consider their possible origin. New complementary experimental results will be presented which raise the interesting question of whether the underlying ground state corresponds to a novel Kondo regime in which the spin channel is gapless while the charge channel is gapped.

**12:15PM B28.00004 Angular Dependence of Quantum Oscillations in  $\text{SmB}_6$** , M. HARTSTEIN, B. S. TAN, Y.-T. HSU, University of Cambridge, B. ZENG, NHMFL, M. CIOMAGA HATNEAN, University of Warwick, N. HARRISON, Z. ZHU, LANL, M. KIOURLAPPOU, A. SRIVASTAVA, University of Cambridge, M. D. JOHANNES, Naval Research Laboratory, T. P. MURPHY, J.-H. PARK, L. BALICAS, NHMFL, N. SHITSEVALOVA, National Academy of Sciences of Ukraine, G. G. LONZARICH, University of Cambridge, G. BALAKRISHNAN, University of Warwick, S. E. SEBASTIAN, University of Cambridge — Recent proposals of low-dimensional electronic states in the Kondo insulator,  $\text{SmB}_6$  have lead to renewed interest in the material. In this study we present quantum oscillation measurements of high quality single-crystals of  $\text{SmB}_6$ . Magnetic torque was measured in magnetic fields up to 40 T, allowing the observation of quantum oscillation frequencies ranging from 50 T to 15,000 T in multiple samples prepared by different groups. The size and the angular dependence of the oscillations indicate the striking concurrence of an electronically insulating bulk and a large, bulk Fermi surface. Comparison of the measured oscillations with similar measurements of metallic rare-earth hexaborides supports such a Fermi surface. Our model, previously employed for the metallic hexaborides, describes large ellipsoidally distorted spheres centred at X-points of the Brillouin zone, and smaller ellipsoids positioned at neck points, and gives a good account of the observed frequencies.

**12:27PM B28.00005 Effect of Gap on Quantum Oscillations**, HRIDIS PAL, FRDRIK PICHON, Laboratoire de Physique des Solides, Universit Paris-Sud, JEAN-NOL FUCHS, Laboratoire de Physique Thorique de la Matire Condense, Universit Pierre et Marie Curie, Paris, MARK GOERBIG, GILLES MONTAMBAUX, Laboratoire de Physique des Solides, Universit Paris-Sud — One of the manifestations of the quantization of energy levels in a magnetic field is quantum oscillations. In a metal, oscillations in several physical observables occur each time a Landau level crosses the Fermi level, and is, therefore, a Fermi surface property. In a gapped system, since there is no Fermi surface, such oscillations are not expected. One can ask, what happens to these oscillations as a metal is slowly turned into an insulator by introducing a gap at the Fermi level. To address this, we consider a simple model of two overlapping bands that hybridize to open a gap, and investigate how the oscillations change as the gap is slowly increased, both at zero and non-zero temperature. We show that the oscillations in such gapped systems show marked deviation from the canonical Lifshitz-Kosevich results routinely used to study quantum oscillations in metals.

**12:39PM B28.00006 Quantum oscillation in narrow-gap topological insulators<sup>1</sup>**, LONG ZHANG, XUE-YANG SONG, FA WANG, Peking University — The canonical understanding of quantum oscillation in metals is challenged by the observation of de Haas-van Alphen effect in an insulator,  $\text{SmB}_6$  [Tan *et al.*, Science **349**, 287 (2015)]. Based on a two-band model with inverted band structure, we show that the periodically narrowing hybridization gap in magnetic fields can induce the oscillation of low-energy density of states in the bulk, which is observable provided that the activation energy is small and comparable to the Landau level spacing. Its temperature dependence strongly deviates from the Lifshitz-Kosevich theory. The nontrivial band topology manifests itself as a nonzero Berry phase in the oscillation pattern, which crosses over to a trivial Berry phase by increasing the temperature or the magnetic field. Further predictions to experiments are also proposed.

**12:51PM B28.00007 Reduction of the low-temperature bulk gap in the topological Kondo insulator samarium hexaboride under high magnetic fields<sup>1</sup>**, STEVEN WOLGAST, YUN SUK EO, KAI SUN, CAGLIYAN KURDAK, University of Michigan, Department of Physics, DAE-JEONG KIM, ZACHARY FISK, University of California at Irvine, Department of Physics and Astronomy — The mixed-valent insulator samarium hexaboride exhibits a narrow bandgap at low temperatures, formed by strong-correlation interactions between itinerant  $d$  electrons and  $f$  states localized to the Sm ions, and surface states accessible to transport below about 2 K. Spectroscopic measurements of the bandgap suggest a gap size of 15-20 meV, but transport measurements of thermally-activated carriers suggest the Fermi energy is about 3 meV below the conduction band edge. Here, we study the activated transport gap in pulsed magnetic fields up to 60 T between 1.5 K and 4 K. The magnetoresistance of the surface states, which has only very weak temperature dependence, is distinct from that of the bulk states, which exhibit thermally-activated behavior. The activation energy shrinks by 50% at fields up to 60 T. Data up to 93 T suggest that the transport gap continues to close, but is only fully-closed at even higher fields. We compare the measured reduction to theoretically-expected behavior due to Zeeman shifts of the Sm ion  $f$ -state transition energies. Meanwhile, the surface state shows no hints of Shubnikov-de Haas oscillations, which places constraints on any 2D surface carrier's mobility.

<sup>1</sup>Performed in part at the NHMFL (NSF CA DMR-1157490 and the State of Florida), and the LNF (NNIN, supported by NSF). Supported by NSF grant Nos. DMR-1006500, DMR-1441965, and DMR-0801253.

**1:03PM B28.00008 Magnetotransport Measurements on  $\text{SmB}_6$  - Cornering the Parameter Space for Carrier Density and Mobility<sup>1</sup>**, YUN SUK EO, STEVEN WOLGAST, CAGLIYAN KURDAK, KAI SUN, Dept. of Physics, University of Michigan, DAE-JEONG KIM, ZACHARY FISK, Dept. of Physics and Astronomy, University of California, Irvine, MONICA CIOMAGA HATNEAN, GEETHA BALAKRISHNAN, Dept. of Physics, University of Warwick — There is growing interest in studying the conducting surface of  $\text{SmB}_6$ , which is believed to originate from its nontrivial band topology. Up to date, different measurement techniques, including ARPES, dHvA, and Hall bar transport still disagree on important parameters such as the carrier density. In order to find the carrier density ( $n$ ) and mobility ( $\mu$ ) for the Dirac pockets participating in transport, we measure magnetotransport on Corbino devices fabricated on (100), (110), and (111) surfaces grown by floating zone and flux methods. Our samples do not exhibit Shubnikov-de Haas oscillations at high field pulsed measurements up to 90 Tesla, which provides an upper bound of  $\mu$  of each channels. Also, angle-dependent magnetotransport up to 35 T allows us to extract an effective  $n$  and  $\mu$  of the combined channels. Together, a parameter space that confines the possible  $n$  and  $\mu$  of each channel is constructed, and appears to be in agreement with ARPES reports. Additionally, the effective  $n$  and  $\mu$  change up to 20 percent when applying magnetic field up to 35 T. We will discuss how the Landau fan diagram can be nonlinear by this effect.

<sup>1</sup>This project was funded by NSF grant DMR-1006500. This project was performed at the National High Magnetic Field Laboratory, and in the Lurie Nanofabrication Facility.

**1:15PM B28.00009 Kondo Interactions from Band Reconstruction in  $\text{YbInCu}_4$** , JASON HANCOCK, University of Connecticut, IGNACE JARRIGE, Brookhaven National Laboratory, AKIO KOTANI, Photon Factory, H. YAMAOKA, RIKEN, N. TSUIJII, K. ISHII, JAEA, M. UPTON, D. CASA, J. KIM, T. GOG, Argonne — We combine resonant inelastic x-ray scattering and model calculations in the Kondo lattice compound  $\text{YbInCu}_4$ , a system characterized by a dramatic increase in Kondo temperature and associated valence fluctuations below a first-order valence transition at  $T \simeq 42$  K. The bulk-sensitive, element-specific, and valence-projected charge excitation spectra reveal an unusual quasigap in the Yb-derived state density which drives an instability of the electronic structure and renormalizes the low-energy effective Hamiltonian at the transition. Our results provide long-sought experimental evidence for a link between temperature-driven changes in the low-energy Kondo scale and the higher-energy electronic structure of this system.

**1:27PM B28.00010 Temperature-dependent Helicity of In-gap states of  $\text{SmB}_6$ <sup>1</sup>**, SOOYOUNG JANG, Lawrence Berkeley Natl Lab, POSTECH, J.D. DENLINGER, Lawrence Berkeley Natl Lab, C.-H. MIN, F. REINERT, U. Würzburg, BOYOUN KANG, B.-K. CHO, GIST, D.J. KIM, Z. FISK, UC Irvine, KEUN SU KIM, POSTECH, J. W. ALLEN, U. of Michigan — Mixed-valent  $\text{SmB}_6$  with a temperature (T) dependent bulk gap is the first candidate example of a new class of strongly correlated topological insulators with  $f$ - $d$  band inversion. Previous angle-resolved photoemission (ARPES) on cleaved  $\langle 100 \rangle$  surfaces of  $\text{SmB}_6$  have quantified the T-evolution of (i) the Sm  $4f$  state coherence, (ii) the X-point  $f$ -conduction band energy and many-body gap destabilization, and (iii) the intimately connected fate of in-gap states. In this work we additionally characterize the T-evolution of the in-gap state orbital angular momentum helicity using circular dichroism. We show that the onset of dichroism, above 100K, coincides with the dimensional crossover from high T 3D non-helical bulk  $d$ -band states crossing  $E_F$  to low T 2D in-gap surface states where the dichroic asymmetry reaches 100%. With the assumption of topological surface state anti-parallel spin-momentum locking, this result can be viewed as supporting previous spin-resolved ARPES measurements of in-gap state helical spin structure.

<sup>1</sup>Supported by U.S. DOE at the Advanced Light Source (DE-AC02-05CH11231).

**1:39PM B28.00011 In-gap states on the non-polar (110) surface of  $\text{SmB}_6$ <sup>1</sup>**, J.D. DENLINGER, SOOYOUNG JANG, Lawrence Berkeley Nat'l Lab, C.-H. MIN, F. REINERT, U. Würzburg, BOYOUN KANG, B.-K. CHO, GIST, D.J. KIM, Z. FISK, U.C. Irvine, J.W. ALLEN, U. of Michigan — Mixed-valent  $\text{SmB}_6$  with a temperature-dependent bulk gap is the first candidate example of a new class of strongly correlated topological insulators with  $f$ - $d$  band inversion. The topological origin of in-gap states on cleaved (001) surfaces as measured by angle-resolved photoemission (ARPES) is not without controversy, since the  $\bar{X}$  states span the full  $\sim 20$  meV hybridization gap at low temperature without exhibiting any clear Dirac point. Furthermore, reports exist of band-bending due to the polarity of the (001) surface and depth-dependent deviations from bulk stoichiometry or Sm valency. In this work we explore ARPES of the non-polar (110) surface of  $\text{SmB}_6$  prepared by polishing and high-temperature annealing. We find in-gap states at  $\bar{X}$  and  $\bar{Y}$  points with very similar properties as the (001)  $\bar{X}$  states. We discuss the relevance of these findings to the TI and other proposed models, and to the recent discrepancy between 2D [1] and 3D [2] interpretations of dHvA Fermi surface orbits.

**1:51PM B28.00012 Effect of Magnetic Substitution on Topological Kondo Insulator SmB<sub>6</sub>**, TRISTIN METZ, YASUYUKI NAKAJIMA, XIANGFENG WANG, JOHNPIERRE PAGLIONE, University of Maryland, College Park — The Kondo topological insulator SmB<sub>6</sub> is an ideal candidate to realize protected metallic surface states driven by strong electron correlations. Recent experiments [1] provide evidence for one-dimensional electron transport on the surface of SmB<sub>6</sub>, associated with the existence of topologically nontrivial chiral edge states at the boundaries of intrinsic surface ferromagnetic domains. If these surface states are indeed topologically nontrivial they will be destroyed by the introduction of time reversal symmetry breaking magnetic impurities. We investigate the effect of magnetic impurities on SmB<sub>6</sub> through transport measurements in Fe and Ni substituted SmB<sub>6</sub> at very low temperatures. **Session B29 DCMP: Quantum Spin Hall Effect** 328 - Dong-Ling Deng, University of Maryland

**11:15AM B29.00001 Quantum spin Hall effect in two-dimensional transition-metal dichalcogenide Haeckelites<sup>1</sup>**, SI-MIN NIE, ZHIDA SONG, HONGMING WENG, ZHONG FANG, Chinese Academy of Sci (CAS), T03 TEAM — The Quantum Spin Hall (QSH) effect, discovered nearly ten years ago, is such a promising option, because it can be viewed as the time-reversal-invariant version of the QH effect, which does NOT need any external magnetic field and can be in principle realized at room temperature. So far, QSH effect has only been observed in HgTe/CdTe and InAs/GaSb quantum wells. Both of them require precisely controlled MBE growth and ultralow temperature. The study of 2D TI has been seriously hampered due to lack of proper materials with large band gap, stable structure, and easy fabrication. In this report, I will introduce a family of the single layer 2D transition metal dichalcogenide (TMD) Haeckelites MX<sub>2</sub> (M=W or Mo, X=S, Se or Te), which can host QSH effect. The phonon spectra indicate that these Haeckelites are dynamically stable. Further, a simple tight-binding model based on square-like lattice has been established to uncover the underlying mechanism. This will extend further studies from graphene-based hexagonal lattice to square-like lattice and broad the range for searching topological materials largely.

**11:27AM B29.00002 Quantum Spin Hall Effect in thin films of topological crystalline insulators.**, RYSZARD BUCZKO, SHIVA SAFAEI, MARTA GALICKA, PERLA KACMAN, Institute of Physics Polish Academy of Sciences, Warsaw, Poland — The quantum spin Hall effect (QSHE) is predicted to exist in topological crystalline insulator materials [1]. Using a tight-binding approach we demonstrate that in (111)-oriented thin films of SnSe and SnTe the energy gaps depend in an oscillatory fashion on the layer thickness. The calculated topological invariant indexes and edge state spin polarizations show that in the negative energy gaps regions (~20–40 monolayers) a 2D topological insulator phase appears. In this range of thicknesses in both SnSe and SnTe, edge states are obtained with Dirac cones having opposite spin polarization in their two branches. While in SnTe layers a single Dirac cone appears at the projection of  $\Gamma$  point of the 2D Brillouin zone, in SnSe layers three Dirac cones at  $M$  points projections are obtained. Unfortunately, in SnSe films an overlapping of bands at  $\Gamma$  and  $M$  diminishes the final band gap in the vicinity of all  $M$  points and the edge states appear either against the background of the bands or within a very small energy gap. We show that this problem can be removed by applying to the layers a biaxial strain [2]. This should enable observation of the QSHE also in SnSe layers. 1. S. Safaei, et al., New J. Phys. 17, 063041 (2015). 2. S. Safaei et al, arXiv: 1508.01364 [cond-mat.mtrl-sci].

**11:39AM B29.00003 Transport in quantum spin Hall systems in parallel magnetic fields**, MICHAEL WIMMER, RAFAL SKOLASINSKI, TU Delft, Netherlands, DMITRY PIKULIN, University of British Columbia, Canada, JASON ALICEA, Caltech, US — Edge states in quantum spin Hall (QSH) systems are protected by time-reversal symmetry, resulting in a quantized conductance. A magnetic field breaks that protection, and should lead to a deviation from perfect quantization. We will discuss generic features of semiconductor-based QSH systems (such as HgTe/CdTe and InAs/GaSb) that affect the magnetic field dependence of edge state conductance, focusing on the effect of an in-plane field.

**11:51AM B29.00004 Giant Rashba spin splitting with unconventional spin texture in a quantum spin Hall insulator<sup>1</sup>**, CARLOS MERA ACOSTA, OSCAR BABILONIA, University of Sao Paulo, CP 66318, 05315-970, Sao Paulo, SP, Brazil, LEONARDO ABDALLA, University of Colorado, Boulder, Colorado 80309, USA, ADALBERTO FAZZIO, University of Sao Paulo, CP 66318, 05315-970, Sao Paulo, SP, Brazil — We propose a non-centrosymmetric honeycomb-lattice quantum spin Hall effect family formed by atoms of the groups IV, V and VII of the periodic table. We make a structural analysis, a  $Z_2$  characterization. According to our ab-initio phonon calculations, the system formed by Bi, Pb and I atoms is only mechanically stable system. This material presents a Rashba-type spin-splitting and a hexagonal warping effect, which lead to an unusual spin texture. Due to this spin texture, the backscattering is forbidden for both edge conductivity channels and bulk conductivity channels. This suggests that, contrary to what happens in most systems with nontrivial topological phases, the bulk states would not pose a problem for spintronic devices. The value of the spin-splitting due to the Rashba effect is about 60 meV, which is huge compared with the values found in 2D systems and surprisingly is on the order of the highest found in 3D systems.

**12:03PM B29.00005 Large band gap quantum spin hall insulators of fluorinated Pb-X (X= C, Si, Ge, Sn)**, JOSE EDUARDO PADILHA, Universidade Federal do Parana - Jandaia do Sul, RENATO BORGES PONTES, Universidade Federal de Goias, TOME MAURO SCHMIDT, ROBERTO HIROKI MIWA, Universidade Federal de Uberlandia, ADALBERTO FAZZIO, Universidade de Sao Paulo — The Quantum Spin Hall Insulating (QSHI) phase was first observed in the HgTe/CdTe quantum well structure. However, the observed band gap of 5 meV is too small for practical applications. Other materials have also been proposed for the observation of the QSHI phase, such as silicene, germanene, stanene, and its halogenated phases. The spin-orbit interaction is a key feature in topological insulators, raising the interest in heavy elements, such as Bismuth. In fact, Bi is responsible for the high spin-orbit coupling that drives the band inversion in Bi<sub>2</sub>Se<sub>3</sub> and Bi<sub>2</sub>Te<sub>3</sub>. Another element that also has a large spin-orbit interaction is Lead (Pb). Here we present a set of 2D QSH insulators with a very large band gap based on fluorinated Pb-X (X= C, Si, Ge, Sn). First-principles phonon dispersion calculations indicate that these systems are structurally and mechanically stable. By performing DFT-based electronic structure calculations we show that 2D Pb-X functionalized with fluorine are topological insulators with very large band gaps (over 0.7 eV). Additional calculations, for nanoribbons structures, show the presence of a Dirac cone at the center of the Brillouin zone. These results can establish a new route to the observation of QSHI phase at room temperature.

**12:15PM B29.00006 Fully and partially iodinated germanane as a platform for the observation of the quantum spin Hall effect.** , JOSE EDUARDO PADILHA, Universidade Federal do Parana, ADALBERTO FAZZIO, LEONARDO ABDALLA, ANTONIO JOSE ROQUE DA SILVA, Universidade de Sao Paulo — The Quantum Spin Hall Effect (QSHE) proposed in 2005 by Kane and Mele for graphene and by S.-C. Zhang et al. in 2006 for the HgTe/CdTe, became a very exciting area of condensed matter physics. Several materials have been proposed to overcome the issue of the small SOC band gap presented by the graphene and HgTe/CdTe structures, such the elemental materials germanene, stanene and others binary compounds with band gaps that goes to several meV to few eV. Motivated by the recent isolation of the trivial insulator germanane, a fully hydrogenated germanene, we show that a partially substitution of the hydrogen atoms in only one side of the material by iodine, creates a two dimensional topological insulator with a large band gap of 0.49 eV. This functionalization opens up new routes for the observation of the quantum spin Hall effect in a fully two-dimensional material. We also show that creating nanoroads or nanoribbons with the pattern functionalization of germanane by iodine in a ordered or disordered way, topologically protected interfaces states arises at the boundary of germanane/iodinated germanane.

**12:27PM B29.00007 Spin Hall Conductivity and Spin Chern Number for Dirac Systems** , ELIF YUNT, OMER FARUK DAYI, Istanbul Tech Univ — A semiclassical differential form formalism of the spin Hall effect for Dirac systems is presented. In this formalism, space coordinates and momenta are usual dynamical variables, whereas spin is not a dynamical degree of freedom. Spin depicts itself in the matrix-valuedness of equations of motion. We demonstrate that the main contribution to the spin Hall conductivity is given by the spin Chern number whether the spin is conserved or not at the quantum level. We illustrated the formulation within the Kane-Mele model of graphene in the absence and in the presence of the Rashba spin-orbit coupling term. Kane-Mele Model of graphene, which incorporates intrinsic spin-orbit interaction, constitutes the first example of a two dimensional topological insulator. We established the anomalous Hall conductivity as well as the spin Hall conductivity from the term linear in the electric field and the Berry curvature in the the anomalous velocity term. In a basis where the component of spin under consideration is diagonal this term is diagonal. We argue that this semiclassical procedure of calculating the spin Hall conductivity can be generalized to any dimension.

**12:39PM B29.00008 Room Temperature Quantum Spin Hall Insulators with a Buckled Square Lattice** , WEI LUO, HONGJUN XIANG, None — Two-dimensional (2D) topological insulators (TIs), are excellent candidates for coherent spin transport related applications. Currently, most known 2D TIs are based on a hexagonal lattice. Here, we propose that there exists the quantum spin Hall effect (QSHE) in a new tight-binding (TB) model for a two-orbital system with the buckled square lattices. We show that the band inversion is due to the hybridization between the  $p_x$  and  $p_y$  orbitals, while the spin-orbit coupling (SOC) induced nearest-neighbor effective hopping is responsible for a band gap opening at the Dirac cone. Through performing global structure optimization, we predict a new three-layer quasi-2D (Q2D) structure which has the lowest energy among all structures with the thickness less than 6.0 Å for the BiF system. It is identified to be a Q2D TI with a large band gap (0.69 eV). The electronic states of the Q2D BiF system near the Fermi level are mainly contributed by the middle Bi square lattice, which are sandwiched by two inert BiF<sub>2</sub> layers. This is beneficial since the interaction between a substrate and the Q2D material may not change the topological properties of the system, as we demonstrate in the case of the NaF substrate. Our analysis shows that the low-energy physics of the Q2D BiF system can be qualitatively described by our newly proposed two-orbital TB model. Our study not only predicts a Q2D QSH insulator for realistic room temperature (RT) applications, but also provides a new lattice system for engineering topological states such as quantum anomalous Hall effect.

**12:51PM B29.00009 Superconducting quantum spin-Hall systems with giant orbital g-factors<sup>1</sup>** , EWELINA HANKIEWICZ, ROLF REINTHALER, GRIGORY TKACHOV, Wurzburg University, Germany — Topological aspects of superconductivity in quantum spin-Hall systems (QSHSs) such as thin layers of three-dimensional topological insulators (3D TIs) or two-dimensional TIs are in the focus of current research. Here, we describe a novel superconducting quantum spin-Hall effect (quantum spin Hall system in the proximity to the s-wave superconductor and in the orbital in-plane magnetic field), which is protected against elastic backscattering by combined time-reversal and particle-hole symmetry [1]. This effect is characterized by spin-polarized edge states, which can be manipulated in weak magnetic fields due to a giant effective orbital g-factor, allowing the generation of spin currents. The phenomenon provides a novel solution to the outstanding challenge of detecting the spin-polarization of the edge states. Here we propose the detection of the edge polarization in the three-terminal junction using unusual transport properties of superconducting quantum Hall-effect: a non-monotonic excess current and a zero-bias conductance splitting. <sup>1</sup>We thank for the financial support the German Science Foundation (DFG), grants No HA 5893/4-1 within SPP 1666, HA5893/5-2 within FOR1162 and TK60/1-1 (G.T.), as well the ENB graduate school "Topological insulators".

**1:03PM B29.00010 Effective spin dephasing mechanism in confined two-dimension topological insulators** , JUNJIE QI, Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, HAIWEN LIU, International Center for Quantum Materials and School of Physics, Peking University, Beijing 100871, China, HUA JIANG, College of Physics, Optoelectronics and Energy, Soochow University, Suzhou 215006, China, X.C. XIE, International Center for Quantum Materials and School of Physics, Peking University, Beijing 100871, China, XIE'S GROUP TEAM — A Kramers pair of helical edge states in quantum spin Hall effect (QSHE) is robust against normal dephasing but not robust to spin dephasing. In our work, we provide an effective spin dephasing mechanism in the puddles of two-dimension QSHE, which is simulated as quantum dots modeled by 2D massive Dirac Hamiltonian. We demonstrate that the spin dephasing effect can originate from the combination of the Rashba spin-orbit coupling and electron-phonon interaction, which gives rise to inelastic backscattering in edge states within the topological insulator quantum dots, although the time-reversal symmetry is preserved throughout. Finally, we discuss the tunneling between extended helical edge states and local edge states in the QSH quantum dots, which leads to backscattering in the extended edge states. These results can explain the more robust edge transport in InAs/GaSb/AlSb QSH systems.

**1:15PM B29.00011 Effects of magnetic impurities on transport in 2D topological insulators** , XIAOQIAN DANG, J.D. BURTON, EVGENY TSYMBAL, University of Nebraska-Lincoln — Understanding the transport properties of topological insulators could bring such materials from fundamental research to potential applications. Here we report on the theoretical investigations of the effects of magnetic impurities on transport properties of model two-dimensional (2D) topological insulators (TIs). We utilize the tight-binding form of the Bernevig-Hughes-Zhang model and investigate the transport properties by employing the Landauer-Büttiker formalism. We explore the current distribution in 2D TIs resulting from scattering by a magnetic impurity which breaks time-reversal symmetry. We find that a magnetic impurity could drive anti-resonant behavior of the conductance, as revealed from full backscattering of the electron current flowing at one of the edges of the TI. This phenomenon occurs due to spin-flip scattering when the Fermi energy matches the impurity state and the magnetic moment of the impurity is aligned along the TI edge. Additionally, we explore the effect of an external magnetic gate attached to the system and show that changing the magnetization orientation within the gate allows the control of conductance. This geometric setup could be realized experimentally providing the opportunity to tune transport properties of 2D TIs by a magnetic gate.

**1:27PM B29.00012 One-dimensional edge states in Bi(111) bilayer grown on Sb<sub>2</sub>Te<sub>3</sub>**<sup>1</sup>, YAOYI LI, SHIVANI RAJPUT, DUSHYANT TOMER, LIAN LI, Univ of Wisconsin, Milwaukee — Well-ordered Bi bilayer islands with zigzag edges are grown epitaxially on Sb<sub>2</sub>Te<sub>3</sub>(111) film by molecular beam epitaxy. Scanning tunneling microscopy imaging shows that the Bi film assumes the lattice of the Sb<sub>2</sub>Te<sub>3</sub>, thus is coherently strained. Tunneling spectroscopy further reveals robust edge states, confirming it as a two-dimensional topological insulator. This is consistent with first-principles calculations that indicate the preservation of the topological nature of the Bi bilayer and edge states with only an energy shift even in the presence of strong interaction between Bi and Sb<sub>2</sub>Te<sub>3</sub>. These findings suggest that the interface between 2D and 3D TIs can be a promising platform to synthesize new topological matter.

**1:51PM B29.00014 Hunting down magnetic monopoles in 2D topological insulators**, HE, Stony Brook University and BNL, CMPMSD AT BNL TEAM — Contrary to the existence of electric charge, magnetic monopoles have never been observed. It is thus extraordinary to find that magnetic monopoles can be pictured conceptually in topological insulators. For 2D topological insulators, the topological invariant corresponds to the total flux of an effective magnetic field (the Berry curvature) over the reciprocal space. Upon compactifying the Brillouin zone to a compact manifold as a torus, the non-zero total flux can be considered to originate from magnetic monopoles with quantized charge. The intrinsic difficulty via extending a 2D problem to a 3D reciprocal space, and then demonstrate that analytical continuation offers a natural solution in which 1) the magnetic monopoles emerge naturally in pairs each forming a string above and below the Brillouin zone, and 2) the total charge below the real axis gives exactly the topological invariant. In essence, the robustness of the topological invariant is protected by the total charge in the lower complex plane, a mapping intriguing even mathematically. Finally, we will illustrate the physical transition, providing a natural description of the metallic nature in the phase boundary, and offering a clear explanation of the induced via a local change in reciprocal space.

**2:03PM B29.00015 Circle of crossings and Berry curvatures in 2D topological insulators**<sup>1</sup>, MARIUS RADU, YULI LYANDA-GELLER, Department of Physics and Astronomy, Purdue University — HgTe forms a two-dimensional topological insulator when sandwiched between CdTe barriers for a HgTe layer wider than the critical thickness. We derive single-particle and two-particle interaction Hamiltonians describing physics of these compounds by using  $\mathbf{k} \cdot \mathbf{p}$  theory and extended Kane model. We include contributions from upper conduction bands with orbital states of p-symmetry that bring about the terms describing lack of inversion symmetry in host semiconductors. A crucial ingredient is hetero-interface contribution to intrinsic spin-orbit interactions that drives significant anticrossing gaps in spectra at zero wavevector, but results in a circle of spectral crossings at finite wavevectors. Single-particle Hamiltonian and two-particle Hamiltonian contain important spin-dependent terms. The spin-dependent interaction couples orbital motion of one particle with evolution of spin of the other particle. Such particle-particle interactions do not conserve spin and lower the symmetry of exchange interactions, leading, e.g., to Dzyaloshinskii-Moriya exchange term. We study the effects of new interactions on Berry curvature and spin-Hall conductance.

**Session B30 DMP: Ferroelectric Walls, Heterostructures and Superlattices** 329 - Rossitza Pentcheva, University of Duisburg-Essen

**11:15AM B30.00001 Two-dimensional electron gases at head-to-head and tail-to-tail domain walls in ferroelectric thin films.**<sup>1</sup>, PABLO GARCÍA-FERNÁNDEZ, Universidad de Cantabria, JORGE ÍÑIGUEZ, Luxembourg Institute of Science and Technology, JAVIER JUNQUERA, Universidad de Cantabria — Symmetry breaking at ferroelectric domain walls gives rise to new physical properties, offering the opportunity to use the domain walls themselves as a functional separate object in a device. One example is the appearance of an enhanced conductivity at the boundaries between ferroelectric domains in oxides. A realistic first-principles simulation of the domain walls is limited to highly-symmetric cleanly-cut walls in order to keep the number of atoms in the simulation box small. Here we use a recently developed second-principles method that treats all the lattice degrees of freedom and the relevant electronic ones on the same foot with high accuracy at a modest computational cost. We apply it to the demanding physical problem of head-to-head (HH) and tail-to-tail (TT) domain walls in ferroelectric PbTiO<sub>3</sub> thin films. These interfaces present a large and unfavourable electrostatic energy due to the polarization-induced bound charge at the domain wall. An accurate simulation should capture eventual charge transfers between the walls, and the concomitant electron-lattice coupling. We show how the polarization discontinuity in HH and TT domain walls in PbTiO<sub>3</sub> thin films can be effectively screened by the formation of two-dimensional electron gases of electrons and holes.

**11:27AM B30.00002 First-principles prediction of a native ferroelectric metal<sup>1</sup>**, JORGE INIGUEZ, Luxembourg Institute of Standards and Technology, ALESSIO FILIPPETTI, CNR-IOM SLACS Cagliari, VINCENZO FIORENTINI, Universit di Cagliari and CNR-IOM SLACS Cagliari, FRANCESCO RICCI, Universit di Cagliari, PIETRO DELUGAS, Istituto Italiano di Tecnologia IIT — The possibility that metals may support ferroelectricity is an intriguing open issue. Over the years, various compounds have been referred to as ferroelectric metals, including non-centrosymmetric metals as well as ferroelectrics whose polar distortion survives moderate metallicity induced by doping or proximity. Yet, we think none of these systems embodies a truly ferroelectric metal with native switchable polarization and native metallicity coexisting in a single phase. Here we report a first-principles prediction of such a material. We show that the layered perovskite Bi<sub>5</sub>Ti<sub>5</sub>O<sub>17</sub> has a non-zero density of states at the Fermi level and metal-like conductivity, as well as a spontaneous polarization in zero field. Further, we predict that the polarization of Bi<sub>5</sub>Ti<sub>5</sub>O<sub>17</sub> is switchable both in principle (the material complies with the sufficient symmetry requirements) and in practice (in spite of being a metal, Bi<sub>5</sub>Ti<sub>5</sub>O<sub>17</sub> can sustain a sizable potential drop along the polar direction, as needed to revert its polarization by application of an electric bias). Our results also reveal striking behaviors – such as the self screening mechanism at work in thin Bi<sub>5</sub>Ti<sub>5</sub>O<sub>17</sub> layers – emerging from the intimate interplay between polar distortions and free carriers in such an exotic material.

**11:39AM B30.00003 Polarization in asymmetrical intermixed interfaces in SrTiO<sub>3</sub>/PbTiO<sub>3</sub> superlattices**, SIMON DIVILOV, MARIVI FERNANDEZ-SERRA, GREG HSING, MATTHEW DAWBER, State Univ of NY- Stony Brook — We used first principles density functional theory to study the effects on polarization of asymmetrical intermixing. In our systems, one interface has intermixed A-cations and the other one is pure. We analyze both monodomain and polydomain SrTiO<sub>3</sub>/PbTiO<sub>3</sub> (STO/PTO) superlattices with varying periods. We report how the difference in energy and spontaneous polarization, between the two stable polarization states, scales with period, domain size, thickness of the intermixed layer and oxygen vacancies. Our results are used to explain the origin of the intrinsic polarization asymmetry observed in experimental measurements of ferroelectric hysteresis loops.

**11:51AM B30.00004 Domain Structure and Properties in Inhomogeneously-Strained Ferroelectric Thin Films**, LANE MARTIN, University of California, Berkeley — Epitaxial thin-film growth and the ability to deterministically apply lattice mismatch strain has enabled dramatic control over the structure and properties of a range of ferroelectric materials. Modern ferroelectric films, including bilayer and superlattice heterostructures, have also provided access to exotic structures and properties not available in the bulk. In this work, we focus on recent advances in our understanding of how strain can be manipulated and controlled to elicit new types of responses and new understandings about response in ferroelectric materials. In particular, we will explore new modalities of strain control of ferroelectric materials that go beyond traditional lattice mismatch effects and how this can be used to enhance performance, independently tune susceptibilities, and provide new insights into the nature of these complex materials. In particular, we will focus on the deterministic production of large strain gradients (on the order of  $>10^{-5} \text{ m}^{-1}$ ) via purposeful compositional gradients. We will highlight work on compositionally-graded versions of PbZr<sub>1-x</sub>Ti<sub>x</sub>O<sub>3</sub> and Ba<sub>1-x</sub>Sr<sub>x</sub>TiO<sub>3</sub> where careful control of lattice mismatch and chemistry combine to produce large strain gradients, exotic properties, and new approaches to independently control traditionally coupled properties. As part of this discussion, we will explore the evolution of the crystal and domain structure as a function of the end-members of the compositional gradient, thickness of the film, and substrate. Advanced band-excitation piezoresponse force microscopy, switching spectroscopy, and non-linearity studies have been applied. These studies reveal both unexpected crystal and domain structures can be stabilized in these heterostructures and exotic low- and high-field responses can be obtained. Of particular interest will be the results of temperature-dependent probes of susceptibility which reveal large, nearly temperature-independent properties from 25-500C and the observation of highly-mobile ferroelastic domain wall structures which can give rise to local enhancement of susceptibilities. These observations could represent a ground-breaking advance in the performance of these materials.

**12:27PM B30.00005 Epitaxial strain effects on layered polar oxides from first-principles**, XUEZENG LU, JAMES RONDINELLI, Department of Materials Science and Engineering, Northwestern University, MATERIALS THEORY AND DESIGN GROUP TEAM — Epitaxial strain is a powerful tool to generate ferroelectric phases in thin films owing to polarization-strain coupling. The coupling of the oxygen rotations to strain can also be exploited to realize oxygen rotation-sensitive properties such as metal-insulator transitions and magnetic reconstructions. Here, we use electronic structure calculations to investigate the effects of biaxial strain on (001) thin films of the hybrid-improper ferroelectric Ca<sub>3</sub>Ti<sub>2</sub>O<sub>7</sub>. Besides the bulk *Cmc*<sub>21</sub> phase, we also find a new phase emerges under both experimentally accessible biaxial compressive and tensile strains. Furthermore, a large change in the dielectric anisotropy of the film is found at the tensile phase boundary, which we propose could be electric field tunable. Our results may offer a route to search for new functionalities in layered-perovskite oxides.

**12:39PM B30.00006 First-principles study of charge-order-driven ferroelectricity in LaVO<sub>3</sub>/SrVO<sub>3</sub> superlattices<sup>1</sup>**, SE YOUNG PARK, Rutgers University, ANIL KUMAR, Los Alamos National Laboratory, KARIN RABE, Rutgers University — We investigate the structure and electronic properties of the 1:1 superlattice composed of LaVO<sub>3</sub> and SrVO<sub>3</sub> using the density functional theory plus U (DFT+U) method. We find two low-energy antiferromagnetic Mott-insulating phases with distinct charge ordering patterns. In one of these phases, spontaneous polarization normal to the interface is nonzero due to a layered charge-ordering. The polarization calculated by the Berry phase method is 32  $\mu\text{C}/\text{cm}^2$ ; we have identified a possible switching path on which the system remains insulating. When fully relaxed, the energy per 5-atom-unit-cell of the polar state is only 3 meV higher than the non-polar state and we find that the energy difference can be reduced to zero by tensile strain. This suggests that the polar state could be induced by applied electric field, and, depending on the switching process, a ferroelectric hysteresis loop could be observed.

**12:51PM B30.00007 Microwave conductance of ferroelectric domain walls in lead titanate**, ALEXANDER TSELEV, YE CAO, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, TN 37831, PU YU, Department of Physics and Collaborative Innovation Center for Quantum Matter, Tsinghua University, Beijing 100084, China, SERGEI V. KALININ, PETRO MAKSYMOVYCH, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, TN 37831 — Numerous theoretical works predicted electronically conducting domain walls in otherwise insulating ferroelectric crystals. A number of recent experiments reported conducting walls, although conductivity itself and a conclusive proof of conductance mechanism remain elusive, largely due to the electrical contact problem. The latter can be overcome using high-frequency AC voltage. Here we will present our successful measurements of microwave conductance at 180° domain walls in lead titanate using microwave microscopy. AC conducting domain walls can be repeatably reconfigured and have extraordinary stability in time and temperature. AC conductivity is detected even when DC is not. Quantitative modeling reveals that the conductance of domain walls is comparable to doped silicon. We will also present a new and robust mechanism to create charged domain walls in any ferroelectric lattice. Overall, this sets the stage for a new generation of local experiments on conducting domain walls, and furthers the prospects of their application in fast electronic devices. **1:03PM B30.00008 Metastable antiparallel polarization configurations in BaTiO<sub>3</sub>/PbZr<sub>0.2</sub>Ti<sub>0.8</sub>O<sub>3</sub> epitaxial bilayer**, PAVEL SALEV, ALEXEI GRIGORIEV, The University of Tulsa — A combination of LGD and semiconductor theories predicts the electrostatic screening of a large polarization mismatch between BaTiO<sub>3</sub> (BTO) and Pb(Zr,Ti)O<sub>3</sub> (PZT) ferroelectric layers. The source of this screening is in an increased concentration of interfacial free charge carriers due to the strong bending of electronic bands inside the layers. The enhanced concentration of free charges at the interface can allow for independent polarization reversal in each ferroelectric layer suggesting possible antiparallel polarization configurations in BTO/PZT bilayer. We confirmed these theoretical predictions of layer-by-layer switching by demonstrating double polarization switching in epitaxial BTO/PZT thin films. The layer-by-layer switching leads to formation of head-to-head (H-H) and tail-to-tail (T-T) polarization configurations, which have an enhanced dielectric permittivity when compared to parallel polarization domain configurations. While both H-H and T-T states are unstable at a zero electric field, we found that antiparallel polarization configurations can be stabilized by applying a small bias. Our findings provide a pathway to engineer new multilayer systems with switchable multistate polarizations and dielectric responses.

**1:15PM B30.00009 Thickness dependence of ferroelectric stability in SrRuO<sub>3</sub>/BaTiO<sub>3</sub>/La<sub>0.7</sub>Sr<sub>0.3</sub>MnO<sub>3</sub> ferroelectric tunnel junctions**, J. D. BURTON, EVGENY TSYMBAL, University of Nebraska - Lincoln — Ferroelectric tunnel junctions (FTJs) must meet key requirements in order to become viable device structures. One factor which can limit functionality is the thickness of the ferroelectric layer. The ferroelectric must be thin enough that a detectable tunnel current can flow through it, but if it is too thin, screening of the depolarization field by the electrodes will be insufficient for polarization stability. One mechanism to produce a large change in the tunneling resistance, i.e. a large tunneling electro resistance (TER), is to use asymmetric electrodes. This is disadvantageous from the point of view of switchability, however: the electric field due to the mismatch between metal work functions leads to a preference for one polarization state over the other and, in thinner FTJs, may render one of the polarization states unstable. To explore this effect we perform first-principles density functional calculations on SrRuO<sub>3</sub>/BaTiO<sub>3</sub>/La<sub>0.7</sub>Sr<sub>0.3</sub>MnO<sub>3</sub> (SRO/BTO/LSMO) FTJs with varying BTO thicknesses. We find an energetic preference for polarization to point away from the LSMO electrode. FTJs with BTO thicknesses at or below 4 unit-cells polarization pointing toward LSMO is unstable, and therefore are unswitchable. Analysis reveals that, in addition to the work function mismatch, the difference in screening lengths and the intrinsic layer-by-layer polar nature of LSMO play a significant role in this instability. We will also present an analysis of these effects on the tunneling barrier profile as well as on the TER effect.

**1:27PM B30.00010 Ferroelectric switching in epitaxial PbZr<sub>0.2</sub>Ti<sub>0.8</sub>O<sub>3</sub>/ZnO/GaN heterostructures**, JUAN WANG, PAVEL SALEV, ALEXEI GRIGORIEV, The University of Tulsa — As a wide-bandgap semiconductor, ZnO has gained substantial interest due to its favorable properties including high electron mobility, strong room-temperature luminescence, etc. The main obstacle of its application is the lack of reproducible and low-resistivity p-type ZnO. P-type doping of ZnO through the interface charge injection, which can be achieved by the polarization switching of ferroelectric films, is a tempting solution. We explored ferroelectric switching behavior of PbZr<sub>0.2</sub>Ti<sub>0.8</sub>O<sub>3</sub>/ZnO/GaN heterostructures epitaxially grown on Sapphire substrates by RF sputtering. The electrical measurements of Pt/PbZr<sub>0.2</sub>Ti<sub>0.8</sub>O<sub>3</sub>/ZnO/GaN ferroelectric-semiconductor capacitors revealed unusual behavior that is a combination of polarization switching and a diode I-V characteristics.

**1:39PM B30.00011 Room-temperature Ferroelectricity in Uniaxially Strained Single-crystalline SrTiO<sub>3</sub> Freestanding Films**, DI LU, GLAM, Dept. of Phys., Stanford Univ., SAM CROSSLEY, HYEOK YOON, GLAM, Dept. of Appl. Phys., Stanford Univ., YASUYUKI HIKITA, SIMES, SLAC, HAROLD HWANG, GLAM, Dept. of Appl. Phys., Stanford Univ.; SIMES, SLAC — Single crystal pure bulk SrTiO<sub>3</sub> (STO) is an incipient ferroelectric whose dielectric permittivity rises to high values as temperature is reduced, but remains paraelectric to the lowest observable temperatures. Ferroelectric phases of STO may be stabilized via doping and strain, whose common effect is to split the spatial free energy well of ionic displacements. With epitaxial strain of the order of a few percent, Curie temperatures  $T_C \sim 293$  K have been observed. By exploiting a highly novel process to exfoliate epitaxial oxide films deposited by pulsed laser deposition, we have isolated sub-100 nm-thick freestanding films of STO which are readily manipulated and mechanically strained to high levels. Measurements of the in-plane dielectric properties for various applied strains reveal a continuously tunable ferroelectric  $T_C$ . A two-order-of-magnitude enhanced dielectric response is displayed by a 1.2%-strained sample at  $T_C \sim 290$  K, as compared with the same sample unstrained at the same temperature. This is consistent with a phenomenological Ginzburg-Landau model, and previous studies on anchored films. The functional properties of strained STO have generated intense interest and debate, and have been suggested for device applications due to e.g. high voltage-tunable dielectric properties. Our work exhibits strain as a continuously variable experimental degree of freedom, which can induce numerous functional effects.

**1:51PM B30.00012 Manipulation of Carrier Density near Ferroelectric/Semiconductor Interfaces**, MEHMET KESIM, University of Connecticut, I. BURC MISIRLIOGLU, Sabanci University, JOSEPH MANTESE, United Technologies Research Center, S. PAMIR ALPAY, University of Connecticut — Switchable polarization of a ferroelectric (FE) opens up the opportunity to control the charge density and transport characteristics at the FE/metal and FE/semiconductor (SC) heterointerfaces. Carrier manipulation near such regions can be used in high density non-volatile memories, switchable diodes, and photovoltaic devices. FEs can be utilized as gate oxides in a metal oxide field-effect transistor configuration for non-volatile memory applications with lower gate voltages compared to that of transistors with linear dielectrics. The channel conductance can be modulated reversibly, for instance, by tuning the magnitude and spatial distribution of polarization in the FE. In this study, we show that FE heterostructures can be used to manipulate the conductivity of a FE/SC interface. We employ a non-linear thermodynamic model based on Landau-Ginzburg-Devonshire (LGD) theory to obtain the equilibrium polarization of heterostructures. The carriers along the heterostructures are mapped through coupling the LGD equation with the Maxwell equations and Fermi – Dirac distribution of charged carriers/ionized dopants in the FE and SC. We consider various configurations including FE/SC/paraelectric and FE/SC/FE stacks to investigate the carrier distribution and band bending near such interfaces. The resulting properties are explained through the phase transition characteristics and domain structure of the stacks.

### 11:15AM B31.00001 Self-Interaction Corrected Density Functional Approximations with Unitary Invariance: Applications to Molecules

, MARK PEDERSON, Department of Chemistry, Johns Hopkins University — For a system of  $2N$  electrons, the Fermi-hole may be interpreted as the square of a normalized "Fermi orbital",  $F(\mathbf{a}) \equiv \rho_{\sigma}(\mathbf{a}, \mathbf{r}) / \sqrt{\rho_{\sigma}(\mathbf{a})}$ . This normalized orbital captures all of the spin density at its position of definition, or descriptor,  $(\mathbf{a})$ . Given a set of  $N$  quasi-classical electronic positions  $(\mathbf{a}_i)$  and a spin density-matrix composed of  $N$  Kohn-Sham orbitals, the resulting set of Fermi orbitals may then be used to construct a set of localized Loewdin-orthonormalized orbitals[1]. These orbitals are explicitly a functional of the spin density and are related to the Kohn-Sham orbitals by a unitary transformation that is parametrically dependent on the set quasi-classical electronic descriptors. The construction of such localized orbitals allows for the restoration of unitary invariance into the original Perdew-Zunger self-interaction correction[2,3] and provides a possible simplification compared to the localization-equation based solution of self-interaction corrected functionals[4]. This talk will discuss the construction of this Fermi-orbital-based self-interaction corrected method and the minimization algorithm that relies upon analytical derivatives[3] of the self-interaction energy with respect to the Fermi-orbital descriptors. Recent applications to a large set of molecules including aromatic molecules, molecules with open transition-metal centers, and molecules with frustrated Kekule' structures will be discussed. Initial applications indicate improvements in atomization energies of pi-bonded systems and demonstrate the desired downward shift of orbital energies relative to their Kohn-Sham counterparts. [1]W.L.Luken and D.N. Beratan, *Theo. Chim. Acta* **61**, 265-281 (1982). [2]M.R. Pederson, A. Ruzsinszky and J. P. Perdew, *J. Chem. Phys.* **140**, 121103 (2014). [3]M.R. Pederson and T. Baruah, *Advance in Atomic, Molecular and Optical Physics* **64**, 153-180 (2015). [4]M. R. Pederson, R. A. Heaton, and C. C. Lin, *J. Chem. Phys.* **80**, 1972 (1984).

### 11:51AM B31.00002 Fermi-orbitals for improved electronic structure calculations on coordination complexes.<sup>1</sup>

, DER-YOU KAO, Department of Mechanical and Aerospace Engineering, The George Washington University, MARK R. PEDERSON, Department of Chemistry, Johns Hopkins University, JAMES D. LEE, Department of Mechanical and Aerospace Engineering, The George Washington University — An improved density-functional formalism[1,2] proceeds by adopting the Perdew-Zunger expression for a self-interaction-corrected (SIC) density-functional energy but evaluates the total energy based on Fermi Orbitals (FOs). Each localized electron is represented by an FO, determined from the occupied Kohn-Sham orbitals and a semi-classical FO descriptor. The SIC energy is then minimized through the gradients of the energy with respect to these descriptors. In addition to providing a review of the methodology, work here identifies the need for an algorithm which thoroughly searches over initial configurations. The strategy for sampling and prioritizing initial configurations is described. Applications on coordination complexes are presented. The FO descriptors and FOs for semi-classical and quantum-mechanical understanding of bonding is discussed. Cohesive energies are improved and the eigenvalues are shifted downward relative to the standard DFT results. Spin-dependent vibrational spectra, as a possible means for spectroscopic determination of the transition-metal moment, are also presented. [1]Pederson et al, *JCP*, **140**, 121103 (2014). [2]Baruah & Pederson, *AAMOPS*, **64**, 153-180 (2015).

### 12:03PM B31.00003 Fermi orbital self-interaction corrected electronic structure of molecules beyond local density approximation<sup>1</sup>

, TORSTEN HAHN, SIMON LIEBING, JENS KORTUS, Institute for Theoretical Physics, TU Freiberg, Germany, MARK PEDERSON, Department of Chemistry, Johns Hopkins University, Baltimore, Maryland 21218, USA — The correction of the self-interaction error that is inherent to all standard density functional theory (DFT) calculations is an object of increasing interest. We present our results on the application of the recently developed Fermi-orbital based approach for the self-interaction correction (FO-SIC) to a set of different molecular systems [1,2]. Our study covers systems ranging from simple diatomic to large organic molecules. Our focus lies on the direct estimation of the ionization potential from orbital eigenvalues and on the ordering of electronic levels in metal-organic molecules. Further, we show that the Fermi orbital positions in structurally similar molecules appear to be transferable. [1] M. R. Pederson, A. Ruzsinszky, and J. P. Perdew, *J. Chem. Phys.* **140**, 121103 (2014). [2] M. R. Pederson, *J. Chem. Phys.* **142**, 064112 (2015).

### 12:15PM B31.00004 Magnetic Exchange Couplings in Transition Metal Complexes from DFT<sup>1</sup>

, JUAN PERALTA, Dept of Physics and Sci of Adv. Mat. Program, Central Michigan Univ — In this talk I will review our current efforts for the evaluation of magnetic exchange couplings in transition metal complexes from density functional theory. I will focus on the performance of different DFT approximations, including a variety of hybrid density functionals, and show that hybrid density functionals containing approximately 30% Hartree-Fock type exchange are in general among the best choice in terms of accuracy. I will also describe a novel computational method to evaluate exchange coupling parameters using analytic self-consistent linear response theory. This method avoids the explicit evaluation of energy differences, which can become impractical for large systems. Our approach is based on the evaluation of the transversal magnetic torque between two magnetic centers for a given spin configuration using explicit constraints of the local magnetization direction *via* Lagrange multipliers. This method is applicable in combination with any modern density functional with a noncollinear spin generalization and can be utilized as a "black-box". I will show proof-of-concept calculations in frustrated  $\text{Fe}_7^{\text{III}}$  disk-shaped clusters, and dinuclear  $\text{Cu}^{\text{II}}$ ,  $\text{Fe}^{\text{III}}$ , and heteronuclear complexes.

<sup>1</sup>NSF DMR-1206920

### 12:27PM B31.00005 Local spin analyses using density functional theory

, BAYILEYEGN ABATE, JUAN PERALTA, Central Michigan University — Local spin analysis is a valuable technique in computational investigations magnetic interactions on mono- and polynuclear transition metal complexes, which play vital roles in catalysis, molecular magnetism, artificial photosynthesis, and several other commercially important materials. The relative size and complex electronic structure of transition metal complexes often prohibits the use of multi-determinant approaches, and hence, practical calculations are often limited to single-determinant methods. Density functional theory (DFT) has become one of the most successful and widely used computational tools for the electronic structure study of complex chemical systems; transition metal complexes in particular. Within the DFT formalism, a more flexible and complete theoretical modeling of transition metal complexes can be achieved by considering noncollinear spins, in which the spin density is 'allowed to' adopt noncollinear structures in stead of being constrained to align parallel/antiparallel to a universal axis of magnetization. In this meeting, I will present local spin analyses results obtained using different DFT functionals. Local projection operators are used to decompose the expectation value  $\langle S^2 \rangle$  of the total spin operator; first introduced by Clark and Davidson.

### 12:39PM B31.00006 The Lieb-Oxford bound and the exchange-correlation kernel from the strictly-correlated electrons functional<sup>1</sup>

, PAOLA GORI-GIORGI, VU University Amsterdam — I will present some recent results based on the strictly-correlated electrons (SCE) functional: 1) a rigorous method to set lower bounds to the optimal particle-number dependent constant appearing in the Lieb-Oxford bound, and 2) an investigation of exact properties in the time domain, including an analytical expression for the kernel in one-dimension, with an analysis of its behavior for the case of bond-breaking excitations.

<sup>1</sup>ERC Consolidator Grant 648932

**1:15PM B31.00007 Exchange-correlation functionals from a local interpolation along the adiabatic connection**, STEFAN VUCKOVIC, VU University Amsterdam, TOM IRONS, ANDREW TEALE, Nottingham University, ANDREAS SAVIN, UPMC Paris, PAOLA GORI-GIORGI, VU University Amsterdam — We use the adiabatic connection formalism to construct a density functional by doing an interpolation between the weak and the strong coupling regime. Combining the information from the two limits, we are able to construct an exchange-correlation (xc) density functional free of the bias towards weakly correlated system, which is present in the majority of approximate xc functionals. Previous attempts in doing the interpolation between the two regimes, such as the interaction strength interpolation (ISI), had a fundamental flaw: the lack of size-consistency, as the corresponding functional depends non-linearly on the global (integrated over all space) ingredients. To recover size-consistency in such a framework, we move from the global to local quantities. We use the energy densities as local quantities in the gauge of the electrostatic potential of the xc hole. We use the “strictly-correlated electrons” (SCE) approach to compute the energy densities in the strong-coupling limit and the Lieb maximization algorithm to extract the energy densities from the low-coupling regime. We then test the accuracy of the local interpolation schemes by using the nearly exact local energy densities. In this talk I am going to present our results with the emphasis on strongly correlated systems.

**1:27PM B31.00008 The exact density functional for two electrons in one dimension**, ARON COHEN, University of Cambridge, PAULA MORI-SANCHEZ, Universidad Autonoma de Madrid — The exact universal density functional  $F[\rho]$  is calculated for real space two-electron densities in one dimension  $\rho(x)$  with a soft-Coulomb interaction. It is calculated by the Levy constrained search  $F[\rho] = \min_{\Psi \rightarrow \rho} \langle \Psi | \hat{T} + \hat{V}_{ee} | \Psi \rangle$  over wavefunctions of a two-dimensional Hilbert space  $\Psi(x_1, x_2) \rightarrow \rho(x_1)$  and can be directly visualized. We do an approximate constrained search via density matrices and a direct approximation to natural orbitals. This allows us to make an accurate approximation to the exact functional that is calculated using a search over potentials. We investigate the exact functional and the performance of many approximations on some of the most challenging electronic structure in two-electron systems, from strongly-correlated electron transfer to the description of a localized-delocalized transition. The exact Kohn-Sham potential,  $v_s(x)$ , and exact Kohn-Sham eigenvalues,  $\epsilon_i$ , are calculated and this allows us to discuss the band-gap problem versus the perspective of the exact density functional  $F[\rho]$  for all numbers of electrons. We calculate the derivative discontinuity of the exact functional in an example of a Mott-Insulator, one-dimensional stretched  $H_2$ .

**1:39PM B31.00009 Landscape of the exact energy functional for a simplified universe**, PAULA MORI-SANCHEZ, Universidad Autonoma de Madrid, ARON COHEN, University of Cambridge — One of the great challenges of electronic structure theory is the quest for the exact functional of density functional theory (DFT). Its existence is proven, but it is a complicated multivariable functional that is almost impossible to conceptualize. In this talk we study the asymmetric two-site Hubbard model because it has only a two-dimensional universe of density matrices, hence the exact functional becomes a simple function of two variables whose three dimensional energy landscape can be visualized and explored. A walk on this unique landscape, tilted to an angle defined by the one-electron Hamiltonian, gives a valley whose minimum is the exact total energy. This is contrasted with the landscape of some approximate functionals, explaining their failure for electron transfer in the strongly correlated limit. We show concrete examples of pure-state density matrices that are not  $v$ -representable due to the underlying non-convex nature of the energy landscape. The exact functional is calculated for all numbers of electrons, including fractional, allowing the derivative discontinuity to be visualized and understood. The fundamental gap for all possible systems is obtained solely from the derivatives of the exact functional.

**1:51PM B31.00010 Spontaneous charge carrier localization in extended one-dimensional systems**, VOJTĚCH VLČEK<sup>1</sup>, HELEN EISENBERG, Hebrew University of Jerusalem, Israel, GERD STEINLE-NEUMANN, Bayerisches Geoinstitut, Universität Bayreuth, Germany, ROI BAER, Hebrew University of Jerusalem, Israel — Charge carrier localization in extended atomic systems can be driven by disorder, point defects or distortions of the ionic lattice. Herein we give first-principles theoretical computational evidence that it can also appear as a purely electronic effect in otherwise perfectly ordered periodic structures and we show that electronic eigenstates can spontaneously localize upon excitation. Optimally-tuned range separated density functional calculations reveal that in trans-polyacetylene and polythiophene the hole density localizes on a length scale of several nanometers. This is due to exchange induced translational symmetry breaking of the charge density. Ionization potentials, optical absorption peaks, excitonic binding energies and the optimally-tuned range parameter itself all become independent of polymer length when it exceeds the critical localization length scale. These first-principles findings show, for the first time, that charge localization is not caused by lattice distortion but rather it is their cause, changing the physical models of polaron formation and dynamics, helping to explain experimental findings that polarons in conjugated polymers form instantaneously after exposure to ultrafast light pulses.

**2:03PM B31.00011 Self-consistent calculation of Hubbard U parameters within linear-scaling DFT**, GLENN MOYNIHAN, School of Physics, CRANN and AMBER, Trinity College Dublin, GILBERTO TEOBALDI, Stephenson Institute, University of Liverpool, DAVID D. O'REGAN, School of Physics, CRANN and AMBER, Trinity College Dublin — DFT+U has proven to be a computationally efficient method for correcting for the underestimation of electron localization effects, or for the absent derivative discontinuity, inherent in conventional density functionals. Invoking an approximate interpretation of DFT+U as a corrective penalty functional for the spurious curvature of the total-energy with respect to subspace occupancy, the Hubbard U parameter may be calculated [1,2], in which case DFT+U may be considered to be fully first-principles approach. We describe our approach for computing the Hubbard U and Hund's J parameters within ONETEP, a linear-scaling DFT code which comprises a complete DFT+U+J [3] implementation including ionic forces and a flexible choice of population analyses [4,5]. We discuss issues of charge preservation and self-consistency, and we demonstrate the capability of our method by means of numerical tests on the ground-state properties of selected molecules that present challenges for approximate DFT. **11:51AM B32.00002 First-principles determination of the structural, vibrational, and thermodynamic properties of Methylammonium Lead Iodide Perovskite**, WISSAM SAIDI, University of Pittsburgh, WISSAM SAIDI TEAM — Intrinsic energy-loss processes in solar cells ultimately increase the operational temperature, which can have profound effect on the power conversion efficiency of solar cells. Here I report investigations on the temperature effects on structural and mechanical properties of  $CH_3NH_3PbI_3$  using well-converged first-principles calculations with van der Waals dispersion corrections. The computed lattice parameters for cubic and tetragonal phases at finite temperature are found within 1% of experimentally measured values. Furthermore, the finite-temperature potential energy surface shows how the mechanical properties of the cubic and tetragonal phases of  $CH_3NH_3PbI_3$  evolve with temperature. Finally, I discuss the implications of these calculations on the nature of the tetragonal-to-cubic phase transition, and show that the underpinnings of this transition can be largely attributed to the phonons associated with methylammonium cations.

**12:03PM B32.00003 Rashba Spin-Orbit Coupling Enhanced Carrier Lifetime in  $\text{CH}_3\text{NH}_3\text{PbI}_3$** <sup>1</sup>, FAN ZHENG, LIANG Z. TAN, University of Pennsylvania, SHI LIU, Carnegie Institution for Science, ANDREW M. RAPPE, University of Pennsylvania — Organometal halide perovskites are promising solar-cell materials for next-generation photovoltaic applications, in particular these materials have long carrier lifetime and diffusion length. Recently, the strong spin-orbit coupling of organometal halide perovskites have attracted the great attention, the consequences of the Rashba effect, driven by this strong spin-orbit coupling, on the photovoltaic properties of these materials are largely unexplored. In this work, taking the electronic structure of methylammonium lead iodide as an example, we propose an intrinsic mechanism for enhanced carrier lifetime in 3D Rashba materials. Based on first-principles calculations and a Rashba spin-orbit model, we demonstrate that the recombination rate is reduced due to the spin-forbidden transition. These results are important for understanding the fundamental physics of organometal halide perovskites and for optimizing and designing the materials with better performance. The proposed mechanism including spin degrees of freedom offers a new paradigm of using 3D Rashba materials for photovoltaic applications.

**12:15PM B32.00004 Rotational Dynamics of Organic Cations in  $\text{CH}_3\text{NH}_3\text{PbI}_3$  Perovskite**, TIANRAN CHEN, BENJAMIN FOLEY, Univ of Virginia, BAHAR IPEK, Univ of Delaware, MADHUSUDAN TYAGI, JOHN COPLEY, CRAIG BROWN, NCNR, JOSHUA CHOI, SEUNG-HUN LEE, Univ of Virginia — Methylammonium lead iodide ( $\text{CH}_3\text{NH}_3\text{PbI}_3$ ) based solar cells have shown impressive power conversion efficiencies of above 20%. However, the microscopic mechanism of the high photovoltaic performance is yet to be fully understood. Particularly, the dynamics of  $\text{CH}_3\text{NH}_3^+$  cations and their impact on relevant processes are still poorly understood. Using elastic and quasi-elastic neutron scattering techniques and group theoretical analysis, we studied rotational modes of the  $\text{CH}_3\text{NH}_3^+$  cation in  $\text{CH}_3\text{NH}_3\text{PbI}_3$ .<sup>[1]</sup> Our results show that, in the cubic and tetragonal phases, the  $\text{CH}_3\text{NH}_3^+$  ions exhibit four-fold rotational symmetry of the C-N axis ( $C_4$ ) along with three-fold rotation around the C-N axis ( $C_3$ ), while in orthorhombic phase only  $C_3$  rotation is present. Around room temperature, the characteristic relaxation time for the  $C_4$  rotation is found to be 5ps while for the  $C_3$  rotation is 1ps. The T-dependent rotational relaxation times were fitted with Arrhenius equations to obtain activation energies. Our data show a close correlation between the  $C_4$  rotational mode and the temperature dependent dielectric permittivity. Our findings on the rotational dynamics of  $\text{CH}_3\text{NH}_3^+$  and the associated dipole have important implications on understanding the low exciton binding energy and slow charge recombination rate in  $\text{CH}_3\text{NH}_3\text{PbI}_3$  which are directly relevant for the high solar cell performance. **12:27PM B32.00005 Imaging the long diffusion lengths of photo-generated carriers in mixed halide perovskite films**<sup>1</sup>, SHUHAO LIU, Department of Physics, Case Western Reserve University, LILI WANG, CLEMENS BURDA, Department of Chemistry, Case Western Reserve University, XUAN GAO, Department of Physics, Case Western Reserve University — Organometal halide perovskite has emerged as a promising photovoltaic material due to its low-cost synthesis process and outstanding performance. Though long diffusion length of photo-generated carriers plays a very important role in its success, a direct measurement of carrier diffusion lengths is still lacking. We fabricated highly crystalline  $\text{CH}_3\text{NH}_3\text{PbI}_{3-x}\text{Cl}_x$  thin film devices on  $\text{SiO}_2/\text{Si}$  substrate with either nickel or gold as contact electrodes and parylene as encapsulation layer. By performing spatially scanned photocurrent imaging measurement with a local illumination spot, we show that photo-generated carriers in the prepared perovskite have very long diffusion lengths, with hole diffusion length  $L_h = 22 \pm 7 \mu\text{m}$  and electron diffusion length  $L_e = 8 \pm 4 \mu\text{m}$ . Our work provides scanning photocurrent microscopy as a powerful tool to directly extract hole and electron diffusion lengths at the same time, and may be further used to elucidate the vastly different carrier diffusion lengths (on order of 100nm to 100 $\mu\text{m}$ ) in organometal halide perovskites prepared by different methods.

**12:39PM B32.00006 Characterizing structural overpotentials for bubble evolution on nanostructured semiconductor-electrocatalyst interfaces**, ROBERT H. CORIDAN, Department of Chemistry and Biochemistry, University of Arkansas — Nanostructured electrocatalysts can improve the kinetics of solar-driven photocatalysis at a semiconductor-liquid junction while minimizing the effect on the energetics of that junction. A relevant example is Pt-decorated Si electrodes for hydrogen evolution from water splitting. Nanostructuring can also impair the reaction kinetics by introducing mass transport overpotentials. For reactions that evolve gas, the active surface area can be blocked by bubbles on discrete catalytic sites, possibly halting the reaction entirely. Here, we explore these issues by measuring the high-frequency dynamics of bubbles evolved from nanostructured electrocatalysts at a semiconductor-electrolyte interface. Using transmission x-ray phase contrast microscopy, we can image gas-evolving reactions as a way to directly measure the effects of adhesion, catalyst structure, and buoyancy on the reaction kinetics. From these measurements, we develop a model for electrolytic bubble evolution and transport that considers coalescence on neighboring sites, surface interactions, and the non-equilibrium shape dynamics of bubbles. This model can be used to identify favorable catalyst motifs that promote bubble clearance and mitigate their influence on reaction kinetics for water splitting applications.

**12:51PM B32.00007 TBA**, GORDANA DUKOVIC, University of Colorado — No abstract available.

**1:27PM B32.00008 Highly stable bimetallic AuIr/TiO<sub>2</sub> catalyst: physical origin of the intrinsic stability against sintering.**, ERNESTO MARINERO, CHAN WAN HAN, School of Materials Engineering, Purdue University, PAULAMI MAJUNDAR, School of Chemical Engineering, Purdue University, ANTONIO AGUILAR-TAPIA, RODOLFO ZANELLA, CCADET, Universidad Nacional Autonoma de Mexico, JEFFREY GREELEY, School of Chemical Engineering, Purdue University, VOLKAN OTARLAN, School of Materials Engineering, Purdue University — It has been a long-lived research topic in the field of heterogeneous catalysis to find a way to stabilizing supported Au catalysts against sintering. Herein, we report highly stable AuIr bimetallic nanoparticles on TiO<sub>2</sub> synthesized by sequential deposition-precipitation. To understand the physical origin of the high stability AuIr/TiO<sub>2</sub> system, we have used scanning transmission electron microscopy (STEM), STEM-tomography and density functional theory (DFT) calculations. 3D structures of AuIr/TiO<sub>2</sub> obtained by STEM-tomography indicate that AuIr nanoparticles on TiO<sub>2</sub> have intrinsically lower free energy and less driving force for sintering than Au nanoparticles. DFT calculations on segregation behavior of AuIr slabs on TiO<sub>2</sub> showed that the presence of Ir near the TiO<sub>2</sub> surface increases the adhesion energy of the bimetallic slabs to the TiO<sub>2</sub> and the attractive interactions between Ir and TiO<sub>2</sub> lead to higher stability of the AuIr nanoparticles compared to Au nanoparticles.

**1:39PM B32.00009 Surface Proton Hopping and Coupling Pathway of Water Oxidation on Cobalt Oxide Catalyst.**, HIEU PHAM, Lawrence Berkeley National Laboratory, MU-JENG CHENG, University of California, Berkeley, HEINZ FREI, LIN-WANG WANG, Lawrence Berkeley National Laboratory — We propose an oxidation pathway of water splitting on cobalt oxide surface with clear thermodynamic and kinetic details. The density-functional theory studies suggest that the coupled proton-electron transfer is not necessarily sequential and implicit in every elementary step of this mechanistic cycle. Instead, the initial O-O bond could be formed by the landing of water molecule on the surface oxos, which is then followed by the dispatch of protons through the hopping manner and subsequent release of di-oxygen. Our theoretical investigations of intermediates and transition states indicate that all chemical conversions in this pathway, including the proton transfers, are possible with low activation barriers, in addition to their favorable thermodynamics. Our hypothesis is supported by recent experimental observations of surface superoxide that is stabilized by hydrogen bonding to adjacent hydroxyl group, as an intermediate on fast-kinetics catalytic site.

**1:51PM B32.00010 The Dye Sensitized Photoelectrosynthesis Cell (DSPEC) for Solar Water Splitting and CO<sub>2</sub> Reduction<sup>1</sup>** , THOMAS MEYER, LEILA ALIBABAEI, BENJAMIN SHERMAN, MATTHEW SHERIDAN, University of North Carolina at Chapel Hill, DENNIS ASHFORD, Eastman Chemical, ALEX LAPIDES, KYLE BRENNAMAN, ANIMESH NAYAK, SUBHANGI ROY, KYUNG-RYANG WEE, MELISSA GISH, JERRY MEYER, JOHN PAPANIKOLAS, University of North Carolina at Chapel Hill — The dye-sensitized photoelectrosynthesis cell (DSPEC) integrates molecular level light absorption and catalysis with the bandgap properties of stable oxide materials such as TiO<sub>2</sub> and NiO. Excitation of surface-bound chromophores leads to excited state formation and rapid electron or hole injection into the conduction or valence bands of n or p-type oxides. Addition of thin layers of TiO<sub>2</sub> or NiO on the surfaces of mesoscopic, nanoparticle films of semiconductor or transparent conducting oxides to give core/shell structures provides a basis for accumulating multiple redox equivalents at catalysts for water oxidation or CO<sub>2</sub> reduction.

**2:03PM B32.00011 The Interface Between Chemical and Oxide Materials in the DSPEC.<sup>1</sup>** , THOMAS MEYER, LEILA ALIBABAEI, BENJAMIN SHERMAN, MATTHEW SHERIDAN, University of North Carolina at Chapel Hill, DENNIS ASHFORD, Eastman Chemical, ALEX LAPIDES, KYLE BRENNAMAN, ANIMESH NAYAK, SUBHANGI ROY, University of North Carolina at Chapel Hill — Significant challenges exist for both chemical and oxide materials in the Dye Sensitized Photoelectrosynthesis Cell (DSPEC) for water oxidation or CO<sub>2</sub> reduction. They arise from light absorption, the energetics of electron or hole injection, the accumulation of multiple redox equivalents at catalysts for water oxidation or water/CO<sub>2</sub> reduction in competition with back electron transfer, and sustained, long term performance. These challenges are being met by the use of a variety of chromophores (metal complexes, organic dyes, porphyrins), broad application of nanoparticle mesoscopic oxide films, atomic layer deposition (ALD) to prepare core/shell and stabilizing overlayer structures, and recent advances in the molecular catalysis of water oxidation and CO<sub>2</sub> reduction.

## **Monday, March 14, 2016 11:15AM - 2:15PM – Session B33 DPOLY: Polymers in Batteries 336 - Brad Frieberg, NIST**

**11:15AM B33.00001 Correlating morphology to dc conductivity in polymerized ionic liquids<sup>1</sup>** , CIPRIAN IACOB, Department of Materials Science and Engineering, The Pennsylvania State University, University Park, PA 16802 USA, ATSUSHI MATSUMOTO, TADASHI INOUE, Department of Macromolecular Science, Osaka University, Toyonaka, Osaka 560-0043 Japan, JAMES RUNT, Department of Materials Science and Engineering, The Pennsylvania State University, University Park, PA 16802 USA — Polymerized ionic liquids (PILs) combine the attractive mechanical characteristics of polymers and unique physico-chemical properties of low molecular weight ionic liquids in the same material. PILs have shown remarkable advantages when employed in electrochemical devices such as dye-sensitized solar cells and lithium batteries, among others. Understanding their ionic transport mechanism is the key for designing highly conductive PILs. In the current study, the correlation between morphology and charge transport in two homologous series of PILs with systematic variation of the alkyl chain length and anions is investigated using broadband dielectric spectroscopy, rheology, differential scanning calorimetry and X-ray scattering. As the alkyl chain length increases, the backbone-to-backbone separation increases, and dc-conductivity consequently decreases. The cations dominate structural dynamics since they are attached to the polymer chains, while the anions are smaller and more mobile ionic species thereby controlling the ionic conductivity. Further interpretation of decoupling of dc conductivity from the segmental relaxation enabled the correlation between polymer morphology and dc conductivity.

**11:27AM B33.00002 Formation and growth of lithium metal dendrites through solid block copolymer membranes** , KATHERINE HARRY, UC Berkeley, KENNETH HIGA, Lawrence Berkeley National Laboratory, NITASH BALSARA, UC Berkeley — Dendrite growth from lithium metal in electrochemical systems is the primary problem that precludes the wide use of lithium metal as an anode material. While polystyrene-block-poly(ethylene oxide) copolymer electrolytes extend cell life by suppressing dendrite growth, dendrites eventually do grow and the batteries fail by a short-circuit. *In situ* hard X-ray microtomography experiments coupled with stress simulations shed light on the formation and growth of dendritic structures through stiff solid polymer electrolyte membranes.

**11:39AM B33.00003 All Solid-State Lithium Metal Batteries Using Cross-linked Polymer Electrolytes** , QIWEI PAN, CHRISTOPHER LI, Drexel University, SOFT MATERIALS TEAM — Nowadays, to prepare all solid-state lithium metal batteries with high rate capability and stability using solid polymer electrolytes (SPEs) is still a grand challenge because of the interfaces between the SPE and the electrodes. In this presentation, we report a series of hybrid SPEs with controlled network structures by using POSS as cross-linker. These hybrid network SPEs show promising ionic conductivity, mechanical properties, and lithium dendrite growth resistance. All solid-state LiFePO<sub>4</sub>/Li batteries were also prepared using these SPEs as the electrolytes to study the effect of conductivity and mechanical properties of the SPEs on the performance of the batteries. At 90 °C, the prepared cells show high rate capability and stability. Capacity up to 160 mAh/g can be obtained at a C/2 rate during the galvanostatic cycling. Capacity retention of the cells is higher than 80% after 250 cycles. Battery performance at 60 °C and decay mechanism of the batteries will also be discussed.

## 11:51AM B33.00004 NMR Investigations of Structure and Dynamics in Polymers for Energy Storage Applications<sup>1</sup>

, STEVEN GREENBAUM, Hunter College of the City University of New York — Materials innovation is needed to realize major progress in energy storage capacity for lithium batteries and capacitors. Polymers hold considerable promise as ion conducting media in batteries and electrochemical capacitors and as dielectrics in thin film capacitors. Structural studies of materials utilized in lithium battery technology are hampered by the lack of long-range order found in well-defined crystalline phases. Powder x-ray diffraction yields structural parameters that have been averaged over hundreds of lattice sites, and is unable to provide structural information about amorphous phases. Our laboratory uses solid state nuclear magnetic resonance (NMR) methods to investigate structural and chemical aspects of lithium ion cathodes, anodes, electrolytes, interfaces and interphases. NMR is element- (nuclear-) specific and sensitive to small variations in the immediate environment of the ions being probed, for example  $\text{Li}^+$ , and in most cases is a reliably quantitative spectroscopy in that the integrated intensity of a particular spectral component is directly proportional to the number of nuclei in the corresponding material phase. NMR is also a powerful tool for probing ionic and molecular motion in lithium battery electrolytes with a dynamic range spanning some ten orders of magnitude through spin-lattice relaxation and self-diffusion measurements. Broadband relaxometry based on Fast Field Cycling NMR (FFCNMR) methods can span three to four of these orders of magnitude in a single set of measurements. Results of several recent NMR investigations performed on our lab will be presented. We explore the ion transport mechanism in polyether-based and lithium polymer electrolytes and those based on other base polymers, in particular, the extent to which ionic motion is coupled to polymer segmental motion. Polycarbonates are being considered as a possible replacement for polypropylene in high power thin film capacitors due to their favorable dielectric properties. We investigate the effects of incorporation of two types of additives in the polymer film on the ring-flip motions corresponding to the  $\gamma$  relaxation: (i) high dielectric constant ceramic particles; (ii) polar organic diluent molecules. The low frequency realm of broadband relaxometry allows meaningful comparison with dielectric relaxation studies of these samples performed by collaborators.

<sup>1</sup>Work Supported in part by the U.S. Office of Naval Research

## 12:27PM B33.00005 Li conductivity in siloxane-based polymer electrolytes

, ERIC STACY, Department of Physics and Astronomy, University of Tennessee, Knoxville, Tennessee 37996, United States, FEI FAN, HONGBO FENG, CATALIN GAINARU, JIMMY MAYS<sup>1</sup>, ALEXEI SOKOLOV<sup>2</sup>, Department of Chemistry, University of Tennessee, Knoxville, Tennessee 37996, United States — Polymer electrolytes containing lithium ions are ideal candidates for electrochemical devices and energy storage applications. Understanding their ionic transport mechanism is the key for rational designing of highly conductive polymer matrices. Complementing dielectric spectroscopy investigations by results from rheology and differential scanning calorimetry we focused on the interplay between dynamics of lithium ions and the polymer matrix based on polysiloxane backbone. Our results demonstrate that the conductivity and the degree of decoupling between ion dynamics and structural relaxation depend strongly not only on the ions concentration, but also on the polarity and size of the polymeric side-groups.

<sup>2</sup>Chemical Science Division, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, United States

## 12:39PM B33.00006 Systematic Experimental and Computational Investigation of Ion Transport in Novel Polyether Electrolytes

, DANIELLE PESKO, University of California, Berkeley, MICHAEL WEBB, California Institute of Technology, YUKYUNG JUNG, QI ZHENG, Cornell University, THOMAS MILLER III, California Institute of Technology, GEOFFREY COATES, Cornell University, NITASH BALSARA, University of California, Berkeley — Polyethers, such as poly(ethylene oxide) (PEO), are considered to be the most promising polymer electrolyte materials due to their high ionic conductivity and electrochemical stability, both essential for battery applications. To gain a fundamental understanding of the transport properties of polyether systems, we design a systematic set of linear PEO-like polymers to explore the effect of adding carbon spacers to the backbone of the chain. Ac impedance spectroscopy is employed to measure the ionic conductivity of polyether/lithium salt electrolytes; the results elucidate tradeoffs between lowering the glass transition temperature and diluting the polar groups on the polymer chain. Molecular-level insight is provided by molecular dynamics simulations of the polyether electrolytes. We define the useful and intuitive metric of “connectivity”, a parameter calculated from simulations which describes the physical arrangements of solvation sites in a polymer melt. Direct comparison of experiment and theory allows us to determine the relationship between connectivity and conductivity. The comparison provides insight regarding the factors that control conductivity, and highlights considerations that must be taken when designing new ion-conducting polymers.

## 12:51PM B33.00007 Highly Flexible Self-Assembled $\text{V}_2\text{O}_5$ Cathodes Enabled by Conducting Diblock Copolymers

, HYOSUNG AN, JARED MIKE, Texas AM University, KENDALL SMITH, LISA SWANK, YEN-HAO LIN, STACY PESEK, RAFAEL VERDUZCO, Rice University, JODIE LUTKENHAUS, Texas AM University — Structural energy storage materials combining load-bearing mechanical properties and high energy storage performance are desired for applications in wearable devices or flexible displays. Vanadium pentoxide ( $\text{V}_2\text{O}_5$ ) is a promising cathode material for possible use in flexible battery electrodes, but it remains limited by low  $\text{Li}^+$  diffusion coefficient and electronic conductivity, severe volumetric changes upon cycling, and limited mechanical flexibility. Here, we demonstrate a route to address these challenges by blending a diblock copolymer bearing electron- and ion-conducting blocks, poly(3-hexylthiophene)-*block*-poly(ethyleneoxide) (P3HT-*b*-PEO), with  $\text{V}_2\text{O}_5$  to form a mechanically flexible, electro-mechanically stable hybrid electrode.  $\text{V}_2\text{O}_5$  layers were arranged parallel in brick-and-mortar-like fashion held together by the P3HT-*b*-PEO binder. This unique structure significantly enhances mechanical flexibility, toughness and cyclability without sacrificing capacity. Electrodes comprised of 10 wt% polymer have unusually high toughness ( $293 \text{ kJ/m}^3$ ) and specific energy ( $530 \text{ Wh/kg}$ ), both higher than reduced graphene oxide paper electrodes.

## 1:03PM B33.00008 Effects of plasticization on ionic conductivity enhancement of crosslinked polymer electrolyte membrane

, RUIXUAN HE, THEIN KYU, University of Akron, DR. KYU'S TEAM — Glass transition temperatures ( $T_g$ ) of solid polymer electrolyte membranes (PEM), comprised of polyethylene glycol diacrylate (PEGDA) prepolymer, lithium bis(trifluoromethanesulfonyl) imide (LiTFSI) salt, and succinonitrile (SCN) plasticizer, were systematically examined before and after crosslinking in the isotropic region guided by their ternary phase diagram. With increasing LiTFSI concentration, the  $T_g$  of uncured binary PEGDA/LiTFSI mixture increases drastically due to molecular complexation between lithium cation and ether oxygen, but ionic conductivity is very low ( $<10^{-6} \text{ S cm}^{-1}$ ). Upon curing, this  $T_g$  increases and further reduces ionic conductivity. Upon adding SCN plasticizer, the  $T_g$  of PEM has significantly decreased to  $-60^\circ\text{C}$  and ionic conductivity also increased to the superionic conductor level of  $10^{-3} \text{ S cm}^{-1}$ . The analysis of ionic conductivity vs.  $T_g$  behavior by Vogel-Tamman-Fulcher(VTF) equation revealed that this ionic conductivity enhancement is due to SCN plasticization resulting in lowering the network  $T_g$  as well as lowering the activation energy. Supported by NSF-DMR 1161070.

## 1:15PM B33.00009 Atomistic Simulations of Ternary Polymer Electrolytes Containing Ionic Liquids: Ion Transport and Viscoelastic Behavior

, SANTOSH MOGURAMPELLY, VENKAT GANESAN, Univ of Texas, Austin — Influence of the BMIMPF<sub>6</sub> ionic liquid on ion transport and viscoelastic properties of ternary polymer electrolytes containing polyethylene oxide solvated with LiPF<sub>6</sub> salt and the underlying mechanisms are investigated. By employing atomistic molecular dynamics and trajectory extended kinetic Monte Carlo simulation techniques, we observe enhanced ionic mobilities and conductivities of the PEO/LiPF<sub>6</sub>-BMIMPF<sub>6</sub> ternary electrolytes upon the addition ionic liquid into the PEO/LiPF<sub>6</sub> binary electrolyte. The dispersion of the BMIMPF<sub>6</sub> ionic liquid into the PEO/LiPF<sub>6</sub> electrolyte is found to (a) promote dissociation of existing LiPF<sub>6</sub> ion-pairs and (b) slightly accelerate the polymer segmental dynamics. Together, these effects are observed to collectively give rise to an increase in ionic mobilities and conductivities of the ternary polymer electrolyte. On the other hand, Rouse analysis reveals that the storage and loss modulus of the ternary polymer electrolytes are coupled to their ion conducting properties.

**1:27PM B33.00010 Effects of cation and anion solvation on ion transport in functionalized perfluoropolyethers electrolytes**, KSENIA TIMACHOVA, MAHATI CHINTAPALLI, Univ of California - Berkeley, KEVIN OLSEN, JOSEPH DESIMONE, University of North Carolina - Chapel Hill, NITASH BALSARA, Univ of California - Berkeley — Advances in polymer electrolytes for use in lithium batteries have been limited by the incorporation of selective lithium binding groups that provide necessary solvation for the lithium but ultimately restrict the mobility of the lithium ions relative to anions. Perfluoropolyether electrolytes (PFPE) are a new class of nonflammable liquid polymer electrolytes that have been functionalized with solvating groups for both lithium ions and fluorinated anions. PFPEs with different endgroups mixed with  $\text{LiN}(\text{SO}_2\text{CF}_3)_2$  salt have shown substantial differences in conductivity and allows us to investigate the effects of varying solvating environments on ion transport. To study the independent motion of cations and anions in these systems, the individual diffusion coefficients of the  $\text{Li}^+$  and  $(\text{SO}_2\text{CF}_3)_2^-$  ions were measured using pulsed-field gradient nuclear magnetic resonance (PFG-NMR). Comparing conductivity calculated using these diffusion coefficients with electrochemical measurements yields an estimation for the number of charge carrier in the system. The amount of salt dissociation, not the mobility of the salt, is the primary driver of differences in electrochemical conductivities between PFPEs with different solvating groups.

**1:39PM B33.00011 Aggregate-mediated charge transport in ionomeric electrolytes**, KERAN LU, JANNA MARANAS, SCOTT MILNER, Pennsylvania State University — Polymers such PEO can conduct ions, and have been studied as possible replacements for organic liquid electrolytes in rechargeable metal-ion batteries. More generally, fast room-temperature ionic conduction has been reported for a variety of materials, from liquids to crystalline solids. Unfortunately, polymer electrolytes generally have limited conductivity; these polymers are too viscous to have fast ion diffusion like liquids, and too unstructured to promote cooperative transport like crystalline solids. Ionomers are polymer electrolytes in which ionic groups are covalently bound to the polymer backbone, neutralized by free counterions. These materials also conduct ions, and can exhibit strong ionic aggregation. Using coarse-grained molecular dynamics, we explore the forces driving ionic aggregation, and describe the role ion aggregates have in mediating charge transport. The aggregates are string-like such that ions typically have two neighbors. We find ion aggregates self-assemble like worm-like micelles. Excess charge, or free ions, occasionally coordinate with aggregates and are transported along the chain in a Grotthuss-like mechanism. We propose that controlling ionomer aggregate structure through materials design can enhance cooperative ion transport.

**1:51PM B33.00012 Versatile cation transport in imidazolium based polymerized ionic liquids**, CHRISTOPHER EVANS, UCSB, RACHEL SEGALMAN, University of California, Santa Barbara — Polymerized ionic liquids (PIL) with tethered imidazolium groups are able to conduct a diverse array of cations relevant for energy applications. The well-known complexation of imidazolium with transition metals is exploited to bind ions such as  $\text{H}^+$ ,  $\text{Li}^+$ ,  $\text{Cu}^{2+}$ , and  $\text{Ni}^{2+}$  by doping the neutral PIL with the appropriate Cation-TFSI $^-$  salt. Conductivities were first determined via AC impedance indicating that  $\text{H}^+$  salts lead to the highest conductivity (due to low ion mass and potential Grotthuss mechanism) followed by  $\text{Cu}^{2+}$ ,  $\text{Li}^+$ ,  $\text{Ag}^+$ , and  $\text{Ni}^{2+}$ . The equilibrium constant for imidazolium complexation is larger for  $\text{Cu}^{2+}$  relative to  $\text{Li}^+$ ,  $\text{Ag}^+$ , and  $\text{Ni}^{2+}$  imidazolium complexes leading to greater salt dissociation and higher conductivities. For LiTFSI and CuTFSI $_2$  salts, metallic lithium or copper electrodes were employed in battery cells to pass a steady DC current and confirm that the cations are in fact carrying current. Interestingly, the divalent  $\text{Cu}^{2+}$  also ionically crosslinks the polymer leading to a plateau in the viscosity. Thus, divalent ions provide a unique route to high conductivity, high modulus polymeric electrolytes. Future studies involving ZnTFSI $_2$  and MgTFSI $_2$  for battery applications are proposed to examine how versatile the PIL platform is for cation transport.

**2:03PM B33.00013 Ion conduction in high ion content PEO-based ionomers.**, DAVID CALDWELL II, JANNA MARANAS, Pennsylvania State University — Solid Polymer Electrolytes (SPEs) can enable the design of batteries that are safer and have higher capacity than batteries with traditional volatile organic electrolytes. The current limitation for SPEs is their low conductivity, resulting from a conduction mechanism strongly coupled to the dynamics of the polymer host matrix. Our previous work indicated the possibility of a conduction mechanism through the use of ion aggregates. In order to investigate this mechanism, we performed a series of molecular dynamics simulations of PEO-based ionomers at high ion content. Our results indicate that conduction through ion aggregates are partially decoupled from polymer dynamics and could enable the development of higher conductive SPEs.

**Session B34 DPOLY DCOMP FIAP: Where Simulation, Theory, and Experiment Meet Across Length Scales I** 337 - Robert Riggelman, University of Pennsylvania

**11:15AM B34.00001 Theory of Chirality Transfer in Block Copolymer Melts**, ISHAN PRASAD, GREGORY GRASON, Univ of Mass - Amherst — Block copolymers assemble into a rich spectrum of ordered phases, with complexity driven by asymmetry in copolymer architecture. Despite decades of study, influence of intrinsic chirality on equilibrium mesophase assembly of block copolymers is not well understood and largely unexplored. Self-consistent field theory has been largely instrumental in prediction of physical properties of polymeric systems. Recently, a polar orientational self-consistent field (oSCF) theory was adopted to model chiral block copolymers having a thermodynamic preference for cholesteric ordering in chiral segments, and which confirmed the equilibrium stability of a helical cylinder morphology observed for chiral diblocks. Here, I describe a newly developed oSCF theory for chiral nematic copolymers, where segment orientations are characterized by quadrupolar interactions, and focus our study on intra-domain nematic ordering in flexible block copolymer assemblies, and in particular, mechanisms of transfer of segment chirality to mesochiral symmetries of self-assembled bicontinuous network morphologies.

**11:27AM B34.00002 Relationship of Structural and Stress Relaxation in Disordered Diblock Copolymer Melts**, TAHER GHASIMAKBARI, DAVID MORSE, University of Minnesota — We use molecular dynamics simulations to study the relationship between the relaxation of composition fluctuations and the relaxation of stress and birefringence in simple models of disordered block copolymer melts. Simulations of different simulation models of in corresponding thermodynamic states of unentangled melts are shown to exhibit equivalent dynamical behavior, thus confirming dynamic universality for unentangled systems. Structural relaxation is characterized by measuring the van Hove dynamic structure function  $S(q^*, t)$  at the critical wavenumber  $q^*$  at which the static structure function is maximum, and measuring how the associated relaxation time depends on distance from the order-disorder transition. The behavior of this quantity is compared to that of the dynamic viscoelastic modulus  $G(t)$ , which is obtained by computing autocorrelations of stress fluctuations. Relationship to relevant experiments is also briefly discussed.

**11:39AM B34.00003 Equilibrium and Kinetics of Block Copolymers Micelles**, JOSHUA MYSONA, DAVID MORSE, University of Minnesota — Both equilibrium properties of micelles, such as the critical micelle concentration (CMC), and dynamical properties such as the micelle lifetime are difficult to study in simulations because of the slow dynamics of the processes by which micelles are created and destroyed. We first discuss a method of precisely identifying the CMC in a simple model of block copolymer micelles in a homopolymer matrix, which makes use of thermodynamic integration to compute the free energy of formation. We then examine the free energy barriers to competing mechanisms for creating and destroying micelles, which could occur predominantly either by a step-wise process involving insertion and extraction of single molecules or by fission and fusion of entire micelles.

**11:51AM B34.00004 Connecting Molecular Dynamics Simulations and Fluids Density Functional Theory of Block Copolymers<sup>1</sup>**, LISA HALL, The Ohio State University — Increased understanding and precise control over the nanoscale structure and dynamics of microphase separated block copolymers would advance development of mechanically robust but conductive materials for battery electrolytes, among other applications. Both coarse-grained molecular dynamics (MD) simulations and fluids (classical) density functional theory (fDFT) can capture the microphase separation of block copolymers, using similar monomer-based chain models and including local packing effects. Equilibrium free energies of various microphases are readily accessible from fDFT, which allows us to efficiently determine the equilibrium nanostructure over a large parameter space. Meanwhile, MD allows us to visualize specific polymer conformations in 3D over time and to calculate dynamic properties. The fDFT density profiles are used to initialize the MD simulations; this ensures the MD proceeds in the appropriate microphase separated state rather than in a metastable structure (useful especially for nonlamellar structures). The simulations equilibrate more quickly than simulations initialized with a random state, which is significant especially for long chains. We apply these methods to study the interfacial behavior and microphase separated structure of diblock and tapered block copolymers. Tapered copolymers consist of pure A and B monomer blocks on the ends separated by a tapered region that smoothly varies from A to B (or from B to A for an inverse taper). Intuitively, tapering increases the segregation strength required for the material to microphase separate and increases the width of the interfacial region. Increasing normal taper length yields a lower domain spacing and increased polymer mobility, while larger inverse tapers correspond to even lower domain spacing but decreased mobility. Thus the changes in dynamics with tapering cannot be explained by mapping to a diblock system at an adjusted effective segregation strength.

**12:27PM B34.00005 Multi-fluid models of polymeric liquids**, DOUGLAS TREE, GLENN FREDRICKSON, Univ of California - Santa Barbara — Industrial processes for producing polymer-based materials often operate away from equilibrium, making the final microstructure – and thus the properties of the material – dependent on processing history. Current simulation methods struggle to accurately describe such processes. Traditional fluid dynamics is able to capture transport behavior, but lacks the complex phase behavior characteristic of many polymeric liquids. Coarse-grained particle models can handle the complexity, but are constrained by time and length scales. Consequently, we explore an alternative field-theoretic framework based on the “two-fluid” model originally proposed by Brochard and de Gennes. To demonstrate feasibility, we derive a model and develop an efficient numerical method for a ternary polymer solution. Subsequently, we use this model and method to examine the physics of the immersion precipitation process, used industrially to produce polymer membranes.

**12:39PM B34.00006 Using Self Consistent Field Theory on Polymeric Mixtures**, KIER VON KONIGSLOW, CHUL PARK, RUSSELL THOMPSON, University of Waterloo — The ability to predict the solubility of a particular solvent in a polymer fluid is essential to the production of polymer foams. For the past 40 years, the primary model employed to this end has been an expansion of Flory-Huggins lattice fluid theory developed by Sanchez and Lacombe (S-L theory). S-L theory, while useful in the uniform limit, is limited to homogeneous systems. Self-Consistent Field Theory (SCFT), which has long been in use in polymer physics, is a mean-field theory capable of modeling the equilibrium behaviour of both homogeneous and inhomogeneous systems. We are investigating whether SCFT, applied to polymer-solvent mixtures, is in agreement with SL-theory in the homogeneous limit. Should this prove successful, we hope to use SCFT to model more general mixtures, including inhomogeneous nanocellular polymer foam systems.

**12:51PM B34.00007 The Effects of Branching and Deuterium Labeling on Polymer Blend Miscibility<sup>1</sup>**, JEFFREY DEFELICE, Dartmouth College, JULIA HIGGINS, Imperial College, JANE LIPSON, Dartmouth College — Local structural or chemical changes made to one component of a polymer blend can have a significant impact on miscibility. In this talk we will focus on several blends involving linear and 4-arm star polystyrene (PS), both hydrogenous and deuterated, and poly(vinylmethylether) (PVME). We consider the effect of the structural change on the miscibility of PS/PVME, then turn to the added effect of deuterium labeling, both on this blend and for isotopic PS mixtures. Using our Locally Correlated Lattice (LCL) model we are able to identify trends in the physical properties of pure components, such as: free volume, thermal expansion coefficient, and cohesive energy density. We find that branching and labeling, both independently and cumulatively, affect pure component properties. Our ability to correlate structural and chemical changes with trends in physical properties leads to predictions about the compatibility of pure components, and thus their blend miscibility.

**1:03PM B34.00008 Monte Carlo field-theoretic simulations of a homopolymer blend<sup>1</sup>**, RUSSELL SPENCER, MARK MATSEN, University of Waterloo — Fluctuation corrections to the macrophase segregation transition (MST) in a symmetric homopolymer blend are examined using Monte Carlo field-theoretic simulations (MC-FTS). This technique involves treating interactions between unlike monomers using standard Monte-Carlo techniques, while enforcing incompressibility as is done in mean-field theory. When using MC-FTS, we need to account for a UV divergence. This is done by renormalizing the Flory-Huggins interaction parameter to incorporate the divergent part of the Hamiltonian. We compare different ways of calculating this effective interaction parameter. Near the MST, the length scale of compositional fluctuations becomes large, however, the high computational requirements of MC-FTS restrict us to small system sizes. We account for these finite size effects using the method of Binder cumulants, allowing us to locate the MST with high precision. We examine fluctuation corrections to the mean field MST,  $\chi N = 2$ , as they vary with the invariant degree of polymerization,  $\bar{N} = \rho^2 a^6 N$ . These results are compared with particle-based simulations as well as analytical calculations using the renormalized one loop theory.

**1:15PM B34.00009 Development of Simulation Methods in the Gibbs Ensemble to Predict Polymer-Solvent Phase Equilibria**, THOMAS GARTNER, University of Delaware, Dept. of Chemical and Biomolecular Engineering, THOMAS EPPS, ARTHI JAYARAMAN, University of Delaware, Dept. of Chemical and Biomolecular Engineering, Dept. of Materials Science and Engineering — Solvent vapor annealing (SVA) of polymer thin films is a promising method for post-deposition polymer film morphology control. The large number of important parameters relevant to SVA (polymer, solvent, and substrate chemistries, incoming film condition, annealing and solvent evaporation conditions) makes systematic experimental study of SVA a time-consuming endeavor, motivating the application of simulation and theory to the SVA system to provide both mechanistic insight and scans of this wide parameter space. However, to rigorously treat the phase equilibrium between polymer film and solvent vapor while still probing the dynamics of SVA, new simulation methods must be developed. In this presentation, we compare two methods to study polymer-solvent phase equilibrium—Gibbs Ensemble Molecular Dynamics (GEMD) and Hybrid Monte Carlo/Molecular Dynamics (Hybrid MC/MD). Liquid-vapor equilibrium results are presented for the Lennard Jones fluid and for coarse-grained polymer-solvent systems relevant to SVA. We found that the Hybrid MC/MD method is more stable and consistent than GEMD, but GEMD has significant advantages in computational efficiency. We propose that Hybrid MC/MD simulations be used for unfamiliar systems in certain choice conditions, followed by much faster GEMD simulations to map out the remainder of the phase window.

### **1:27PM B34.00010 Effect of Composition and Chain Length on $\chi$ Parameter of Polyolefin Blends: A Molecular Dynamics Study**, RAJESH KHARE, ASHWIN RAVICHANDRAN, CHAU-CHYUN CHEN, Texas Tech Univ —

Polymer blends exhibit complex phase behavior which is governed by several factors including temperature, composition and molecular weight of components. The thermodynamics of polymer blends is commonly described using the  $\chi$  parameter. While variety of experimental studies exist on identifying the factors affecting the  $\chi$  parameter, a detailed molecular scale understanding of these is a topic of current research. We have studied the effect of blend composition and chain length on  $\chi$  parameter values for two model polyolefin blends. The blends studied are: polyisobutylene (PIB)/polybutadiene (PBD) and polyethylene (PE)/atactic polypropylene (aPP). Molecular dynamics simulations in combination with the integral equation theory formalism proposed by Schweizer and Curro [Journal of Chemical Physics, 91, 5059 (1989)] are used to determine the  $\chi$  parameter for these systems and thereby study the effect of blend composition and chain length. The resulting  $\chi$  parameter values are explained in terms of the molecular structure of these polymeric systems.

**1:39PM B34.00011 Molecular Simulation of Olefin Oligomer Blend Phase Behavior**, QILE CHEN, TIMOTHY LODGE, ILJA SIEPMANN, University of Minnesota, MRSEC COLLABORATION — Material properties (e.g. toughness) of polyolefin mixtures are closely tied to their phase behavior that often cannot be accurately predicted by the widely used Flory-Huggins (FH) theory. In this work, configurational-bias Monte Carlo (CBMC) simulations in the Gibbs ensemble were used to compute the phase behavior of oligomeric olefins. The cohesive energy density of pure melts and the free energy of mixing were obtained from these simulations, and the discrepancy between the binary interaction  $\chi$  parameter from simulation and from the FH theory was quantified. Structural analysis and the calculated excess mixing properties provided some rationale into the interpretation of these results.

### **1:51PM B34.00012 A Semi-Empirical Multi-Scale Dynamic Monte Carlo Model of Organic Photovoltaic Performance in RIR-MAPLE Bulk Heterojunction Films**, ADRIENNE STIFF-ROBERTS, AYOMIDE ATEWOLOGUN, Duke University (RT-MRSEC) —

A semi-empirical method for investigating the performance of OPVs in resonant infrared, matrix-assisted pulsed laser evaporation (RIR-MAPLE) films is explored. Emulsion-based RIR-MAPLE offers a unique experimental backdrop for investigating trends through simulation and gaining a better understanding of how different thin film characteristics impact OPV device performance. A novel multi-scale formulation of the Dynamic Monte Carlo (DMC) model is developed based on observable morphology features. Specifically, using confocal microscopy, we observe the presence of micro-scale regimes of pure materials and nano-scale regions of the composite blend. This enables us to assign weighted percentages to DMC implementations on two different scales: the microscale and nanoscale regions. In addition to this, we use input simulation parameters acquired by characterization of as-deposited films. The semi-empirical multi-scale model presented serves as a unique simulation opportunity for exploring different properties of RIR-MAPLE deposited OPVs, their effects on OPV performance and potential design routes for improving device efficiencies. This work was supported, in part, by the Office of Naval Research under Grant N00014-10-1-0481 and the NSF Triangle MRSEC on Soft Matter.

### **11:15AM B35.00001 Liquid-like bundles of crosslinked actin filaments contract without motors**

, KIMBERLY WEIRICH, University of Chicago — The actin cytoskeleton is a dynamic, structural material that drives cellular-scale deformations during processes such as cell migration and division. Motor proteins are responsible for actively driving many deformations by buckling and translocating actin filaments. However, there is evidence that deformations, such as the constriction of the actin bundle that drives the separation of cells during division, can occur without motors, mediated instead by crosslinker proteins. How might crosslinkers, independent of motors, drive contraction of a bundle? Using a model system of purified proteins, we show that crosslinkers, analogous to molecular cohesion, create an effective surface tension that induces bundle contraction. Crosslinked short actin filaments form micron-sized spindle-shaped bundles. Similar to tactoid granules found at the isotropic-nematic phase transition in liquid crystals, these bundles coarsen and coalesce like liquid droplets. In contrast, crosslinked long filaments coarsen into a steady state of bundles that are frozen in a solid-like network. Near the liquid-solid boundary, filaments of intermediate length initially form bundles that spontaneously contract into tactoid droplets. Our results, that crosslinked actin bundles are liquid-like with an effective surface tension, provide evidence for a mechanism of motor-independent contractility in biological materials.

### **11:51AM B35.00002 F-actin Severing Facilitates Distinct Mechanisms of Stress Relaxation in the Actin Cytoskeleton<sup>1</sup>**, TAEYOON KIM, Weldon School of Biomedical Engineering, Purdue University, WONYEONG JUNG, School of Mechanical Engineering, Purdue University, MICHAEL MURRELL, Systems Biology Institute and Department of Biomedical Engineering —

Rheological behaviors of actin cytoskeleton play an important role in physiological processes including cell migration and division. The actin cytoskeleton shows a wide variety of viscoelastic responses to external mechanical cues, such as strain-stiffening and stress relaxation. It has been hypothesized that the stress relaxation originates mainly from transient nature of cross-linkers that connect pairs of F-actins. By contrast, potential impacts of rich F-actin dynamics to the stress relaxation have been neglected in most previous studies. Here, using a computational model, we demonstrated that severing of F-actins induced by buckling during strain-stiffening can facilitate a very distinct mode of stress relaxation in the actin cytoskeleton from that induced by the transient cross-linkers. We also explored conditions where the severing-induced stress relaxation becomes prominent. This finding provides a more complete understanding of rheological behaviors of the actin cytoskeleton.

### **12:03PM B35.00003 A cycling state that can lead to glassy dynamics in intracellular transport**

, MONIKA SCHOLZ, Univ of Chicago, STANISLAV BUROV, Bar-Ilan University, KIMBERLY L. WEIRICH, BJORN J. SCHOLZ, Univ of Chicago, S.M ALI TABELI, University of Northern Iowa Cedar Falls, MARGARET L. GARDEL, AARON DINNER, Univ of Chicago — Power-law dwell times have been observed for molecular motors in living cells, but the origins of these trapped states are not known. We introduce a minimal model of motors moving on a two-dimensional network of filaments, and simulations of its dynamics exhibit statistics comparable to those observed experimentally. Analysis of the model trajectories, as well as experimental particle tracking data, reveals a state in which motors cycle unproductively at junctions of three or more filaments. We formulate a master equation for these junction dynamics and show that the time required to escape from this vortex-like state can account for the power-law dwell times. We identify trends in the dynamics with the motor valency for further experimental validation. We demonstrate that these trends exist in individual trajectories of myosin II on an actin network. We discuss how cells could regulate intracellular transport and, in turn, biological function, by controlling their cytoskeletal network structures locally.

**12:15PM B35.00004 Stochastic Molecular Transport on Microtubule Bundles with Structural Defects**, M.W. GRAMLICH, Washington University School of Medicine in St. Louis, S.M. ALI TABEL, University of Northern Iowa — Intracellular transport involves complex coordination of multiple components such as: the cytoskeletal network and molecular motors. Perturbations in this process can amplify over time and space, thereby affecting transport. One little studied component of transport are structural defects in the cytoskeletal network. In this talk we will present a stochastic model of the interaction of the molecular motor, kinesin-1, and a bundled cytoskeletal network of microtubules, and explicitly explore the role of microtubule ends (a type of defect) on long-range transport. We will show how different types of end distributions can ultimately result in the same observed transport behavior for bundles. We compare transport on completely uniform bundles, found in the axon, to completely random bundles, found in dendrites. Because of the un-biased random bundle nature, defects affect transport on dendrite bundles more than on uniform bundles in the axon. Further, defects act as large spatial-scale traps that result in random wait-times which have been assumed in previous models.

**12:27PM B35.00005 Size scaling of microtubule asters in confinement<sup>1</sup>**, JAMES PELLETIER, Dept., of Physics, Massachusetts Institute of Technology, Dept., of Systems Biology, Harvard Medical School, CHRISTINE FIELD, Dept., of Systems Biology, Harvard Medical School, KASPARS KRUTKRAMELIS, Dep., of Chemical Engineering, University of Wyoming, NIKTA FAKHRI, Dept., of Physics, Massachusetts Institute of Technology, JOHN OAKEY, Dept., of Chemical Engineering, University of Wyoming, JAY GATLIN, Dept., of Molecular Biology, University of Wyoming, TIMOTHY MITCHISON, Dept., of Systems Biology, Harvard Medical School — Microtubule asters are radial arrays of microtubules (MTs) nucleated around organizing centers (MTOCs). Across a wide range of cell types and sizes, aster positioning influences cellular organization. To investigate aster size and positioning, we reconstituted dynamic asters in *Xenopus* cytoplasmic extract, confined in fluorinated oil microfluidic emulsions. In large droplets, we observed centering of MTOCs. In small droplets, we observed a breakdown in natural positioning, with MTOCs at the droplet edge and buckled or bundled MTs along the interface. In different systems, asters are positioned by different forces, such as pushing due to MT polymerization, or pulling due to bulk or cortical dynein. To estimate different contributions to aster positioning, we biochemically perturbed dynactin function, or MT or actin polymerization. We used carbon nanotubes to measure molecular motions and forces in asters. These experimental results inform quantitative biophysical models of aster size and positioning in confinement.

**12:39PM B35.00006 The role of catch-bonds in acto-myosin mechanics and cell mechanosensitivity**, UMUT AKALP, FRANCK J. VERNEREY, Univ of Colorado - Boulder — Contraction and spreading of adherent cells are important phenomena in range of cellular processes such as differentiation, morphogenesis, and healing. In this presentation, we propose a novel mechanism of adherent cell mechanosensing, based on the idea that the contractile acto-myosin machinery behaves as a catch-bond. For this, we construct a simplified model of the acto-myosin structure that constitute the building block of stress fibers and express the stability of cross-bridges in terms of the force-dependent bonding energy of the acto-myosin bond. Consistent with experimental measurements, we then consider that the energy barrier of the acto-myosin bond increases for tension and show that this response is enough to explain the force-induced stabilization of an SF. The resulting model eventually takes the form of a force-sensitive, active visco-elastic material, powered by ATP hydrolysis. The model is used to investigate the organization and contraction of the actin cytoskeleton of cells laying on arrays of microposts. Upon comparison with experimental observations and measurements, simulations show that the catch-bond hypothesis is satisfactory to predict the sensitivity of adherent cells to substrate stiffness as well as the complex organization of the actin cytoskeleton.

**12:51PM B35.00007 Feedback Interactions of Polymerized Actin with the Cell Membrane: Waves, Pulses, and Oscillations<sup>1</sup>**, ANDERS CARLSSON, Washington University in St Louis — Polymerized filaments of the protein actin have crucial functions in cell migration, and in bending the cell membrane to drive endocytosis or the formation of protrusions. The nucleation and polymerization of actin filaments are controlled by upstream agents in the cell membrane, including nucleation-promoting factors (NPFs) that activate the Arp2/3 complex to form new branches on pre-existing filaments. But polymerized actin (F-actin) also feeds back on the assembly of NPFs. We explore the effects of the resulting feedback loop of F-actin and NPFs on two phenomena: actin pulses that drive endocytosis in yeast, and actin waves traveling along the membrane of several cell types. In our model of endocytosis in yeast, the actin network is grown explicitly in three dimensions, exerts a negative feedback interaction on localized patch of NPFs in the membrane, and bends the membrane by exerting a distribution of forces. This model explains observed actin and NPF pulse dynamics, and the effects of several interventions including i) NPF mutations, ii) inhibition of actin polymerization, and iii) deletion of a protein that allows F-actin to bend the cell membrane. The model predicts that mutation of the active region of an NPF will enhance the accumulation of that NPF, and we confirm this prediction by quantitative fluorescence microscopy. For actin waves, we treat a similar model, with NPFs distributed over a larger region of the cell membrane. This model naturally generates actin waves, and predicts a transition from wave behavior to spatially localized oscillations when NPFs are confined to a small region. We also predict a transition from waves to static polarization as the negative-feedback coupling between F-actin and the NPFs is reduced.

**1:27PM B35.00008 Whole Cell Model of Actin Diffusion and Reaction based on Single Molecule Speckle Microscopy Measurements**, LAURA MCMILLEN, DIMITRIOS VAVYLONIS, Lehigh University, VAVYLONIS GROUP TEAM — It is debated whether transport of actin across the cell by diffusion alone is sufficiently fast to account for the rapid reorganization of actin filaments at the leading edge of motile cells. In order to investigate this question, we created a 3D model of the whole cell that includes reaction and diffusion of actin using a particle Monte Carlo method. For the lamellipodium of the simulated cell we use the model by Smith et al. Biophys. J 104:247 (2013), which includes two diffuse pools of actin, one which is slowly diffusing and the other which diffuses more quickly, as well as a pool of filamentous actin undergoing retrograde flow towards the cell center. We adjusted this model to fit a circular geometry around the whole cell. We also consider actin in the cell center which is either diffusing or in stationary filamentous form, representing cortical actin or actin in stress fibers. The local rates of polymerization and the lifetime distributions of polymerized actin were estimated from single molecule speckle microscopy experiments by the group of N. Watanabe. With this model we are able to simulate prior experiments that monitored the redistribution of actin after photoactivation or fluorescence recovery after photobleaching in various parts of the cell. We find that transport by diffusion is sufficient to fit these data, without the need for an active transport mechanism, however significant concentration gradients may develop at steady state.

**1:39PM B35.00009 Chemotaxis to Excitable Waves in Dictyostelium Discoideum<sup>1</sup>**, ARPAN BHOWMIK, Rice Univ, WOUTER-JAN RAPPEL, University of California, San Diego, HERBERT LEVINE, Rice Univ — In recent years, there have been significant advances in our understanding of the mechanisms underlying chemically directed motility by eukaryotic cells such as Dictyostelium. In particular, the LEGI model has proven capable of providing a framework for quantitatively explaining many experiments that present Dictyostelium cells with tailored chemical stimuli and monitor their subsequent polarization. Here, we couple the LEGI approach to an excitable medium model of the cAMP wave-field that is self-generated by the cells and investigate the extent to which this class of models enables accurate chemotaxis to the cAMP waveforms expected in vivo. Our results indicate that the ultra-sensitive version of the model does an excellent job in providing natural wave rectification, thereby providing a compelling solution to the “back-of-the-wave paradox” during cellular aggregation.

**1:51PM B35.00010 Mechanical feedback stabilizes budding yeast morphogenesis**, SAMHITA BANAVAR, MICHAEL TROGDON, LINDA PETZOLD, OTGER CAMPAS, Univ of California - Santa Barbara — Walled cells have the ability to remodel their shape while sustaining an internal turgor pressure that can reach values up to 10 atmospheres. This requires a tight and simultaneous regulation of cell wall assembly and mechanochemistry, but the underlying mechanisms by which this is achieved remain unclear. Using the growth of mating projections in budding yeast (*S. cerevisiae*) as a motivating example, we have developed a theoretical description that couples the mechanics of cell wall expansion and assembly via a mechanical feedback. In the absence of a mechanical feedback, cell morphogenesis is inherently unstable. The presence of a mechanical feedback stabilizes changes in cell shape and growth, and provides a mechanism to prevent cell lysis in a wide range of conditions. We solve for the dynamics of the system and obtain the different dynamical regimes. In particular, we show that several parameters affect the stability of growth, including the strength of mechanical feedback in the system. Finally, we compare our results to existing experimental data.

**2:03PM B35.00011 Mechanical Trade-offs in Experimentally Evolved Multicellular Yeast**, SHANE JACOBSEN, JENNIFER PENTZ, WILLIAM RATCLIFF, PETER YUNKER, Georgia Tech — The evolution of multicellularity as much about physics as it is about biology, as selection acts on the physical properties of multicellular bodies. Nascent multicellular organisms are confronted by internal and external forces that act on large length scales and are capable of fracturing intercellular bonds. We study the evolution of the mechanical properties of multicellular 'snowflake' yeast that were selected for increased size over ~1,500 generations<sup>1,2</sup>. While these snowflakes evolve to be larger by mitigating internal forces, they also become more susceptible to fracturing when faced with external compressive forces. Using confocal microscopy and direct mechanical measurements, we investigate the physical underpinnings and consequences of this strength-toughness trade-off. **References:** <sup>1</sup>W. Ratcliff *et al.* 2012. PNAS. 109:1959–1600. <sup>2</sup>W. Ratcliff *et al.* 2015. Nature Communications. 6:6102.

## Monday, March 14, 2016 11:15AM - 2:15PM –

Session B36 GSOF DBIO GSNP/DFD: Active Matter II 339 - Robin Selinger, Kent University

**11:15AM B36.00001 Material Flows in an Active Nematic Liquid Crystal**, STEPHEN DECAMP, GABRIEL REDNER, APARNA BASKARAN, MICHAEL HAGAN, ZVONIMIR DOGIC, Brandeis University — Active matter systems are composed of energy consuming constituent components which drive far-from-equilibrium dynamics. As such, active materials exhibit energetic states which would be unfavorable in passive, equilibrium materials. We study one such material; an active nematic liquid crystal which exists in a dynamical steady state where  $\pm 1/2$  defects are continuously generated and annihilated at a constant rate. The active nematic is composed of micron-sized microtubule filaments which are highly concentrated into a quasi-2D film that resides on an oil-water interface. Kinesin motor proteins drive inter-filament sliding which results in net extensile motion of the microtubule film. Notably, we find a mesophase in which motile  $\pm 1/2$  defects, acquire system-spanning orientational order. Currently, we are tracking material flows generated by the active stresses in the system to measure length scales at which energy is dissipated, and to measure the relation between internally generated flows and bend in the nematic field.

**11:27AM B36.00002 Antipolar ordering of topological charges in active liquid crystals**, JORN DUNKEL, MIT, ANAND OZA, Courant Institute — Recent experiments demonstrated that ATP-driven microtubule-kinesin bundles can self-assemble into two-dimensional active liquid crystals that exhibit a rich creation and annihilation dynamics of topological defects, reminiscent of particle-pair production processes in quantum systems. This remarkable discovery has sparked considerable theoretical and experimental interest. Here, we present and validate a minimal continuum theory for this new class of active matter systems by merging universality ideas with the classical Landau-de Gennes theory. The resulting model agrees quantitatively with recently published data and, in particular, predicts a previously unexplained regime of antipolar order. Our analysis implies that active liquid crystals are governed by the same generic ordering principles that determine the non-equilibrium dynamics of dense bacterial suspensions and elastic bilayer materials. Moreover, the theory manifests a profound energetic analogy with strongly interacting quantum gases. Generally, our results suggest that complex nonequilibrium pattern-formation phenomena might be predictable from a few fundamental symmetric-breaking and scale-selection principles.

**11:39AM B36.00003 Points or vectors? The polar structure of disclinations in active and passive nematics**, LUCA GIOMI, ARTHUR VROMANS, Leiden University — Topological defects play a pivotal role in the physics of liquid crystals and represent one of the most prominent and well studied aspects of mesophases. While in two-dimensional nematics, disclinations are traditionally treated as point-like objects, recent experimental studies on active nematics have suggested that half-strength disclinations might in fact possess a polar structure. In this talk I will provide a precise definition of polarity for half-strength nematic disclinations, introduce a simple and robust method to calculate this quantity from experimental and numerical data and investigate how the orientational properties of active and passive half-strength disclinations affect their dynamics.

**11:51AM B36.00004 Theory and Experiments of Topologically Driven Flows in Nematic Suspensions**, CHRISTOPHER CONKLIN, JORGE VINALS, University of Minnesota, CHENHUI PENG, YUBING GUO, SERGIJ SHIVANOVSKII, QI-HUO WEI, OLEG LAVRENTOVICH, Kent State University — We present theory, numerical solutions, and experiments of electric field driven flows in nematic liquid crystals (LC) in which a patterned molecular orientation acts as an electrolytic active medium. Surface patterning by photoalignment in a thin cell is used to create various alignments of a nematic liquid crystal film, that may include topological defects. The active patterned LC electrolyte converts electric field energy into LC flows and transport of embedded particles of any type (fluid, solid, gaseous) along predefined trajectories, and without limitation on the electric nature (charge, polarizability) of these particles and interfaces. Flow is quadratic in the electric field which leads, even for an imposed AC field, to systematic flow velocities, including persistent vortices of controllable rotation speed and direction. The latter are essential for micro- and nanoscale mixing applications.

**12:03PM B36.00005 Controlling Defects and Flow in Active Nematic Suspensions<sup>1</sup>**, SURAJ SHANKAR, Department of Physics, Syracuse University, PAU GUILLAMAT BASSEDAS, JORDI IGNÉS-MULLOL, FRANCESC SAGUÉS, Department of Physical Chemistry and IN2UB, Universitat de Barcelona, M. CRISTINA MARCHETTI, Department of Physics, Syracuse University — Experiments on active nematics composed of cytoskeletal biopolymers activated by molecular motors have shown that in these systems topological defects drive self-sustained flows and the transition to spatio-temporal chaos. In active nematics, defects become dynamical entities and behave like self-propelled particles. In a freely suspended nematic layer the defect speed is controlled by the activity and the viscosity of the active fluid that is so far unknown. Experiments, however, are carried out on very thin nematic layers at an oil-water interface. Our collaborators in Barcelona have shown that increasing the viscosity of the oil can substantially slow down the defects and increase their number. Considering a model of an active nematic at an oil-water interface, we have calculated the defect speed as a function of oil viscosity and find that theory and experiments agree well when the oil viscosity is changed over four orders of magnitude. Importantly, by combining theory and experiments these results provide a parameter-free estimate for the interfacial viscosity of the active nematic layer, which has never been measured before.

**12:15PM B36.00006 Active nematics on the surface of a torus<sup>1</sup>**, PERRY ELLIS, YA-WEN CHANG, ALBERTO FERNANDEZ-NIEVES, Georgia Institute of Technology — Nematic materials on the surface of a sphere must have a net topological charge of  $s = +2$ . In equilibrium nematics experiments have shown that this net topological charge can be realized with four  $s = +1/2$  defects, which also corresponds to the theoretically expected ground state configuration. Surprisingly, even though active nematics are continuously driven out of equilibrium by the internal energy of the nematogens, when confined to the surface of a sphere these materials can also realize this net topological charge with four  $s = +1/2$  defects. In contrast to the spherical confinement case, the situation for toroidal confinement has not been experimentally explored despite the existence of theory and simulation work examining the structure of ordered materials on the surface of a torus. Here, we experimentally realize an extensile active nematic confined to a toroidal surface and explore how the interplay between topology, activity, and nematic elasticity affect the structure and dynamics of the material.

<sup>1</sup>PWE is supported by FLAMEL under grant NSF 1258425

**12:27PM B36.00007 Dynamics and Instabilities of an overdamped active nematic liquid crystal<sup>1</sup>**, ELIAS PUTZIG, APARNA BASKARAN, Brandeis University — Active nematics have been studied extensively in the context of suspensions of active particles, with a Stokes equation describing the flow of the surrounding fluid. Here we will present a continuum model of an overdamped (often termed 'dry') active nematic, where activity enters through self-induced flows. These flows represent the ability of the internal forces to convect, shear, or rotate the nematic order. The self-induced shear gives rise to an instability in the homogeneous ordered state which is analogous to that seen in active suspensions. The self-induced rotation gives rise to a new instability. A phase diagram from this model will be presented, and the phenomenology will be compared with what is seen in experimental and simulated active systems.

<sup>1</sup>We would like to acknowledge grant support through NSF (NSF-DMR-1149266), (DMR-0820492), (NIH-5T32EB009419) and IGERT (DGE-1068620).

**12:39PM B36.00008 Viscoelastic and elastomeric active matter: linear instability and nonlinear dynamics**, EWAN J. HEMINGWAY, Durham University, M. E. CATES, University of Cambridge, M. C. MARCHETTI, Syracuse University, S. M. FIELDING, Durham University — We consider a continuum model of active viscoelastic matter, whereby a model of an active nematic liquid-crystal is coupled to a minimal model of polymer dynamics with a viscoelastic relaxation time  $\tau_c$ . To explore the resulting interplay between active and polymeric dynamics, we first generalise a linear stability analysis (from earlier studies without polymer) to derive criteria for the onset of spontaneous flow. Perhaps surprisingly, our results show that the spontaneous flow instability persists even for divergent polymer relaxation times. We explore the novel dynamical states to which these instabilities lead by means of nonlinear numerical simulations. This reveals oscillatory shear-banded states in 1D, and activity-driven turbulence in 2D, even in the limit  $\tau_c \rightarrow \infty$ . Adding polymer can also have calming effects, increasing the net throughput of spontaneous flow along a channel in a new type of "drag-reduction", an effect that may have implications for cytoplasmic streaming processes within the cell.

**12:51PM B36.00009 A Kinetic Model of Active Extensile Bundles**, DANIEL GOLDSTEIN, BULBUL CHAKRABORTY, APARNA BASKARAN, Brandeis Univ — Recent experiments in active filament networks reveal interesting rheological properties (Dan Chen: APS March Meeting 2015 D49.00001). This system consumes ATP to produce an extensile motion in bundles of microtubules. This extension then leads to self generated stresses and spontaneous flows. We propose a minimal model where the activity is modeled by self-extending bundles that are part of a cross linked network. This network can reorganize itself through buckling of extending filaments and merging events that alter the topology of the network. We numerically simulate this minimal kinetic model and examine the emergent rheological properties and determine how stresses are generated by the extensile activity. We will present results that focus on the effects of confinement and network connectivity of the bundles on stress fluctuations and response of an active gel.

**1:03PM B36.00010 Shortening actin filaments cause force generation in actomyosin network to change from contractile to extensile**, NITIN KUMAR, MARGARET GARDEL, James Franck Institute, University of Chicago — Motor proteins in conjunction with filamentous proteins convert biochemical energy into mechanical energy which serves a number of cellular processes including cell motility, force generation and intracellular cargo transport. In-vitro experiments suggest that the forces generated by kinesin motors on microtubule bundles are extensile in nature whereas myosin motors on actin filaments are contractile. It is not clear how qualitatively similar systems can show completely different behaviors in terms of the nature of force generation. In order to answer this question, we carry out in vitro experiments where we form quasi 2D filamentous actomyosin networks and vary the length of actin filaments by adding capping protein. We show that when filaments are much shorter than their typical persistence length (approximately 10 microns), the forces generated are extensile and we see active nematic defect propagation, as seen in the microtubule-kinesin system. Based on this observation, we claim that the rigidity of rods plays an important role in dictating the nature of force generation in such systems. In order to understand this transition, we selectively label individual filaments and find that longer filaments show considerable bending and buckling, making them difficult to slide and extend along their length.

**1:15PM B36.00011 Dynamics of Actively Driven Crosslinked Microtubule Networks**, VIKRANT YADAV, KASIMIRA STANHOPE, University of Massachusetts, Amherst, ARTHUR A. EVANS, University of Wisconsin, Madison, JENNIFER L. ROSS, University of Massachusetts, Amherst — We have designed a model experiment to explore dynamics of crosslinked active microtubule clusters crosslinked with MAP65. Microtubule clusters are allowed to settle on a slide coated with kinesin-1 molecular motors, which move microtubules. We systematically tune either concentration of cross linkers bound to microtubule ( $\rho_c$ ) or the global concentration of microtubules ( $\rho_{MT}$ ). We quantified the shape of the cluster by measuring the standard deviation ( $\sigma$ ) of the cluster outline. At low  $\rho_{MT}$  or  $\rho_c$  the network is in an expanding state. At higher  $\rho_{MT}$  or  $\rho_c$  expansion slows down, reaches zero at a critical density, and become negative indicating contraction. Further increase of  $\rho_{MT}$  or  $\rho_c$  halts any kind of dynamics. The  $\rho_{MT}$ - $\rho_c$  phase space shows distinct regions of extensile, contractile and static regimes. We model these results using active hydrodynamic theory. Microtubules are modeled as active rods whereas effect of crosslinkers is modeled using a collision term that prefers anti-parallel alignment of microtubules. A linearized analysis of hydrodynamic equation predicts existence of density driven expanding, contracting, and static phases for microtubule clusters.

**1:27PM B36.00012 Competing dynamic phases of active polymer networks<sup>1</sup>**, SIMON FREEDMAN, Univ of Chicago, SHILADITYA BANERJEE, AARON R. DINNER, James Franck Institute, Univ of Chicago — Recent experiments on in-vitro reconstituted assemblies of F-actin, myosin-II motors, and cross-linking proteins show that tuning local network properties can changes the fundamental biomechanical behavior of the system. For example, by varying cross-linker density and actin bundle rigidity, one can switch between contractile networks useful for reshaping cells, polarity sorted networks ideal for directed molecular transport, and frustrated networks with robust structural properties. To efficiently investigate the dynamic phases of actomyosin networks, we developed a coarse grained non-equilibrium molecular dynamics simulation of model semiflexible filaments, molecular motors, and cross-linkers with phenomenologically defined interactions. The simulation's accuracy was verified by benchmarking the mechanical properties of its individual components and collective behavior against experimental results at the molecular and network scales. By adjusting the model's parameters, we can reproduce the qualitative phases observed in experiment and predict the protein characteristics where phase crossovers could occur in collective network dynamics. Our model provides a framework for understanding cells' multiple uses of actomyosin networks and their applicability in materials research.

**1:39PM B36.00013 Rapid non-equilibrium turnover fluidizes entangled F-actin solutions**, PATRICK M. MCCALL, Dept of Physics, Univ of Chicago, DAVID R. KOVAR, Depts of MGCB and BMB, Univ of Chicago, MARGARET L. GARDEL, Dept of Physics, Univ of Chicago — The actin cytoskeleton of living cells is a semiflexible polymer network which regulates cell division, motility, and morphogenesis by controlling cell shape. These complex shape-changing processes require both mechanical deformation and remodeling of the actin cytoskeleton. Molecular motors generate internal forces to drive deformation, while cytoskeletal remodeling is regulated by non-equilibrium polymer turnover. Although the mechanical properties of equilibrium actin filament (F-actin) networks are well-described by theories of semiflexible polymers, these theories do not incorporate the effects of non-equilibrium turnover. To address this experimentally, we developed a model system in which both the turnover rate and the length distribution of purified F-actin can be tuned independently at steady-state through the combined action of actin regulatory proteins. Specifically we tune the concentrations of cofilin, profilin, and formin to regulate F-actin severing, recycling, and nucleation, respectively. We find that the actin turnover rate can be tuned by cofilin up to 25-fold ( $31 \pm 2$  subunits/sec/filament). Surprisingly, changes in turnover rate have no effect on the steady-state F-actin length distribution, which is instead set by formin concentration. Passive microrheology measurements show that increased turnover leads to striking fluidization in both entangled and crosslinked networks. Non-equilibrium turnover thus enables modulation of network mechanics, which impacts force transmission and material deformation.

**1:51PM B36.00014 Critical forces for actin filament buckling and force transmission influence transport in actomyosin networks**, SAMANTHA STAM, Univ of Chicago, MARGARET GARDEL, Dept. of Physics, Univ of Chicago — Viscoelastic networks of biopolymers coordinate the motion of intracellular objects during transport. These networks have nonlinear mechanical properties due to events such as filament buckling or breaking of cross-links. The influence of such nonlinear properties on the time and length scales of transport is not understood. Here, we use in vitro networks of actin and the motor protein myosin II to clarify how intracellular forces regulate active diffusion. We observe two transitions in the mean-squared displacement of cross-linked actin with increasing motor concentration. The first is a sharp transition from initially subdiffusive to diffusive-like motion that requires filament buckling but does not cause net contraction of the network. Further increase of the motor density produces a second transition to network rupture and ballistic actin transport. This corresponds with an increase in the correlation of motion and thus may be caused when forces propagate far enough for global motion. We conclude that filament buckling and overall network contraction require different amounts of force and produce distinct transport properties. These nonlinear transitions may act as mechanical switches that can be turned on to produce observed motion within cells.

**2:03PM B36.00015 Detection of Non-Equilibrium Fluctuations in Active Gels<sup>1</sup>**, ALEXANDRU BACANU, Massachusetts Institute of Technology, USA, CHASE BROEDERSZ, Ludwig-Maximilians-University of Munich, Germany, JANNES GLADROW, Georg-August University of Goettingen, Germany, FRED MACKINTOSH, Vrije Universiteit, Netherlands, CHRISTOPH SCHMIDT, Georg-August University of Goettingen, Germany, NIKTA FAKHRI, Massachusetts Institute of Technology, USA — Active force generation at the molecular scale in cells can result in stochastic non-equilibrium dynamics on mesoscopic scales. Molecular motors such as myosin can drive steady-state stress fluctuations in cytoskeletal networks. Here, we present a non-invasive technique to probe non-equilibrium fluctuations in an active gel using single-walled carbon nanotubes (SWNTs). SWNTs are semiflexible polymers with intrinsic fluorescence in the near infrared. Both thermal and active motor-induced forces in the network induce transverse fluctuations of SWNTs. We demonstrate that active driven shape fluctuations of the SWNTs exhibit dynamics that reflect the non-equilibrium activity, in particular the emergence of correlations between the bending modes. We discuss the observation of breaking of detailed balance in this configurational space of the SWNT probes.

### Session B37 GSOF DBIO: Phase Transitions and Self-Assembly in Biological Systems II 340

— Michael Hagan, Brandeis University

**11:15AM B37.00001 Imaging the Dynamics of Individual Viruses in Solution<sup>1</sup>**, AARON GOLDFAIN, REES GARMANN, YOAV LAHINI, Harvard University, John A. Paulson School of Engineering and Applied Sciences, VINOTHAN MANOHARAN, Harvard University, John A. Paulson School of Engineering and Applied Sciences and the Department of Physics — We have developed optical microscopy techniques that can detect and track individual, unlabeled viruses at thousands of frames per second. We use these techniques to study fast, dynamic processes in the life cycles of bacteriophages (viruses that infect bacteria). I will describe experiments that capture the ejection of double stranded DNA from bacteriophage  $\lambda$ . During the 1-2 second ejection, the DNA genome transitions from a compact, highly ordered spool within the capsid into an extended random coil in solution. By quantifying the amount of light scattered from a single  $\lambda$  phage as its DNA ejects, we measure the amount of DNA remaining in the virus capsid as a function of time. Measuring small fluctuations in the rate of ejection may uncover clues about the complex conformational rearrangements that the DNA undergoes while escaping the capsid.

<sup>1</sup>Funded in part by the NSF GRFP

**11:27AM B37.00002 Chirality of Viral Capsids**, SANJAY DHARMAVARAM, Dept. of Mechanical and Aerospace Engineering, UCLA, FANGMING XIE, University of Science and Technology, China, ROBIJN BRUINSMA, Dept. of Physics and Astronomy, UCLA, WILLIAM KLUG, Dept. of Mechanical and Aerospace Engineering, UCLA, JOSEPH RUDNICK, Dept. of Physics and Astronomy, UCLA — Most icosahedral viruses are classified by their T-number which identifies their capsid in terms of the number of capsomers and their relative arrangement. Certain T-numbers ( $T = 7$  for instance) are inherently chiral (with no reflection planes) while others (e.g.  $T = 1$ ) are achiral. We present a Landau-Brazovskii (LB) theory for weak crystallization in which a scalar order parameter that measures density of capsid proteins successfully predicts the various observed T-numbers and their respective chiralities. We find that chiral capsids gain stability by spontaneously breaking symmetry from an unstable chiral state. The inherently achiral LB-free energy does not preferentially select a particular chiral state from its mirror reflection. Based on the physical observation that proteins are inherently chiral molecules with directional interactions, we propose a new chiral term to the LB energy as a possible selection mechanism for chirality.

**11:39AM B37.00003 A Simple Model for Immature Retrovirus Capsid Assembly<sup>1</sup>**, STEFAN PAQUAY, PAUL VAN DER SCHOOT, Eindhoven University of Technology, The Netherlands, BOGDAN DRAGNEA, Indiana University, Bloomington, Indiana — In this talk I will present simulations of a simple model for capsomeres in immature virus capsids, consisting of only point particles with a tunable range of attraction constrained to a spherical surface. We find that, at sufficiently low density, a short interaction range is sufficient for the suppression of five-fold defects in the packing and causes instead larger tears and scars in the capsid. These findings agree both qualitatively and quantitatively with experiments on immature retrovirus capsids, implying that the structure of the retroviral protein lattice can, for a large part, be explained simply by the effective interaction between the capsomeres.

<sup>1</sup>We thank the HFSP for funding under grant RGP0017/2012.

**11:51AM B37.00004 Autophagy selectivity through receptor clustering** , ANDREW RUTENBERG, AIDAN BROWN<sup>1</sup>, Dalhousie University — Substrate selectivity in autophagy requires an all-or-none cellular response. We focus on peroxisomes, for which autophagy receptor proteins NBR1 and p62 are well characterized. Using computational models, we explore the hypothesis that physical clustering of autophagy receptor proteins on the peroxisome surface provides an appropriate all-or-none response. We find that larger peroxisomes nucleate NBR1 clusters first, and lose them due to competitive coarsening last, resulting in significant size-selectivity. We then consider a secondary hypothesis that p62 inhibits NBR1 cluster formation. We find that p62 inhibition enhances size-selectivity enough that, even if there is no change of the peroxophagy rate, the volume of remaining peroxisomes can significantly decrease. We find that enhanced ubiquitin levels suppress size-selectivity, and that this effect is more pronounced for individual peroxisomes. Sufficient ubiquitin allows receptor clusters to form on even the smallest peroxisomes. We conclude that NBR1 cluster formation provides a viable physical mechanism for all-or-none substrate selectivity in peroxophagy. We predict that cluster formation is associated with significant size-selectivity.

**12:03PM B37.00005 Statistical Mechanics and Thermodynamics of Viral Evolution** , BARBARA JONES, JAMES KAUFMAN, IBM Research – Almaden — Using methods drawn from physics we study the life cycle of viruses. We analyze a model of viral infection and evolution using the “grand canonical ensemble” and formalisms from statistical mechanics and thermodynamics. Using this approach we determine possible genetic states of a model virus and host as a function of two independent pressures—immune response and system temperature. We show the system has a real thermodynamic temperature, and discover a new phase transition between a positive temperature regime of normal replication and a negative temperature “disordered” phase of the virus. We distinguish this from previous observations of a phase transition that arises as a function of mutation rate. From an evolutionary biology point of view, at steady state the viruses naturally evolve to distinct quasispecies. The approach used here could be refined to apply to real biological systems, perhaps providing insight into immune escape, the emergence of novel pathogens and other results of viral evolution.

**12:15PM B37.00006 Metastable Amyloid Phases and their Conversion to Mature Fibrils** , MARTIN MUSCHOL, TATIANA MITI, MENTOR MULAJ, Dept. of Physics, University of South Florida, Tampa FL 33620, JEREMY SCHMIT, Dept. of Physics, Kansas State University, Manhattan, KS 66506 — Self-assembly of proteins into amyloid fibrils plays a key role in both functional biological responses and pathogenic disorders which include Alzheimer's disease and type II diabetes. Amyloid fibril assembly frequently generates compact oligomeric and curvilinear polymeric intermediates which are implicated to be toxic to cells. Yet, the relation between these early-stage oligomeric aggregates and late-stage rigid fibrils, which are the hallmark structure of amyloid plaques, has remained unclear. Our measurements indicate that lysozyme amyloid oligomers and their curvilinear fibrils only form after crossing a salt and protein concentration dependent threshold. These oligomeric aggregates are structurally distinct from rigid fibrils and are metastable against nucleation and growth of rigid fibrils. Our experimental transition boundaries match well with colloidal model predictions accounting for salt-modulated charge repulsion. We also report our preliminary findings on the mechanism by which these metastable oligomeric phases are converted into stable amyloid fibrils.

**12:27PM B37.00007 Patterns for Fluid Management: The Mechanical Origins of Microarchitectures** , ASJA RADJA, MAXIM LAVRETOVICH , ERIC HORSLEY, RANDALL KAMIEN, ALISON SWEENEY, University of Pennsylvania — Pollen grains are the vehicles for the male germ line in land plants and are famous for the intricate microarchitectures of their protective coverings. It is not known whether these sub-micron-scale patterns have a functional role. A given microarchitectural pattern is maintained over geological time within a single species, yet, despite similar mechanisms of pollen development in all species, different species have extremely variable patterns. Until recently, many proposed mechanisms of pollen pattern formation were attributed to top-down assembly processes directed by the pollen cytoskeleton. We propose a novel view in which bottom-up mechanical processes akin to thermodynamic phase transitions may cause the final pollen structure. Here, we present a temporal view of pattern formation using several microscopy techniques. Our data show a rapid appearance of surface microstructures. We test the hypothesis of bottom-up pattern formation by physically manipulating the pattern formation process with mechanical forces and chemical solvents. Our data are consistent with bottom-up formation of these patterns; we discuss a hypothesis of pattern formation in this system involving Brazovskii phase transitions templated on a spherical geometry.

**12:39PM B37.00008 Pollen Patterning as a Brazovskii Phase Transition on a Sphere** , MAXIM LAVRETOVICH, ERIC HORSLEY, ASJA RADJA, ALISON SWEENEY, RANDALL KAMIEN, University of Pennsylvania — Pollen grains acquire intricate, varied surface patterns during development. The patterns are reproducible within a single plant species, and yet exhibit a wide variation among species, despite having similar developmental steps. We model this pattern formation on spherical grains as a phase transition to a spatially modulated phase, characterized by an unstable wavelength  $\lambda_0$ . On the infinite, flat plane, the patterned phase consists of uniform stripes, as shown by Brazovskii. We find that, by contrast, the patterns may be much more varied on a spherical surface because the topological defects which must be present in the pattern may be accommodated in a variety of ways. This variation may explain the wide range of observed pollen patterns. We also argue that the first-order character of the transition may be responsible for the robust reproducibility of the patterns in a single plant species. Finally, we compute the free energy difference between the unpatterned, smooth phase and robust patterned phases on the sphere. These calculations point toward possible future experimental tests of our model.

**12:51PM B37.00009 Non-deterministic self-assembly of two tile types on a lattice** , SALVATORE TESORO, University of Cambridge — I will present a complex behaviour that is both interesting from a statistical and complex systems point of view and from a more abstract point of view on complexity and evolutionary theory. I will introduce simple a theoretical framework to predict and describe all possible growth behaviours that self-assembly of two tile types can produce on a 2D lattice, given binary interaction rules between the faces of the tiles in the system. Such simple set up can give rise to critical transitions between bound and unbound growth regimes and other non-critical behaviours. I will illustrate how this work completes efforts conducted by Ahnert et Al. in the field of Complexity and Evolution, whereby deterministic self-assembly pathways have been exploited as a useful tool in addressing questions on complexity and modularity in nature. I will further show how this theoretical framework can be experimentally verified using DNA-tiles as a building material and providing experimental validation of the theoretical predictions made.

**1:03PM B37.00010 Generic Phase Diagram of Binary Superlattices<sup>1</sup>** , ALEXEI TKACHENKO, Brookhaven National Laboratory — Emergence of a large variety of self-assembled superlattices is a dramatic recent trend in the fields of nanoparticle and colloidal sciences. Motivated by this development, we propose a model that combines simplicity with a remarkably rich phase behavior, applicable to a wide range of such self-assembled systems. Those include nanoparticle and colloidal assemblies driven by DNA-mediated interactions, electrostatics, and possibly, by controlled drying. In our model, a binary system of Large and Small hard sphere (L and S) interact via selective short-range (“sticky”) attraction. In its simplest version, this Binary Sticky Sphere model features attraction only between ‘S’ and ‘L’ particles, respectively. We demonstrate that in the limit when this attraction is sufficiently strong compared to  $kT$ , the problem becomes purely geometrical: the thermodynamically preferred state should maximize the number of S-L contacts. A general procedure for constructing the phase diagram as a function of system composition  $f$ , and particle size ratio  $r$ , is outlined. In this way, the global phase behavior can be calculated very efficiently, for a given set of plausible candidate phases. Furthermore, the geometric nature of the problem enables us to generate those candidate phases through a well defined and intuitive construction. We calculate the phase diagrams both for 2D and 3D systems, and compare the results with existing experiments. Most of the 3D superlattices observed to date are featured in our phase diagram, while several more are yet to be discovered.

### 1:15PM B37.00011 Geometric and Topological Transitions of Small Clusters of Liquid Particles

JAMES GIAMMONA, OTGER CAMPAS, Univ of California - Santa Barbara — The geometry and topology of small particle clusters has been studied in several disciplines due to the fundamental nature of the problem and its relevance to applications. Recent theoretical work can predict observed packings for small numbers of hard, spherical particles, but little is known about how using deformable particles changes the geometry and topology of these clusters. To study this problem, we simulate small clusters of liquid particles using a Langevin approach and obtain the geometrical and topological transitions for clusters of  $N$  particles (up to  $N=7$ ) as the particles interfacial tension and adhesion energy are varied. As particles become more adhesive and increase their contact angle, we observe well-defined packing transitions in the clusters. For  $N=5$ , a topological transition occurs at a critical value of the contact angle. For  $N=6$ , we obtain two stable cluster geometries for a given value of the contact angle, namely an 8-faced deltahedron and an octahedron. For  $N=7$ , there appears to be a complex landscape of cluster geometries and topologies, with transitions occurring at well-defined values of the contact angle. Our findings can help in the controlled assembly of particular arrangements of small clusters of bubbles or adherent droplets.

### 1:27PM B37.00012 Helices Of Helices

MAHSA SIAVASHPOURI, MARK ZAKHARY, Brandeis Univ, CHRISTIAN WACHAUF, HENDRIK DIETZ, Technische Universität München, ZVONIMIR DOGIC, Brandeis University — Twisted ribbons are characteristic structural motifs that are prevalent in nature. However correlation between the macroscopic properties of the final self-assemblies and the microscopic features of the constituent molecules remain unknown. We describe a new class of supramolecular 1D assemblages with tunable mechanical properties. Using DNA origami technique, we design and structure rod-like colloidal particles that have excluded volume interactions and self-assemble into twisted ribbons in presence of attractive interactions mediated by non-absorbing polymers. By comparing behavior of DNA origami filaments and rodlike viruses we demonstrate that self-assembly into 1D twisted ribbons is universal and independent of the system materials. Tuning the molecular properties of the DNA origami particles, determines the physical properties of the entire self-assembled structures. Furthermore, to understand the connection between the chirality at the molecular scale and the macroscopic chiral structures, we measured twist periodicity (pitch) of cholesteric phase associated to various DNA origami designs which can develop a new framework in understanding microscopic origin of chirality in liquid crystals.

### 1:39PM B37.00013 Theory of Microphase separation in bidisperse Chiral membranes

RAUNAK SAKHARDANDE, STEFAN STANOJEVIEA, ARVIND BASKARAN, MICHAEL HAGAN, APARNA BASKARAN, BULBUL CHAKRABORTY, Brandeis University — We discuss the phase behavior of bidisperse chiral colloidal membranes, which are monolayers of rodlike molecules containing two species of rods, each with opposite handedness. Using a Ginzburg Landau theory, we show that the system exists in three stable states, separated by first-order phase transitions: a compositionally homogeneous state, macrophase separation between the two rod species, and a micro-phase separated state in which the minority rod species forms circular domains with a well-defined, narrow size distribution. We find that the phase behavior can be controlled by tuning two parameters, one associated with the driving force for membrane assembly, and the other related to the difference in chirality between the two rod species. We discuss implications of the calculated phase diagram for a recently developed experimental system in which bidisperse colloidal membranes comprised of two species of rodlike viruses exhibit micro-phase separation.

### 1:51PM B37.00014 Measuring the equation of state for a 2D colloidal membrane: A microfluidic approach to buffer exchange

ANDREW BALCHUNAS, RAFAEL CABANAS, SETH FRADEN, ZVONIMIR DOGIC, Brandeis University — Previous work has shown that monodisperse rod-like colloidal particles, such as a filamentous bacteriophage, self assemble into a 2D monolayer smectic in the presence of a non-adsorbing depleting polymer. These structures have the same functional form of bending rigidity and lateral compressibility as conventional lipid bi-layers, so we name the monolayer smectic a colloidal membrane. We have developed a microfluidic device such that the osmotic pressure acting on a colloidal membrane may be controlled via a full in situ buffer exchange. Rod density within individual colloidal membranes was measured as a function of osmotic pressure and a first order phase transition, from 2D fluid to 2D solid, was observed.  $k_{on}$  and  $k_{off}$  rates of rod to membrane binding were measured by lowering the osmotic pressure until membrane evaporation occurred.

### 2:03PM B37.00015 Tuning Raft Interactions in Colloidal Membranes using Component Chirality

JOIA MILLER, Brandeis University, PRERNA SHARMA, Indian Institute of Science, ZVONIMIR DOGIC, Brandeis University — Two-dimensional colloidal membranes composed of rods of different lengths display rich phase behavior. In particular, the chirality of constituent rods stabilizes assembly of colloidal rafts, micron-sized droplets enriched in one type of rod floating in a membrane background with a different rod composition. Raft interactions are mediated by local rod twisting due to their rods' inherent chirality, leading to long-range repulsive interactions. We explore the behavior of rafts while reducing the net chirality of the membrane background. Even in the achiral limit, stable or metastable rafts form. However, in the achiral case the long-range interactions between rafts are attractive but not pairwise additive, resulting in the assembly of clusters of individual rafts. The membrane background has large-scale density fluctuations which we correlate to the raft interactions. Our work demonstrates a new method for assembly of well-defined clusters, one that does not rely on complex colloidal synthesis, but rather on the unique anisotropic environment of the colloidal membranes.

### 11:15AM B38.00001 Nanoparticle Ordering in Semicrystalline Polymers

VIANNEY GIMENEZ-PINTO, DAN ZHAO, SANAT KUMAR, Columbia University — One way to engineer the macroscopic properties of a crystalline polymer matrix is to place nanoparticles into them, but in an organized manner. We have recently found that NP organization can be controlled by varying the crystal growth rate. We develop a coarse-grained model to study this situation. In particular, we focus on the out-of-equilibrium dynamics of nanoparticles being pushed/engulfed by a solidification front depending on crystallization velocity  $v_s$ . Particle engulfment occurs when  $v_s$  is higher than a critical velocity  $v_c$ . When  $v_s$  is smaller than  $v_c$ , particles are pushed by the crystallization front and organize in a 2-D plane. Even though most models for particle engulfment consider dynamic force equilibrium at  $v_c$ , we show the system is not in equilibrium in this regime. Thus, we consider conditions for engulfment based on particle velocity with respect to crystal growth rate. Our results agree with experimental observations on anisotropic organization of nanoparticles in semicrystalline polymers driven by crystallization speed.

### 11:27AM B38.00002 Dispersion of Mixed Brush Gold Nanorods in Polymer Matrices

ROBERT FERRIER, JASON KOSKI, ROBERT RIGGLEMAN, RUSSELL COMPOSTO, University of Pennsylvania — In this work we investigate, both experimentally and through hybrid particle/self-consistent field theoretic (hSCFT) calculations, the dispersion state of gold nanorods (AuNRs) grafted with homopolymer, bidispersed, or mixed polymer brushes. AuNRs are grafted with 11.5 kg/mol PS (HNRs), 11.5 kg/mol PS and 5.3 kg/mol PS (BNRs), or 11.5 kg/mol PS and 5 kg/mol poly(methyl methacrylate) (PMMA) (MBNRs) and cast in PS or PMMA films consisting of short to very long chains compared to the grafted brush. We further investigated the MBNR systems by varying the length of the PS brush. Overall, we find that the MBNRs dispersed markedly better than the other brush types (HNRs or BNRs) in PS matrices. We utilize hSCFT calculations, in particular potential of mean force (PMF) and brush profile calculations, to elucidate the thermodynamics of these systems. The PMFs and brush profiles exhibit similar trends for the BNRs and MBNRs where the short grafted chain forces the longer grafted chain away from the AuNR surface and promotes wetting by the matrix chains. The hSCFT calculations demonstrated qualitative trends consistent with the aggregation observed for AuNRs in PMMA matrices. Therefore, we have demonstrated that MBNR dispersion in polymer matrices is enhanced compared to the HNR and BNR cases, which extends the dispersion window for new combinations of nanorods and polymers.

**11:39AM B38.00003 Examination of nanoparticle dispersion using a novel GPU based radial distribution function code** , THOMAS ROSCH, National Institute of Standards and Technology, MATTHEW WADE, Case Western Reserve University, FREDERICK PHELAN, National Institute of Standards and Technology — We have developed a novel GPU-based code that rapidly calculates radial distribution function (RDF) for an entire system, with no cutoff, ensuring accuracy. Built on top of this code, we have developed tools to calculate the second virial coefficient ( $B_2$ ) and the structure factor from the RDF, two properties that are directly related to the dispersion of nanoparticles in nanocomposite systems. We validate the RDF calculations by comparison with previously published results, and also show how our code, which takes into account bonding in polymeric systems, enables more accurate predictions of  $g(r)$  than current state of the art GPU-based RDF codes currently available for these systems. In addition, our code reduces the computational time by approximately an order of magnitude compared to CPU-based calculations. We demonstrate the application of our toolset by the examination of a coarse-grained nanocomposite system and show how different surface energies between particle and polymer lead to different dispersion states, and effect properties such as viscosity, yield strength, elasticity, and thermal conductivity.

**11:51AM B38.00004 Analysis of the kinetics of filler segregation in granular block copolymer microstructure** , BONGJOON LEE, Carnegie Mellon University, MARKUS BLEUEL, NIST Center for Neutron Research, DAVID OTT, MICHAEL BOCKSTALLER, Carnegie Mellon University, CARNEGIE MELLON UNIVERSITY TEAM — To realize the application of block copolymers in areas ranging from dynamically tunable photonic crystals to solid-state electrolytes, it is important to understand the role of additives in the evolution of microstructure (i.e. grain size and shape as well as distribution) during thermal processing. Previous studies have revealed the interaction of filler species (such as homopolymers or particle additives) to drive the segregation of filler into grain boundary regions, thereby stabilizing grain boundary and arresting grain growth. In this contribution we present a novel approach based on combined Ultra-Small Angle Neutron Scattering (USANS) and electron microscopy analysis (involving large area image reconstruction) to quantitatively determine the kinetics of filler segregation and its affect on grain size evolution in block copolymer blends. Calculation of the scattering length density of the grain boundary network is shown to provide detailed information about the rate and time dependence of filler segregation. For the particular case of a poly(styrene-*b*-isoprene)/*d*-polystyrene blends system it is found that 2 vol% of filler segregation during the early stage of thermal annealing is sufficient to arrest grain growth.

**12:03PM B38.00005 Localization of Individual Nanoparticle in the Perforated Lamellar Phase of Self-assembled Block Copolymer Driven by Entropy Minimization** , TAE WON NAM, Korea Adv Inst of Sci & Tech — Although precisely controlled microdomains of block copolymers (BCP) provide an excellent guiding matrix for multiple nanoparticles (NPs) to be controllably segregated into a desired polymer block, localization and positioning of individual NPs have not been demonstrated. Here, we report a unique one-to-one positioning phenomenon of guest Au NPs in the host BCP microdomains; each of polystyrene-functionalized Au NPs is embedded within the perforation domain of hexagonally perforated lamellar (HPL) morphology of poly(dimethylsiloxane-*b*-styrene) BCP. The local minimization of free energy achieved by the placement of Au NPs into the center of the perforation domain is theoretically supported by the self-consistent field theory (SCFT) simulation. We propose a novel design principle for more precisely controllable nanocomposites by developing a new route of NP arrangement within a polymer matrix.

**12:15PM B38.00006 Predicting the dynamics and thermodynamics of nanoparticles in block copolymers** , ROBERT RIGGLEMAN, University of Pennsylvania — In applications involving polymer nanocomposites, controlling the dispersion of the nanoparticles is one of the most critical aspects of their design. For example, optimal mechanical properties are typically found when particles are maximally dispersed, while varying the interparticle spacing on the nm length scale can tune the optical properties of a composite. In all of these cases, the distribution of nanoparticles is a complex interplay of entropic and energetic interactions between the matrix polymers, nanoparticles, particle surface-grafted polymers, and even the processing conditions. Recently, my group has been extending the polymer field theory framework to enable the study of inhomogeneous polymer nanocomposites. The framework has the advantage of being computationally efficient and able to treat anisotropic particles (nanorods) and explicit surface chemistry, such as grafted nanoparticles. In this talk, I will describe some of our recent results with the method studying the distribution and interactions between nanoparticles in block copolymer matrices. First, I will show how we have quantified the interactions between nanoparticles and block copolymer grain boundaries. Second, I will describe our more recent efforts using non-equilibrium methods to study the role of processing, such as solvent annealing, on the distribution of nanoparticles in block copolymer thin films.

**12:51PM B38.00007 A Novel Method to Characterize Nanorod Orientation and Aggregation in Polymer Nanocomposites**<sup>1</sup> , ETHAN GLOR, ROBERT FERRIER, RUSSELL COMPOSTO, ZAHRA FAKHRAAI, Univ of Pennsylvania — Gold nanorods provide an ideal system for the systematic change of optical properties through changes in the rod aspect ratio. Furthermore, the dispersity and orientation of the nanorods within a polymer matrix greatly affects the optical properties of the composites. Here, we use spectroscopic ellipsometry to characterize the properties of nanocomposite thin films. The optical properties of the nanorod are modeled as an effective index of refraction for a disordered meta-material. This effective medium index is then related to the longitudinal surface plasmon resonance (LSPR) of the nanorods. The degree of birefringence in the LSPR frequency, as determined by variable angle ellipsometry measurements, can help determine the average orientation of the rods in the thin film as well as the degree of aggregation. With this method, one can quickly and accurately define the average orientation and average aggregation of nanorods within a nanocomposite with a single measurement. Ellipsometry also allows us to perform *in-situ* variable temperature measurements to monitor properties such as nanoparticle shape and the glass transition temperature of the matrix.

**1:03PM B38.00008 Microstructure of 3D-Printed Polymer Composites Investigated by Small-Angle Neutron Scattering**<sup>1</sup> , TAE HUI KANG, Oak Ridge National Lab, BRETT G. COMPTON, University of Tennessee, WILLIAM T. HELLER, VOKER S. URBAN, CHAD E. DUTY, CHANGWOO DO, Oak Ridge National Lab — Polymer composites printed from the large scale printer at Manufacturing Demonstration Facility at Oak Ridge National Laboratory have been investigated by small-angle neutron scattering (SANS). For the Acrylonitrile Butadiene Styrene (ABS)/Carbon Fiber (CF) composites, the microstructure of polymer domains and the alignment of CF have been characterized across the layer from the printed piece. CF shows strong anisotropic alignment along the printing direction due to the flow of polymer melt at the nozzle. Order parameter of the anisotropy which ranges from -0.11 to -0.06 exhibits strong correlation with the position within the layer: stronger alignment near the layer interface. It is also confirmed that the existence of CF reduces the polymer domain correlation length significantly and reinforces the mechanical strength of the polymer composites. For the Epoxy/nano-clay platelet composites, the effect of processing condition, nozzle size, and the addition of the another filler, Silicon Carbide (SC), have been investigated by SANS. Nano-clay platelet shows strong anisotropic alignment along the printing direction as well. Order parameter of the anisotropy varies according to nozzle size and presence of the SC, and difference disappears at high Q region.

**1:15PM B38.00009 Large Volume Self-Organization of Polymer/Nanoparticle Hybrids with Millimeter Scale Grain Sizes using Brush Block Copolymers**, DONGPO SONG, JAMES WATKINS, Department of Polymer Science and Engineering, University of Massachusetts Amherst — The lack of sufficient long-range order in self-assembled nanostructures is a bottleneck for many nanotechnology applications. In this work, we report that exceptionally large volume of highly ordered arrays (single grains) on the order of millimeters in scale can be rapidly created through a unique innate guiding mechanism of brush block copolymers (BBCPs). The grain volume is over 1 billion times larger relative to that of typical self-assembled linear BCPs (LBCPs). The use of strong interactions between nanoparticles (NPs) and BBCPs enables the high loadings of functional materials, up to 76 wt% (46 vol%) in the target domain, while maintaining excellent long-range order. Overall this work provides a simple route to precisely control the spatial orientation of functionalities at nanometer length scales over macroscopic volumes, thereby enabling the production of hybrid materials for many important applications.

**1:27PM B38.00010 Tuning the interactions between nanoparticles in block copolymer domains**, BEN LINDSAY, University of Pennsylvania, JEFFREY METH, DuPont, RUSSELL COMPOSTO, ROBERT RIGGLEMAN, University of Pennsylvania — Block copolymer nanocomposites have the potential to become a platform for new materials with improved thermal, electrical, or optical properties compared to neat polymers. However, it is critical to control the dispersion of the nanoparticles in the block copolymer matrix, and thus it is important to understand how nanoparticles interact with each other within block copolymer domains. In this work, we use a polymer nanocomposite field theory (PNC-FT) that was recently developed in our group to study the interactions of nanoparticles within both cylindrical and lamellar block copolymer structures. We find that the nanoparticles induce a curvature in the A-B interface in the block copolymer, which plays a significant role in the interparticle interactions, leading to a non-monotonic potential of mean force between the particles. This effect becomes more pronounced as the nanoparticle size increases. Finally, we will also present results showing the effect of nanoparticle surface functionality (polymer grafting) on the interparticle interactions.

**1:39PM B38.00011 Novel Polymer Nanocomposites Resulted from Melt Processing of Polystyrene-Based Substrates Coated with Layer-by-Layer Assemblies**, IMAN SOLTANI, RICHARD J. SPONTAK, North Carolina State Univ — The novel polymer nanocomposites (PNCs) prepared through two steps of coating polystyrene-based substrates with layer-by-layer (LBL) deposition of montmorillonite and alternative polyelectrolyte layers of polyethyleneimine and polyethylene terephthalate ionomer, followed by their cyclic melt pressing, demonstrated particular morphologies. Transmission electron microscopy images at high magnification scales showed the occurrence of swollen intercalation and flocculated exfoliations of clay platelets, down to a few nanometer thickness, inside and sometimes out of LBL assemblies crushed portions. In fact, intercalation and exfoliation of clay platelets, established in LBL assemblies, increased by shear applied through their repetitive melt pressing. Additionally, x-ray diffractometry traces confirmed the aforementioned increase in clay intercalation. These high aspect ratio LBL assemblies portions formed highly tortuous labyrinths, which may work as scavenging centers to promote barrier properties of the PNCs against transport of gases like oxygen and carbon dioxide. It is despite spontaneously low interaction between hydrophobic styrenic groups and almost hydrophilic natural clay and moderate efficiency of cyclic pressing for providing intensive shear stress on samples.

**1:51PM B38.00012 Stabilization of PS/PLA cocontinuous blends by interfacial graphene<sup>1</sup>**, LIAN BAI, Department of Chemical Engineering and Materials Science, University of Minnesota, SIYAO HE, Department of Chemistry, University of Minnesota, JOHN FRUEHWIRTH, Department of Chemical Engineering and Materials Science, University of Minnesota, ANDREAS STEIN, Department of Chemistry, University of Minnesota, XIANG CHENG, CHRISTOPHER MACOSKO, Department of Chemical Engineering and Materials Science, University of Minnesota — Reduced graphene oxide (r-GO) is known to be effective in increasing the conductivity of cocontinuous polymer blends with a lower electrical percolation threshold. However, little is known regarding the localization and dynamics of r-GO along with morphology change during annealing. In this study, we develop a facile method to stabilize the polystyrene (PS)/polylactic acid (PLA) cocontinuous blends with r-GO jammed at interface. In this method, the non-functionalized GO is premixed with PLA via solvent method, and then reduced in-situ at 210°C to obtain a PLA/r-GO polymer composite. This composite is further mixed with PS via batch melt compounding. We observe the migration of r-GO from the PLA phase to the interface during annealing. The interfacial r-GO suppresses the coarsening of cocontinuous morphology and increases the conductivity of the filled polymer blend. Moreover, we systematically investigate the relationship between r-GO localization, rheological and conductivity change during annealing of r-GO filled PLA/PS blends.

**11:15AM B39.00001 Real-time Visualization of Tissue Dynamics during Embryonic Development and Malignant Transformation**, KENNETH YAMADA, National Institutes of Health, National Institute of Dental and Craniofacial Research — Tissues undergo dramatic changes in organization during embryonic development, as well as during cancer progression and invasion. Recent advances in microscopy now allow us to visualize and track directly the dynamic movements of tissues, their constituent cells, and cellular substructures. This behavior can now be visualized not only in regular tissue culture on flat surfaces ('2D' environments), but also in a variety of 3D environments that may provide physiological cues relevant to understanding dynamics within living organisms. Acquisition of imaging data using various microscopy modalities will provide rich opportunities for determining the roles of physical factors and for computational modeling of complex processes in living tissues. Direct visualization of real-time motility is providing insight into biology spanning multiple spatio-temporal scales. Many cells in our body are known to be in contact with connective tissue and other forms of extracellular matrix. They do so through microscopic cellular adhesions that bind to matrix proteins. In particular, fluorescence microscopy has revealed that cells dynamically probe and bend the matrix at the sites of cell adhesions, and that 3D matrix architecture, stiffness, and elasticity can each regulate migration of the cells. Conversely, cells remodel their local matrix as organs form or tumors invade. Cancer cells can invade tissues using microscopic protrusions that degrade the surrounding matrix; in this case, the local matrix protein concentration is more important for inducing the micro-invasive protrusions than stiffness. On the length scales of tissues, transiently high rates of individual cell movement appear to help establish organ architecture. In fact, isolated cells can self-organize to form tissue structures. In all of these cases, in-depth real-time visualization will ultimately provide the extensive data needed for computer modeling and for testing hypotheses in which physical forces interact closely with cell signaling to form organs or promote tumor invasion.

**11:51AM B39.00002 Emergence of tissue mechanics from cellular processes: shaping a fly wing**, MATTHIAS MERKEL, Max Planck Institute for the Physics of Complex Systems, Dresden (MPI-PKS), RAPHAEL ETOURNAY, Max Planck Institute of Molecular Biology and Genetics, Dresden (MPI-CBG), MARKO POPOVIC, AMITABHA NANDI, MPI-PKS, HOLGER BRANDL, MPI-CBG, GUILLAUME SALBREUX, Crick Institute, London, SUZANNE EATON, MPI-CBG, FRANK JLICHER, MPI-PKS — Nowadays, biologists are able to image biological tissues with up to 10,000 cells in vivo where the behavior of each individual cell can be followed in detail. However, how precisely large-scale tissue deformation and stresses emerge from cellular behavior remains elusive. Here, we study this question in the developing wing of the fruit fly. To this end, we first establish a geometrical framework that exactly decomposes tissue deformation into contributions by different kinds of cellular processes. These processes comprise cell shape changes, cell neighbor exchanges, cell divisions, and cell extrusions. As the key idea, we introduce a tiling of the cellular network into triangles. This approach also reveals that tissue deformation can also be created by correlated cellular motion. Based on quantifications using these concepts, we developed a novel continuum mechanical model for the fly wing. In particular, our model includes active anisotropic stresses and a delay in the response of cell rearrangements to material stresses. A different approach to study the emergence of tissue mechanics from cellular behavior are cell-based models. We characterize the properties of a cell-based model for 3D tissues that is a hybrid between single particle models and the so-called vertex models.

**12:03PM B39.00003 Quantifying the mechanics of embryonic tissues in vivo and in situ**, OTGER CAMPAS, University of California, Santa Barbara — The sculpting of tissues and organs involves a tight spatiotemporal regulation of several physical fields, including active mechanical stresses and the local material properties. Despite the relevance of mechanics in embryonic morphogenesis, very little is known about the mechanisms by which tissue mechanics affects/controls developmental processes, mainly because it has not been possible to quantify mechanics within developing tissues in vivo and in situ. I will present two new techniques that permit direct quantification of (1) mechanical stresses at both tissue and cellular scales and (2) the material properties of the cellular microenvironment, in situ within living tissues and developing organs. Using these novel techniques, we characterize the mechanics of cell aggregates (in vitro), living mouse mandibles (ex vivo) and live zebrafish embryonic tissues (in vivo).

**12:15PM B39.00004 Cancer cell elasticity response to the mechanics of microenvironment**, JINGQIANG LI, RAYMOND FANG, KEVIN JIANG, Rice University, IAN LIAN, Lamar University, CHING-HWA KIANG, Rice University, RICE UNIVERSITY TEAM, LAMAR UNIVERSITY TEAM — Cells can sense and respond to the mechanical properties of their microenvironment. In particular, the rigidity of the cell's microenvironment is regarded as a physical parameter of interest given its regulation of various cellular processes, including proliferation, differentiation and migration. Currently, in vitro cancer studies primarily performed by monolayer culture grown on the rigid polystyrene surfaces, but in vivo cancer cells interact with much softer tissue. Here, we utilize a new soft substrate cell culture platform to mimic tissues with various stiffness within the physiological range (0.2–100 kPa). We apply atomic force microscopy (AFM) to probe the elastic behaviors of three different cancer cell lines so as to emulate the essential features in the in vivo microenvironment. We observed that the substrate stiffness has a significant effect on the cell morphology and elasticity. The results of our study could have important implications regarding to the physics of cancer metastasis.

**12:27PM B39.00005 Cell Membrane Softening in Cancer Cells**, SEBASTIAN SCHMIDT, CHRIS HNDEL, JOSEF KS, Leipzig University — Biomechanical properties are useful characteristics and regulators of the cell's state. Current research connects mechanical properties of the cytoskeleton to many cellular processes but does not investigate the biomechanics of the plasma membrane. We evaluated thermal fluctuations of giant plasma membrane vesicles, directly derived from the plasma membranes of primary breast and cervical cells and observed a lowered rigidity in the plasma membrane of malignant cells compared to non-malignant cells. To investigate the specific role of membrane rigidity changes, we treated two cell lines with the Acetyl-CoA carboxylase inhibitor Sorafenib. It changed the lipidome of cells and drastically increased membrane stiffness by up-regulating short chained membrane lipids. These altered cells had a decreased motility in Boyden chamber assays. Our results indicate that the thermal fluctuations of the membrane, which are much smaller than the fluctuations driven by the cytoskeleton, can be modulated by the cell and have an impact on adhesion and motility.

**12:39PM B39.00006 Network motifs that stabilize the hybrid epithelial/mesenchymal phenotype<sup>1</sup>**, MOHIT KUMAR JOLLY, DONGYI JIA, Rice Univ, SATYENDRA TRIPATHI, SAMIR HANASH, SENDURAI MANI, MD Anderson Cancer Center, ESHEL BEN-JACOB, HERBERT LEVINE, Rice Univ — Epithelial to Mesenchymal Transition (EMT) and its reverse – MET – are hallmarks of cancer metastasis. While transitioning between E and M phenotypes, cells can also attain a hybrid epithelial/mesenchymal (E/M) phenotype that enables collective cell migration as a cluster of Circulating Tumor Cells (CTCs). These clusters can form 50-times more tumors than individually migrating CTCs, underlining their importance in metastasis. However, this hybrid E/M phenotype has been hypothesized to be only a transient one that is attained en route EMT. Here, via mathematical modeling, we identify certain 'phenotypic stability factors' that couple with the core three-way decision-making circuit (miR-200/ZEB) and can maintain or stabilize the hybrid E/M phenotype. Further, we show experimentally that this phenotype can be maintained stably at a single-cell level, and knockdown of these factors impairs collective cell migration. We also show that these factors enable the association of hybrid E/M with high stemness or tumor-initiating potential. Finally, based on these factors, we deduce specific network motifs that can maintain the E/M phenotype. Our framework can be used to elucidate the effect of other players in regulating cellular plasticity during metastasis.

**12:51PM B39.00007 Combinatorial Interventions Inhibit the Epithelial-to-Mesenchymal Transition and Support Hybrid Cellular Phenotypes<sup>1</sup>**, JORGE G. T. ZANUDO, S.N. STEINWAY, The Pennsylvania State University, P.J. MICHEL, D.J. FEITH, T.P. LOUGHRAN JR., University of Virginia School of Medicine, REKA ALBERT, The Pennsylvania State University — Epithelial-to-mesenchymal transition (EMT) is a developmental process hijacked by cancer cells to leave the primary tumor site and spread to other parts of the body. The molecular network regulating EMT involves the cooperation and cross-talk between multiple signaling pathways and key transcription factors, which we incorporated into systems-level logical network model for EMT. Using the EMT network model, we investigate potential EMT-suppressing interventions by identifying which individual and combinatorial perturbations suppress the induction of EMT by TGF $\beta$ , an important signal driving EMT in liver cancer. We find that all non-trivial interventions are combinatorial and involve the inhibition of the SMAD complex together with other targets, several of which we experimentally tested and validated using liver cancer cell lines. We compare the combinatorial interventions with the results from a network control method we recently developed, which allowed us to determine the specific feedback regulatory motifs through which the interventions suppress EMT. Our results also reveal that blocking certain network components gives rise to steady states that are intermediate to the epithelial and mesenchymal states, supporting the existence of hybrid epithelial-mesenchymal states.

**1:03PM B39.00008 Testing the differential adhesion hypothesis across the epithelial-mesenchymal transition**, STEVE PAWLIZAK, ANATOL FRITSCH, STEFFEN GROSSER, LINDA OSWALD, Leipzig University, LISA MANNING, Syracuse University, JOSEF KAS, Leipzig University — We analyze the properties of three epithelial/mesenchymal cell lines that exhibit a shift in cadherin levels characteristic of an epithelial-mesenchymal transition (EMT) associated with processes such as metastasis, to quantify the role of cell cohesion in cell sorting and compartmentalization. We develop a unique set of methods to measure cell-cell adhesiveness, cell stiffness and cell shapes, and compare the results to predictions from cell sorting in mixtures of cell populations. We find that the final sorted state is extremely robust among all three cell lines independent of epithelial or mesenchymal state, suggesting that cell sorting may play an important role in organization and boundary formation in tumours. We find that surface densities of adhesive molecules do not correlate with measured cell-cell adhesion, but do correlate with cell shapes, cell stiffness and the rate at which cells sort, in accordance with an extended differential adhesion hypothesis (DAH). Surprisingly, the DAH does not correctly predict the final sorted state. This suggests that these tissues are not behaving as immiscible fluids, and that dynamical effects such as directional motility, friction and jamming may play an important role in tissue compartmentalization across the EMT.

**1:15PM B39.00009 Polymeric Nanocomposite that Mimics in vivo ECM Topography in Tissue using Magnetic Field-induced Particle Self-assembly.**, JIYUN KIM, JACK STAUNTON, KANDICE TANNER, National Institutes of Health — 3D biomaterials that mimic a certain physical or chemical aspect of cellular environment have been used to recreate the diversity of the tissue microenvironment. Especially, physical characteristics of these materials such as topography, dimension and stiffness, have known to have crucial effects on cell fate and cell malignancy. Here, we propose a technique that is able to create diverse topographies in 3D polymeric scaffold for the purpose of mimicking the structural aspect of tissue microenvironment. To achieve this, we exploit the magnetic field-directed assembly of super paramagnetic particles to fabricate chain-distributed architecture such that we can study the effects of extracellular matrix (ECM) topography on cell behavior. First, we chemically cross-link proteins including fibronectin, laminin and bovine albumin serum on the surface of magnetic particles to make the building blocks for artificial topography. Then, we assemble these particles by applying the parallel magnetic field in a surrogate polymeric matrix and solidify the matrix to maintain the assembled topography. Using this simple technique, we patterned diverse topographies in 3D including globular, fibril or interfaced architectures without chafing other material characteristics of the scaffold matrix, such as stiffness and molecular diffusion. We demonstrated that the fibril architecture guides the dendritic extension of fibroblasts and neuron-like cells, compared to the cells grown in the globular architecture lacking anisotropic guidance cues.

**1:27PM B39.00010 Interplay of differential cell mechanical properties, motility, and proliferation in emergent collective behavior of cell co-cultures<sup>1</sup>**, LEO SUTTER, DAN KOLBMAN, Rochester Institute of Technology, MINGMING WU, MINGLIN MA, Cornell University, MOUMITA DAS, Rochester Institute of Technology — The biophysics of cell co-cultures, i.e. binary systems of cell populations, is of great interest in many biological processes including formation of embryos, and tumor progression. During these processes, different types of cells with different physical properties are mixed with each other, with important consequences for cell-cell interaction, aggregation, and migration. The role of the differences in their physical properties in their collective behavior remains poorly understood. Furthermore, until recently most theoretical studies of collective cell migration have focused on two dimensional systems. Under physiological conditions, however, cells often have to navigate three dimensional and confined micro-environments. We study a confined, three-dimensional binary system of interacting, active, and deformable particles with different physical properties such as deformability, motility, adhesion, and division rates using Langevin Dynamics simulations. Our findings may provide insights into how the differences in and interplay between cell mechanical properties, division, and motility influence emergent collective behavior such as cell aggregation and segregation experimentally observed in co-cultures of breast cancer cells and healthy breast epithelial cells.

**1:39PM B39.00011 How do heterogeneities in single cell rigidity influence the mechanical behavior at the tissue level?**, DAPENG BI, Rockefeller University, FRANZISKA WETZEL, ANATOL FRITSCH, University of Leipzig, M. CRISTINA MARCHETTI, M. LISA MANNING, Syracuse University, JOSEF KAES, University of Leipzig — It has been long recognized that solid tumor tissues are mechanically more rigid than surrounding healthy tissues. However recent experiments have shown that in primary tumor samples from patients with mammary and cervix carcinomas, cells exhibit a broad distribution of rigidities, with a higher fraction of softer and more contractile cells compared to normal tissues. This gives rise to a paradox: does softness emerge from adaptation to mechanical and chemical cues in the external microenvironment, or are soft cells already present inside a primary solid tumor? Motivated by these observations, we study a model of dense tissues that incorporates the experimental data for cell stiffness variations to reveal that, surprisingly, tumors with a significant fraction of very soft cells can still remain rigid. Moreover, in tissues with the observed distributions of cell stiffnesses, softer cells spontaneously self-organize into lines or streams, possibly facilitating cancer metastasis.

**1:51PM B39.00012 Modeling the Spatiotemporal Evolution of the Melanoma Tumor Microenvironment**, ALEXANDRA SIGNORIELLO, MARCUS BOSENBERG, Yale University, MARK SHATTUCK, City College of New York, COREY O'HERN, Yale University — The tumor microenvironment, which includes tumor cells, tumor-associated macrophages (TAM), cancer-associated fibroblasts, and endothelial cells, drives the formation and progression of melanoma tumors. Using quantitative analysis of in vivo confocal images of melanoma tumors in three spatial dimensions, we examine the physical properties of the melanoma tumor microenvironment, including the numbers of different cell types, cell size, and morphology. We also compute the nearest neighbor statistics and measure intermediate range spatial correlations between different cell types. We also calculate the step size distribution, mean-square displacement, and non-Gaussian parameter from the spatial trajectories of different cell types in the tumor microenvironment.

**2:03PM B39.00013 Stochastic modeling and experimental analysis of phenotypic switching and survival of cancer cells under stress**, SEYED ALIREZA ZAMANI DAHAJ, NIRAJ KUMAR, BALA SUNDARAM, JONATHAN CELLI, RAHUL KULKARNI, Department of Physics, University of Massachusetts Boston — The phenotypic heterogeneity of cancer cells is critical to their survival under stress. A significant contribution to heterogeneity of cancer cells derives from the epithelial-mesenchymal transition (EMT), a conserved cellular program that is crucial for embryonic development. Several studies have investigated the role of EMT in growth of early stage tumors into invasive malignancies. Also, EMT has been closely associated with the acquisition of chemoresistance properties in cancer cells. Motivated by these studies, we analyze multi-phenotype stochastic models of the evolution of cancer cell populations under stress. We derive analytical results for time-dependent probability distributions that provide insights into the competing rates underlying phenotypic switching (e.g. during EMT) and the corresponding survival of cancer cells. Experimentally, we evaluate these model-based predictions by imaging human pancreatic cancer cell lines grown with and without cytotoxic agents and measure growth kinetics, survival, morphological changes and (terminal evaluation of) biomarkers with associated epithelial and mesenchymal phenotypes. The results derived suggest approaches for distinguishing between adaptation and selection scenarios for survival in the presence of external stresses.

**11:15AM B40.00001 Direct measurement of surface stress of stretched soft solids.** , QIN XU, ERIC DUFRESNE, Mechanical Engineering and Materials Science, Yale University — The wetting profile of liquid droplets on soft solids is determined by the competition between elasticity and solid surface stress. Near the contact point, the bulk elasticity becomes negligible such that Neumann's classic analysis nicely captures the wetting geometry and provides us an effective approach to directly measure the solid surface stress. Here, we report our experiments using confocal microscopy in studying the wetting of liquids on soft PDMS gels. While the droplets are sitting on the top, the substrates are biaxially strained. We observe that the wetting profiles and the three-phase contact angles are changing dramatically as the substrate is stretched. With Neumann's principle, we obtain the quantitative relation between surface stress of the PDMS and the applied strain. These results suggest a significant strain-dependence of surface energy and surface stress for our PDMS.

**11:27AM B40.00002 A numerical modeling capability for the interplay between surface energy and elasticity in soft materials** , DAVID HENANN, YUHAO WANG, Brown University — Surface energy is an important factor in the deformation of fluids but is typically a minimal or negligible effect in solids. However, when a solid is soft and its characteristic dimension is small, forces due to surface energy can become important and induce significant elastic deformation. The interplay between surface energy and elasticity can lead to interesting elasto-capillary phenomena. We have developed a finite-element formulation for problems involving these effects in both 2D and 3D settings and will demonstrate the simulation capability by examining two elasto-capillary problems. (1) The Rayleigh-Plateau instability in an elastic material — In a fluid, this instability causes fluid jets to break up into droplets; however, as shown in recent experiments (Mora et al., PRL, 2010), break-up is prohibited in an elastic material, resulting in a stable undulatory configuration. (2) The effect of fluid-filled droplet inclusions on a soft solid — When the matrix material is stiff, the presence of fluid-filled inclusions leads to a more compliant composite material; however, recent experiments (Style, et al., Nature Physics, 2014) have shown that when the matrix material is more compliant, the presence of droplets leads to stiffening. In this talk, we will show that our simulation capability predicts all experimentally observed phenomena and provides a straightforward route for describing nonlinear aspects of elasto-capillarity, which are difficult to address via analytics.

**11:39AM B40.00003 Elastocapillary Deformations and Fracture of Soft Gels** , KAREN DANIELS, NC State University, MARION GRZELKA, ENS-Cachan, JOSHUA BOSTWICK, Clemson University — When a droplet is placed on the surface of a soft gel, the surface deforms by an amount proportional to the elastocapillary length calculated from the ratio of surface tension and elastic modulus. For sufficiently large deformations, the gel can fracture due to the forces generated under the liquid-gel contact line. We observe that a starburst of channel fractures forms at the surface of the gel, driven by fluid propagating away from the central droplet. To understand the initiation of these cracks, we model the substrate as an incompressible, linear-elastic solid and quantify the elastic response. This provides quantitative agreement with experimental measurements of the number of fracture arms as a function of material properties and geometric parameters. In addition, we find that the initiation process is thermally-activated, with delay time that decreases as a function of the elastocapillary length.

**11:51AM B40.00004 Surface tension and deformation in soft adhesion** , KATHARINE JENSEN, Yale University — Modern contact mechanics was originally developed to account for the competition between adhesion and elasticity for relatively stiff deformable materials like rubber, but much softer sticky materials are ubiquitous in biology, engineering, and everyday consumer products. In such soft materials, the solid surface tension can also play an important role in resisting shape change, and significantly modify the physics of contact with soft matter. We report indentation and pull-off experiments that bring small, rigid spheres into adhesive contact with compliant silicone gel substrates, varying both the surface functionalization of the spheres and the bulk elastic properties of the gels. We map the resulting deformation profiles using optical microscopy and image analysis. We examine the substrate geometry in light of capillary and elastic theories in order to explore the interplay of surface tension and bulk elasticity in governing soft adhesion.

**12:27PM B40.00005 Elastocapillary Swelling: When coalesced structures curl apart** , DOUGLAS HOLMES, Boston University, PIERRE-THOMAS BRUN, MIT, ANUPAM PANDEY, University of Twente, SUZIE PROTIERE, Institut Jean Le Rond d'Alembert — We consider the elastocapillary rise between swellable structures using a favorable solvent. We study the elastocapillary rise and subsequent swelling-induced bending, and characterize the dynamic deformations and resulting equilibrium configurations for various beam geometries. Our analysis highlights the importance of two characteristic length scales, and uses these lengths to predict both the elastocapillary rise and the critical curvature for peeling. We predict the transition between coalescence dominated beams and bending dominated beams using a balance of bending, stretching, and surface energies, and use a relaxed constraint on Euler's elastica to describe the fluid ratcheting.

**12:39PM B40.00006 Effects of elasto-capillarity on periodic films folding and unfolding** , OSAMA BILAL, ANDRE FOEHR, JINWOONG CHA , CHIARA DARAI, Department of Mechanical and Process Engineering, ETH-Zurich — Thin films interact with liquid surfaces through elastocapillary forces. These forces can control structural deformations of wetted thin films. Deformations arise from the interplay between the elastic strain energy in the bulk of the films, and the energy on the surface. In this work, we study the interplay between the surface tension of water and periodic patterns on different thin films. Our analysis explores the utilization of these periodically patterned films for the deployability of micro and nano-systems. The main attention is paid to the experimental results of this phenomenon and the results are supported by numerical analysis.

**12:51PM B40.00007 Wrinkles and folds in a compressed granular raft** , ETIENNE JAMBON-PUILLET, CHRISTOPHE JOSSERAND, SUZIE PROTIERE, Institut Jean le Rond d'Alembert, Univ Paris 6 UPMC, CNRS UMR 7190, France — Wrinkles and folds occur in a wide variety of situations, we find them in Nature but also in man-made products. They typically appear when a thin sheet bound to a foundation is compressed. Here we demonstrate that particle laden interfaces, despite being made of discrete very hard particles, can form wrinkles and folds like a soft elastic solid. We call granular raft a close packed monolayer of heavy, athermal particles at the interface between two fluids. We use beads of different materials with diameters ranging from 30  $\mu\text{m}$  to 0.8  $\text{mm}$  dispersed at a planar oil/water interface. Upon uniaxial compression the raft buckles out of plane like a soft elastic solid and forms a periodic wrinkling pattern, then the deformation localizes in a large unique fold/crease. This behavior is reminiscent of a compressed elastic sheet floating on water. We will highlight similarities and differences between the mechanical properties of our discrete heavy granular raft and a continuous elastic floating film. Finally we will show how elasticity and gravity contribute to rationalize the original shape of the fold we observe.

**1:03PM B40.00008 Wrapping with a splash** , DEEPAK KUMAR, University of Massachusetts Amherst, JOSEPH PAULSEN, Syracuse University, THOMAS RUSSELL, NARAYANAN MENON, University of Massachusetts Amherst — Ultrathin sheets have been used to encapsulate drops of one fluid in another. When the sheet is thin enough that bending energies are much smaller than interfacial energies, experiment and theory show that optimal wrappings are achieved without any special sheet design [1]. Here we study wrappings generated by the impact of an oil droplet onto an ultrathin (30-200 nm) polystyrene film floating on water. Depending on the energy of impact, a large deformation of the air-water interface is followed by formation of an oil phase wrapped around by the polymer film, submerged in the water. Even though the energetic cost of bending of the polymer film is very small, we find that successful wrapping requires an impact energy much larger than the energy difference between the initial and final configurations. We explore the dynamics of the fluid and the sheet in this process with a view to devising an efficient method to create optimal wrappings. [1] J.D. Paulsen, V. Dmery, C.D. Santangelo, T.P. Russell, B. Davidovitch, and N. Menon, doi:10.1038/nmat4397 (2015).

**1:15PM B40.00009 Deformation of flexible micro helices under flow**, MARINE DAIEFF, ANKE LINDNER, OLIVIA DU ROURE, PMMH-ESPCI, Paris, France, ALEXANDER MOROZOV, University of Edinburgh, United Kingdom, JONATHAN PHAM, ALFRED CROSBY, University of Massachusetts, Amherst, USA — The interaction of small helices with fluids is important because of its relevance to both fundamental science and technological applications, such as swimming microrobots or microflow sensors. Helically shaped flagella are also exploited by swimming microorganisms to move through their surrounding fluids. Here we study experimentally the deformation of flexible helical ribbons under flow in a microfluidic channel. The size of the helix is typically microscale for the diameter and nanoscale for the thickness. We focus on two different aspects: the overall shape of the helix and the viscous frictional properties. The frictional coefficients determined by our experiments are consistent with calculated values in the context of resistive force theory. Deformation of helices by viscous flow is well-described by non-linear finite extensibility. Due to the non-uniform distribution of the pitch under distributed loading, we identify both linear and nonlinear behavior along the contour length of a single helix. Utilizing our system, we explore the impact of non-Newtonian fluid properties on the mechanics of helix-fluid interactions.

**1:27PM B40.00010 Dynamics and propulsion of a rotating flexible helical rod near a no-slip rigid boundary**, MOHAMMAD JAWED, HUSSAIN KARIMI, PEDRO REIS, Massachusetts Institute of Technology — We study the effect of a no-slip rigid boundary on the locomotion of uni-flagellar bacteria in a viscous fluid at low Reynolds number conditions, through a combination of computer simulations and experiments. In our analogue model experiments, we exploit the prominence of geometry in this class of problems to rescale the original micron-scale system onto the desktop-scale. We manufacture elastomeric filaments with fully customizable geometric and material properties, and rotate them in a glycerin bath at a finite distance away from a rigid boundary. The experimental results are compared against numerical simulations that combine the Discrete Elastic Rods method in conjunction with Lighthill Slender Body Theory. The no-slip boundary condition on the wall is implemented by the method of images. We first show that the filament buckles above a critical rotation frequency due to fluid loading, and then quantify the dependence of this critical threshold on the distance from the boundary. Excellent agreement is found between experiments and simulations, with no fitting parameters. Moreover, we find that the generated propulsion force is strongly affected by the presence of a nearby boundary.

**1:39PM B40.00011 Fluid-structure interaction of reticulated porous wings**, ELIZABETH STRONG, MOHAMMAD JAWED, PEDRO REIS, MIT — Insects of the orders *Neuroptera* and *Hymenoptera* locomote via flapping flight with reticulated wings that have porous structures that confers them with remarkable lightweight characteristics. Yet these porous wings still perform as contiguous plates to provide the necessary aerodynamic lift and drag required for flight. Even though the fluid flow past the bulk of these insects may be in high Reynolds conditions, viscosity can dominate over inertia in the flow through the porous sub-features. Further considering the flexibility of these reticulated wings yields a highly nonlinear fluid-structure interaction problem. We perform a series of dynamically-scaled precision model experiments to gain physical insight into this system. Our experiments are complemented with computer simulations that combine the Discrete Elastic Rods method and a model for the fluid loading that takes into account the 'leakiness' through the porous structure. Our results are anticipated to find applications in micro-air vehicle aerodynamics.

**1:51PM B40.00012 Switchable and Tunable Aerodynamic Drag on Cylinders**, MARK GUTTAG, FRANCISCO LOPZ JIMNEZ, MIT, PRIYANK UPADHYAYA, SHANMUGAM KUMAR, Masdar Institute, PEDRO REIS, MIT — We report results on the performance of Smart Morphable Surfaces (Smporhs) that can be mounted onto cylindrical structures to actively reduce their aerodynamic drag. Our system comprises of an elastomeric thin shell with a series of carefully designed subsurface cavities that, once depressurized, lead to a dramatic deformation of the surface topography, on demand. Our design is inspired by the morphology of the giant cactus (*Carnegiea gigantea*) which possesses an array of axial grooves, thought to help reduce aerodynamic drag, thereby enhancing the structural robustness of the plant under wind loading. We perform systematic wind tunnel tests on cylinders covered with our Smorhs and characterize their aerodynamic performance. The switchable and tunable nature of our system offers substantial advantages for aerodynamic performance when compared to static topographies, due to their operation over a wider range of flow conditions.

**2:03PM B40.00013 Fanning the Optimal Breeze with an Abanico**, GRACE GOON, JOEL MARTHELOT, PEDRO REIS, MIT, MIT EGS LAB TEAM — Flexible hand-held fans, or abanicos, are universally employed as cooling devices that are both portable and sustainable. Their to and fro axial motion about one's hand generates an airflow that increases the evaporation rate near the skin and refreshes. We study this problem in the context of fluid-structure interaction, through precision model experiments. We first characterize the elastic properties of a semi-circular thin plates with various thickness and evaluate their aerodynamic performance in a custom built apparatus. The air velocity profile that results from the flapping motion of the fan is characterized for different driving conditions. A systematic variation of the geometric and elastic parameters, along with an exploration of the parameter space of the periodic driving motion (amplitude and frequency), allows us to establish optimal design and operational conditions for maximal output of the generated airflow, while minimizing the input power.

**Session B42 DPOLY: Physics of Copolymers** | 345 - Chaitanya Ullal, Rensselaer Polytechnic Institute

**11:15AM B42.00001 Block Copolymer Bottlebrushes: New Routes to Ever Smaller Microdomain Sizes**, MAHESH MAHANTHAPPA, Univ of Minn - Minneapolis, FRANK SPEETJENS, Univ of Wisconsin - Madison — Block copolymer self-assembly presents exciting opportunities for the development of nanotemplates for advanced lithography applications, wherein the microdomain sizes (~10–100 nm) are governed by the total copolymer degree of polymerization,  $N$ . However, this methodology is limited in its smallest achievable length scale, since AB diblock copolymers self-assemble only above a critical  $N$  that depends on the magnitude of the effective segmental interaction parameter  $\chi_{AB}$ . Numerous recent reports have focused on developing “high  $\chi_{AB}$ ” AB diblocks that self-assemble at low values of  $N$ . In this talk we explore the ability of non-linear polymer architectures to induce block copolymer ordering at reduced length scales. Thus, we describe the melt and thin-film self-assembly behavior of block copolymer bottlebrushes derived from linking the block junctions of low molecular weight AB diblocks. We quantitatively demonstrate that increasing the bottlebrush backbone degree of polymerization ( $N_{\text{backbone}}$ ) results in a larger reduction in the critical copolymer arm degree of polymerization ( $N_{\text{arm}}$ ) required for self-assembly, thus reducing the length scales at which these materials self-assemble.

**11:15AM B41.00001 Whole-brain calcium imaging with cellular resolution in freely behaving *Caenorhabditis elegans***, JEFFREY NGUYEN, FREDERICK SHIPLEY, ASHLEY LINDER, GEORGE PLUMMER, MOCHI LIU, SAGAR SETRU, JOSHUA SHAEVITZ, ANDREW LEIFER, Princeton University — The ability to acquire large-scale recordings of neuronal activity in awake and unrestrained animals is needed to provide new insights into how populations of neurons generate animal behavior. Acquiring this data, however, is challenging because it is difficult to track and image individual neurons as an animal deforms its posture and moves many body lengths. Here, we present an instrument capable of recording intracellular calcium transients from the majority of neurons in the head of a freely behaving *Caenorhabditis elegans* with cellular resolution while simultaneously recording the animals position, posture, and locomotion. 3D volumetric fluorescent images of neurons expressing the calcium indicator GCaMP6s are recorded at 6 head-volumes/s using spinning disk confocal microscopy. At the same time, we record low magnification images of the animal to measure the animals behavior and track its head as it moves. We develop a time independent neuronal matching algorithm that uses non-rigid point set registration and machine learning to correctly match neurons across time. Using this method, we are able to observe calcium transients from up to 90 neurons for over 4 min and correlate the neural activity with the animals behavior.

**11:27AM B41.00002 Dynamics of adaptive immunity against phage in bacterial populations**, SERENA BRADDE, CUNY, MARIJA VUCELJA, University of Virginia, TIBERIU TESILEANU, CUNY, VIJAY BALASUBRAMANIAN, University of Pennsylvania — The CRISPR (clustered regularly interspaced short palindromic repeats) mechanism allows bacteria to adaptively defend against phages by acquiring short genomic sequences (spacers) that target specific sequences in the viral genome. We propose a population dynamical model where immunity can be both acquired and lost. The model predicts regimes where bacterial and phage populations can co-exist, others where the populations oscillate, and still others where one population is driven to extinction. Our model considers two key parameters: (1) ease of acquisition and (2) spacer effectiveness in conferring immunity. Analytical calculations and numerical simulations show that if spacers differ mainly in ease of acquisition, or if the probability of acquiring them is sufficiently high, bacteria develop a diverse population of spacers. On the other hand, if spacers differ mainly in their effectiveness, their final distribution will be highly peaked, akin to a “winner-take-all” scenario, leading to a specialized spacer distribution. Bacteria can interpolate between these limiting behaviors by actively tuning their overall acquisition rate.

**11:27AM B42.00002 Rich Phase Behavior of Sphere-Forming Asymmetric ABA'C Block Copolymer Melts<sup>1</sup>**, SID CHANPURIYA, AKASH ARORA, KYUNGTAEE KIM, KEVIN DORFMAN, FRANK BATES, Univ of Minnesota - Twin Cities — Motivated by self-consistent field theory simulations, the effect of ABA' corona block length asymmetry on the phase behavior of ABA'C-type tetrablock terpolymers has been examined. The chosen model system, poly(styrene)-*b*-poly(isoprene)-*b*-poly(styrene)-*b*-poly(ethylene oxide) (SIS'O), has been characterized using a combination of small-angle X-ray scattering, transmission electron microscopy, and dynamic mechanical spectroscopy. Asymmetric SIS'O tetrablocks reveal a rich variety of sphere-forming phases over compositions and molecular weights where symmetric SISO polymers formed only hexagonally oriented cylinders. These include FCC, HCP, and complex symmetries such as the Frank-Kasper  $\sigma$  and A15 phases.

<sup>1</sup>NSF Award 1333669

**11:39AM B42.00003 Formation of Frank-Kasper  $\sigma$ -phase from polydisperse diblock copolymers**, MEIJIAO LIU, WEIHUA LI, Fudan University, AN-CHANG SHI, McMaster University — Recent experimental and theoretical studies have revealed a number of complex spherical phases including the complex Frank-Kasper  $\sigma$ -phase, which consists of 30 spheres in a unit cell. It is desirable to understand the mechanisms for the formation of the complex spherical phases such as the A15-phase and the Frank-Kasper  $\sigma$ -phase in block copolymers. Based on the observation that the A15-phase and the Frank-Kasper  $\sigma$ -phase are composed of spherical domains with different sizes, we hypothesize that polydispersity of the block copolymers could be used to obtain these complex phases. We tested this hypothesis by carrying out self-consistent field theory for polydisperse AB diblock copolymers. Specially we studied the relative stability of various spherical phases, including the fcc, bcc, A15 and Frank-Kasper  $\sigma$ -phase, in binary blends composed of AB block copolymers different lengths of the A-blocks. Our results revealed that the Frank-Kasper  $\sigma$ -phase could be stabilized by tailoring the length ratio as well as the compositions of the two diblock copolymers. The distribution of the diblocks in the system indicates that copolymer segregation is the origin of the formation of spherical domains with different sizes.

**11:39AM B41.00003 Distinguishing Feedback Mechanisms in Clock Models<sup>1</sup>**, ALEXANDER GOLDEN, DAVID LUBENSKY, University of Michigan, Ann Arbor — Biological oscillators are very diverse but can be classified based on dynamical motifs such as type of feedback. The *S. Elongatus* circadian oscillator is a novel circadian oscillator that can operate at constant protein number by modifying covalent states. It can be reproduced in vitro with only 3 different purified proteins: KaiA, KaiB, and KaiC. We use computational and analytic techniques to compare models of the *S. Elongatus* post-translational oscillator that rely on positive feedback with models that rely on negative feedback. We show that introducing a protein that binds competitively with KaiA to the KaiB-KaiC complex can distinguish between positive and negative feedback as the primary driver of the rhythm, which has so far been difficult to address experimentally.

**11:51AM B41.00004 Starvation-induced dormancy in *E. coli***, EMRAH SIMSEK, MINSU KIM, Emory Univ — Isogenic bacterial populations can exhibit phenotypic heterogeneity. Phenotypic heterogeneity is often viewed as a bet-hedging strategy to cope with environmental fluctuations, and believed to be under genetic control. The experimental evidence of this view, however, is limited. Here, we report experimental evidence that prompts reconsideration of this view. Observing how starved *E. coli* cells resume growth upon nutrient upshift at the single-cell level in real time, we revealed that physiological and metabolic state of starved cells, as well as growth resumption kinetics, vary from cell to cell. Upon nutrient upshift, a majority of cells resume growth instantly, but a small fraction maintain a non-growth state for several hours or days (i.e., long lag time). Hence they are dormant cells. The fraction strongly depends on the duration of starvation. The dormancy does not confer resistance to starvation. Oxidative damage accumulated during starvation leads to the appearance of dormant cells. Taken together, our data suggests that a dormant subpopulation appears as an inevitable consequence of starvation, rather than cellular decision to cope with starvation. Hence, the existence of a genetic program and adaptive value as a bet-hedging strategy to cope with starvation stress may not be needed to explain the emergence of bacterial dormancy.

**11:51AM B42.00004 Phase Behavior of SIS'O Tetrablock Terpolymers: A Self-consistent Field Theory Study**

, AKASH ARORA, DAVID C. MORSE, FRANK S. BATES, KEVIN D. DORFMAN, Univ of Minn - Minneapolis — Block copolymers with three or more blocks show richer phase behavior than diblock copolymers. In this work, we use self-consistent field theory (SCFT) to study the phase behavior of *ABA'C* type tetrablock terpolymers. In particular, we are motivated by experimental studies on poly(styrene-*b*-isoprene-*b*-styrene-*b*-ethylene oxide) (SIS'O) that report interesting phases such as core-shell spheres and cylinders, the Frank-Kasper  $\sigma$  phase, and the dodecagonal quasicrystalline morphology. We compare SCFT predictions to experimental results for SIS'O copolymers using values of the Flory-Huggins interaction parameters that are estimated from analysis of literature data on related systems.

**12:03PM B42.00005 Preparation and Morphology of AB<sub>n</sub> Mictoarm Block Copolymers.**

, ATSUSHI TAKANO, MOMOKA WATANABE, YUSUKE ASAI, Department of applied chemistry, Graduate School of Engineering, Nagoya University, JIRO SUZUKI, High Energy Accelerator Research Organization (KEK), YUSHU MATSUSHITA, Department of applied chemistry, Graduate School of Engineering, Nagoya University — A series of AB<sub>n</sub> mictoarm block copolymers (bottle brush copolymers) consisting of polystyrene (S) as a backbone and polyisoprenes (I) as grafts were precisely synthesized by an anionic polymerization, and their microphase-separated structures were investigated by transmission electron microscopy (TEM) and small-angle X-ray scattering (SAXS). A copolymer with composition of  $\phi_S=0.57$  and number of grafts(*n*) of 10 shows characteristic cylindrical structure, where microdomains of S reveals hexagonal cross section with non-constant mean curvature interface. While a sample with composition of  $\phi_S=0.37$  and number of grafts(*n*) of 40 shows spherical structure with rather large S isolated domains and characteristic domain packing manner was found. Furthermore composition dependence of microphase-separated structures for SIn mictoarm block copolymers were investigated and compared to SI diblock copolymer system.

**12:03PM B41.00005 Queueing-Based Synchronization and Entrainment for Synthetic Gene Oscillators<sup>1</sup>**

, WILLIAM MATHER, NICHOLAS BUTZIN, PHILIP HOCHENDONER, CURTIS OGLE, Dept. of Physics, Virginia Polytechnic Inst. and State University — Synthetic gene oscillators have been a major focus of synthetic biology research since the beginning of the field 15 years ago. They have proven to be useful both for biotechnological applications as well as a testing ground to significantly develop our understanding of the design principles behind synthetic and native gene oscillators. In particular, the principles governing synchronization and entrainment of biological oscillators have been explored using a synthetic biology approach. Our work combines experimental and theoretical approaches to specifically investigate how a bottleneck for protein degradation, which is present in most if not all existing synthetic oscillators, can be leveraged to robustly synchronize and entrain biological oscillators. We use both the terminology and mathematical tools of queueing theory to intuitively explain the role of this bottleneck in both synchronization and entrainment, which extends prior work demonstrating the usefulness of queueing theory in synthetic and native gene circuits. We conclude with an investigation of how synchronization and entrainment may be sensitive to the presence of multiple proteolytic pathways in a cell that couple weakly through crosstalk.

**12:15PM B41.00006 Effect of correlations between minima on a complex energy landscape**

, SAI TEJA PUSULURI, Department of physics, Ohio University, ALEX H LANG, Computational Neurobiology Laboratory, Salk Institute, PANKAJ MEHTA, Department of physics, Boston University, HORACIO E CASTILLO, Department of physics, Ohio University — We recently modeled cellular interconversion dynamics[1] by using an epigenetic landscape model[2] inspired by neural network models[3]. Given an arbitrary set of patterns, the model can be used to construct an energy landscape in which those patterns are the global minima. We study the possible stable states and metastable states of the landscapes thus constructed. We consider three different cases: i) choosing the patterns to be random and independently distributed ii) choosing a set of patterns directly derived from the experimental cellular transcription factor expression data for a representative set of cell types in an organism and iii) choosing randomly generated trees of hierarchically correlated patterns, inspired by biology. For each of the three cases, we study the energy landscapes. In particular we study the basins of attraction of both the stable states and the metastable states, we compute the configurational entropy as a function of energy, and we demonstrate how those results depend on the correlations between the patterns.

**12:15PM B42.00006 Frank-Kasper sigma phase stabilized by tailored architectures of block copolymers.**

, WEIHUA LI, MEIJIAO LIU, NAN XIE, FENG QIU, State Key Laboratory of Molecular Engineering of Polymers, Department of Macromolecular Science, Fudan University, AN-CHANG SHI, Department of Physics, McMaster University — Block copolymer self-assembly forms diverse interesting ordered morphologies, of which the spherical phase is of particular interest because it resembles the similar space symmetry as atomic crystals and has a tunable period on nanoscale. Moreover, the packing lattice of spherical domains dictated by the adjustable competition between the entropic and interfacial energies is programmable. For AB diblock copolymers, it has been known that the stable spherical phase is mainly bcc except for a very narrow region of fcc at the vicinity of the order-disorder transition. When introducing variable number of blocks and architectures to form complex AB-type block copolymers, the A15 phase was predicted as stable. However, a striking experiment observed a new spherical phase, the complex Frank-Kasper sigma phase that consists of 30 spheres in a unit cell, in the PI-*b*-PLA diblock copolymer as well as a SISO tetrablock terpolymer. Inspired by this experiment, we studied the stability of all known spherical phases of fcc, bcc, A15 and sigma in various block copolymers including conformationally asymmetric AB diblock, AB<sub>m</sub> miktoarm, and BABC tetrablock copolymers. We have revealed the formation mechanism of the nonclassical A15 and sigma phases due to the tailored architectures.

**12:27PM B42.00007 From the Disordered State to the Frank-Kasper Sigma Phase: Readily Tuning the Phase Behavior of Block Polymers via Lithium Salt Addition**, MATTHEW IRWIN, ROBERT HICKEY, FRANK BATES, TIMOTHY LODGE, Univ of Minn - Minneapolis — Sphere-forming block copolymers have long been known to assemble onto a body-centered cubic (BCC) lattice, but recent work has demonstrated that with the correct thermal treatments, more exotic morphologies such as dodecagonal quasicrystals or the Frank-Kasper sigma phase can be observed. In this presentation, we show that a similar variety of morphologies can be obtained by simply adding small amounts of lithium bis(trifluoromethane)sulfonimide (LiTFSI), which preferentially partitions into one of the domains. Using small-angle X-ray scattering, we have found that block copolymers, which are disordered when neat, can form spheres with liquid-like packing, BCC crystals, the Frank-Kasper sigma phase, or hexagonally close packed crystals upon increasing the salt loading. This work demonstrates a unique, alternative route to highly segregated sphere-forming block copolymers and examines the universality of the formation of these complex morphologies.

**12:27PM B41.00007 The Power Spectrum of Ionic Nanopore Currents: The Role of Ion Correlations**, MIRA ZORKOT, RAMIN GOLESTANIAN, DOUWE BONTHUIS, University of Oxford — Measuring the ionic current passing through a nanometer-scale membrane pore has emerged over the past decades as a versatile technique to study molecular transport. These measurements suffer from high noise levels that typically exhibit a power law dependence on the frequency. A thorough theoretical understanding of the power spectrum is essential for the optimisation of experimental setups and for the use of measurement noise as a novel probe of the nanopore's microscopic properties. We calculate the power spectrum of electric-field-driven ion transport through nanopores using both linearized mean-field theory and Langevin dynamics simulations. With only one fitting parameter, the linearized mean-field theory accurately captures the dependence of the simulated power spectrum on the pore radius and the applied electric field. Remarkably, the linearized mean-field theory predicts a plateau in the power spectrum at low frequency  $f$ , which is confirmed by the simulations at low ion concentration. At high ion concentration, however, the power spectrum follows a power law that is reminiscent of the  $1/f$  dependence found experimentally at low frequency. Based on simulations with and without ion-ion interactions, we attribute the low-frequency power law dependence to ion-ion correlations

**12:39PM B41.00008 Statistical Models of Adaptive Immune populations**, ZACHARY SETHNA, CURTIS CALLAN, Princeton University, ALEKSANDRA WALCZAK, THIERRY MORA, Ecole Normale Suprieure — The availability of large ( $10^4$ - $10^6$  sequences) datasets of B or T cell populations from a single individual allows reliable fitting of complex statistical models for naïve generation, somatic selection, and hypermutation. It is crucial to utilize a probabilistic/informational approach when modeling these populations. The inferred probability distributions allow for population characterization, calculation of probability distributions of various hidden variables (e.g. number of insertions), as well as statistical properties of the distribution itself (e.g. entropy). In particular, the differences between the T cell populations of embryonic and mature mice will be examined as a case study. Comparing these populations, as well as proposed mixed populations, provides a concrete exercise in model creation, comparison, choice, and validation.

**12:39PM B42.00008 Characterization of Lithium Polysulfide Salts in Homopolymers and Block Copolymers<sup>1</sup>**, DUNYANG WANG, KEVIN WUJCIK, NITASH BALSARA, University of California Berkeley — Ion-conducting polymers are important for solid-state batteries due to the promise of better safety and the potential to produce higher energy density batteries. Nanostructured block copolymer electrolytes can provide high ionic conductivity and mechanical strength through microphase separation. One of the potential use of block copolymer electrolytes is in lithium-sulfur batteries, a system that has high theoretical energy density wherein the reduction of sulfur leads to the formation of lithium polysulfide intermediates. In this study we investigate the effect of block copolymer morphology on the speciation and transport properties of the polysulfides. The morphology and conductivities of polystyrene-*b*-poly(ethylene oxide) (SEO) containing lithium polysulfides were studied using small-angle X-ray scattering and ac impedance spectroscopy. UV-vis spectroscopy is being used to determine nature of the polysulfide species in poly(ethylene oxide) and SEO.

**12:51PM B42.00009 Congruent Lamellar-to-Disorder Phase Transitions in Diblock Copolymer-Homopolymer Ternary Blends**, ROBERT HICKEY, TIMOTHY GILLARD, MATTHEW IRWIN, TIMOTHY LODGE, FRANK BATES, University of Minnesota — Symmetric ternary blends of AB diblock copolymers and the corresponding A and B homopolymers are predicted to be characterized by a multicritical Lifshitz point within mean-field theory. Previous studies have shown that fluctuations destroy the predicted Lifshitz point and lead to a bicontinuous microemulsion ( $B_{\mu}E$ ) channel, which separates the lamellar and 2-phase regions in the ternary phase prism. Here, we establish the existence of a line of congruent first-order lamellar-to-disorder transitions when appropriate amounts of poly(cyclohexylethylene) (C) and poly(ethylene) (E) homopolymers are mixed with the corresponding symmetric CE diblock copolymer. We present complimentary optical transmission, small-angle X-ray scattering, transmission electron microscopy (TEM), and rheological results obtained using two experimental protocols: (1) fixing the CE volume fraction and varying the C/E ratio, and (2) setting the C/E ratio at the condition of congruency and varying CE volume fraction from 0 to 1. These results establish a quantitative and facile method for identifying the detailed phase behavior in the vicinity of the  $B_{\mu}E$ , and provide fresh insight into the nature of such mixtures near the nominal Lifshitz conditions. Surprisingly, well-ordered lamellae are revealed by TEM at compositions within 1% of the  $B_{\mu}E$  channel, suggesting a remarkably close approach to the predicted, mean-field unbinding transition. Moreover, the width of the  $B_{\mu}E$  narrows to about 1% under congruent conditions.

**12:51PM B41.00009 Networks In Real Space: Characteristics and Analysis for Biology and Mechanics**, CARL MODES, MARCELO MAGNASCO, The Rockefeller University, ELENI KATIFORI, University of Pennsylvania — Functional networks embedded in physical space play a crucial role in countless biological and physical systems, from the efficient dissemination of oxygen, blood sugars, and hormonal signals in vascular systems to the complex relaying of informational signals in the brain to the distribution of stress and strain in architecture or static sand piles. Unlike their more-studied abstract cousins, such as the hyperlinked internet, social networks, or economic and financial connections, these networks are both constrained by and intimately connected to the physicality of their real, embedding space. We report on the results of new computational and analytic approaches tailored to these physical networks with particular implications and insights for mammalian organ vasculature.

**1:03PM B41.00010 A kinetic model for chemical neurotransmission<sup>1</sup>**, GUILLERMO RAMIREZ-SANTIAGO, Instituto de Matematicas, UNAM Juriquilla, ALEJANDRO MARTINEZ-VALENCIA, FRANCISCO FERNANDEZ DE MIGUEL, Instituto de Fisiologia Celular, UNAM — Recent experimental observations in presynaptic terminals at the neuromuscular junction indicate that there are stereotyped patterns of cooperativeness in the fusion of adjacent vesicles. That is, a vesicle in hemifusion process appears on the side of a fused vesicle and which is followed by another vesicle in a priming state while the next one is in a docking state. In this talk we present a kinetic model for this morphological pattern in which each vesicle state previous to the exocytosis is represented by a kinetic state. This chain states kinetic model can be analyzed by means of a Master equation whose solution is simulated with the stochastic Gillespie algorithm. With this approach we have reproduced the responses to the basal release in the absence of stimulation evoked by the electrical activity and the phenomena of facilitation and depression of neuromuscular synapses. This model offers new perspectives to understand the underlying phenomena in chemical neurotransmission based on molecular interactions that result in the cooperativity between vesicles during neurotransmitter release.

**1:03PM B42.00010 Unbinding Transition of the  $\alpha$ -BN Phase of BABCB Tetra-block Terpolymers**, ASHKAN DEHGHAN, McMaster University, HURMIZ SHAMANA, University of Guelph, CHRIS GUBBELS, AN-CHANG SHI, McMaster University — We study the phase behaviour of BABCB/B multiblock terpolymer/homopolymer blends using real-space self-consistent field theory. We focus on the effects of the added homopolymers on the structure of the  $\alpha$ -BN phase, formed in the pure BABCB system. In the  $\alpha$ -BN phase, the A and C blocks form spheres sitting on a three dimensional layered structure, resembling that of graphite. Our results demonstrate that the added homopolymers would aggregate in the regions between the layers in the  $\alpha$ -BN phase. We use this property of the added homopolymers as a mechanism for separating the layers. By examining the effects of homopolymer/multiblock interactions and their relative degree of polymerization on the overall phase behaviour of the system, we identified a critical homopolymer concentration at which the layers composed of A/C spheres unbind to form free standing sheets, resembling the structure of graphene.

**1:15PM B42.00011 Simulation of free energies of bicontinuous morphologies formed through block copolymer/homopolymer self-assembly**, POORNIMA PADMANABHAN, Cornell University, FRANCISCO MARTINEZ-VERACOECHEA, None, FERNANDO ESCOBEDO, Cornell University — Different types of bicontinuous phases can be formed from A-B diblock copolymers by the addition of A-type homopolymers over a range of compositions and relative chain lengths. Particle-based molecular simulations were used to study three bicontinuous phases – double gyroid (G), double diamond (D) and plumber's nightmare (P) - near their triple point of coexistence. For 3-D ordered phases, the stability of the morphology formed in simulation is highly sensitive to box size whose exact size is unknown a-priori. Accurate free energy estimates are required to ascertain the stable phase, particularly when multiple competing phases spontaneously form at the conditions of interest. A variant of thermodynamic integration was implemented to obtain free energies and hence identify the stable phases and their optimal box sizes by tracing a reversible path that connects the ordered and disordered phases. Clear evidence was found of D-G and D-P phase coexistence, consistent with previous predictions for the same blend using Self-consistent field theory. Our simulations also allowed us to examine the microscopic details of these coexisting bicontinuous phases and detect key differences between the microstructure of their nodes and struts.

**1:15PM B41.00011 Analysis of aggregation of platelets in thrombosis**, are key players in thrombus formation by first rolling over collagen bound von Willebrand factor followed by formation of a platelet aggregate. The first adhered platelets bind additional platelets until the whole injury is sealed off by a platelet aggregate. The coagulation plug by creating a tight fibrin network, and then wound contraction takes place because of morphological changes in platelet activation and aggregation mainly through fibrinogen polymerization into fibrin fibers. The process includes multiple steps and local shear-rate which regulate and control the process. Coagulation can be divided into two pathways: the intrinsic and the extrinsic. The intrinsic pathway is initiated by the exposure of a negatively charged. It is able to activate factor XII, using a complex of high-molecular-weight kininogen as cofactors. Thrombin is the final enzyme that is needed to convert fibrinogen into fibrin with the exposure of tissue factor to the circulating blood, which is the major initiator of coagulation. There are several steps in the coagulation cascade, resulting in large amounts of thrombin. It is dependent on the presence of pro-coagulant surfaces such as phospholipids—which include phosphatidylserine (PS)—on their outer membrane. PS-bearing surfaces are able to increase the concentration and co-localizing coagulation factors. Aggregation of platelets are analyzed and compared to adhesion of platelets.

**1:27PM B41.00012 Oxidant Signaling in Cells Revealed by Single Rare-Earth Based Nanoparticle Imaging**, CEDRIC BOUZIGUES, MOUNA ABDESSELEM, RIVO RAMODIHARILAFY, THIERRY GACOIN, Ecole Polytechnique, PIERRE-LOUIS THARAUX, PARCC - Inserm - HEGP, ANTIGONI ALEXANDROU, Ecole Polytechnique — The spatio-temporal organization of signaling pathways controls the cell response. Reactive oxygen species (ROS) are second messengers involved in the control of numerous normal and pathological processes and their local concentration is thus tightly regulated. However, the dynamics of ROS production and organization is mostly unknown, due to the lack of efficient probes. We developed single ROS sensitive Eu<sup>3+</sup>-doped nanoparticle imaging to quantitatively probe the intracellular ROS response. We revealed specific temporal patterns of ROS production under different types of stimulation (PDGF and ET-1) and quantitatively identified mechanisms of transactivation, which notably control the dynamics of the cell response. By using a microfluidic system, we apply spatially controlled stimulations and displayed the maintenance of asymmetric ROS concentration in the cell under a PDGF gradient. We then developed a ratiometric method using a nanoparticle mix, to quantitatively detect ROS with a 500 ms temporal resolution. We thus elucidate molecular mechanisms responsible for the control of the oxidant production kinetics. Altogether, our results reveal regulation mechanisms controlling ROS spatio-temporal organization, which can be crucial for the buildup of the cell response.

**1:27PM B42.00012 Sequence-Specific Copolymer Compatibilizers designed via a Genetic Algorithm<sup>1</sup>**, VENKATESH MEENAKSHISUNDARAM, TARAK PATRA, JUI-HSIANG HUNG, DAVID SIMMONS, Univ of Akron — For several decades, block copolymers have been employed as surfactants to reduce interfacial energy for applications from emulsification to surface adhesion. While the simplest approach employs symmetric diblocks, studies have examined asymmetric diblocks, multiblock copolymers, gradient copolymers, and copolymer-grafted nanoparticles. However, there exists no established approach to determining the optimal copolymer compatibilizer sequence for a given application. Here we employ molecular dynamics simulations within a genetic algorithm to identify copolymer surfactant sequences yielding maximum reductions in the interfacial energy of model immiscible polymers. The optimal copolymer sequence depends significantly on surfactant concentration. Most surprisingly, at high surface concentrations, where the surfactant achieves the greatest interfacial energy reduction, specific non-periodic sequences are found to significantly outperform any regularly blocky sequence. This emergence of polymer sequence-specificity within a non-sequenced environment adds to a recent body of work suggesting that specific sequence may have the potential to play a greater role in polymer properties than previously understood.

**1:39PM B42.00013 Effect of the Degree of Hydrogen Bonding on Asymmetric Lamellar Phase Transformation in Binary Block Copolymer Blends**, JONGHEON KWAK, SUNG HYUN HAN, HONG CHUL MOON, POSTECH, VICTOR PRYAMITSYN, VENKAT GANESAN, University of Texas, JIN KON KIM, POSTECH — A binary mixture of two block copolymers whose blocks are capable of forming the hydrogen bonding allows one to obtain various microdomains that could not be expected for neat block copolymer. For instance, we reported that the binary blend of asymmetric polystyrene-*block*-poly(2-vinylpyridine) copolymer (as-PS-*b*-P2VP) and polystyrene-*block*-polyhydroxystyrene copolymer (as-PS-*b*-PHS) blends where the hydrogen bonding occurred between P2VP and PHS showed asymmetric lamellar microdomains. Since asymmetric lamellar microdomains are formed due to the interface curvature change by favorable hydrogen bonding interaction between the hydroxyl group and nitrogen atom, a large ratio of lamellar width (thus, enhanced asymmetry) could potentially be achieved by increasing the degree of the hydrogen bonding. We employed two kinds of binary blends (polystyrene-*block*-poly(4-vinylpyridine) (as-PS-*b*-P4VP)/as-PS-*b*-PHS and as-PS-*b*-P2VP/as-PS-*b*-PHS). It was observed by SAXS and TEM that as-PS-*b*-P4VP/as-PS-*b*-PHS blend which exhibits much stronger hydrogen bonding formed asymmetric lamellar morphology at more asymmetric volume fraction where as-PS-*b*-P2VP/as-PS-*b*-PHS blend could not form and the experimental results show qualitative agreement with the SST model prediction.

**1:39PM B41.00013 Regulatory inhibition of biological tissue mineralization through post-nucleation shielding<sup>1</sup>**, JOSHUA CHANG, National Institutes of Health, ROBERT MIURA, New Jersey Institute of Technology — In vertebrates, insufficient availability of calcium and phosphate ions in extracellular fluids leads to loss of bone density and neuronal hyper-excitability. To counteract this problem, calcium ions are present at high concentrations throughout body fluids at concentrations exceeding the saturation point. This condition leads to the opposite situation where unwanted mineral sedimentation may occur. Remarkably, ectopic or out-of-place sedimentation into soft tissues is rare, in spite of the thermodynamic driving factors. This fortunate fact is due to the presence of auto-regulatory proteins that are found in abundance in bodily fluids. Yet, many important inflammatory disorders such as atherosclerosis and osteoarthritis are associated with this undesired calcification. Hence, it is important to gain an understanding of the regulatory process and the conditions under which it can go awry. We adapted mean-field classical nucleation theory to the case of surface-shielding in order to study the regulation of sedimentation of calcium phosphate salts in biological tissues.

**1:51PM B42.00014 Microphase-separated structures within randomly end-linked copolymer networks**, DI ZENG, RYAN HAYWARD, Univ of Mass - Amherst — Self-assembly within randomly cross-linked or end-linked copolymer networks provides a robust method to generate co-continuous nanometer-scale structures. Here, we investigate self-assembly within copolymer networks prepared by end linking of several different pairs of telechelic polymers in a common solvent. For sufficiently high levels of immiscibility between the constituent polymers, removal of solvent leads to microphase separation into disordered nanoscale structures. Using a variety of characterization methods, including transmission electron microscopy, small-angle X-ray scattering, differential scanning calorimetry, and dynamic mechanical analysis, we find that these networks exhibit co-continuous morphologies over a wide range of volume fraction of the two components, with a characteristic length scale that can be tuned by adjusting the molecular weight of the starting polymers.

**2:03PM B42.00015 Effects of Blockiness on the phase behavior of random copolymers**, GORDON VANDERWOUDE, AN-CHANG SHI, McMaster University — Theoretical study of random block copolymers remains a challenging topic due in part to the sheer enormity of their phase space. In this study we use the self-consistent field theory to investigate the phase behaviour of linear (AB)*n*-type and (AB)*n*-C-type multiblock copolymers with randomly distributed A and B blocks. In particular, we examine the effect of blockiness of the random copolymers on the formation of ordered phases. The blockiness can be quantified by the average length of individual A or B blocks, which can be taken as a measure of the heterogeneity of the random copolymers. We observed that the critical value of the  $\chi$  parameter, at which the order-disorder transition occurs, decreases with increasing blockiness in the (AB)*n* copolymers. We also observed that the phase behaviour of the (AB)*n*-C copolymers depends strongly on the blockiness of the random chain. In particular, the blockiness governs whether or not the A/B blocks can phase separate within the A/B domains, thus dictating whether the (AB)*n*-C behaves as A/B-C diblock copolymers or as ABC terpolymers. The theoretical phase diagrams will be compared with available experiments.

**11:15AM B43.00001 Global and local avalanches in cohesive and non cohesive granular material: crackling and seismicity** , JONATHAN BARES, LMGC Montpellier, France — Commonly, granular materials yield or flow if sufficiently large stress is applied, leading to avalanche-like behavior. For experimentally wedge split cohesive granular material and sheared 2D and 3D grains, we seek to understand the dynamics of these burst of activity from the local to the global scale. Whether the system rearranges locally like in the case of a fracture front propagating in a cohesive material or in the whole system like in the case of sheared granular medium, similar free scale statistics are observed for the intensity of the rearrangements. We present first an experimental setup that allows growing well-controlled tensile cracks in brittle heterogeneous solids of tunable microstructure. Also, force networks and displacement fields are measured both on two and three-dimensional sheared material for cyclically sheared photoelastic and hydrogel particles. Avalanches, their size, location and duration are extracted at the global scale from the rapid variation of the stored energy whereas at the local scale they are measured from the energy drop, displacement and acoustic activity. Statistics of those different quantities are computed and correlated to test their intrinsic entanglement and analyze their universal dynamics.

**11:51AM B43.00002 Experimental Avalanches in a Rotating Drum.**<sup>1</sup> , ALINE HUBARD, Levich Institute of City College of New York, COREY O'HERN, Department of Mechanical Engineering & Materials Science, Department of Applied Physics, and Department of Physics, Yale University, MARK SHATTUCK, Levich Institute and Physics Department of The City College of New York and CUNY Graduate Center — We address the question of universality in granular avalanches and the system size effects on it. We set up an experiment made from a quasi-two-dimensional rotating drum half-filled with a monolayer of stainless-steel spheres. We measure the size of the avalanches created by the increased gravitational stress on the pile as we quasi-statically rotate the drum. We find two kinds of avalanches determined by the drum size. The size and duration distributions of the avalanches that do not span the whole system follow a power law and the avalanche shapes are self-similar and nearly parabolic. The distributions of the avalanches that span the whole system are limited by the maximal amount of potential energy stored in the system at the moment of the avalanche.

**12:03PM B43.00003 Stability of Granular Packings Jammed under Gravity: Avalanches and Unjamming**<sup>1</sup> , CARL MERRIGAN, Brandeis University , SUMIT BIRWA, TIFR Hyderabad, SHUBHA TEWARI, UMass Amherst, BULBUL CHAKRABORTY, Brandeis University — Granular avalanches indicate the sudden destabilization of a jammed state due to a perturbation. We propose that the perturbation needed depends on the entire force network of the jammed configuration. Some networks are stable, while others are fragile, leading to the unpredictability of avalanches. To test this claim, we simulated an ensemble of jammed states in a hopper using LAMMPS. These simulations were motivated by experiments with vibrated hoppers where the unjamming times followed power-law distributions<sup>2</sup>. We compare the force networks for these simulated states with respect to their overall stability. The states are classified by how long they remain stable when subject to continuous vibrations. We characterize the force networks through both their real space geometry and representations in the associated force-tile space<sup>3</sup>, extending this tool to jammed states with body forces.

**12:15PM B43.00004 Structure of jammed configurations and their relation to unjamming times**<sup>1</sup> , SUMIT KUMAR BIRWA, TIFR Centre for Interdisciplinary Sciences, Hyderabad, CARL MERRIGAN, BULBUL CHAKRABORTY, Brandeis University, SHUBHA TEWARI, University of Massachusetts, Amherst — The distribution of the times for the cessation of flow of grains falling under gravity in a vertical hopper is known to be exponential. Recent experiments have shown, however, that the time lapse between avalanches follows a power-law distribution when the hopper is unjammed using periodic vertical vibrations<sup>2</sup>. The reasons for this distribution of the unjamming times, which indicates the time needed for an applied continuous perturbation to induce another avalanche, are not well understood. We report on a numerical simulation of granular hopper flow using LAMMPS<sup>3</sup> in which we seek to understand the origin and scope of this behavior. We find that cessation of flow is related to the formation of a stable arch that spans the system. However, the actual structure of the jammed configuration varies and is closely related to the unjamming time. We find that the symmetry of the arches is an important parameter in determining the strength of the jammed configurations. Using different force thresholds, we have characterized the contact networks around the arches which provides stability to the packed structure and analyzed the strength of various jammed configurations.

**12:27PM B43.00005 Intermittent Flow of Granular Matter in an Annular Geometry** , TED BRZINSKI, KAREN E. DANIELS, NC State University — Granular solids can be subjected to a finite stress below which the response is elastic. Above this yield stress, however, the material fails catastrophically, undergoing a rapid plastic deformation. In the case of a monotonically increasing stress the material exhibits a characteristic stick-slip response. We investigate the statistics of this intermittent failure in an annular shear geometry, driven with a linear-ramp torque in order to generate the stick-slip behavior. The apparatus is designed to allow visual access to particle trajectories and inter-particle forces (through the use of photoelastic materials). Additionally, twelve piezoelectric sensors at the outer wall measure acoustic emissions due to the plastic deformation of the material. We vary volume fraction, and use both fixed and deformable boundaries. We measure how the distribution of slip size and duration are related to the bulk properties of the packing, and compare to systems with similar governing statistics.

**12:39PM B43.00006 Effect of interstitial fluid on event-size distribution for granular hoppers.** , JUHA KOIVISTO, DOUGLAS DURIAN, Univ of Pennsylvania — The discharge of granular hoppers is avalanche-like in that flow proceeds until probabilistically interrupted by the formation of a stable arch over the hole. The average event size appears to diverge at a critical hole size, thus defining a putative clogging transition. However, we now believe that instead it grows exponentially as a power of the hole diameter, so in fact all hoppers are susceptible to clogging<sup>1</sup>. To investigate the influence of grain dynamics on arch formation, we conducted a series of experiments where the event size distribution was measured for grains in a system that was totally submerged in water. We find that the distribution is exponential, just as for dry non-cohesive grains in air. However, for a given hole the number of grains in the average event decreases roughly with a factor of two, and the critical hole size increases by 10%. Thus, submerged hoppers are more susceptible to clogging and dynamics play a role. In air, the “effective temperature” set by rms grain speed helps to prevent arch formation.

**12:51PM B43.00007 Non-local rheology for dense granular flows in avalanches** , ADRIEN IZZET, ERIC CLEMENT, BRUNO ANDREOTTI, ESPCI — A local constitutive relation was proposed to describe dense granular flows (GDR MiDi, EPJE 2004). It provides a rather good prediction of the flowing regime but does not foresee the existence of a creep regime as observed by Komatsu et al. (PRL 2001). In the context of a 2D shear cell, a relaxation length for the velocity profile was measured (Bouzid et al., PRL 2013) which confirmed the existence of a flow below the standard Coulomb yield threshold. A correction for the local rheology was proposed. To test further this non-local constitutive relation, we built an inclined narrow channel within which we monitor the flow from the side. We managed to observe the creep regime over five orders of magnitude in velocity and fit the velocity profiles in the depth with an asymptotic solution of the non-local equation. However, the boundary condition at the free surface needs to be selected in order to calibrate the non-local rheology over the whole range of stresses in the system. In this perspective, we complement the experimental results with 2D simulations of hard and frictional discs on an inclined plane in which we introduce a surface friction force proportional to the effective pressure in the granular. We analyze these results in the light of the non-local rheology.

**1:03PM B43.00008 Jamming and chaotic dynamics in different granular systems** , HOMAYOON MAGHSOODI, ERIK LUIJTEN, Northwestern University — Although common in nature and industry, the jamming transition has long eluded a concrete, mechanistic explanation. Recently, Banigan *et al.* (Nat. Phys. **9**, 288–292, 2013) proposed a method for characterizing this transition in a granular system in terms of the system’s chaotic properties, as quantified by the largest Lyapunov exponent. They demonstrated that in a two-dimensional shear cell the jamming transition coincides with the bulk density at which the system’s largest Lyapunov exponent changes sign, indicating a transition between chaotic and non-chaotic regimes. To examine the applicability of this observation to realistic granular systems, we study a model that includes frictional forces within an expanded phase space. Furthermore, we test the generality of the relation between chaos and jamming by investigating the relationship between jamming and the chaotic properties of several other granular systems, notably sheared systems (Howell, D., Behringer R. P., Veje C., Phys. Rev. Lett. **82**, 5241–5244, 1999) and systems with a free boundary. Finally, we quantify correlations between the largest Lyapunov vector and collective rearrangements of the system to demonstrate the predictive capabilities enabled by adopting this perspective of jamming.

**1:15PM B43.00009 3D imaging of particle-scale rotational motion in cyclically driven granular flows** , MATT HARRINGTON, University of Pennsylvania, DYLAN POWERS, University of Maryland, ERIC COOPER, Pomona College, WOLFGANG LOSERT, University of Maryland — Recent experimental advances have enabled three-dimensional (3D) imaging of motion, structure, and failure within granular systems. 3D imaging allows researchers to directly characterize bulk behaviors that arise from particle- and meso-scale features. For instance, segregation of a bidisperse system of spheres under cyclic shear can originate from microscopic irreversibilities and the development of convective secondary flows. Rotational motion and frictional rotational coupling, meanwhile, have been less explored in such experimental 3D systems, especially under cyclic forcing. In particular, relative amounts of sliding and/or rolling between pairs of contacting grains could influence the reversibility of both trajectories, in terms of both position and orientation. In this work, we apply the Refractive Index Matched Scanning technique to a granular system that is cyclically driven and measure both translational and rotational motion of individual grains. We relate measured rotational motion to resulting shear bands and convective flows, further indicating the degree to which pairs and neighborhoods of grains collectively rotate.

**1:27PM B43.00010 Characterizing local forces and rearrangements inside a gravity-driven granular flow** , EMMA THACKRAY, KERSTIN NORDSTROM, Mount Holyoke College — While the gravity-driven flow of a granular material in a silo geometry can be modeled by the Beverloo equation, the mesoscale-level particle rearrangements and interactions that drive this flow are not well-understood. We have constructed a quasi-two-dimensional system of bidisperse, millimeter-scale disks with photoelastic properties that make force networks within the material visible. The system is contained in an acrylic box with an adjustable bottom opening. We can approach the clogging transition by adjusting this opening and by adding external forcing to the top of the flowing pile. By placing the system between cross-polarizers, we can obtain high-speed video of this system during flow, and extract intensity signals that can be used to identify and quantify localized, otherwise indeterminate forces. We can simultaneously track individual particle motions, which can be used to identify shear transformation zones in the system. We are therefore able to correlate local forces with rearrangements within the system, and characterize the evolution of this interplay on the approach to the clogging transition.

**1:39PM B43.00011 Dynamic structural network evolution in compressed granular systems.** , LIA PAPADOPOULOS, University of Pennsylvania, JAMES PUCKETT, Gettysburg College, KAREN DANIELS, North Carolina State University, DANIELLE BASSETT, University of Pennsylvania — The heterogeneous dynamic behavior of granular packings under shear or compression is not well-understood. In this study, we use novel techniques from network science to investigate the structural evolution that occurs in compressed granular systems. Specifically, we treat particles as network nodes, and pressure-dependent forces between particles as layer-specific network edges. Then, we use a generalization of community detection methods to multilayer networks, and develop quantitative measures that characterize changes in the architecture of the force network as a function of pressure. We observe that branchlike domains reminiscent of force chains evolve differentially as pressure is applied: topological characteristics of these domains at rest predict their coalescence or dispersion under pressure. Our methods allow us to study the dynamics of mesoscale structure in granular systems, and provide a direct way to compare data from systems under different external conditions or with different physical makeup.

**1:51PM B43.00012 Self organization and shear-jamming in magnetic photoelastic particles** , MEREDITH COX, DONG WANG, Duke University, JONATHAN BARES, LMGC Montpellier, France, BOB BEHRINGER, Duke University — Many experimental studies of simple particles in granular systems have been conducted, but the behavior of complex particles in such systems has not been addressed. There has been a growing interest in functionalized microparticles, and the study of these complex particles may reveal interesting analogues between micro- and macroparticles. We perform experiments to investigate magnetic particles in a 2D granular material close to the jamming transition. We incrementally compress and shear photoelastic particles containing magnets and image the interparticle forces in each compression using a photoelastic technique. To track the orientation of individual particles, we draw UV-visible bars on each particle and image each compression of the system under ultraviolet light. We repeat the experimental procedure using varying ratios of magnetic to nonmagnetic particles from 0% magnetic to 100% magnetic. By using custom software to resolve particle deformations, we extract particle contact and pressure.

University of Edinburgh

**11:15AM B44.00001 Towards a Model Selection Rule for Quantum State Tomography<sup>1</sup>**, TRAVIS SCHOLTEN, ROBIN BLUME-KOHOUT, Sandia Natl Labs — Quantum tomography on large and/or complex systems will rely heavily on model selection techniques, which permit on-the-fly selection of small efficient statistical models (e.g. small Hilbert spaces) that accurately fit the data. Many model selection tools, such as hypothesis testing or Akaike's AIC, rely implicitly or explicitly on the Wilks Theorem, which predicts the behavior of the loglikelihood ratio statistic (LLRS) used to choose between models. We used Monte Carlo simulations to study the behavior of the LLRS in quantum state tomography, and found that it disagrees dramatically with Wilks' prediction. We propose a simple explanation for this behavior; namely, that boundaries (in state space and between models) play a significant role in determining the distribution of the LLRS. The resulting distribution is very complex, depending strongly both on the true state and the nature of the data. We consider a simplified model that neglects anisotropy in the Fisher information, derive an almost analytic prediction for the mean value of the LLRS, and compare it to numerical experiments. While our simplified model outperforms the Wilks Theorem, it still does not predict the LLRS accurately, implying that alternative methods may be necessary for tomographic model selection.

**11:27AM B44.00002 Experimental Demonstration of Self-Guided Quantum Tomography**, ROBERT J. CHAPMAN, School of Electrical and Computer Engineering, RMIT University, CHRISTOPHER FERRIE, EQuS, School of Physics, University of Sydney, ALBERTO PERUZZO, School of Electrical and Computer Engineering, RMIT University — Robust and precise quantum state characterization is critical for future quantum experiments and technologies, and yet is a fundamentally challenging task. Standard and adaptive quantum tomography procedures are impractical for systems being prepared today due to the exponential scaling of quantum state space. These techniques are sensitive to statistical noise and require highly precise measurement settings. We present an experimental demonstration of autonomous and robust self-guided quantum tomography. Self-guided quantum tomography iteratively learns a quantum state using a stochastic gradient ascent algorithm. As a result it is robust against statistical noise and measurement errors. In addition, self-guided quantum tomography does not require any computationally expensive optimization, necessary for adaptive quantum tomography, or post-processing, required for standard quantum tomography. We demonstrate the robustness of self-guided quantum tomography by engineering the level of statistical noise and experimental errors, achieving measurement fidelities greater than standard quantum tomography in a range of one- and two-qubit experiments. Our demonstration opens pathways towards robust quantum state characterization in current and near-future experiments, where standard techniques are already impractical.

**11:39AM B44.00003 Improved precision-guaranteed quantum tomography<sup>1</sup>**, TAKANORI SUGIYAMA, Dep. of Systems Innovation, Osaka University — Quantum tomography is one of the standard tool in current quantum information experiments for verifying that a state/process/measurement prepared in the lab is close to an ideal target. Precision-guaranteed quantum tomography (Sugiyama, Turner, Murao, PRL 111, 160406 2013) gives rigorous error bars on a result estimated from arbitrary finite data sets from any given informationally complete tomography experiments. The rigorous error bars were derived with a real-valued concentration inequality called Hoeffding's inequality. In this talk, with a vector-valued concentration inequality, we provide an improved version of the error bars of precision-guaranteed quantum tomography. We examine the new error bars for specific cases of multi-qubit systems and numerically show that the degree of improvement becomes large as the dimension of the system increases.

**11:51AM B44.00004 Gate Set Tomography on two qubits**, ERIK NIELSEN, ROBIN BLUME-KOHOUT, JOHN GAMBLE, KENNETH RUDINGER, Sandia National Laboratories — Gate set tomography (GST) is a method for characterizing quantum gates that does not require pre-calibrated operations, and has been used to both certify and improve the operation of single qubits. We analyze the performance of GST applied to a simulated two-qubit system, and show that Heisenberg scaling is achieved in this case. We present a GST analysis of preliminary two-qubit experimental data, and draw comparisons with the simulated data case. Finally, we will discuss recent theoretical developments that have improved the efficiency of GST estimation procedures, and which are particularly beneficial when characterizing two qubit systems. Sandia is a multiprogram laboratory operated by Sandia Corporation, a Lockheed Martin Company, for the United States Department of Energy's National Nuclear Security Administration under Contract DE-AC04-94AL85000.

**12:03PM B44.00005 Hamiltonian tomography for quantum many-body systems with arbitrary couplings<sup>1</sup>**, SHENG-TAO WANG, Univ of Michigan - Ann Arbor, DONG-LING DENG, Condensed Matter Theory Center and Joint Quantum Institute, University of Maryland, College Park, LUMING DUAN, Univ of Michigan - Ann Arbor — Characterization of qubit couplings in many-body quantum systems is essential for benchmarking quantum computation and simulation. We propose a tomographic measurement scheme to determine all the coupling terms in a general many-body Hamiltonian with arbitrary long-range interactions, provided the energy density of the Hamiltonian remains finite. Different from quantum process tomography, our scheme is fully scalable with the number of qubits as the required rounds of measurements increase only linearly with the number of coupling terms in the Hamiltonian. The scheme makes use of synchronized dynamical decoupling pulses to simplify the many-body dynamics so that the unknown parameters in the Hamiltonian can be retrieved one by one. We simulate the performance of the scheme under the influence of various pulse errors and show that it is robust to typical noise and experimental imperfections.

**12:15PM B44.00006 Quantum Compressed Sensing Using 2-Designs**, YI-KAI LIU, NIST, SHELBY KIMMEL, University of Maryland — We develop a method for quantum process tomography that combines the efficiency of compressed sensing with the robustness of randomized benchmarking. Our method is robust to state preparation and measurement errors, and it achieves a quadratic speedup over conventional tomography when the unknown process is a generic unitary evolution. Our method is based on PhaseLift, a convex programming technique for phase retrieval. We show that this method achieves approximate recovery of almost all signals, using measurements sampled from spherical or unitary 2-designs. This is the first positive result on PhaseLift using 2-designs. We also show that exact recovery of all signals is possible using measurements sampled from unitary 4-designs. Previous positive results for PhaseLift required spherical 4-designs, while PhaseLift was known to fail in certain cases when using spherical 2-designs.

**12:27PM B44.00007 Scalable randomized benchmarking of non-Clifford gates<sup>1</sup>**, ANDREW CROSS, EASWAR MAGESAN, LEV BISHOP, JOHN SMOLIN, JAY GAMBETTA, IBM T J Watson Res Ctr — Randomized benchmarking is a widely used experimental technique to characterize the average error of quantum operations. Benchmarking procedures that scale to enable characterization of  $n$ -qubit circuits rely on efficient procedures for manipulating those circuits and, as such, have been limited to subgroups of the Clifford group. However, universal quantum computers require additional, non-Clifford gates to approximate arbitrary unitary transformations. We define a scalable randomized benchmarking procedure over  $n$ -qubit unitary matrices that correspond to protected non-Clifford gates for a class of stabilizer codes. We present efficient methods for representing and composing group elements, sampling them uniformly, and synthesizing corresponding  $\text{poly}(n)$ -sized circuits. The procedure provides experimental access to two independent parameters that together characterize the average gate fidelity of a group element.

**12:39PM B44.00008 Benchmarking of Quantum Control in ESR**, GUANRU FENG, KYUNGDEOCK PARK, FRANKLIN H CHO, BRANDON BUONACORSI, ROBABEH RAHIMI, JONATHAN BAUGH, RAYMOND LAFLAMME, Institute for Quantum Computing, University of Waterloo — Quantum error correction is essential for realizing scalable quantum computation. Key ingredients for quantum error correction are highly polarized ancilla qubits and high-fidelity quantum control. While NMR quantum processors have demonstrated high control fidelity, the requirement to prepare highly polarized spin qubits on demand is a major challenge. Electron-nuclear hyperfine coupled spin systems provide a possible solution: electrons can be fully polarized at accessible fields and temperatures, and their polarization is typically reset much faster than nuclei by spin relaxation. This makes open system cooling methods, such as heat bath algorithm cooling, possible. In this talk, I will describe our recent efforts to improve the precision of microwave control in a custom electron spin resonance spectrometer. In particular, we use randomized benchmarking of quantum gates to quantify control errors, and carefully take into account the resonator transfer function in correcting pulses. Moreover, we implement a protocol that distinguishes coherent and incoherent errors, which gives deeper insight into the nature of the remaining control imperfections and how to address them.

**12:51PM B44.00009 Informational completeness in bounded-rank quantum-state tomography<sup>1</sup>**, CHARLES BALDWIN, IVAN DEUTSCH, AMIR KALEV, University of New Mexico — Quantum-state tomography is a demanding task, however, it can be made more efficient by applying prior information about the system. A common prior assumption is that the state being measured is pure, or close to pure, since most quantum information protocols require pure states. Measurements of pure states can be constructed to be more efficiently than measurements of an arbitrary state, and for these types of measurements, there exists two different notions of informational completeness. One notion, called strict-completeness, is more useful for practical applications since it is compatible with convex optimization and is robust to noise. We present a unified framework for both notions of completeness for a certain type of measurements. These are measurements that allow algebraic reconstruction of a few density matrix elements. The framework also aids in the construction of new strictly-complete measurements. Moreover, the results are easily generalized to the case when the prior information is the state has bounded rank.

**1:03PM B44.00010 The power of being positive: Robust state estimation made possible by quantum mechanics<sup>1</sup>**, AMIR KALEV, CHARLES BALDWIN, Univ of New Mexico — Quantum-state tomography (QST) is generally expensive to implement experimentally. Nevertheless, in state-of-the-art experiments in quantum information science the goal is not to produce arbitrary states but states that have very high purity. Including this prior information in QST results in more manageable tomography protocols. In the context of pure-state tomography, and more generally, of bounded-rank states (states with rank  $\leq r$ ) tomography, a natural notion of informational completeness emerges, *rank- $r$  completeness*. The purpose of this contribution is two fold. First, to prove and emphasize the significance of a less intuitive, yet more powerful, notion of completeness for practical QST, *rank- $r$  strict-completeness*. This notion is made possible due to the positive semidefinite property of density matrices. Strictly-complete quantum measurements ensure a robust estimation of the state of the system, regardless of the convex estimator we use. Thus, pragmatically, quantum state tomography should be done using these kind of measurements. Second, to argue, based on strong numerical indication, that it is fairly straightforward to experimentally implement such measurements by measuring only few random orthonormal bases. For example, in our numerical experi

**1:15PM B44.00011 Bayesian mean estimation for finite two-photon experiments**, BRIAN WILLIAMS, PAVEL LOUGOVSKI, Oak Ridge National Lab — Estimations of quantum probabilities are commonly made utilizing frequency based methods to invert Born's rule where  $X$  is found  $k$  out of  $n$  times,  $P(X) = |\langle \psi | X | \psi \rangle|^2 \approx k/n$ . For an infinite measurement number the maximum likelihood estimation (MLE) represents the true probability. Unfortunately, the number of measurements in any experiment is finite. Given this, better estimates are provided by Bayesian mean estimation (BME). We present a novel method utilizing an experiment-specific probability distribution to make fully informed estimations of any quantum probability, efficiency parameter, or complete density matrix. Our method accounts for the finite measurement number, inter-basis parameter dependence, and estimate physicality. No knowledge of the pathway/detector efficiencies or the photon number generated by the source is required. Only knowledge of the raw singles and coincidence counts is needed. We present our estimation procedure for a single basis experiment, the extension to multiple bases, the application to state tomography to estimate strictly physical quantum states, simulation results comparing MLE and BME estimates, and experimental application of our method using our numerical tomography package TOMOHAK based on slice sampling.

**1:27PM B44.00012 How to construct the optimal Bayesian measurement in quantum statistical decision theory<sup>1</sup>**, FUYUHIKO TANAKA, Osaka Univ — Recently, much more attention has been paid to the study aiming at the application of fundamental properties in quantum theory to information processing and technology. In particular, modern statistical methods have been recognized in quantum state tomography (QST), where we have to estimate a density matrix (positive semidefinite matrix of trace one) representing a quantum system from finite data collected in a certain experiment. When the dimension of the density matrix gets large (from a few hundred to millions), it gets a nontrivial problem. While a specific measurement is often given and fixed in QST, we are also able to choose a measurement itself according to the purpose of QST by using quantum statistical decision theory. Here we propose a practical method to find the best projective measurement in the Bayesian sense. We assume that a prior distribution (e.g., the uniform distribution) and a convex loss function (e.g., the squared error) are given. In many quantum experiments, these assumptions are not so restrictive. We show that the best projective measurement and the best statistical inference based on the measurement outcome exist and that they are obtained explicitly by using the Monte Carlo optimization.

**1:39PM B44.00013 Experimental Estimation of Average Fidelity of a Clifford Gate on a 7-qubit Quantum Processor**, DAWEI LU, University of Waterloo, HANG LI, Tsinghua University, DENIS-ALEXANDRE TROTTIER, University of Waterloo, JUN LI, University of Science and Technology of China, AHARON BRODUTCH, ANTHONY KRISMANICH, AHMAD GHAVAMI, GARY DMITRIENKO, University of Waterloo, GUILU LONG, Tsinghua University, JONATHAN BAUGH, RAYMOND LAFLAMME, University of Waterloo, UNIVERSITY OF WATERLOO TEAM, TSINGHUA UNIVERSITY COLLABORATION, USTC COLLABORATION — The traditional approach of characterizing a given quantum gate via quantum process tomography (QPT) requires exponential number of experiments. Therefore, estimating the average fidelity of the quantum gate by QPT is not practical for large-scale systems. In this talk, I will discuss about how to certify a Clifford gate within polynomial complexity using a twirling protocol. In particular, we adopted this method in NMR and certified a 7-qubit quantum Clifford gate with only 1600 experiments (in contrast, QPT requires millions of experiments). This Clifford gate is important as it generates maximal coherence from single coherence, and non-trivial for benchmarking the coherent control in experiment. We show that the average fidelity of this gate is over 87% after accounting for the decoherence effect, and to date this is the largest experimental gate-characterization. This twirling protocol is efficient and scalable, and can also be extended to other systems straightforwardly.

**1:51PM B44.00014 Crosstalk characterization by eigenvalue estimation: Theory<sup>1</sup>**, MARCUS DA SILVA, Raytheon BBN Technologies — As qubit systems continue to grow and long coherence times become routine, the dominating sources of error shift away from decoherence and towards control errors. One pervasive source of control errors is crosstalk – where control fields intended for one qubit leak onto other qubits. In this talk we describe a method to quantify crosstalk by estimating the eigenvalues of the system's evolution using a technique known as "spectrum estimation". We discuss the wide applicability of the method, and demonstrate similar accuracy scaling to the robust phase estimation algorithm of Kimmel, Low, and Yoder.

<sup>1</sup>We acknowledge funding from ARO under contract W911NF-14-C-0048.

**2:03PM B44.00015 Crosstalk characterization in superconducting qubits by eigenvalue estimation: Experiment<sup>1</sup>**, MATTHEW WARE, KIN CHUNG FONG, COLM A. RYAN, BRIAN HASSIK, THOMAS OHKI, MARCUS P. DA SILVA, Raytheon BBN Technologies, RAYTHEON BBN TECHNOLOGIES TEAM — Superconducting qubit devices offer a promising path towards a scalable quantum computer. As these systems continue to grow in size and complexity, crosstalk errors, which build up during long control sequences, lead to an overall loss in control fidelity. In this talk we explore the use of eigenvalue estimation (a.k.a. "spectrum estimation") in superconducting systems as a high-accuracy method to detect and quantify crosstalk between qubits, and demonstrate how these techniques allow for quick identification and estimation of system crosstalk.

<sup>1</sup>We acknowledge funding from ARO under contract W911NF-14-C-0048.

**Session B45 GQI: Semiconductor Qubits: Multidot Qubits and Dynamical Control** 348 - Vanita Srinivasa, Laboratory for Physical Sciences/University of Maryland, College Park, MD

**11:15AM B45.00001 Multiple quantum dot spin qubits**, SEIGO TARUCHA, The University of Tokyo & Riken Center for Emergent Matter Science — To date various techniques of implementing spin qubits and entangling gates have been developed with quantum dots (QDs). The necessary step for further scaling up the qubit system is to increase the number of QDs with a well-controlled charge state to prepare multiple qubits and improve the fidelity of the qubit gates as well. I will first review spin-1/2 qubit gates with triple QDs for operating three qubits, local and non-local entangling gates, and SWAP gates. I show that the fidelity of these spin manipulations is significantly increased by decreasing the data acquisition time. Secondly I will refer to quadruple and quintuple QDs to implement multiple spin qubits. For the triple QD we use two sets of two coupled dots in the spin blockade regime to demonstrate operation of three individual spin qubits. We use an exchange coupling between the neighboring dots to make two sets of SWAPs and an inhomogeneous Zeeman field difference between the neighboring dots (between the remote dots) to make local (non-local) control of S-T<sub>0</sub> oscillations. We apply the same technique for the quadruple QD to coherently manipulate individual four spins. We finally discuss a way to further scale up the qubit system using multiple QDs.

**11:51AM B45.00002 A new look at encoded-qubit quantum dot quantum computing in silicon**, CHARLES TAHAN, YUN-PIL SHIM, RUSKO RUSKOV, Laboratory for Physical Sciences — Although the properties of spin-based qubits are specified by the material system they reside in, it's possible to modify those properties by encoding a qubit into multiple physical spins. Here we consider new operating regimes for encoded spin qubits and discuss their relevance to spin-based quantum computing and qubit-qubit coupling, especially in silicon quantum dot systems. We will also briefly discuss recent developments in g-factor theory in silicon quantum dots and their possible implications.

**12:03PM B45.00003 High quality exchange rotations in spin qubits using symmetric gating<sup>1</sup>**, F. MARTINS, F. K. MALINOWSKI, P. D. NISSEN, C. M. MARCUS, F. KUEMMETH, Center for quantum devices, Niels Bohr Institute, University of Copenhagen, Denmark, E. BARNES, Department of Physics, Virginia Tech / Condensed Matter Theory Center and Joint Quantum Institute, Department of Physics, University of Maryland, USA, G. C. GARDNER, S. FALLAHI, M. J. MANFRA, Department of Physics and Astronomy and Birck Nanotechnology Center, Purdue University, USA — We present results on a singlet-triplet qubit implemented in a GaAs/AlGaAs heterostructure and we show that exchange oscillations can be realized either by tilting the double well potential, the conventional method, or by symmetrically lowering the barrier, as originally suggested by Loss and DiVincenzo. The two methods are compared here. We find that lowering the barrier between dots has much less relative exchange noise compared to tilting the potential. Since exchange rotations are sensitive to electrical noise and relatively insensitive to nuclear noise, this yields significantly enhanced free induction decay times and quality factors. Our results are comparable to those reported recently in silicon quantum dot devices, obtained using similar techniques.

<sup>1</sup>Support through IARPA-MQCO, LPS-MPO-CMTC, Army Research Office, and the Danish National Research Foundation is acknowledged

**12:15PM B45.00004 Charge noise mitigation in triple-dot encoded spin qubits**, EMILY PRITCHETT, HRL Laboratories — The immediate scalability of electrons confined to semiconductor quantum dots makes them one of the most attractive platforms for quantum information processing; however, 1/f charge noise associated with electrical confinement has been a leading source of noise in quantum dot systems. Recently, there has been a surge of experimental and theoretical work aimed at charge noisemitigation in quantum dot systems implementing AC- or DC-control of triple dots at "sweet spots". In this talk, we compare the symmetric operation point (SOP)DC control technique implemented in Reed, et al. [arXiv:1508.01223] to the resonant exchange (RX) AC control technique [Medford, et al., PRL 111, 050501 (2013), Taylor, et al., PRL 111, 050502 (2013), Russ, et al., Phys. Rev. B 91, 235411 (2015)]. Numerical results suggest that both DC and AC triple-dot control can offer a comparably substantial reduction in charge noise; however, the validity of the rotating wave approximation forces a trade-off between speed and accuracy for RX qubits, while the performance of SOP qubits actually improves at shorter gate times.

**12:27PM B45.00005 The validity of the RWA and gate operation speedup by violating RWA in resonant-driven qubit systems<sup>1</sup>**, YANG SONG, Condensed Matter Theory Center, Dept. of Physics, Univ. of Maryland — The rotating wave approximation (RWA) is ubiquitously used in understanding (quasi)resonant driven systems and designing pulses for state evolution. Following the practice in atomic and NMR physics, a wide range of semiconducting qubit systems are driven resonantly to manipulate the qubit, including single-spin/resonant exchange (RX)/various singlet-triplet(ST)/spin-charge hybrid qubits. The purpose of this talk is twofold: (I) Examine the validity of RWA in different qubit systems and analyze the error in terms of quantum computation; (II) Present faster gate operations by going into RWA-invalid regime for resonant-driven qubits (esp. for ST and RX types). We measure the RWA-induced infidelity and discuss it in view of the fault-tolerant error correction threshold and operation speeds. Applying the analytical extension (two orders higher than RWA) greatly reduces the infidelity, in the regime where the RWA is attempted to be used. Moreover, we show that the resonant-driven system is not limited by the Rabi-like weak coupling limit and the associated slow gate speed, much smaller than the level splitting (e.g., the small Zeeman energy gradient in ST qubits). We demonstrate the universal one qubit gates for driving strength up to a few level splitting, achieving fast control with only simple sinusoidal pulses. We also solve for the 'shifted sinusoidal' pulses needed for ST qubits where the exchange coupling cannot change signs.

**12:39PM B45.00006 Leakage of The Quantum Dot Hybrid Qubit in The Strong Driving Regime<sup>1</sup>**, YUAN-CHI YANG, MARK FRIESEN, S. N. COPPERSMITH, Univ of Wisconsin, Madison — Recent experimental demonstrations of high-fidelity single-qubit gates suggest that the quantum dot hybrid qubit is a promising candidate for large-scale quantum computing. The qubit is comprised of three electrons in a double quantum dot, and can be protected from charge noise by operating in an extended sweet-spot regime. Gate operations are based on exchange interactions mediated by an excited state. However, strong resonant driving causes unwanted leakage into the excited state. Here, we theoretically analyze leakage caused by strong driving, and explore methods for increasing gate fidelities.

<sup>1</sup>This work was supported in part by ARO (W911NF-12-0607), NSF (PHY-1104660), ONR (N00014-15-1-0029), and the University of Wisconsin-Madison.

**12:51PM B45.00007 Tenfold increase in the Rabi decay time of the quantum dot hybrid qubit**, BRANDUR THORGRIMSSON, University of Wisconsin-Madison, DOHUN KIM, Yonsei University, Seoul, South Korea, C.B. SIMMONS, DANIEL R. WARD, RYAN H. FOOTE, D. E. SAVAGE, M. G. LAGALLY, MARK FRIESEN, S. N. COPPERSMITH, M. A. ERIKSSON, University of Wisconsin-Madison — The quantum dot hybrid qubit is formed from three electrons in a double quantum dot. In previous work, we showed that the hybrid qubit has the speed of a charge qubit and the stability of a spin qubit. Here, we show that the hybrid qubit is also highly tunable, and can be tuned into regimes with desirable coherence properties. By changing the interdot tunnel rate by only 25%, from 5 GHz to 6.25 GHz, we are able to increase the Rabi decay time by a factor of ten, from 18 ns to 177 ns. We attribute this improvement to the refinement of an extended sweet spot in the energy dispersion of the hybrid qubit, where the qubit is less susceptible to charge noise, which is a dominant source of decoherence. This work was supported in part by ARO (W911NF-12-0607) and NSF (DMR-1206915 and PHY-1104660). Development and maintenance of the growth facilities used for fabricating samples is supported by DOE (DE-FG02-03ER46028). This research utilized NSF-supported shared facilities at the University of Wisconsin-Madison.

**1:03PM B45.00008 Effect of Charge Noise on Landau-Zener Interferometry in double quantum dots**, ZHENYI QI, MARK FRIESEN, SUSAN COPPERSMITH, MAXIM VAVILOV, Univ of Wisconsin, Madison — We study the effect of charge noise on the dynamics of semiconductor quantum dot qubits. Recent experiments have demonstrated relatively long coherence times in these systems; however at the same time, the visibility of the Landau-Zener interference pattern is relatively low. We argue that the electromagnetic noise of the environment affects the coherence of the qubit near the charge degeneracy point, including the singlet-triplet avoided level crossing, and results in the reduced visibility of the Landau-Zener interferometry when the singlet-triplet avoided level crossing happens in the vicinity of the charge degeneracy point. Using a master equation, we describe the evolution of the density matrix for the qubit assuming weak coupling of the quantum dot to its electromagnetic environment and compare our results to experimental data.

**1:15PM B45.00009 Noise-induced collective quantum state preservation in spin qubit arrays<sup>1</sup>**, EDWIN BARNES, Department of Physics, Virginia Tech and Condensed Matter Theory Center, University of Maryland, DONG-LING DENG, ROBERT THROCKMORTON, YANG-LE WU, Condensed Matter Theory Center, University of Maryland — The hyperfine interaction with nuclear spins (or, Overhauser noise) has long been viewed as a leading source of decoherence in individual quantum dot spin qubits. We show that in a coupled multi-qubit system consisting of as few as four spins, interactions with nuclear spins can have the opposite effect where they instead preserve the collective quantum state of the system. This noise-induced state preservation can be realized in a linear spin qubit array using current technological capabilities. Our proposal requires no control over the Overhauser fields in the array; only experimental control over the average interqubit coupling between nearest neighbors is needed, and this is readily achieved by tuning gate voltages. Our results illustrate how the role of the environment can transform from harmful to helpful in the progression from single-qubit to multi-qubit quantum systems.

<sup>1</sup>Work supported by LPS-MPO-CMTC and IARPA-MQCO

**1:27PM B45.00010 Decoupling a spin qubit from high-frequency Larmor dynamics of a GaAs nuclear spin bath<sup>1</sup>**, FILIP K. MALINOWSKI, FREDERICO MARTINS, PETER D. NISSEN, MARK S. RUDNER, CHARLES M. MARCUS, FERDINAND KUEMMETH, Center for Quantum Devices, Niels Bohr Institute, University of Copenhagen, EDWIN BARNES, Department of Physics, Virginia Tech, SAEED FALLAHI, GEOFFREY C. GARDNER, MICHAEL J. MANFRA, Department of Physics and Astronomy and Birck Nanotechnology Center, Purdue University — We present a technique of decoupling a spin qubit in a GaAs/AlGaAs heterostructure from low- and high-frequency noise arising from hyperfine interaction of electrons with nuclear spins. We use Carr-Purcell-Meiboom-Gill sequences in which we synchronize the repetition rate of  $\pi$  pulses to difference Larmor frequencies of  $^{69}\text{Ga}$ ,  $^{71}\text{Ga}$  and  $^{75}\text{As}$  nuclei. This decouples the qubit both from low-frequency noise due to diffusion of nuclear spins and from noise at selected high frequencies, allowing us to apply more than a thousand  $\pi$  pulses in a sequence. We demonstrate a coherence time of a singlet-triplet qubit of 0.87 ms, i.e. five orders of magnitude longer than the inhomogeneous dephasing time intrinsic to GaAs.

<sup>1</sup>Support through IARPA-MQCO, Army Research Office, LPS-MPO-CMTC, the Villum Foundation and the Danish National Research Foundation is acknowledged.

**1:39PM B45.00011 Noise filtering of composite pulses for singlet-triplet qubits<sup>1</sup>**, XIN WANG, XU-CHEN YANG, City University of Hong Kong — Dynamically corrected gates are useful measures to combat decoherence in spin qubit systems. They are, however, mostly designed assuming the static-noise model and may thus be considered low-frequency noise filters. In this talk we carefully examine the applicability of a particular type of dynamically corrected gates, namely the SUPCODE designed for singlet-triplet qubits, under realistic  $1/f^\alpha$  noises. Through randomized benchmarking, we have found that SUPCODE offers improvement of the gate fidelity for  $\alpha > 1$  and the improvement becomes exponentially more pronounced with the increase of the noise exponent  $\alpha$  up to 3. On the other hand, for small  $\alpha$  SUPCODE will not offer any improvement. We also present the computed filter transfer functions for the SUPCODE gates for nuclear and charge noise respectively and have found that they are consistent with the finding from the benchmarking.

<sup>1</sup>The work is supported by grants from City University of Hong Kong (Projects No. 9610335 and No. 7200456).

**1:51PM B45.00012 Dynamical Decoupling with pulse errors for ensembles of interacting spins**, E. S. PETERSEN, A. M. TYRSHKIN, S. A. LYON, Princeton University — Dynamical decoupling (DD) is a well-known approach for decoupling quantum (spin) systems from their environments. Theoretically, the performance of DD pulse sequences is often analyzed using a single spin approximation in which environmental noise is included through single spin operators. This approach has successfully analyzed the effectiveness of many popular DD pulse sequences (like CPMG and XY4) to cancel environmental noise even in the presence of unavoidable pulse errors. However, this methodology does not describe the effect of DD on the spin-spin interactions present in experiments involving large numbers of spins. Here, we go beyond the usual single-spin model, extending the analysis of DD sequences to include such spin-spin interactions. We find that when using certain popular DD sequences (like CPMG), coherence times of ensembles with dipolar interactions between spins can be drastically influenced by pulse errors. While sequences with ideal pulses do not decouple the spin-spin interactions, the presence of even small pulse errors can partially (or even greatly) decouple the spin-spin interactions thus leading to longer coherence times. Furthermore, the extent that these interactions are decoupled is highly dependent on the type of DD sequence used, and not necessarily the number of pulses involved. These calculations explain results of past experiments (Tyrshkin et al, arxiv: 1011.1903).

**2:03PM B45.00013 Dynamic field-frequency lock for tracking magnetic field fluctuations in electron spin resonance experiments**, ABRAHAM ASFAW, ALEXEI TYRSHKIN, STEPHEN LYON, Department of Electrical Engineering, Princeton University, Princeton NJ 08544 — Global magnetic field fluctuations present significant challenges to pulsed electron spin resonance experiments on systems with long spin coherence times. We will discuss results from experiments in which we follow instantaneous changes in magnetic field by locking to the free induction decay of a proton NMR signal using a phase-locked loop. We extend conventional field-frequency locking techniques used in NMR to follow slow magnetic field drifts by using a modified Carr-Purcell-Meiboom-Gill (CPMG) pulse sequence in which the phase of the  $\pi$ -pulses follows the phase of the proton spins at all times. Hence, we retain the ability of the CPMG pulse sequence to refocus local magnetic field inhomogeneities without refocusing global magnetic field fluctuations. In contrast with conventional field-frequency locking techniques, our experiments demonstrate the potential of this method to dynamically track global magnetic field fluctuations on timescales of about 2 seconds and with rates faster than a kHz. This frequency range covers the dominant noise frequencies in our electron spin resonance experiments as previously reported.

Session B46 GIMS: Instrumentation I: Detectors, Sensors, Signal Processing & Analysis 311 - James Matey, NIST

**11:15AM B46.00001 Contemporary Issues in Ultra-Low Alpha Particle Counting**, MICHAEL GORDON, IBM TJ Watson Research Center — Single-Event Upsets (SEU) in CMOS devices are caused by the passage of ionizing radiation either from terrestrial neutrons or from the natural alpha particle radiation within the materials surrounding the transistors. Interactions of the neutrons with the silicon cause spallation reactions which emit energetic highly ionizing elements. Alpha particles, on the other hand, can upset the devices through direct ionization rather than through a nuclear reaction as in the case of the neutrons. In order to minimize the alpha-particle component of SEU, the radiation from the materials within a distance 100  $\mu\text{m}$  of the transistors, currently needs to have an alpha particle emissivity of less than 2 alpha particles per khr per square centimeter. Many alpha particle detectors have background levels that are larger than this, which can make these measurements inaccurate and time consuming. This talk will discuss what is involved in making alpha particle emissivity measurements of materials used in the semiconductor industry using an ultra-low background commercially-available ionization detector. Detector calibration and efficiency, radon adsorption on the samples, and the effect of surface charge on electrically insulating samples will be discussed.

**11:27AM B46.00002 TRIASSIC: the Time-Resolved Industrial Alpha-Source Scanning Induced Current microscope**, ARTHUR PALLONE, Norwich University — Time-resolved ion beam induced current (TRIBIC) microscopy yields useful information such as carrier mobility and lifetimes in semiconductors and defect locations in devices; however, traditional TRIBIC uses large, expensive particle accelerators that require specialized training to operate and maintain. The time-resolved industrial alpha-source scanning induced current (TRIASSIC) microscope transforms TRIBIC by replacing the particle accelerator facility with an affordable, tabletop instrument suitable for use in research and education at smaller colleges and universities. I will discuss the development of, successes with, setbacks to and future directions for TRIASSIC.

**11:39AM B46.00003 Superconducting Nuclear Recoil Sensor for Directional Dark Matter Detection<sup>1</sup>**, ANN JUNGHANS, KEVIN BALDWIN, MARKUS HEHLEN, Los Alamos National Laboratory, RANDY LAFLER, DINESH LOOMBA, NGUYEN PHAN, University of New Mexico, NINA WEISSE-BERNSTEIN, Los Alamos National Laboratory — The Universe consists of 72% dark energy, 23% dark matter and only 5% of ordinary matter. One of the greatest challenges of the scientific community is to understand the nature of dark matter. Current models suggest that dark matter is made up of slowly moving, weakly interacting massive particles (WIMPs). But detecting WIMPs is challenging, as their expected signals are small and rare compared to the large background that can mimic the signal. The largest and most robust unique signature that sets them apart from other particles is the day-night variation of the directionality of dark matter on Earth. This modulation could be observed with a direction-sensitive detector and hence, would provide an unambiguous signature for the galactic origin of WIMPs. There are many studies underway to attempt to detect WIMPs both directly and indirectly, but solid-state WIMP detectors are widely unexplored although they would present many advantages to prevalent detectors that use large volumes of low pressure gas. We present first results of a novel multi-layered architecture, in which WIMPs would interact primarily with solid layers to produce nuclear recoils that then induce measureable voltage pulses in adjacent superconductor layers.

**11:51AM B46.00004 It may be possible to use Speech Recognition Algorithms to sort through Particle Detection**, RICHARD KRISKE, University of Minnesota — There are some similarities between recognizing speech and written language and in recognizing Particle interaction and decays. In the Viterbi Algorithm or speech recognition, a target word is recursively compared with the unknown utterance. Say one remembered the word Motion in a song and wanted to find that song. First the letter M is typed in and the most common words with M show up say it is the word "Menards", then an "O" is typed in and statistically the most common word is now "Movies", now the "t" is typed in and the most common word is "Motley Crue" finally all the letters are typed in and the song that matches is "Motion Lyrics". We all recognize the Algorithm and perhaps a few have realized that this Algorithm could also be applied to Decay Chains in Particle Scattering and Detection. Also there may come a day when perhaps Neutrinos where transmitted with the purpose of Communication, one system would be to use a type of "Morse Code", but another could be to use Decay Chains themselves. Perhaps the sender could tune the Energy such that the information received would rely on the Energy being transmitted, since it may be that only a few of the particles are received, too few for "Morse Code" to work.

**12:03PM B46.00005 Bayesian 2D Current Reconstruction from Magnetic Images**, COLIN B. CLEMENT, MATTHEW K. BIERBAUM, KATJA NOWACK, JAMES P. SETHNA, Cornell University — We employ a Bayesian image reconstruction scheme to recover 2D currents from magnetic flux imaged with scanning SQUIDS (Superconducting Quantum Interferometric Devices). Magnetic flux imaging is a versatile tool to locally probe currents and magnetic moments, however present reconstruction methods sacrifice resolution due to numerical instability. Using state-of-the-art blind deconvolution techniques we recover the currents, point-spread function and height of the SQUID loop by optimizing the probability of measuring an image. We obtain uncertainties on these quantities by sampling reconstructions. This generative modeling technique could be used to develop calibration protocols for scanning SQUIDS, to diagnose systematic noise in the imaging process, and can be applied to many tools beyond scanning SQUIDS.

**12:15PM B46.00006 ABSTRACT WITHDRAWN —**

**12:27PM B46.00007 Detection of zeptojoule microwave pulses using an electrothermal bifurcation**, JOONAS GOVENIUS, RUSSELL LAKE, KUAN TAN, MIKKO MÖTTÖNEN, Department of Applied Physics, Aalto University, Finland — We utilize electrothermal feedback for the threshold detection of weak 8.4 GHz microwave pulses containing approximately  $200 \times h \times (8.4 \text{ GHz}) \approx 1.1 \times 10^{-21} \text{ J}$  of energy. The feedback couples the electrical and thermal degrees of freedom in the central component of our detector, a metallic nanowire that absorbs the incoming microwave radiation and transduces the temperature change into a radio-frequency electrical signal. We can tune the feedback in situ, which provides access to both positive and negative feedback regimes with rich nonlinear dynamics. In particular, strong positive feedback leads to the emergence of two metastable electron temperature states in the millikelvin range. We use these states in the threshold detection protocol.

**12:39PM B46.00008 Micro-Hall devices for magnetic, electric and photo-detection**, A. GILBERTSON, Imperial College, H. SADEGHI, Lancaster University, V. PANCHAL, O. KAZAKOVA, National Physical Laboratory, C.J. LAMBERT, Lancaster University, S.A. SOLIN<sup>1</sup>, L.F. COHEN, Imperial College — Multifunctional mesoscopic sensors capable of detecting local magnetic ( $B$ ), electric ( $E$ ), and optical fields can greatly facilitate image capture in nano-arrays that address a multitude of disciplines. The use of micro-Hall devices as  $B$ -field sensors [1] and, more recently as  $E$ -field sensors [2] is well established. Here we report the real-space voltage response of InSb/AlInSb micro-Hall devices to not only local  $E$ -, and  $B$ -fields but also to photo-excitation using scanning probe microscopy. We show that the ultrafast generation of localised photocarriers results in conductance perturbations analogous to those produced by local  $E$ -fields. Our experimental results are in good agreement with tight-binding transport calculations in the diffusive regime. At room temperature, samples exhibit a magnetic sensitivity of  $>500 \text{ nT}/\sqrt{\text{Hz}}$ , an optical noise equivalent power of  $>20 \text{ pW}/\sqrt{\text{Hz}}$  ( $\lambda = 635 \text{ nm}$ ) comparable to commercial photoconductive detectors, and charge sensitivity of  $>0.04 \text{ e}/\sqrt{\text{Hz}}$  comparable to that of single electron transistors. **12:51PM B46.00009 Understanding the TERS Effect with On-line Tunneling and Force Feedback Using Multiprobe AFM/NSOM with Raman Integration**, AARON LEWIS, Hebrew University of Jerusalem. Dept. of Applied Physics, Jerusalem, Israel, RIMMA DEKHTER, PATRICIA HAMRA, YOSHI BAR-DAVID, HESHAM TAHA, Nanonics Imaging Ltd., Jerusalem, Israel — Tip enhanced Raman scattering (TERS) has evolved in several directions over the past years. The data from this variety of methodologies has now accumulated to the point that there is a reasonable possibility of evolving an understanding of the underlying cause of the resulting effects that could be the origin of the various TERS enhancement processes. The objective of this presentation is to use the results thus far with atomic force microscopy (AFM) probes with noble metal coating, etching, transparent gold nanoparticles with and without a second nanoparticle [Wang and Schultz, ANALYST 138, 3150 (2013)] and tunneling feedback probes [R. Zhang et. al., NATURE 498, 82 (2013)]. We attempt at understanding this complex of results with AFM/NSOM multiprobe techniques. Results indicate that TERS is dominated by complex quantum interactions. This produces a highly confined and broadband plasmon field with all  $k$  vectors for effective excitation. Normal force tuning fork feedback with exposed tip probes provides an excellent means to investigate these effects with TERS probes that we have shown can circumvent the vexing problem of jump to contact prevalent in conventional AFM methodology and permit on-line switching between tunneling and AFM feedback modes of operation.

**1:03PM B46.00010 A Cantilever Torque Magnetometer for Measuring Hall Conductivity**, SAMUEL MUMFORD, E. M. LEVENSON-FALK, Stanford University, AMIR YACOBY, Harvard University, AHARON KAPITULNIK, Stanford University — We propose a cantilever-based torque magnetometer of Corbino-disc patterned samples in magnetic field. Applying a voltage difference across the disc, a magnetic dipole moment is created which will interact with the magnetic field, exerting a torque on the cantilever. A circulating current will flow in the presence of potential difference between the two edges of the disc which is placed at the end of a vibrating cantilever. The induced magnetic dipole moment will interact with the magnetic field, creating a torque. The measured torque yields information about the transverse conductance of the ring - hence  $\sigma_{xy}$ .

**1:15PM B46.00011 Carbon Nanotube Bolometer for Absolute FTIR Spectroscopy**, SOLOMON WOODS, NIST, JORGE NEIRA, Jung Research and Development Corp., NATHAN TOMLIN, JOHN LEHMAN, NIST — We have developed and calibrated planar electrical-substitution bolometers which employ absorbers made from vertically-aligned carbon nanotube arrays. The nearly complete absorption of light by the carbon nanotubes from the visible range to the far-infrared can be exploited to enable a device with read-out in native units equivalent to optical power. Operated at cryogenic temperatures near 4 K, these infrared detectors are designed to have time constant near 10 ms and a noise floor of about 10 pW. Built upon a micro-machined silicon platform, each device has an integrated heater and thermometer, either a carbon nanotube thermistor or superconducting transition edge sensor, for temperature control. We are optimizing temperature-controlled measurement techniques to enable high resolution spectral calibrations using these devices with a Fourier-transform spectrometer.

**1:27PM B46.00012 Optical design of a compact near-infrared multispecies gas sensor**, JOSHUA LARSON, FATIMA TOOR, Univ of Iowa — In this work we present the design of a compact and cost effective near infrared (NIR) gas sensor system that can detect nitrous oxide ( $\text{NO}_x$ ), ammonia ( $\text{NH}_3$ ), and methane ( $\text{CH}_4$ ) simultaneously. These three gases were chosen as they are environmental pollutants and their monitoring is especially important in agricultural states like Iowa. As a first step in our design process, we have developed a Matlab model based on Beer-Lambert's law to generate sample sensor data for each of the gases at different concentrations. The data measured from the sensor system will be as a function of time instead of wavelength, so we performed Fourier Transform analysis on the sensor data to convert it to voltage versus time. The simulated sensor data will enable to design software algorithms to separate the absorption signals for each of the three gases. As a second step, we have developed a lab-based sensor system comprising of three components: (i) a NIR lead sulfide ( $\text{PbS}$ ) photodiode, (ii) an LED that emits 1900 nm to 2600 nm, and (iii) an optical cavity where the gases are introduced. We are designing the optical cavity using ray optics COMSOL finite element method simulator using the principles of a compact chaotic cavity that will allow the LED light to have a path length of greater than 100 m within the cavity, enabling high sensitivity gas detection. Our end goal is to have an autonomous drone mounted device that is simple and inexpensive to use. We plan to license this technology to agricultural equipment manufacturers.

**1:39PM B46.00013 Enthalpy of sublimation as measured using a silicon oscillator.**, HAMZA SHAKEEL, J.M. POMEROY, National Institute of Standards and Technology — In this study, we report the enthalpy of sublimation of common gases (nitrogen, oxygen, argon, carbon dioxide, neon, krypton, xenon, and water vapor) using a large area silicon oscillator with a sub-ng ( $\approx 0.027 \text{ ng/cm}^2$ ) mass sensitivity. The double paddle oscillator design enables high frequency stability (17 ppb) at cryogenic temperatures and provides a consistent technique for enthalpy measurements. The enthalpies of sublimation are derived from the rate of mass loss during programmed thermal desorption and are detected as a change in the resonance frequency of the self-tracking oscillator. These measured enthalpy values show excellent agreement with the accepted literature values.

**1:51PM B46.00014 Conversion of far ultraviolet to visible radiation: absolute measurements of the conversion efficiency of tetraphenyl butadiene<sup>1</sup>**, ROBERT E. VEST, National Institute of Standards and Technology, MICHAEL A. COPLAN, University of Maryland, CHARLES W. CLARK, Joint Quantum Institute — Far ultraviolet (FUV) scintillation of noble gases is used in dark matter and neutrino research<sup>2</sup> and in neutron detection.<sup>3</sup> Upon collisional excitation, noble gas atoms recombine into excimer molecules that decay by FUV emission. Direct detection of FUV is difficult. Another approach is to convert it to visible light using a wavelength-shifting medium. One such medium, tetraphenyl butadiene (TPB) can be vapor-deposited on substrates. Thus the quality of thin TPB films can be tightly controlled. We have measured the absolute efficiency of FUV-to-visible conversion by 1  $\mu\text{m}$ -thick TPB films vs. FUV wavelengths between 130 and 300 nm, with 1 nm resolution. The energy efficiency of FUV to visible conversion varies between 1% and 5%. We make comparisons with other recent results.<sup>4</sup>

## Monday, March 14, 2016 11:15AM - 2:15PM – Session B47 DCMP: Molecular Assembly on Surfaces 312 -

**11:15AM B47.00001 Supra-molecular networks for CO<sub>2</sub> capture<sup>1</sup>**, JERZY SADOWSKI, JOHN KESTELL, Brookhaven National Laboratory — Utilizing capabilities of low-energy electron microscopy (LEEM) for non-destructive interrogation of the real-time molecular self-assembly, we have investigated supramolecular systems based on carboxylic acid-metal complexes, such as trimesic and mellitic acid, doped with transition metals. Such 2D networks can act as host systems for transition-metal phthalocyanines (MPc; M = Fe, Ti, Sc). The electrostatic interactions of CO<sub>2</sub> molecules with transition metal ions can be tuned by controlling the type of TM ion and the size of the pore in the host network. We further applied infrared reflection-absorption spectroscopy (IRRAS) to determine of the molecular orientation of the functional groups and the whole molecule in the 2D monolayers of carboxylic acid. The kinetics and mechanism of the CO<sub>2</sub> adsorption/desorption on the 2D molecular network, with and without the TM ion doping, have been also investigated.

**11:27AM B47.00002 Experimental and Computational Comparison of the Self-Assembled Nanostructures of Pentacene Derivatives on Gold**, AMANDA LARSON, RYAN MILLER, JUN WANG<sup>1</sup>, KARSTEN POHL, University of New Hampshire — Pentacene derivatives can tailor the standard pentacene molecule for unique properties beneficial to organic photovoltaic devices. Increased solubility, photo-oxidative resistance, thermal stability and tailor-able HOMO-LUMO gaps make novel pentacene derivatives enticing for further study. Scanning tunneling microscopy and density functional theory was used to examine the atomic interface between gold and the pentacene derivatives: 6,13-dichloropentacene (DCP) and 5,6,7-trithiapentacene-13-one (TTPO), electron donors exhibiting self-assembled monolayer structures on gold surfaces. Comparing DCP, TTPO and pentacene highlights the effects of differing substituents to the self-assembled structures. In particular, the unique 3-dimensional angular assembly of TTPO is examined and clarified through use of extensive computation. The lateral arrangement of the molecule is unique, causing the thiol substituent side of the molecule to be angled down towards the gold surface, while the long-axis of TTPO is parallel to the gold surface; distinctive from previously observed pentacene and pentacene derivative assemblies. By understanding the differences in self-assembly of similar molecules, we are developing novel pathways towards molecular control of organic-metal interfaces.

**11:39AM B47.00003 Molecular assembly and organic film growth on complex intermetallic surfaces.**<sup>1</sup>, ABDULLAH AL-MAHBOOB, HEM RAJ SHARMA, Department of Physics, University of Liverpool, UK, JERZY T SADOWSKI, Center for Functional Nanomaterials, Brookhaven National Laboratory, USA, JULIAN LEDIEU, VINCENT FOURNE, Institut Jean Lamour, Universit  de Lorraine, France, RONAN MCGRATH, Department of Physics, University of Liverpool, UK — We extensively studied the role of molecular symmetry and symmetry/structures of wide ranges of substrate-surfaces from non-periodic to periodic to quasi-crystalline in nucleation, growth and phase transition in films made of organic molecular materials. Recently, most interest in quasicrystals is due to the generalization of aperiodic ordering to several classes of systems. Compared to periodic materials, these provide a closer approximation to an isotropic first Brillouin zone, which is of great importance to the design of new functional materials. Here, we present results obtained from our ongoing study of interface mediated molecular assembly extended on complex intermetallic surfaces with specific examples of C<sub>60</sub> and Zn-phthalocyanine on quasicrystalline and approximant surfaces. We employed in-situ real-time low-energy electron microscopy (LEEM) for investigation of the processes in assembly and film growth and post-growth STM study and DFT calculations to understand structural details and growth mechanism.

<sup>1</sup>Research were carried out in part at the Center for Functional Nanomaterials, Brookhaven National Lab, USA; partly at Institut Jean Lamour, Universit  de Lorraine, France; and partly at the Surface Science Research Centre, University of Liverpool, UK.

**11:51AM B47.00004 A theoretical and experimental investigation on the adsorption of pentacene on the Cu(322) surface**, JERONIMO MATOS, University of Central Florida, MICHELE SAUVAGE-SIMKIN, Synchrotron SOLEIL and UR1-CNRS, ALESSANDRO COATI, Synchrotron SOLEIL, YVES GARREAU, Synchrotron SOLEIL and Universit  Paris Diderot, ALINA VLAD, Synchrotron SOLEIL, KATHRIN MULLER, Max Planck Institut fr Festk rperforschung, AZZEDINE BENDOUNAN, Synchrotron SOLEIL, ABDELKADER KARA, University of Central Florida — In this study, complementary techniques including density functional theory (DFT), grazing incidence x-ray diffraction (GIXD), and scanning tunneling microscopy (STM) are used to study the surface distortions induced by the adsorption of pentacene on the stepped Cu(322) surface. GIXD measurements are performed for the clean Cu(322) surface and at various coverages of pentacene, up to one monolayer. For the one monolayer case, reciprocal space maps from GIXD measurement suggest the reconstruction of the steps to double the step width and height, with two pentacene molecules present at each terrace. Complementary DFT calculations are carried out, with and without the self-consistent inclusion of vdW interactions, using the optB88-vdW and PBE functionals. Our investigation illustrates a prototype method for conducting future benchmarking studies to assess the accuracy of the current self-consistent vdW functionals when applied to organic molecule adsorption.

**12:03PM B47.00005 Coverage Dependent Assembly of Anthraquinone on Au(111)**, BRAD CONRAD, Appalachian State Univ, ANDREW DELOACH, North Carolina State University, THEODORE EINSTEIN, University of Maryland - College Park, DANIEL DOUGHERTY, North Carolina State University — A study of adsorbate-adsorbate and surface state mediated interactions of anthraquinone (AnQ) on Au(111) is presented. We utilize scanning tunneling microscopy (STM) to characterize the coverage dependence of AnQ structure formation. Ordered structures are observed up to a single monolayer (ML) and are found to be strongly dependent on molecular surface density. While the complete ML forms a well-ordered close-packed layer, for a narrow range of sub-ML coverages irregular close-packed islands are observed to coexist with a disordered pore network linking neighboring islands. This network displays a characteristic pore size and at lower coverages, the soliton walls of the herringbone reconstruction are shown to promote formation of distinct pore nanostructures. We will discuss these nanostructure formations in the context of surface mediated and more direct adsorbate interactions.

**12:15PM B47.00006 Self-Assembly of Glycine on Cu (001): The tale of Temperature and Polarity**, LIFANG XU, Institute of Physics, Chinese Academy of Sciences, JING XU, Department of Physics, Renmin University of China, ZHESHUAI LIN, Technical Institute of Physics and Chemistry, Chinese Academy of Sciences, SHENG MENG, ENGE WANG, Institute of Physics, Chinese Academy of Sciences — Glycine on Cu(001) is used as an example to illustrate the critical role of molecular polarity and finite temperature effect in self-assembly of bio-molecules at a metal surface. A unified picture for glycine self-assembly on Cu(001) is derived based on full polarity compensation considerations. Temperature plays a non-trivial role: the ground-state structure at 0 K is absent at room temperature, where intermolecular hydrogen bonding overweighs competing molecule-substrate interactions. The unique p(24) structure predicted as the most stable structure was confirmed by ab initio molecular dynamics simulations, whose scanning tunneling microscopy images and anisotropic free-electron-like dispersion are in excellent agreement with experiments. Moreover, the rich self-assembling patterns including the heterochiral and homochiral phases, and their interrelationships are entirely governed by the same mechanism.

**12:27PM B47.00007 Interaction of porphyrins with low coordinated sites on the MgO(001) surface**, OSMAN BARIS MALCIOGLU, MICHEL BOCKSTEDTE, Solid State Physics, FAU Erlangen-Nrnberg, Erlangen Germany — The functionalization of metal oxide surfaces with porphyrins is achieved via site selective linker groups and a specific metal center in the macrocycle. Metal oxide surfaces like MgO(001) have got a rather inert pristine surface and reactive low coordinated sites such as steps and kink-sites. Recently the metallization of H2TPP with Mg via low coordinated sites on MgO(001) has been demonstrated. The underlying mechanisms, however, remain unclear. Here we address this issue. We study the adsorption of H2TPP on MgO(001) and its interaction with low coordinated sites employing ab initio molecular dynamics simulations. We find that H2TPP is mobile on the surface due to steric hindrance from phenyl rings preventing physisorption of the macrocycle, until a step or kink site is encountered. Upon encountering such a site, H2TPP anchors itself to form a rather stable complex, and spontaneously deprotonates from the macrocycle. We discuss the electronic and structural properties of the adsorbate complex, the intermediate and the metallized porphyrins using (hybrid) TDDFT and many body perturbation theory, identifying various effects that can be used to uniquely identify presence of such complexes.

**12:39PM B47.00008 Molecular lifting, twisting, and curling during metal-assisted polycyclic hydrocarbon dehydrogenation.**, DAVIDE CURCIO, LUCA OMICIUOLO, Univ of Trieste - Trieste, Italy, MONICA POZZO, London Centre for Nanotechnology, University College London, UK, PAOLO LACOVIG, SILVANO LIZZIT, Elettra-Sincrotrone Trieste S.C.p.A., Trieste, Italy, NAILA JABEEN, Univ of Trieste - Trieste, Italy, LUCA PETACCIA, Elettra-Sincrotrone Trieste S.C.p.A., Trieste, Italy, DARIO ALFE, London Centre for Nanotechnology, University College London, UK, ALESSANDRO BARALDI, Univ of Trieste - Trieste, Italy — Through a combined experimental and theoretical approach, we show that coronene molecules adsorbed on Ir(111) undergo major changes in conformation during the dissociation process, which brings the molecules from a flat configuration to graphene, through a series of exotic configurations. The complex reaction path involves the tilting upwards of the molecules, which subsequently experience a rotation with respect to the surface. During the lifting, the C-C strain is initially relieved, while as the dehydrogenation proceeds, the molecules experience a progressive increase in the average interatomic distance, and gradually settle to form peculiar dome shaped nanographenes. This reaction mechanism can provide new insight into the surface assisted break-up mechanism of PAHs, which has been demonstrated to be an effective strategy for the synthesis of low dimensional carbon-based materials. Beside the peculiarity of the reaction pathway, using these processes we envisage the unique possibility of creating new structures with different functionalities by encapsulating single atoms below the carbon dome.

**12:51PM B47.00009 Predictive Modeling of Metal-Organic Chains with Active Metal Site**, NASEEM UD DIN, DUY LE, TALAT RAHMAN, Univ of Central Florida — Creation, stabilization, characterization and control of single atom transition metal (TM) sites may lead to significant advancement of the next-generation catalyst. Motivated by the experimental results of Skomski et al. [1], we have performed density functional theory based calculations of TM-dipyridyltetrazine (DT) chains in which TM atoms are stabilized and separated by the DT molecules. Our calculations show that the formation energies of the chains are high, suggesting that these chains can easily be synthesized and stabilized. Moreover, by calculating the adsorption energies of CO, O<sub>2</sub> and O atom on the metal atom sites of the chains we found that these molecules/atoms strongly bond to TM atoms Mo, Cr, Fe and Co occupying these sites, suggesting that these TM-DT chains are potential candidates for CO oxidation catalyst. Details of reaction pathway (energetic and kinetic) of CO oxidation on the chains will be also presented and discussed. [1] D. Skomski, C.D. Tempas, K.A. Smith, and S.L. Tait, "Redox-Active On-Surface Assembly of Organic Chains with Single-Site Pt(II)," *Journal of the American Chemical Society* **136**, 9862-9865 (2014).

**1:03PM B47.00010 The impact of functional group on the electronic structure of coordination center<sup>1</sup>**, ZAHRA HOOSHMAND GHAREHBAGH, DUY L, TALAT S RAHMAN, University of Central Florida — While 9, 10 dicyano-anthracene (DCA) forms a coordination network on Cu(111) surface with Cu adatom coordinated by three DCA molecules [1], its isomers, 9,10-diisocyno-anthracene forms, surprisingly, molecular rows on the same surface [2]. To understand the impact of functional groups on the electronic structure of the coordination center, we have carried out density functional theory based calculations of the electronic structure of a set of naphthalene molecules with different functional groups (N, CN, NC, NH<sub>2</sub>, COH, COOH) adsorbed on Cu(111), with and without a Cu adatom. Our results show that while the interaction between the naphthalene backbone and the Cu(111) surface is dominated by van der Waals (vdW) forces, in all cases considered the functional group forms a covalent bond with the Cu (ad)atom (on) of the surface. The calculated differential charge redistribution shows that the strongest covalent bond is formed by the NC group, which differs remarkably from that formed by the CN group, while the vdW interaction is very similar in both cases. These results provide insights into the different surface coordination behavior of molecules with above-mentioned functional groups. 1. Pawin, G., et al., *A Surface Coordination Network Based on Substrate-Derived Metal Adatoms with Local Charge Excess*. *Angewandte Chemie International Edition*, 2008. 47(44): p. 8442-8445. 2. L. Bartels, Private communication.

<sup>1</sup>Work support in part by NSF Grant CHE-1310327

**1:15PM B47.00011 Spin-Polarized Hybridization at the interface between different 8-hydroxyquinolates and the Cr(001) surface**, JINGYING WANG, ANDREW DELOACH, DANIEL B DOUGHERTY, Department of Physics, North Carolina State University, DOUGHERTY LAB TEAM — Organic materials attract a lot of attention due to their promising applications in spin-tronic devices. It is realized that spin-polarized metal/organic interfacial hybridization plays an important role to improve efficiency of organic spintronic devices. Hybridized interfacial states help to increase spin injection at the interface. Here we report spin-resolved STM measurements of single tris(8-hydroxyquinolinato) aluminum molecules adsorbed on the antiferromagnetic Cr(001). Our observations show a spin-polarized interface state between Alq3 and Cr(001). Tris(8-hydroxyquinolinato) chromium has also been studied and compared with Alq3, which exhibits different spin-polarized hybridization with the Cr(001) surface state than Alq3. We attribute the differences to different character of molecular orbitals in the two different quinolates.

**1:27PM B47.00012 Adsorption of thiophene on Pt, Pd, Au, and Rh(100) surfaces with the role of the van der Waals' interaction**, WALTER MALONE, JERONIMO MATOS, ABDELKADER KARA, University of Central Florida — We explore the adsorption of thiophene (C<sub>4</sub>H<sub>4</sub>S) on Pt(100), Au(100), Pd(100), and Rh(100) surfaces using density functional theory with and without self-consistent van der Waals interactions (vdWs). The six functionals we use are PBE, optB86b-vdW, optB88-vdW, optPBE-vdW, revPBE-vdW, and rPW86-vdW2. We examine a variety of adsorption sites with the molecule's plane both parallel and perpendicular to the surface. In the case of parallel adsorption the highest binding energy occurs when the molecule is centered over a hollow site with the sulfur atom near an atop site. The highest adsorption energy for perpendicular configurations is achieved when the sulfur atom lies over a bridge site and the carbon atoms near hollow sites. We find that for thiophene on the coinage metals the vdW functionals predict higher adsorption energies than those predicted by the PBE functional. On the other hand, for thiophene on the reactive transition metal substrates only optB86b-vdW, optB88-vdW, and optPBE-vdW result in an enhancement in the adsorption energy over the PBE value. We also explore some of the electronic properties of the system including charge transfer and change in the work function. Our results indicate that adsorption characteristics depends heavily on the functional used and geometry.

**1:39PM B47.00013 Manipulating the dipole layer of polar organic molecules on metal surfaces via different charge-transfer channels**, MENG-KAI LIN, Natl Tsing Hua Univ, YASUO NAKAYAMA, Department of Pure and Applied Chemistry, Tokyo University of Science, YING-JIE ZHUANG, CHIN-YUNG WANG, Natl Tsing Hua Univ, TUN-WEN PI, National Synchrotron Radiation Research Center (NSRRC), HISAO ISHII, Graduate School of Advanced Integration Science, Chiba University, S.-J. TANG, Natl Tsing Hua Univ — The key properties of organic films such as energy level alignment (ELA), work functions, and injection barriers are closely linked to this dipole layer. Using angle resolved photoemission spectroscopy (ARPES), we systemically investigate the coverage-dependent work functions and spectra line shapes of occupied molecular orbital states of a polar molecule, chloroaluminum phthalocyanine (CIAIPc), grown on Ag(111) to show that the orientations of the first CIAIPc layer can be manipulated via the molecule deposition rate and post annealing, causing ELA at organic-metal interface to differ for about 0.3 eV between Cl-up and Cl-down configuration. Moreover, by comparing the experimental results with the calculations based on both gas-phase model and realistic model of CIAIPc on Ag(111), we evidence that the different orientations of CIAIPc dipole layers lead to different charge-transfer channels between CIAIPc and Ag, a key factor that controls the ELA at organic-metal interface.

**1:51PM B47.00014 Coulomb blockade and charge ordering in a few layers of TTF-TCNQ investigated by low-temperature STM/STS<sup>1</sup>**, SEOKMIN JEON, PETRO MAKSYMOWYCH, Oak Ridge National Laboratory — In contrast to the vast effort on bulk crystal phases of the prototypical organic charge-transfer complex, TTF-TCNQ, study of low-dimensional phases has been limited to monolayer phases on substrates. In this state, however, none of the physics of the bulk phase is observed owing to the overwhelming effect of the substrate. We investigate the molecular structure and electronic properties of a few layers of TTF-TCNQ grown on Au(111) and Ag(111) using STM/STS at 4.3 K. By decoupling the molecular electronic state from the metal surface, we have made the first observation of the effect of confinement on the electronic properties of TTF-TCNQ. STS reveals a plethora of sharp features due to molecular orbitals, each influenced by charge-transfer between the molecules. We hypothesize the existence of a Mott-insulator state in 3-layer islands, with a Coulomb gap of ~1 eV. In contrast, the corresponding bulk phase is a Peierls insulator with a gap of ~20 meV. The root cause of the nanoscale phase is traced to simultaneous electron confinement and structural frustration, which dramatically modify the energy balance of self-ionization allowing for integer charge transfer. These studies open broad opportunities to explore correlated electron physics in molecular systems.

**2:03PM B47.00015 The evolution of phases and electronic states in potassium doped coronene film<sup>1</sup>**, CHAOQIANG XU, XUDONG XIAO, Department of Physics, The Chinese University of Hong Kong, Shatin, Hong Kong, China — Alkali-metal-doped hydrocarbon materials have been found to exhibit improved superconductivity transition temperature  $T_c$  relative to the traditional organic superconductors. However, theoretical attempts to understand the superconductivity mechanism in this class of materials are still hindered by the limited experimental information available. In our study, we employed scanning tunneling microscopy (STM) and scanning tunneling spectroscopy (STS) to detect both the structures and the electronic properties of the doped hydrocarbon films at molecular scale. By gradually increasing potassium doping level, the evolution of structures and electronic properties in potassium doped coronene film was then investigated. Particularly, a splitting of the lowest unoccupied molecular orbital (LUMO) state was observed when the LUMO was brought to the Fermi level, giving direct evidence of electronic correlation effect in this system. Our results should contribute to a better understanding of the interaction between coronene molecules and potassium atoms and may shed some light to understand the superconductivity properties of this system.

**Session B48 GQI: Quantum Optics with Superconducting Circuits** 349 - Irfan Siddiqi, University of California, Berkeley

**11:15AM B48.00001 Electromagnetically induced transparency in a tunable three-dimensional transmon<sup>1</sup>**, TIEFU LI, QICHUN LIU, Institute of Microelectronics, Tsinghua University, XIAOQING LUO, Beijing Computational Science Research Center, HU ZHAO, Institute of Microelectronics, Tsinghua University, WEI XIONG, ZHEN CHEN, Beijing Computational Science Research Center, YINGSHAN ZHANG, J. S. LIU, WEI CHEN, Institute of Microelectronics, Tsinghua University, FRANCO NORI, Center for Emergent Matter Science (CEMS), RIKEN, J. S. TSAI, Department of Physics, Tokyo University of Science, J. Q. YOU, Beijing Computational Science Research Center — Electromagnetically induced transparency (EIT) has been realized in atomic systems, but fulfilling the EIT conditions for artificial atoms made from superconducting circuits is a more difficult task. Here we report an experimental observation of the EIT in a tunable three-dimensional transmon by probing the cavity transmission. We tune the transmon to adjust its damping rates to fulfill the EIT conditions. From the experimental observations, we clearly identify the EIT and Autler-Townes splitting (ATS) regimes as well as the transition regime in between. Also, the experimental data demonstrate that the threshold  $\Omega_{AIC}$  determined by the Akaike information criterion can describe the EIT-ATS transition better than the threshold  $\Omega_{EIT}$  given by the EIT theory.

**11:27AM B48.00002 Resonance fluorescence from an artificial atom in squeezed vacuum, Part 1: Efficient fluorescence detection<sup>1</sup>**, A. EDDINS, D.M. TOYLI, Quantum Nanoelectronics Laboratory, UC Berkeley, S. PURI, S. BOUTIN, Departement de Physique, Université de Sherbrooke, D. HOVER, V. BOLKHOVSKY, MIT Lincoln Laboratory, W.D. OLIVER, MIT Lincoln Laboratory and Research Laboratory of Electronics, Massachusetts Institute of Technology, A. BLAIS, Departement de Physique, Université de Sherbrooke, I. SIDDIQI, Quantum Nanoelectronics Laboratory, UC Berkeley — The accurate prediction of the fluorescence spectrum of a single atom under coherent excitation, comprising canonical phenomena such as the Mollow triplet, is a fundamental success of quantum optics. Despite considerable efforts, experiments demonstrating a strong modification to the resonance fluorescence spectrum resulting from driving an atomic system with non-classical squeezed light have remained elusive, in part due to challenges in efficient coupling. In this talk, we discuss how we strongly couple microwave-frequency squeezed light to a superconducting artificial atom and detect the resulting fluorescence using a Josephson traveling-wave parametric amplifier (JTWPA). Whereas alternative detection techniques require extensive experimental hardware and long averaging times to resolve fluorescence, the large dynamic range and GHz bandwidth of the JTWPA facilitate direct detection of the Mollow triplet with a spectrum analyzer in minutes, enabling a systematic study with respect to the properties of squeezed vacuum.

<sup>1</sup>This work is funded by the ARO and ONR.

**11:39AM B48.00003 Resonance fluorescence from an artificial atom in squeezed vacuum, Part 2: Squeezing characterization through fluorescence<sup>1</sup>**, D.M. TOYLI, A. EDDINS, Quantum Nanoelectronics Laboratory, UC Berkeley, S. PURI, S. BOUTIN, Departement de Physique, Université de Sherbrooke, D. HOVER, V. BOLKHOVSKY, MIT Lincoln Laboratory, W.D. OLIVER, MIT Lincoln Laboratory and Research Laboratory of Electronics, Massachusetts Institute of Technology, A. BLAIS, Departement de Physique, Université de Sherbrooke, I. SIDDIQI, Quantum Nanoelectronics Laboratory, UC Berkeley — The accurate prediction of the fluorescence spectrum of a single atom under coherent excitation, comprising canonical phenomena such as the Mollow triplet, is a fundamental success of quantum optics. Despite considerable efforts, experiments demonstrating a strong modification to the resonance fluorescence spectrum resulting from driving an atomic system with non-classical squeezed light have remained elusive, in part due to challenges in efficient coupling. In this second of two talks, we discuss observations of the dramatic dependence of the Mollow triplet spectrum on the phase of the squeezed vacuum environment and measurements of subnatural fluorescence linewidths that demonstrate up to 3.5 dB of squeezing below the standard vacuum limit. In addition to realizing two seminal predictions for resonance fluorescence in squeezed vacuum, our work provides simple and robust metrological tools for characterizing squeezed light at microwave frequencies.

**11:51AM B48.00004 Stochastic path integral approach to continuous quadrature measurement of a single fluorescing qubit<sup>1</sup>**, ANDREW N. JORDAN, AREEYA CHANTASRI, University of Rochester, BENJAMIN HUARD, École Normale Supérieure-PSL Research University — I will present a theory of continuous quantum measurement for a superconducting qubit undergoing fluorescent energy relaxation. The fluorescence of the qubit is detected via a phase-preserving heterodyne measurement, giving the cavity mode quadrature signals as two continuous qubit readout results. By using the stochastic path integral approach to the measurement physics, we obtain the most likely fluorescence paths between chosen boundary conditions on the state, and compute approximate correlation functions between all stochastic variables via diagrammatic perturbation theory. Of particular interest are most-likely paths describing increasing energy during the fluorescence. Comparison to Monte Carlo numerical simulation and experiment will be discussed.

**12:03PM B48.00005 Two-mode squeezing in a broadband parametric amplifier** , J. A. GROVER, A. KAMAL, S. GUSTAVSSON, F. YAN, T. P. ORLANDO, W. D. OLIVER, Research Laboratory of Electronics, MIT, D. HOVER, V. BOLKHOVSKY, J. L. YODER, MIT Lincoln Laboratory, C. MACKLIN, K. O'BRIEN, I. SIDDIQI, University of California Berkeley — The Josephson traveling wave parametric amplifier (JTWPA) exhibits gains of greater than 20 dB over a frequency range of a few gigahertz. In addition to being a quantum-limited amplifier over a wide frequency range, the JTWPA is a source of broadband squeezed radiation. We report the observation of broadband squeezing of microwave light generated by a JTWPA by measuring cross correlations between modes separated by up to one gigahertz in frequency. Employing a chain of two JTWPAs, the first as a squeezer and the second as a quantum-limited preamplifier, ensures a high-efficiency measurement of squeezing. We also discuss progress towards employing such two-mode squeezed radiation to realize high-fidelity dispersive readout of superconducting qubits.

This research was funded in part by the U.S. Army Research Office Grant No. W911NF-14-1-0682 and by the Office of the Director of National Intelligence (ODNI), Intelligence Advanced Research Projects Activity (IARPA) and by the Assistant Secretary of Defense for Research & Engineering via MIT Lincoln Laboratory under Air Force Contract No. FA8721-05-C-0002.

**12:15PM B48.00006 Displacement of squeezed propagating microwave states** , KIRILL G. FEDOROV, LING ZHONG, STEFAN POGORZALEK, PETER EDER, MICHAEL FISCHER, JAN GOETZ, FRIEDRICH WULSCHNER, EDWARD XIE, EDWIN MENZEL, FRANK DEPPE, ACHIM MARX, RUDOLF GROSS, Walther-Meißner-Institut; Technische Universität München; Nanosystems Initiative Munich — Displacement of propagating squeezed states is a fundamental operation for quantum communications. It can be applied to fundamental studies of macroscopic quantum coherence and has an important role in quantum teleportation protocols with propagating microwaves. We generate propagating squeezed states using a Josephson parametric amplifier and implement displacement using a cryogenic directional coupler. We study single- and two-mode displacement regimes. For the single-mode displacement we find that the squeezing level of the displaced squeezed state does not depend on the displacement amplitude. Also, we observe that quantum entanglement between two spatially separated channels stays constant across 4 orders of displacement power. We acknowledge support by the German Research Foundation through SFB 631 and FE 1564/1-1, the EU project PROMISCE, and Elite Network of Bavaria through the program ExQM.

**12:27PM B48.00007 Engineering Non-Classical Light with Non-Linear Microwaveguides** , ARNE GRIMSMO, Univ of Sherbrooke, AASHISH CLERK, McGill University, ALEXANDRE BLAIS, Univ of Sherbrooke — The quest for ever increasing fidelity and scalability in measurement of superconducting qubits to be used for fault-tolerant quantum computing has recently led to the development of near quantum-limited broadband phase preserving amplifiers in the microwave regime. These devices are, however, more than just amplifiers: They are sources of high-quality, broadband two-mode squeezed light. We show how bottom-up engineering of Josephson junction embedded waveguides can be used to *design* novel squeezing spectra. Furthermore, the entanglement in the two-mode squeezed output field can be imprinted onto quantum systems coupled to the device's output. These broadband microwave amplifiers constitute a realization of non-linear waveguide QED, a very interesting playground for non-equilibrium many-body physics.

**12:39PM B48.00008 Topological quantum states of light in coupled microwave cavities** , RUICHAO MA, JOHN C. OWEN, AMAN LACHAPPELLE, TAEKWAN YOON, DAVID SCHUSTER, JONATHAN SIMON, University of Chicago — We present a unique photonic platform to explore quantum many-body phenomena in coupled cavity arrays. We create tight binding lattices with arrays of evanescently coupled three-dimensional coaxial microwave cavities. Topologically non-trivial band structures are engineered by utilizing the chiral coupling of the cavity modes to ferrite spheres in a magnetic field. We develop robust, minimal methods to completely characterize the tight-binding Hamiltonian, including all onsite disorder, tunnel coupling, local dissipation and effective flux, using only spectroscopic measurement on specific sites. These efforts pave the way to realize low-disorder, long-coherence, topological tight binding models, where the many-body states can be spectroscopically driven and probed in temporally- and spatially- resolved measurements. Using techniques from circuit QED, effective onsite photon-photon interactions may be introduced by coupling to superconducting qubits. This will allow us to explore the interplay between topology and coherent interaction in these artificial strongly-correlated photonic quantum materials.

**12:51PM B48.00009 Quantum optics with nonlinearly coupled superconducting resonators** , VADIRAJ A.M., C.W.S. CHANG, POL FERNANDEZ-DIAZ, C.M. WILSON, Institute for Quantum Computing, University of Waterloo, Waterloo, Canada — Superconducting circuits provide a robust platform for studying fundamental aspects of light-matter interaction in the circuit QED architecture. Here, we study a novel circuit that couples two superconducting resonators via a nonlinear interaction mediated by a superconducting quantum interference device (SQUID). The interaction hamiltonian has a form analogous to optomechanical systems with the photon number in one resonator coupling to the current in the other. However, the nonlinear coupling constant can be many orders of magnitude larger than in typical optomechanical systems. This can potentially bring the system into a new regime of single-photon coupling between the resonators, enabling novel physics. We will present preliminary results in this direction.

**1:03PM B48.00010 Experimental investigation of a steady-state dynamical phase transition in a Jaynes-Cummings dimer** , JAMES RAFTERY, DARIUS SADRI<sup>1</sup>, Princeton University, STEPHAN MANDT, Columbia University, HAKAN TÜRECİ, ANDREW HOUCK, Princeton University — Experimental progress in circuit-QED has made it possible to study non-equilibrium many-body physics using strongly correlated photons. Such open and driven systems can display new types of dynamical phase transitions [1]. A steady state transition has also been predicted for a Jaynes-Cummings dimer where the photon current between the two cavities acts as an order parameter [2]. Here, we discuss the theory and report measurements of the steady-state behavior of a circuit-QED dimer with in situ tunable inter-cavity coupling and on-site photon-photon interaction. [1] J. Raftery, D. Sadri, S. Schmidt, H. E. Türeci, and A. A. Houck, Phys. Rev. X 4, 031043 (2014). [2] S. Mandt, D. Sadri, A. A. Houck, and H. E. Türeci, New J. Phys. 17 (2015) 053018.

**1:15PM B48.00011 Fock-state stabilization in superconducting circuits using biased Josephson junctions** , JEAN-RENE SOUQUET, AASHISH CLERK, McGill Univ — The ability to prepare and stabilize non-trivial states is a crucial ingredient for quantum information processing. Here, we analyze theoretically a simple scheme for stabilizing Fock states in a superconducting circuit using the nonlinearity inherent in a voltage-biased Josephson junction. Unlike a recent demonstration of Fock state stabilization [1], our protocol does not require any microwave driving. We also discuss how the same system can be used to generate propagating single-photon states with high fidelity, again without the use of microwave drives or pulses.

**1:27PM B48.00012 Steady-state response of coupled non-linear superconducting quantum oscillators** , MATTHEW ELLIOTT, ERAN GINOSSAR, Advanced Technology Institute, University of Surrey — Analytic solutions of non-linear, dissipative quantum systems can provide access to parameter regimes where numerical simulation is unfeasible. In particular, they are useful when these systems are driven at high powers but influenced by quantum fluctuations. We find exact solutions of a Fokker-Planck equation from which we derive the response characteristics of coupled linear and non-linear oscillators under the influence of both coherent and parametric driving. By working in an experimentally feasible parameter regime for superconducting quantum circuits, we model a realistic driven cavity-transmon system and obtain the steady-state frequency response of both cavity and transmon at a range of drive powers, comparing our results with recent experimental data. We show that this method can also be extended to investigate the behaviour of a resonator with a quartic non-linearity which is driven coherently and parametrically, revealing the structure of bifurcations in the steady-state solutions.

**1:39PM B48.00013 Dressed-state engineering for continuous detection of itinerant microwave photons** , KAZUKI KOSHINO, Tokyo Medical and Dental University, ZHIRONG LIN, KUNIHITO INOMATA, RIKEN Center for Emergent Matter Science, TSUYOSHI YAMAMOTO, NEC Smart Energy Research Laboratories, YASUNOBU NAKAMURA, University of Tokyo — Microwave quantum optics using superconducting qubits and transmission lines enables various quantum-optical phenomena that have not been reached in the visible light domain. However, the lack of an efficient detector for itinerant microwave photons has been a long-standing problem. A promising approach is to use the deterministic switching of a  $\Lambda$  system induced by individual photons. Recently, we realized a  $\Lambda$  system by the dressed-state engineering of a qubit-resonator system and achieved a detection efficiency  $\sim 66\%$ . However, this detector should be operated in the time-gated mode, since the drive field to generate the  $\Lambda$ -type transition must be turned off during the qubit readout. Here, we propose a scheme for continuous detection of itinerant microwave photons. In the proposed device, a superconducting qubit is coupled dispersively to two resonators: one is used to form a  $\Lambda$  system that deterministically captures incoming photons and the other is used for continuous monitoring of the event. The proposed device enables continuous operation of the photon detector, preserving the advantages of our previous scheme, such as a high detection efficiency, insensitivity to the signal pulse shape, and short dead times after detection.

**1:51PM B48.00014 Observation of quantum-limited heat conduction over macroscopic distances<sup>1</sup>** , MIKKO MOTTONEN, MATTI PARTANEN, KUAN YEN TAN, JOONAS GOVENIUS, RUSSELL LAKE, MIIKA MAKELA, TUOMO TANTTU, QCD Labs, Department of Applied Physics, Aalto University, Finland — The emerging quantum technological devices, such as the quantum computer, call for extreme performance in thermal engineering at the nanoscale. Importantly, quantum mechanics sets a fundamental upper limit for the flow of information and heat, which is quantified by the quantum of thermal conductance. We present experimental observations of quantum-limited heat conduction over macroscopic distances extending to a meter. We achieved this striking improvement of four orders of magnitude in the distance by utilizing microwave photons travelling in superconducting transmission lines. Thus it seems that quantum-limited heat conduction has no fundamental restriction in its distance. This work lays the foundation for the integration of normal-metal components into superconducting transmission lines, and hence provides an important tool for circuit quantum electrodynamics, the basis of the emerging superconducting quantum computer. In particular, our results may lead to remote cooling of nanoelectronic devices with the help of a far-away in-situ-tunable heat sink.

**11:15AM B50.00001 Self-organization of atoms coupled to a chiral reservoir** , ZACHARY ELDREDGE, Univ of Maryland-College Park, DARRICK CHANG, ICFO, Barcelona, ALEXEY GORSHKOV, Univ of Maryland-College Park — Recently, there has been increasing interest in the properties of confined light in the vicinity of tapered optical nanofibers. Interesting avenues have been suggested concerning cold atoms trapped on the fiber by evanescent light fields. It has been shown that the interaction between atoms coupled to this one-dimensional reservoir leads to equations of motion possessing self-organized stable solutions which exhibit striking many-body dynamics. Finally, it has also been observed that spin-orbit coupling due to the extreme confinement of the light leads to a directionality in the coupling to the fiber. In this paper we explore the implications of a chiral interaction on self-organization and show that the overall configuration exhibits similar behavior to the symmetric case but undergoes dramatic changes in some regions of parameter space. We also present proposals for experimental realizations of our model as well as signatures of chiral behavior.

**11:27AM B50.00002 Novel Infrared Dynamics of Cold Atoms on Hot Graphene** , SANGHITA SENGUPTA, VALERI KOTOV, DENNIS CLOUGHERTY, Univ of Vermont — The low-energy dynamics of cold atoms interacting with macroscopic graphene membranes exhibits severe infrared divergences when treated perturbatively. These infrared problems are even more pronounced at finite temperature due to the (infinitely) many flexural phonons excited in graphene. We have devised a technique to take account (resummation) of such processes in the spirit of the well-known exact solution of the independent boson model. Remarkably, there is also similarity to the infrared problems and their treatment (via the Bloch-Nordsieck scheme) in finite temperature “hot” quantum electrodynamics and chromodynamics due to the long-range, unscreened nature of gauge interactions. The method takes into account correctly the strong damping provided by the many emitted phonons at finite temperature. In our case, the inverse membrane size plays the role of an effective low-energy scale, and, unlike the above mentioned field theories, there remains an unusual, highly nontrivial dependence on that scale due to the 2D nature of the problem. We present detailed results for the sticking (atomic damping rate) rate of cold atomic hydrogen as a function of the membrane temperature and size. We find that the rate is very strongly dependent on both quantities.

**11:39AM B50.00003 Periodically driven system coupled to a fermionic bath: A Keldysh approach** , DONG E. LIU, Microsoft Research Station Q, ALEX LEVCHENKO, Department of Physics, University of Wisconsin-Madison, ROMAN M. LUTCHYN, Microsoft Research Station Q — We develop a Keldysh approach to study a time-periodically driven system with dissipation. We apply this approach to a periodically driven metallic system coupled to a normal metal and a superconducting bath. After integrating out the fermionic bath degrees of freedom and incorporating its effects exactly through self-energy, we find non-equilibrium Green functions for the driven system which take into account effect of the bath. Our formalism allows one to evaluate non-equilibrium distribution function for particles in the periodically-driven system as well as other observable quantities (e.g. tunneling density of states). In the case of a superconducting bath, we study interplay of the proximity-induced superconducting pairing correlations and the dissipation due to light-excited quasiparticles.

**11:51AM B50.00004 Two coupled nonlinear cavities in a driven-dissipative environment** , BIN CAO, KHAN MAHMUD, MOHAMMAD HAFEZI, Joint Quantum Institute, Univ of Maryland-College Park — We investigate two coupled nonlinear cavities that are driven coherently in a dissipative environment. This is the simplest setting containing a good number of features of an array of coupled cavity quantum simulator with Kerr nonlinearity which gives rise to many strongly correlated phases. We find analytical solution for the steady state using the generalized P representation and expressing the master equation in the form of Fokker-Planck equation. A comparison shows a good match of the analytical and numerical solutions across different regimes. We investigate the quantum correlations in the steady state by solving the full master equation numerically, analyzing its second-order coherence, entanglement entropy and Liouvillian gap as a function of drive and detuning. This gives us insights into the nature of bistability and how the tunneling-induced bistability emerges in coupled cavities when going beyond a single cavity. We can understand much of the semiclassical physics in terms of the underlying phase space dynamics of a driven and damped classical pendulum. Furthermore, in the semiclassical analysis, we find steady state solutions with different number density in the two wells that can be considered an analog of double well self-trapped states.

## 12:03PM B50.00005 Non-equilibrium Steady-State Behavior in a Scale-Free Quantum Network

, JIANSHI ZHAO, CRAIG PRICE, QI LIU, NATHAN GEMELKE, The Pennsylvania State University — We describe the nonequilibrium dynamics of a cold atomic gas held in a spatially random optical potential and gravity, subject to a controlled amount of dissipation in the form of an extremely slow dark-state laser cooling process. Reaching local kinetic temperatures below the 100nK scale, such systems provide a novel context for observing the non-equilibrium steady-state (NESS) behavior of a disordered quantum system. For sufficiently deep potentials and strong dissipation, this system can be modeled by a self-organized version of directed percolation, and exhibits power-law decay of phase-space density with time due to the presence of absorbing clusters with a wide distribution of entropy and coupling rates. In the absence of dissipation, such a model cannot apply, and we observe the crossover to exponential loss of phase-space density. We provide measurements of the power-law decay constant by observing the non-equilibrium motion of atoms over a ten-minute period, consistent with  $\gamma = 0.31 \pm 0.04$ , and extract scaling of the absorbed number with dissipation rate, showing another power-law behavior, with exponent  $0.5 \pm 0.2$  over two decades of optical excitation probability.

## 12:15PM B50.00006 Steady States in Fermionic Interacting Dissipative Floquet Systems

, KARTHIK SEETHARAM, CHARLES BARDYN, Caltech, NETANEL LINDNER, Technion, MARK RUDNER, University of Copenhagen, GIL REFAEL, Caltech — The possibility to drive quantum systems periodically in time offers unique ways to deeply modify their fundamental properties, as exemplified by Floquet topological insulators. It also opens the door to a variety of non-equilibrium effects. Resonant driving fields, in particular, lead to excitations which can expose the system to heating. We previously demonstrated that the analog of thermal states can be achieved and controlled in a fermionic Floquet system in the presence of phonon scattering, spontaneous emission, and an energy filtered fermionic bath. However, interactions play an important role in thermalization and present additional sources of heating. We analyze the effects of weak interactions in the presence of dissipation and the role of coherences in determining the steady state of the driven system. Interactions generically create additional excitations and, in contrast to phonons, may sustain inter-Floquet-band coherences at steady state.

## 12:27PM B50.00007 How should we understand non-equilibrium many-body steady states?

, MOHAMMAD MAGHREBI, ALEXEY GORSHKOV, University of Maryland — : Many-body systems with both coherent dynamics and dissipation constitute a rich class of models which are nevertheless much less explored than their dissipationless counterparts. The advent of numerous experimental platforms that simulate such dynamics poses an immediate challenge to systematically understand and classify these models. In particular, nontrivial many-body states emerge as steady states under non-equilibrium dynamics. In this talk, I use a field-theoretic approach based on the Keldysh formalism to study nonequilibrium phases and phase transitions in such models. I show that an effective temperature generically emerges as a result of dissipation, and the universal behavior including the dynamics near the steady state is described by a thermodynamic universality class. In the end, I will also discuss possibilities that go beyond the paradigm of an effective thermodynamic behavior.

## 12:39PM B50.00008 Dissipation induced topological insulators: A recipe

, MOSHE GOLDSTEIN, Tel Aviv University, Israel — It has recently been realized that driven-dissipative dynamics, which usually tends to destroy subtle quantum interference and correlation effects, could actually be used as a resource. By proper engineering of the reservoirs and their couplings, one may drive a system towards a desired quantum-correlated steady state, even in the absence of internal Hamiltonian dynamics. An intriguing class of quantum phases is characterized by topology, including the quantum Hall effect and topological insulators and superconductors. Which of these noninteracting topological states can be achieved as the result of purely dissipative Lindblad-type dynamics? Recent studies have only provided partial answers to this question. In this talk I will present a general recipe for the creation, classification, and detection of states of the integer quantum Hall and 2D topological insulator type as the outcomes of coupling a system to reservoirs, and show how the recipe can be realized with ultracold atoms and other quantum simulators. The mixed states so created can be made arbitrarily close to pure states, and the construction may be generalized to other topological phases.

## 12:51PM B50.00009 Engineering non-Hermitian optical potentials for Polariton Condensation

, SAEED KHAN, Department of Electrical Engineering, Princeton University, LI GE, Department of Engineering Science and Physics, College of Staten Island, CUNY, HAKAN TURECI, Department of Electrical Engineering, Princeton University — We present a theoretical study of incoherently pumped exciton-polariton condensates in general cavity geometries, based on an analysis of the linear non-Hermitian modes of the (optical) pump induced potential. An analytical description is obtained for how the threshold pump power for condensation into a specific mode depends quantitatively on the relative spatial profiles of that mode and the pump. Specifically, we show that for a general pump profile, modes which best organize to balance the amplification from the pump against the repulsive pump potential achieve the lowest threshold power [1]. Reversing this idea, choosing the spatial profile of the pump provides control over which spatial mode condenses at lowest power. Our work hence provides a scheme to engineer non-Hermitian optical potentials for preferential polariton condensation into a specific mode, by an appropriate choice of pump profile. This approach has recently been used to achieve condensation in the flat band of a Lieb chain of micropillar cavities, where the flat band has energy above the ground state and hence cannot be studied in systems in thermal equilibrium [2].

## 1:03PM B50.00010 Collective phases of strongly interacting cavity photons

, RYAN WILSON, United States Naval Academy, Annapolis, MD 21402, MICHAEL FOSS-FEIG, KHAN MAHMUD, MOHAMMAD HAFEZI, Joint Quantum Institute & Joint Center for Quantum Information and Computer Science, University of Maryland, College Park, MD 20742 — We study the steady state phases of the Bose-Hubbard model in the presence of dissipation and coherent driving, which in the limit of strong interactions maps onto a driven-dissipative XX spin- $\frac{1}{2}$  model with transverse and longitudinal fields. Using a site-decoupled mean-field approximation, we identify phases with antiferromagnetic and spin density wave order, in addition to limit cycle phases, where oscillatory dynamics persist indefinitely. We also identify collective bistable phases, where the system supports two steady states among spatially uniform, antiferromagnetic, and limit cycle phases. We compare these mean-field results to exact quantum trajectories for one dimensional cavity arrays. The quantum results exhibit short-range antiferromagnetic and spin density wave order, in good qualitative agreement with the mean-field predictions. In the bistable regime, this system exhibits real-time collective switching between macroscopically distinguishable states. We present a clear physical picture for these dynamics, and establish a simple relationship between the switching times and properties of the quantum Liouvillian.

## 1:15PM B50.00011 Driven-dissipative bosons in open boundary and inhomogeneous cavity arrays

, KHAN W. MAHMUD, University of Maryland, RYAN M. WILSON, United States Naval Academy, MICHAEL FOSS-FEIG, MOHAMMAD HAFEZI, University of Maryland — We study the driven-dissipative Bose-Hubbard model, which describes the physics of coherently pumped photonic cavity arrays as well as strongly interacting ultracold bosons in an optical lattice in a driven dissipative setting. We investigate many-body states and their quantum correlations on finite size lattices with open boundary conditions, a set up which is experimentally relevant. We show that the effects of hard boundaries on the steady-states are nontrivial, and explain the results in terms of finite system size excitations and the underlying phases of a thermodynamically large system. Furthermore, we explore the effects of trap inhomogeneity, such as an external harmonic trap, quantifying the breakdown of local density approximation for finite system size. We use a mixed state version of matrix product states algorithm for the numerical investigation.

**1:27PM B50.00012 Flying over decades**, JUDITH HOELLER, MENA ISSLER<sup>1</sup>, Graduate Student, ATAC IMAMOGLU, Professor — Levy flights have been extensively used in the past three decades to describe non-Brownian motion of particles. In this presentation I give an overview on how Levy flights have been used across several disciplines, ranging from biology to finance to physics. In our publication we describe how a single electron spin 'flies' when captured in quantum dot using the central spin model. At last I motivate the use of Levy flights for the description of anomalous diffusion in modern experiments, concretely to describe the lifetimes of quasi-particles in Josephson junctions.

<sup>1</sup>Finished PhD at ETH in Spring 2015

**1:39PM B50.00013 Multiple timescale analysis of dynamical evolution near two coalescing eigenvalues in open quantum systems**, SAVANNAH GARMON, Osaka Prefecture University, GONZALO ORDONEZ, Butler University — Recently the physics of coalescing eigenvalues at an exceptional point (EP) has been studied in a wide range of physical contexts, including open quantum systems. At an EP  $N$  at which  $N$  eigenvalues coalesce the Hamiltonian can no longer be diagonalized but instead only reduced to a Jordan block of dimension  $N$ . In order to describe the survival probability  $P(t)$  for an initially prepared state in the vicinity of two coalescing levels, we further subdivide the EP2 case into the EP2A and EP2B [1], where the EP2A involves the coalesce of two virtual bound states to form a resonance/anti-resonance pair and the EP2B occurs when two resonances collide to form two new resonances. We show that in the vicinity of the EP2B the usual exponential decay appearing for resonances on intermediate timescales is modified as  $P(t) \sim te^{-\Gamma t}$ . However, the long-time evolution near the EP2B follows a  $1/t^3$  power law decay. Meanwhile the evolution for the EP2A is non-exponential on all timescales, and may be strongly influenced by continuum threshold effects [2]. [1] S. Garmon, M. Gianfreda, and N. Hatano, Phys. Rev. A 92, 022125 (2015). [2] S. Garmon, T. Petrosky, L. Simine and D. Segal, Fortschr. Phys. 61, 261 (2013). [3] N. Hatano and G. Ordóñez, J. Math. Phys. 55, 122106 (2014).

**1:51PM B50.00014 Quantum Spontaneous Stochasticity**, THEODORE DRIVAS, GREGORY EYINK, The Johns Hopkins University — Classical Newtonian dynamics is expected to be deterministic, but recent fluid turbulence theory predicts that a particle advected at high Reynolds-numbers by "nearly rough" flows moves nondeterministically. Small stochastic perturbations to the flow velocity or to the initial data lead to persistent randomness, even in the limit where the perturbations vanish! Such "spontaneous stochasticity" has profound consequences for astrophysics, geophysics, and our daily lives. We show that a similar effect occurs with a quantum particle in a "nearly rough" force, for the semi-classical (large-mass) limit, where spreading of the wave-packet is usually expected to be negligible and dynamics to be deterministic Newtonian. Instead, there are non-zero probabilities to observe multiple, non-unique solutions of the classical equations. Although the quantum wave-function remains split, rapid phase oscillations prevent any coherent superposition of the branches. Classical spontaneous stochasticity has not yet been seen in controlled laboratory experiments of fluid turbulence, but the corresponding quantum effects may be observable by current techniques. We suggest possible experiments with neutral atomic-molecular systems in repulsive electric dipole potentials.

**2:03PM B50.00015 Current-carrying quasi-steady states in a periodically driven many-body system**, MARK RUDNER, Niels Bohr Institute, Copenhagen University, NETANEL LINDNER, Technion, EREZ BERG, Weizmann Institute — We investigate many-body dynamics in a one-dimensional interacting periodically driven system, based on a partially-filled version of Thouless topologically quantized adiabatic pump. The corresponding single particle Floquet bands are chiral, with the Floquet spectrum realizing nontrivial cycles around the quasienergy Brillouin zone. For non-integer filling the system is gapless; here the driving cannot be adiabatic and the system is expected to rapidly absorb energy from the driving field. We identify parameter regimes where scattering between Floquet bands of opposite chirality is exponentially suppressed, opening a long time window where the many-body evolution separately conserves the occupations of the two chiral bands. Within this intermediate time regime we predict that the system reaches a quasi-steady state with uniform crystal momentum occupation within each Floquet band. This state furthermore carries a non-vanishing current given directly by the difference of densities in the right and left moving chiral bands. This remarkable behavior, which holds for both bosons and fermions, may be readily studied experimentally in recently developed cold atom systems.

Session B51 FIAP: Materials: Synthesis, Growth, and Processing Hilton Baltimore Holiday Ballroom 2 - Seunghun Lee, University of Maryland

**11:15AM B51.00001 The impact of neutral impurity concentration on charge drift mobility<sup>1</sup>**, HAO MEI, GUOJIAN WANG, DONGMING MEI, GANG YANG, YUTONG GUAN, Univ of South Dakota — High-purity germanium crystals are being grown using the Czochralski technique at the University of South Dakota. The carrier concentration, mobility and resistivity are measured by Hall Effect system. Many factors contribute to the overall mobility. We investigated the impact of neutral impurity concentration on charge drift mobility. Several samples with measured mobility larger than 35000 cm<sup>2</sup>/Vs from the grown crystals were used for this investigation. With the measured mobility and the ionized impurity concentration, we were able to calculate the neutral impurity concentration by the Matthiessen's rule. The correlations between the neutral impurity concentrations with the radius of the crystals were studied. We report that the concentration of neutral impurity constrains charge draft mobility for high-purity germanium crystals and the non-uniform distribution of neutral impurity could result in an anisotropy of draft time distribution in a given germanium detector.

<sup>1</sup>This work is supported by DOE grant DE-FG02-10ER46709 and the state of South Dakota.

**11:27AM B51.00002 Influences of solid/liquid boundary layer thickness and tilting angle on zone-refinement of germanium crystals**, GANG YANG, YUTONG GUAN, HAO MEI, GUOJIAN WANG, DONGMING MEI, University of South Dakota — In zone-refining of metals, solid/liquid (S/L) boundary layer thickness has an influence on segregation coefficient of impurity atoms. Additionally, the segregation of impurity elements during zone refining can be maximized by adjusting the zone refinement tube with a proper angle. In this paper, we report the influences of S/L boundary layer thickness on the segregation coefficients of boron, phosphor, aluminum and gallium, which have been identified as four main impurities in germanium crystal by Photothermal Ionization Spectroscopy (PTIS). The thickness of S/L boundary layer was found by using a well-known model to fit the experimental data. The optimized segregation coefficients have been used to calculate the impurity distribution along the purified ingot. In addition, we have also optimized the tilting angle of the germanium ingot to investigate the impact on the segregation. This work is supported by DOE grant DE-FG02-10ER46709 and the state of South Dakota.

**11:39AM B51.00003 The Electronic Properties of Nanoscale Meta-lattice Made by High Pressure CVD**, ZHAOHUI HUANG, VINCENT CRESPI, Pennsylvania State University — Meta-lattice can be defined as an artificial 3D superlattice with periodic structural modulation occurred at 10nm scale. One viable route to synthesize can be as follows: A template is first prepared by close-packed nanometer-sized silica spheres, then Si/Ge or a binary semiconductor is infiltrated into voids by high pressure chemical vapor deposition (CVD). Later silica spheres can be removed by chemical method, and voids in the inverse meta-lattice offer the opportunity for a second infiltration. Due to the characteristic length of voids, meta-lattice provides a platform to test novel mesoscopic electronic and thermal phenomena. A meta-lattice solid can show novel physical properties that each constituent infiltrate material does not have. Since a significant portion of atoms are located on the surface, the interface structure details are expected to play a critical role. Here we investigate Si/Ge inverse meta-lattices with or without silica template present. Tight-binding, DFT and GW/BSE techniques are employed to look into the electronic and optical properties.

**11:51AM B51.00004 Aluminum Nitride Grown by Atomic Layer Epitaxy Characterized with Real-Time Grazing Incidence Small Angle X-ray Scattering**, VIRGINIA ANDERSON, NEERAJ NEPAL, SCOOTER JOHNSON, US Naval Research Laboratory, ZACHARY ROBINSON, The College at Brockport, State University of New York, ALEXANDER DEMASI, Boston University, JENNIFER HITE, US Naval Research Laboratory, KARL LUDWIG, Boston University, CHARLES EDDY, US Naval Research Laboratory — Aluminum nitride, gallium nitride, and indium nitride are being considered for many applications, and are currently being used commercially for LEDs. These III-nitride films are conventionally deposited by metalorganic chemical vapor deposition and molecular beam epitaxy. Research into depositing III-nitrides with atomic layer epitaxy (ALE) is underway as it is a fabrication friendly technique for thin films at lower temperatures. AlN deposited with ALE at 500°C have been shown to have good crystallinity, but relatively high carbon and oxygen impurities, and understanding the film deposition mechanism is an ongoing project.<sup>1</sup> Grazing incidence small angle x-ray scattering (GISAXS) is sensitive to surface features, making it useful for real time monitoring of deposition processes. AlN was monitored by GISAXS while being deposited with ALE using trimethylaluminum and hydrogen/nitrogen plasma at the Brookhaven National Synchrotron Light Source and the Cornell High Energy Synchrotron Source. The GISAXS of AlN ALE at nominally 400°C, 450°C, and 500°C was compared to ex situ characterization with XPS and AFM.

<sup>1</sup>N. Nepal et al., *Appl. Phys. Lett.* **103** 082110 (2013)

**12:03PM B51.00005 Parallel Stitching of Two-Dimensional Materials**, XI LING, YUXUAN LIN, MILDRED DRESSSELHAUS, TOMS PALACIOS, JING KONG, Department of Electrical Engineering and Computer Science, Massachusetts Institute of Technology, DEPARTMENT OF ELECTRICAL ENGINEERING AND COMPUTER SCIENCE, MASSACHUSETTS INSTITUTE OF TECHNOLOGY TEAM — Large scale integration of atomically thin metals (e.g. graphene), semiconductors (e.g. transition metal dichalcogenides (TMDs)), and insulators (e.g. hexagonal boron nitride) is critical for constructing the building blocks for future nanoelectronics and nanophotonics. However, the construction of in-plane heterostructures, especially between two atomic layers with large lattice mismatch, could be extremely difficult due to the strict requirement of spatial precision and the lack of a selective etching method. Here, we developed a general synthesis methodology to achieve both vertical and in-plane “parallel stitched” heterostructures between a two-dimensional (2D) and TMD materials, which enables both multifunctional electronic/optoelectronic devices and their large scale integration. This is achieved via selective “sowing” of aromatic molecule seeds during the chemical vapor deposition growth. MoS<sub>2</sub> is used as a model system to form heterostructures with diverse other 2D materials. Direct and controllable synthesis of large-scale parallel stitched graphene-MoS<sub>2</sub> heterostructures was further investigated. Unique nanometer overlapped junctions were obtained at the parallel stitched interface, which are highly desirable both as metal-semiconductor contact and functional devices/systems, such as for use in logical integrated circuits (ICs) and broadband photodetectors.

**12:15PM B51.00006 Solution-Processed hybrid Sb<sub>2</sub>S<sub>3</sub> planar heterojunction solar cell**, WENXIAO HUANG, ISMAIL BORAZAN, DAVID CARROLL, Wake Forest Univ — Thin-film solar cells based on inorganic absorbers permit a high efficiency and stability. Among or those absorber candidates, recently Sb<sub>2</sub>S<sub>3</sub> has attracted extensive attention because of its suitable band gap (1.5eV ~1.7 eV), strong optical absorption, low-cost and earth-abundant constituents. Currently high-efficiency Sb<sub>2</sub>S<sub>3</sub> solar cells have absorber layer deposited on nanostructured TiO<sub>2</sub> electrodes in combination with organic hole transport material (HTM) on top. However it's challenging to fill the nanostructured TiO<sub>2</sub> layer with Sb<sub>2</sub>S<sub>3</sub> and subsequently by HTM, this leads to uncovered surface permits charge recombination. And the existing of Sb<sub>2</sub>S<sub>3</sub>/TiO<sub>2</sub>/HTM triple interface will enhance the recombination due to the surface trap state. Therefore, a planar junction cell would not only have simpler structure with less steps to fabricate but also ideally also have a higher open circuit voltage because of less interface carrier recombination. By far there is limited research focusing on planar Sb<sub>2</sub>S<sub>3</sub> solar cell, so the feasibility is still unclear. Here, we developed a low-toxic solution method to fabricate Sb<sub>2</sub>S<sub>3</sub> thin film solar cell, then we studied the morphology of the Sb<sub>2</sub>S<sub>3</sub> layer and its impact to the device performance. The best device with a structure of FTO/TiO<sub>2</sub>/Sb<sub>2</sub>S<sub>3</sub>/P3HT/Ag has PCE over 5% which is similar or higher than yet the best nanostructure devices with the same HTM. Furthermore, based on solution engineering and surface modification, we improved the Sb<sub>2</sub>S<sub>3</sub> film quality and achieved a record PCE. .

**12:27PM B51.00007 Visible Aligned Carbon Nanotube-MoS<sub>2</sub> Hybrids**, RUI WANG, Department of Physics & Astronomy, Vanderbilt University, Nashville, TN 37235, USA, TU HONG, TIANJIAO WANG, Department of Electrical Engineering & Computer Science, Vanderbilt University, Nashville, TN 37235, USA, AHMAD IFFAT ALI, Department of Chemical & Biomolecular Engineering, Vanderbilt University, Nashville, TN 37235, USA, DEVPAUL SINGH CHANI, Pope John Paul II High School, Hendersonville, TN 37075, USA, YAQIONG XU<sup>1</sup>, Department of Physics & Astronomy, Vanderbilt University, Nashville, TN 37235, USA — Single-walled carbon nanotubes (SWNTs) have gained great interest due to their excellent electrical, mechanical and thermal properties. Recent progress in two-dimensional (2D) materials has opened up new horizons in the realm of physics and engineering that could lead to the revolution of future electronics and optoelectronics. Various hybrid structures have been developed for different applications. Here we report a facile method to synthesize ultrathin 2D hybrids between horizontally-aligned SWNT and monolayer molybdenum sulfide (MoS<sub>2</sub>) through chemical vapor deposition (CVD). These hybrid structures can be imaged under an optical microscope; and their Raman mapping indicates that MoS<sub>2</sub> flakes are partially grown on top of SWNTs. Moreover, strong photocurrent signals have been observed in SWNT-MoS<sub>2</sub> hybrids through scanning photocurrent measurements. These fundamental studies may provide a new way to fabricate 2D hybrids for future electronics and optoelectronics.

<sup>1</sup>Department of Electrical Engineering & Computer Science, Vanderbilt University, Nashville, TN 37235, USA

**12:39PM B51.00008 Synthesis and electrical characterization of Rhenium Diselenide**, BYEONGGIL KANG, YOUNGCHAN KIM, SKKU Advanced Institute of Nanotechnology(SAINT), Sungkyunkwan University, Suwon, 440-746, Korea, CHANGGU LEE, Department of Mechanical Engineering and SKKU Advanced Institute of Nanotechnology(SAINT), Sungkyunkwan University, Suwon, 440-746, Korea, GRAPHENE ENGINEERING LAB. TEAM — Rhenium diselenide (ReSe<sub>2</sub>) as the one of new members of 2-dimensional transition metal dichalcogenide (TMDC) material possesses a high potential for optoelectronic applications. In this work, we report a synthesis method thin single crystalline ReSe<sub>2</sub> via chemical vapor deposition (CVD) and the electrical characterization. The structure of the synthesized ReSe<sub>2</sub>, which has triclinic symmetry, is characterized by transmission electron microscope (TEM). Also, the synthesized ReSe<sub>2</sub> show Raman spectrum characteristics with peaks having same position regardless of the sample thickness due to the low symmetry. We fabricate bottom-gated field effect transistors (FET) with ambipolar behavior and on/off ratio 10<sup>5</sup> and carrier mobility of 0.21cm<sup>2</sup>/Vs (hole) and 0.20cm<sup>2</sup>/Vs (electron).

**12:51PM B51.00009 Growth and Characterization of TMDs (MoS<sub>2</sub>, MoSe<sub>2</sub>, WS<sub>2</sub>, WSe<sub>2</sub> & MoTe<sub>2</sub>) and Their Alloys on Various Substrates**, DAVID BARROSO, ARIANA NGUYEN, SAHAR NAGHIBI, MICHAEL GOMEZ, INGRID LIAO, CHUN-YU HUANG, I-HSI LU, EDWIN PRECIADO, THOMAS EMPANTE, WILLIAM COLEY, DOMINIC MARTINEZ, AIMEE MARTINEZ, Univ of California - Riverside — Transition Metal Dichalcogenides (TMDs) have been of interest over the past years due to their exciting semiconducting properties. In the bulk, TMDs possess a native indirect bandgap and transition to a direct bandgap as they approach the monolayer limit. The bandgaps range from 1.15 eV to 1.95 eV depending on composition. Using organic liquids and/or inorganic powders as precursors, CVD growth has been realized for MX<sub>2</sub> TMDs (M = Mo, W; X = S, Se) and their alloys at tunable compositions. I will present the effect of tuning parameters such as temperature, gas flow, time of heat and hold on the resultant single-layer films. Different precursors can lead to different overall film structures and enable different growth conditions. The films can either be made homogeneous in bandgap or gradients of material/bandgap can be grown. The use of different substrates (dielectric, ferroelectric, piezoelectric, semiconducting, insulating, patterned) allows an additional degree of freedom and sets the stage for subsequent experiments. I will talk about preparation methods tailored toward direct applicability of surface acoustic spectroscopy, scanning photocurrent microscopy, and ferroelectric gating of the single-layer films.

**1:03PM B51.00010 Interfacial reaction between metal-insulator transition material NbO<sub>2</sub> thin film and wide band gap semiconductor GaN**, AGHAM POSADAS, University of Texas at Austin, ALEXANDER KVIT, University of Wisconsin - Madison, ALEXANDER DEMKOV, University of Texas at Austin — Materials that undergo a metal-insulator transition (MIT) are potentially useful for a wide variety of applications including electronic and opto-electronic switches, memristors, sensors, and coatings. In most such materials, the MIT is driven by temperature. In one such material, NbO<sub>2</sub>, the MIT mechanism is primarily of the Peierls-type, in which the dimerization of the Nb atoms without electron correlation causes the transition from metallic to semiconducting. We describe our initial work at combining NbO<sub>2</sub> and GaN in epitaxial form, which could be potentially useful in resistive switching devices operating at very high temperatures. We grow NbO<sub>2</sub> films on GaN(0001)/Si(111) substrates using reactive molecular beam epitaxy from a metal evaporation source and molecular oxygen. X-ray diffraction shows that the films are found to grow with a single out of plane orientation but with three symmetry-related orientation domains in the plane. In situ x-ray photoelectron spectroscopy confirms that the phase pure NbO<sub>2</sub> is formed but that a chemical reaction occurs between the GaN and NbO<sub>2</sub> during the growth forming a polycrystalline interfacial layer. We perform STEM-EELS analysis of the film and the interface to further elucidate their chemical and structural properties.

**1:15PM B51.00011 Impact of Crystalline Structure on the Temperature Dependence of Resistivity<sup>1</sup>**, YUTONG GUAN, GANG YANG, DONGMING MEI, The University of South Dakota — Since HPGe radiation detectors work under cryogenic temperature, the electrical properties at low temperature are essential for the detector performance. In this study, the resistivity of two types of HPGe, i.e. single crystal from Czochralski growth and poly-crystal from zone refining, was investigated in the temperature range from 4.2 to 100K. It was found that there was a turning point on the resistivity vs temperature curves for both types of crystals. However, the turning points for them were significantly different: 30K for single crystalline while 60K for polycrystalline. In order to explore the reason, microstructures of both types of crystals were investigated by optical microscopy. The results showed a very good agreement between electrical properties and microstructures.

<sup>1</sup>This work is supported by DOE grant DE-FG02-10ER46709 and the state of South Dakota.

**1:27PM B51.00012 Atomistic simulations of activated processes in nanoparticles synthesis<sup>1</sup>**, FEDERICO GIBERTI, GIULIA GALLI, Institute for Molecular Engineering, The University of Chicago — Core-shell and Janus nanoparticles are promising building blocks for new, highly efficient solar cells. One of the most common synthetic pathways to produce such nanostructures is the use of cation exchange reactions. Although widely used, these procedures are not completely understood. We employed classical Molecular Dynamics and Monte Carlo simulations to understand these transformation at the molecular level; in particular we investigated the conversion from CdSe (sphalerite) to PbSe (rocksalt) NPs with 2-3 nm diameter. In order to recover the equilibrium free energy surfaces we used state of the art enhanced sampling techniques, including Metadynamics. The formation of hybrid core-shell structures resulted to be an activated process, where the limiting step is the transition of a sphalerite to a rocksalt PbSe nucleus. We found that the barrier height and the stability of the two phases depend on the size of the PbSe nucleus, suggesting that the process could proceed via a two step mechanism, where a small sphalerite nucleus is formed first, and it then transforms to a rocksalt nucleus. Our results give insight into possible manipulation processes at the molecular scale, which could be used to stabilize metastable NPs and tune their physical and chemical properties.

**1:39PM B51.00013 3D Functional Elements Deep Inside Silicon with Nonlinear Laser Lithography**, ONUR TOKEL, AHMET TURNALI, Bilkent University, EMRE ERGECEN, Massachusetts Institute of Technology, IHOR PAVLOV, FATIH OMER ILDAY, Bilkent University — Functional optical and electrical elements fabricated on silicon (Si) constitute fundamental building blocks of electronics and Si-photonics. However, since the highly successful established lithography are geared towards surface processing, elements embedded inside Si simply do not exist. Here, we present a novel direct-laser writing method for positioning buried functional elements inside Si wafers. This new phenomenon is distinct from previous work, in that the surface of Si is not modified. By exploiting nonlinear interactions of a focused laser, permanent refractive index changes are induced inside Si. The imprinted index contrast is then used to demonstrate a plethora of functional elements and capabilities embedded inside Si[1]. In particular, we demonstrate the first functional optical element inside Si, the first information-storage capability inside Si, creation of high-resolution subsurface holograms, buried multilevel structures, and complex 3D architectures in Si, none of which is currently possible with other methods. This new approach complements available techniques by taking advantage of the real estate under Si, and therefore can pave the way for creating entirely new multilevel devices through electronic-photonics integration. [1]Tokel, O., arxiv.org/abs/1409.28

**1:51PM B51.00014 Circular photogalvanic effect in silicon nanowires**, SAJAL DHARA, E. J. MELE, RITESH AGARWAL, University of Pennsylvania — Circular photogalvanic effect (CPGE), the generation of a photocurrent whose magnitude and polarity depends on chirality of optical excitation, is demonstrated in the visible optical range in silicon nanowires, a bulk non-gyrotropic material with weak spin-orbit coupling. CPGE, which is absent in bulk Si is found to arise from interband transitions only at the metal-semiconductor contacts to Si nanowires where inversion symmetry is broken by a Schottky electric field. Furthermore, by applying a bias voltage that modulates this field, the sign and magnitude of the CPGE can be controlled. From excitation energy dependent measurements and symmetry considerations, it is argued that the [110] surface states due to Si chains that are not aligned with the nanowire growth direction and the Schottky field produce an artificial gyrotropic optical medium that supports CPGE. This work reveals the role of the surface states in the generation of chirality-dependent photocurrents in silicon with a purely orbital-based mechanism, and also opens up new possibilities of engineering new functionalities in Si that can be integrated with conventional electronics.

**2:03PM B51.00015 Fabrication of self-forming silver network as transparent conductive electrode with photoresist**, CHAOBIN YANG, JUAN M MERLO, MICHAEL J BURNS, KRZYSZTOF KEMPA, MICHAEL J NAUGHTON, Boston College — It has been reported that a metal wire network, obtained by sputtering with a self-cracking gel film mask, can function as a TCO replacement, perhaps reducing end device cost [1]. Toward further process simplification and cost reduction, we are investigating various electroless deposition schemes to template a wire network electrode. We report here that a conventional photoresist film can be prepared with a network of microcracks and can be used as a mask to electrolessly deposit metal, e.g. silver. With this method, no vacuum chambers are required, and undeposited metal can even be recycled for additional depositions. [1] B. Han, K. Pei, Y. Huang, X. Zhang, Q. Rong, Q. Lin, Y. Guo, T. Sun, C. Guo, D. Carnahan, M. Giersig, Y. Wang, J. Gao, Z. Ren, and K. Kempa, *Adv. Mater.* 26, 873 (2014).

**Session B52 DAMOP: Optomechanics and Hybrid Systems I: Novel Systems** Hilton Baltimore Holiday Ballroom 3 - Tom Purdy, NIST

**11:15AM B52.00001 Exploring the Macroscopic Quantum Physics of Motion with Superfluid He-4**, LAURA DE LORENZO, AARON PEARLMAN, KEITH SCHWAB, Caltech — We demonstrate the use of superfluid helium-4 as an extremely low loss optomechanical element. We form an optomechanical system with a cylindrical niobium superconducting TE<sub>011</sub> resonator whose 40 cm<sup>3</sup> inner cylindrical cavity is filled with <sup>4</sup>He. Coupling is realized via the variations in permittivity resulting from the density profile of the acoustic modes. Acoustic losses in helium-4 below 500 mK are governed by the intrinsic nonlinearity of sound, leading to an attenuation which drops as T<sup>4</sup>, indicating the possibility of quality factors (Q) over 10<sup>10</sup> at 10 mK. In our lowest loss mode, we demonstrate this T<sup>4</sup> law at temperatures down to 50 mK, realizing an acoustic Q of 1.35\*10<sup>8</sup> at 8.1 kHz. When coupled with a low phase noise microwave source, we expect this system to be utilized as a probe of macroscopic quantized motion, for precision measurements to search for fundamental physical length scales, and as a continuous gravitational wave detector. Our estimates suggest that a resonant superfluid acoustic system could exceed the sensitivity of current broad-band detectors for narrow-band sources such as pulsars. De Lorenzo, L. A. and Schwab, K. C., *New J. Phys.* 16, 113020 (2014).

**11:27AM B52.00002 Mechanical Resonance and Damping Properties of Gallium Nitride Nanowires in Selected-Area Growth Arrays Measured via Optical Bragg Scattering<sup>1</sup>**, JOHN HOULTON, Univ of Colorado - Boulder, M. D. BRUBAKER, K. A. BERTNESS, NIST Boulder, C. T. ROGERS, Univ of Colorado - Boulder — We report the use of optical Bragg scattering to measure the mechanical resonance frequencies and quality factors (Q) of gallium nitride (GaN) nanowires (NWs) in selected-area growth arrays. The GaN NWs are grown by catalyst-free molecular beam epitaxy on silicon (111) wafers. Hexagonal arrays of approximately 100 GaN NWs with pitch spacings of 400 - 1000 nm have been prepared. The NWs contained in such arrays have diameters ranging from 100-300 nm and lengths from 3 - 10 μm. A diode laser operating at 640 nm and 2 mW of optical power is used to perform Bragg scattering homodyne detection to passively read out the thermally induced Brownian mechanical motion of the NWs. The first order cantilever-mode mechanical resonance frequencies of these NWs have been measured to be between 2 - 12 MHz. We find that the optical readout via Bragg scattered light allows the simultaneous detection of all lowest order mechanical resonances in a given array. Q factors ranging from 1,000 - 12,000 have been seen at room temperature and 10<sup>-5</sup> Torr pressures. Qs as high as 25,000 have been seen at temperatures of 80 K. These results show that the narrow mechanical resonances observed in freely-grown GaN NWs can also be seen in NWs prepared via selected-area growth.

<sup>1</sup>We gratefully acknowledge funding via NIST MSE Grant # 1553451

**11:39AM B52.00003 Ultra-thin superconducting film coated silicon nitride nanowire resonators for low-temperature applications**, ABHILASH SEBASTIAN, NIKOLAY ZHELEV, ROBERTO DE ALBA, JEEVAK PARPIA, Cornell University — We demonstrate fabrication of high stress silicon nitride nanowire resonators with a thickness and width of less than 50 nm intended to be used as probes for the study of superfluid <sup>3</sup>He. The resonators are fabricated as doubly-clamped wires/beams using a combination of electron-beam lithography and wet/dry etching techniques. We demonstrate the ability to suspend (over a trench of depth ~8 μm) wires with a cross section as small as 30 nm, covered with a 20 nm superconducting film, and having lengths up to 50 μm. Room temperature resonance measurements were carried out by driving the devices using a piezo stage and detecting the motion using an optical interferometer. The results show that metalizing nano-mechanical resonators not only affects their resonant frequencies but significantly reduce their quality factor (Q). The devices are parametrically pumped by modulating the system at twice its fundamental resonant frequency, which results in observed amplification of the signal. The wires show self-oscillation with increasing modulation strength. The fabricated nanowire resonators are intended to be immersed in the superfluid <sup>3</sup>He. By tracking the resonant frequency and the Q of the various modes of the wire versus temperature, we aim to probe the superfluid gap structure.

**11:51AM B52.00004 Optomechanics with superfluid He4 thin films**, CHRISTOPHER BAKER, GLEN HARRIS, DAVID MCAUSLAN, YAUHEN SACHKOU, XIN HE, EOIN SHERIDAN, WARWICK BOWEN, Univ of Queensland — Cavity optomechanics focuses on the interaction between confined light and a mechanical degree of freedom. Vibrational modes of superfluid helium-4 have recently been identified as an attractive mechanical element for cavity optomechanics, thanks to their ultra-low dissipation arising from superfluids viscosity free flow. Here we propose and demonstrate an approach to superfluid optomechanics based on femtogram thin films of superfluid helium condensed on the surface of a microscale microtoroid optical whispering gallery mode resonator. Excitations within the film, known as third sound, manifest as surface waves with a restoring force provided by the van der Waals interaction. We experimentally probe the thermodynamics of these superfluid excitations in real-time, and demonstrate both laser cooling and amplification of the thermal motion. In addition, we propose and demonstrate an entirely new approach to optical forcing based on the atomic recoil of superfluid helium-4. This technique utilizes the thermomechanical effect of superfluids, whereby frictionless fluid flow is generated in response to a local heat source. Using this technique, we achieve superfluid forces on a microtoroid mechanical mode an order of magnitude greater than the equivalent radiation pressure force.

**12:03PM B52.00005 Strong coupling and parametric amplification in mechanical modes of graphene**, JOHN MATHEW, Tata Institute of Fundamental Research, Mumbai, India, RAJ PATEL, Tata Institute of Fundamental Research, Mumbai, India, Birla Institute of Technology & Science, Pilani - K.K.Birla Goa Campus, India, ABHINANDAN BORAH, RAJAMANI VIJAYARAGHAVAN, MANDAR DESHMUKH, Tata Institute of Fundamental Research, Mumbai, India — We demonstrate strong dynamical coupling and parametric amplification in mechanical modes of a graphene drum using an all electrical configuration. Low tension in the system allows large electrostatic tunability of the modes thus enabling dynamic pumping experiments. In the strong coupling regime a red detuned pump gives rise to new eigenmodes having highly tunable mode splitting (cooperativity ~60) with coherent energy transfer. The coupling is also used to amplify the modes under the action of a blue detuned pump. In addition, self-oscillations and parametric amplification of the fundamental vibrational mode is demonstrated with a gain of nearly 3. The low mass and high frequency of these atomically thin resonators could prove useful for studying mode coupling in the quantum regime.

**12:15PM B52.00006 Observation of vacuum-enhanced electron spin resonance of optically levitated nanodiamonds** , TONGCANG LI, THAI HOANG, JONGHOON AHN, JAEHOON BANG, Purdue University — Electron spins of diamond nitrogen-vacancy (NV) centers are important quantum resources for nanoscale sensing and quantum information. Combining such NV spin systems with levitated optomechanical resonators will provide a hybrid quantum system for many novel applications. Here we optically levitate a nanodiamond and demonstrate electron spin control of its built-in NV centers in low vacuum. We observe that the strength of electron spin resonance (ESR) is enhanced when the air pressure is reduced. To better understand this novel system, we also investigate the effects of trap power and measure the absolute internal temperature of levitated nanodiamonds with ESR after calibration of the strain effect. Our results show that optical levitation of nanodiamonds in vacuum not only can improve the mechanical quality of its oscillation, but also enhance the ESR contrast, which pave the way towards a novel levitated spin-optomechanical system for studying macroscopic quantum mechanics. The results also indicate potential applications of NV centers in gas sensing.

**12:27PM B52.00007 Piezo-optomechanical circuits** , KRISHNA COIMBATORE BALRAM<sup>1</sup>, MARCELO DAVANCO, B. ROBERT ILIC, KARTIK SRINIVASAN, NIST - Natl Inst of Stds & Tech — Coherent links between the optical, radio frequency (RF), and mechanical domains are critical for applications ranging from quantum state transfer between the RF and optical domains to signal processing in the acoustic domain for microwave photonics. We develop such a piezo optomechanical circuit platform in GaAs, in which localized and interacting 1550 nm photons and 2.4 GHz phonons are combined with photonic and phononic waveguides. GaAs allows us to exploit the photoelastic effect to engineer cavities with strong optomechanical coupling ( $g_0/2\pi \approx 1.1$  MHz) and the piezoelectric effect to couple RF fields to mechanical motion through surface acoustic waves, which are routed on-chip using phononic crystal waveguides. This platform enables optical readout of electrically-injected mechanical states with an average coherent intracavity phonon number as small as  $\approx 0.05$  and the ability to drive mechanical motion with equal facility through either the optical or electrical channel. This is used to demonstrate a novel acoustic wave interference effect in which optically-driven motion is completely cancelled by electrically-driven motion, and vice versa. As an application of this, we present time-domain measurements of optically-controlled acoustic pulse propagation.

**12:39PM B52.00008 Magneto-optical coupling in whispering gallery mode resonators** , JAMES HAIGH, Hitachi Cambridge Laboratory, Cambridge, CB3 0HE, UK, STEFAN LANGENFELD, NICHOLAS LAMBERT, JEREMY BAUMBERG, Cavendish Laboratory, University of Cambridge, Cambridge, CB3 0HE, UK, ANDREW RAMSAY, Hitachi Cambridge Laboratory, Cambridge, CB3 0HE, UK, ANDREAS NUNNENKAMP, ANDREW FERGUSON, Cavendish Laboratory, University of Cambridge, Cambridge, CB3 0HE, UK — We demonstrate that yttrium iron garnet microspheres support optical whispering gallery modes similar to those in non-magnetic dielectric materials. The direction of the ferromagnetic moment tunes the resonant optical frequency via the Voigt effect, dependent on the angle of the magnetization with respect to the plane of the whispering gallery mode. This parametric coupling of the magnetization to the optical mode may enable analogous experiments to those performed in cavity optomechanics. In addition, the Faraday effect couples the two ordinarily linear polarized modes, split by the geometrical birefringence due to the boundary conditions at the surface. This results in a polarization rotation of the light emitted from the cavity. Our results extend recent work on the strong coupling of microwave photons to magnetization dynamics into the optical domain. An understanding of the magneto-optical coupling in whispering gallery modes, where the propagation direction rotates with respect to the magnetization, is fundamental to the emerging field of cavity optomagnonics. [arXiv:1510.06661].

**12:51PM B52.00009 Quartz-superconductor quantum electromechanical system** , MATT WOOLLEY, MUHAMMAD EMZIR, UNSW Australia, GERARD MILBURN, MARKUS JERGER, University of Queensland, MAXIM GORYACHEV, MIKE TOBAR, University of Western Australia, ARKADY FEDOROV, University of Queensland — Quartz bulk acoustic wave oscillators support mechanical modes with very high resonance frequencies and extremely high quality factors. As such, they provide an appealing platform for quantum optics experiments with phonons, gravitational wave detection, and tests of quantum mechanics. We propose to cool and measure the motion of a quartz oscillator using a transmon, with the coupling mediated by a tuneable superconducting LC circuit. The mechanical motion ( $\sim 250$  MHz) is resonantly coupled to the LC circuit ( $\sim 250$  MHz) by a piezoelectric interaction, the LC circuit is coupled to the transmon ( $\sim 8$  GHz) via sideband transitions, and there is a smaller direct coupling between the quartz oscillator and the transmon. By driving the transmon on its red sideband, the mechanical and electrical oscillators may be cooled close to their quantum ground state. By observing the fluorescence of the qubit, the occupations of the oscillators may be determined via the motional sidebands they induce. A minimal model of this system consists of a qubit coupled to two oscillators, which are themselves mutually coupled. The steady-state of the system and the qubit fluorescence spectrum are evaluated analytically using a perturbative projection operator technique, and verified numerically.

**1:03PM B52.00010 Single photon frequency conversion and channelization based on microwave piezo-optomechanical devices.** , LINRAN FAN, CHANGLIN ZOU, MENNO POOT, RISHENG CHENG, HONG TANG, Yale University — Cavity optomechanics holds very promising potentials for quantum information processing, as it provides both a convenient method to manipulate photons and a platform to bridge different quantum system. Especially, the integration of microwave devices with cavity optomechanics draws great interest as such a hybrid platform can provide strong electrical actuation, ultra-sensitive optical readout, and parametric mechanical signal amplification simultaneously in a single device. This hybrid platform enables great functionalities in manipulating photons, and builds direct link between microwave photon and optical photon, which is important for future quantum network. Aluminum nitride (AlN) is ideal for such hybrid platform. Besides low optical and mechanical loss, AlN possesses strong piezoelectric effect, which gives rise to strong coupling between microwave cavities and mechanical resonators. We will present our recent progress in developing integrated AlN hybrid platform for photon manipulation, such as optical amplification and absorption, cascaded optical delay, single photon frequency shifting, etc.

**1:15PM B52.00011 Displacement linear detection down to thermal fluctuations of a silicon nitride membrane with self-mixing technique<sup>1</sup>** , LORENZO BALDACCI, ALESSANDRO PITANTI, LUCA MASINI, ANDREA ARCANGELI, DANIEL NAVARRO URRIOS, NEST, Istituto Nanoscienze - CNR and Scuola Normale Superiore, ALESSANDRO TREDICUCCI, NEST, Istituto Nanoscienze - CNR and Dipartimento di Fisica E. Fermi, Universit'a di Pisa, SOULMAN RESEARCH GROUP TEAM — Active optomechanical systems exploit the interaction between photons and mechanical vibrations inside a laser cavity. A compound cavity made of a laser diode and an external vibrating reflector is a suitable platform, due to its ease of construction and coupling modulation. Here we use it as a linear displacement detector, by studying the motion of a silicon nitride suspended membrane as the external mirror of a near infrared laser diode. The membrane vibrations cause fluctuations in the laser optical power, which are collected by a photodiode and measured with a spectrum analyzer. The dynamics of the membrane driven by a piezo actuator was investigated in a homodyne configuration. The high Q-factor ( $\sim 10^5$  at low pressure) of the fundamental mechanical mode at 74 kHz enabled direct measurement of thermal motion at room temperature, which holds an average displacement of 20 pm. Therefore, compound cavity systems can be employed as table-top, cost-effective displacement linear detectors. Furthermore, nonlinear optomechanical interactions could be observed, with new possibilities in the study of non-Markovian quantum properties at the mesoscale.

**1:27PM B52.00012 Microwave cavity piezo-opto-mechanical resonators based on film thickness modes operating beyond 10 GHz**, XU HAN, HONG TANG, Yale University — Micromechanical resonators, which support and confine microwave frequency phonons on a scale comparable to optical wavelength, provide a valuable intermediate platform facilitating interactions among electrical, optical, and mechanical domains. High-frequency mechanical resonances ease the refrigeration conditions for reaching quantum mechanical ground state and also hold promise for practical device applications. However, efficient actuation of the highly stiff mechanical motions above gigahertz frequencies remains a challenging task. Here, we demonstrate a high-performance piezo-opto-mechanical resonator operating at 10.4 GHz by exploiting the acoustic thickness mode of an aluminum nitride micro-disk. In contrast to the in-plane mechanical modes, the thickness mode can be easily scaled to high frequencies with low mechanical and optical dissipations. A high  $f \cdot Q$  product of  $1.9 \times 10^{13}$  Hz is achieved in ambient air at room temperature. Moreover, strong piezo-electro-mechanical coupling can be achieved by coupling the thickness mode with a microwave resonator, making it possible for coherent signal conversion. The thickness mode-based piezo-opto-mechanical resonators can be expected to serve as essential elements for advanced hybrid information networks.

**1:39PM B52.00013 Slot-mode optomechanical crystals with enhanced coupling and multimode functionality**<sup>1</sup>, KAREN GRUTTER, MARCELO DAVANCO, KARTIK SRINIVASAN, NIST - Natl Inst of Stds & Tech — A number of cavity optomechanics applications involve multiple interacting optical and mechanical modes. A key challenge in such systems is developing multimode platforms with both flexibility in the optical and mechanical designs and interactions as strong as those shown in single-mode systems. We thus present slot-mode optomechanical crystals, in which photonic and phononic crystal nanobeams separated by a narrow slot couple optomechanically. We pattern these beams to confine a low-loss optical mode in the slot and a mechanical breathing mode at the center of the mechanical beam. This structure has large optomechanical coupling rates and great design flexibility toward multimode systems. We demonstrate this in  $\text{Si}_3\text{N}_4$  slot-mode devices, with 980 nm optical modes coupling to mechanical modes at 3.4 GHz, 1.8 GHz, and 400 MHz. We use  $\text{Si}_3\text{N}_4$  tensile stress to shrink slot widths to 24 nm, greatly enhancing optomechanical coupling. Finally, with this platform, we develop multimode systems with three-beam geometries, in which two different mechanical modes couple to one optical mode and two different optical modes couple to one mechanical mode.

**1:51PM B52.00014 Nonlinearly Coupled Superconducting Lumped Element Resonators**, MICHELE C. COLLODO, ANTON POTOČNIK, ANTONIO RUBIO ABADAL, MINTU MONDAL, MARKUS OPPLIGER, ANDREAS WALLRAFF, Laboratory for Solid State Physics, ETH Zurich — We study SQUID-mediated tunable coupling between two superconducting on-chip resonators in the microwave frequency range. In this circuit QED implementation, we employ lumped-element type resonators, which consist of Nb thin film structured into interdigitated finger shunt capacitors and meander inductors. A SQUID, functioning as flux dependent and intrinsically nonlinear inductor, is placed as a coupling element together with an interdigitated capacitor between the two resonators (cf. A. Baust *et al.*, Phys. Rev. B **91** 014515 (2015)). We perform a spectroscopic measurement in a dilution refrigerator and find the linear photon hopping rate between the resonators to be widely tunable as well as suppressible for an appropriate choice of parameters, which is made possible due to the interplay of inductively and capacitively mediated coupling. Vanishing linear coupling promotes nonlinear effects ranging from onsite- to cross-Kerr interaction. A dominating cross-Kerr interaction related to this configuration is notable, as it induces a unique quantum state. In the course of analog quantum simulations, such elementary building blocks can serve as a precursor for more complex geometries and thus pave the way to a number of novel quantum phases of light

**2:03PM B52.00015 Microwave Reentrant Cavities for Quantum Devices**<sup>1</sup>, NATALIA C. CARVALHO, JEREMY BOURHILL, DANIEL CREEDON, MAXIM GORYACHEV, ARC Centre of Excellence for Engineered Quantum Systems, The University of Western Australia, SERGE GALLIOU, FEMTO-ST Institute, MICHAEL TOBAR, ARC Centre of Excellence for Engineered Quantum Systems, The University of Western Australia — A microwave reentrant cavity is a device able to provide a very sensitive high-Q microwave mode. Its design can be highly advantageous for electromechanical devices and quantum measurements. In this sense, a tuneable device based on a narrow-gap superconducting reentrant cavity is under development. The resonant frequency is able to be fine-tuned over a range larger than 500 MHz at 10 mK with an electrical Q-factor of  $10^5$ . Such a cavity could possibly accommodate a transmon qubit to control and manipulate its quantum state. We are also working on the investigation of bulk acoustic wave (BAW) resonators in microwave reentrant cavities. BAW resonators offer a promising way to process quantum information through the coupling between microwaves and acoustic phonons. Thus, we are developing a device able to excite phonons through non-linearities and the piezoelectricity of the plano-convex quartz crystal. We will detail our experiments that work towards cooling gram scale phonon resonances to the quantum ground state.

**11:27AM B53.00002 Acoustical vortices on a Chip for 3D single particle manipulation and vorticity control**<sup>1</sup>, ANTOINE RIAUD, CNRS Nord pas de Calais, JEAN-LOUIS THOMAS, OLIVIER BOU MATAR, CNRS Paris, MICHAEL BAUDOIN, CNRS Nord pas de Calais — Surface acoustic waves offer most of the basic functions required for on-chip actuation of fluids at small scales: efficient flow mixing, integrated pumping, particles separation, droplet displacement, atomization, division and fusion. Nevertheless some more advanced functions such as 3D particles manipulation and vorticity control require the introduction of some specific kind of waves called acoustic vortices. These helical waves propagate spinning around a phase singularity called the dark core. On the one hand, the beam angular momentum can be transferred to the fluid and create point-wise vorticity for confined mixing, and on the other the dark core can trap individual particles in an acoustic well for single object manipulation. In this presentation, I will show how acoustical vortices on-a-chip can be synthesized with a programmable electronics and an array of transducers<sup>2</sup>. I will then highlight how some of their specificities<sup>3</sup> can be used for acoustical tweezing and twisting.

**11:39AM B53.00003 Coalescence-induced jumping of nanoscale droplets on super-hydrophobic surfaces**, ZHI LIANG, PAWEL KEBLINSKI, Rensselaer Polytechnic Institute, NANOSCALE SCIENCE AND ENGINEERING CENTER TEAM — The coalescence-induced jumping of tens of microns size droplets on super-hydrophobic surfaces has been observed in both experiments and simulations. However, whether the coalescence-induced jumping would occur for smaller, particularly nanoscale droplets, is an open question. Using molecular dynamics simulations, we demonstrate that in spite of the large internal viscous dissipation, coalescence of two nanoscale droplets on a super-hydrophobic surface can result in a jumping of the coalesced droplet from the surface with a speed of a few m/s. Similar to the coalescence-induced jumping of microscale droplets, we observe that the bridge between the coalescing nano-droplets expands and impacts the solid surface, which leads to an acceleration of the coalesced droplet by the pressure force from the solid surface. We observe that the jumping velocity decreases with the droplet size and its ratio to the inertial-capillary velocity is a constant of about 0.126, which is close to the minimum value of 0.111 predicted by continuum-level modeling of Enright et al. [R. Enright, N. Miljkovic, J. Sprittles, K. Nolan, R. Mitchell, and E. N. Wang, ACS Nano 8, 10352 (2014)].

**11:51AM B53.00004 Droplet climbing on a pre-wetted conical fibre**, ZHEN JIAN, ERQIANG LI, S. T. THORODDSEN, King Abdullah University of Science and Technology (KAUST) — We study the motion of a droplet on a wet conical fibre. The conical fibres are fabricated with a glass-puller, with tip diameters of several  $\mu\text{m}$ . With liquid is fed through the hollow fibre and travels up the outside of the cone, forming a droplet, which is initially attached near the tip. This drop grows in size and then detaches and moves on the fibre, at velocities up to 0.25 m/s. We focus on the regime with small Bond number  $Bo = \rho g R^2 / \sigma$  and capillary number  $Ca = \mu U / \sigma$ , where the droplet motion is driven by the pressure gradient due to the continuous curvature change along the conical fibre. High-speed imaging and numerical simulations via the Gerris code are employed to investigate the dynamics of the droplet detachment and climbing. Our focus is on the interface profile near the tip, the mechanism of droplet formation and climbing, and the velocity field in the thin liquid layer on the cone.

**12:03PM B53.00005 Electro-osmotic flow in bicomponent fluids<sup>1</sup>**, ANDREI BAZARENKO, MARCELLO SEGA, University of Vienna — The electroosmotic flow (EOF) is a widely used technique that uses the action of external electric fields on solvated ions to move fluids around in microfluidics devices. For homogeneous fluids, the characteristics of the flow can be well approximated by simple analytical models, but in multicomponent systems such as oil-in-water droplets one has to rely to numerical simulations. The purpose of this study is to investigate physical properties of the EOF in a bicomponent fluid by solving the coupled equations of motions of explicit ions in interaction with a continuous model of the flow. To do so we couple the hydrodynamics equations as solved by a Shan-Chen Lattice-Boltzmann method<sup>2</sup> to the molecular dynamics of the ions<sup>3</sup>. The presence of explicit ions allows us to go beyond the simple Poisson-Boltzmann approximations, and investigate a variety of EOF regimes.

**12:15PM B53.00006 Electrohydrodynamics of toroidal droplets**, ALEXANDROS FRAGKOPOULOS, ERIC BERGER, Georgia Institute of Technology, EKAPOPAIRAM, King Mongkut's Institute of Technology Ladkrabang, ALBERTO FERNANDEZ-NIEVES, Georgia Institute of Technology — Toroidal droplets are unstable and always transform into spherical droplets due to surface tension. This can happen via Rayleigh-Plateau instabilities, or via the shrinking of the handle. Interestingly, charging a toroidal droplet can cause expansion, rather than shrinking, of the handle. In this talk, we will discuss the use of particle image velocimetry to obtain the velocity profile inside both neutral and charged toroidal droplets as they transform into the spherical shape. In particular, we quantify the effect of surface stresses on the velocity field and, consequently, on the shape of the interface as the droplet evolves by either shrinking or expanding.

**12:27PM B53.00007 Study of the (1 + 1)D Long Wavelength Steady States of the Bénard Problem For Ultrathin Films**, CHENGZHE ZHOU, SANDRA TROIAN, California Institute of Technology, 1200 E California Blvd., MC 128-95, Pasadena, CA — We investigate the stationary states of the (1 + 1)D equation  $h_t + [h^3 h_{xxx} + h^2 \gamma_x(h)]_x = 0$  for thin films of thickness  $h(x, t)$  where  $x$  is the spatial variable and  $t$  is time. The variable  $\gamma(h)$ , denotes the surface tension along the gas/liquid interface of the slender bilayer confined between two substrates enforcing thermal conduction within the gap. Equilibrium solutions include flat films, droplets, trenches/ridges and positive periodic steady states (PPSS), the latter conveniently parameterized by a generalized interfacial pressure and the global extremum in shape. We derive perturbative solutions describing PPSS shapes near the stability threshold including their minimal period, average height and free energy. Weakly nonlinear analysis confirms that flat films always undergo a supercritical unstable pitch-fork bifurcation. Globally, our numerical simulations indicate at most one non-trivial PPSS per given period and volume. The free energy of droplet states is also always lower than the relevant corresponding PPSS, suggesting that initial flat films tend to redistribute mass into droplet-like configurations. By solving the linearized eigenvalue problem, we also confirm the unstable nature of PPSS solutions far from the stability threshold.

**12:39PM B53.00008 Collective oscillations and coupled modes in confined microfluidic droplet arrays<sup>1</sup>**, ULF D. SCHILLER, Department of Materials Science and Engineering, Clemson University, JEAN-BAPTISTE FLEURY, RALF SEEMANN, Experimental Physics, Saarland University, GERHARD GOMPPER, Institute of Complex Systems, Forschungszentrum Jülich — Microfluidic droplets have a wide range of applications ranging from analytic assays in cellular biology to controlled mixing in chemical engineering. Ensembles of microfluidic droplets are interesting model systems for non-equilibrium many-body phenomena. When flowing in a microchannel, trains of droplets can form microfluidic crystals whose dynamics are governed by long-range hydrodynamic interactions and boundary effects. In this contribution, excitation mechanisms for collective waves in dense and confined microfluidic droplet arrays are investigated by experiments and computer simulations. We demonstrate that distinct modes can be excited by creating specific 'defect' patterns in flowing droplet trains. While longitudinal modes exhibit a short-lived cascade of pairs of laterally displacing droplets, transversely excited modes form propagating waves that behave like microfluidic phonons. We show that the confinement induces a coupling between longitudinal and transverse modes. We also investigate the life time of the collective oscillations and discuss possible mechanisms for the onset of instabilities. Our results demonstrate that microfluidic phonons can exhibit effects beyond the linear theory, which can be studied particularly well in dense and confined systems.

**12:51PM B53.00009 Drop impact on inclined superhydrophobic surfaces<sup>1</sup>**, WONJAE CHOI, SANI LECLEAR, JOHNATHON LECLEAR, . ABHIJEET, University of Texas at Dallas, KYOO-CHUL PARK, Harvard University — We report an empirical study and dimensional analysis on the impact patterns of water drops on inclined superhydrophobic surfaces. While the classic Weber number determines the spreading and recoiling dynamics of a water drop on a horizontal / smooth surface, for a superhydrophobic surface, the dynamics depends on two distinct Weber numbers, each calculated using the length scale of the drop or of the pores on the surface. Impact on an inclined superhydrophobic surface is even more complicated, as the velocity that determines the Weber number is not necessarily the absolute speed of the drop but the velocity components normal and tangential to the surface. We define six different Weber numbers, using three different velocities (absolute, normal and tangential velocities) and two different length scales (size of the drop and of the texture). We investigate the impact patterns on inclined superhydrophobic surfaces with three different types of surface texture: (i) posts, (ii) ridges aligned with and (iii) ridges perpendicular to the impact direction. Results suggest that all six Weber numbers matter, but affect different parts of the impact dynamics, ranging from the Cassie-Wenzel transition, maximum spreading, to anisotropic deformation.

**1:03PM B53.00010 Spreading of water nanodroplets on graphene**, JOSEPH ANDREWS, SHAYANDEV SINHA, PETER CHUNG, SIDDHARTHA DAS, Univ of Maryland-College Park — Understanding the wetting of 2D materials is central to the successful application of these materials in a variety of disciplines that involve the interaction of a liquid with such layered substrates. Recent studies focusing on wetting statics and contact angle selection on graphene-coated solids indicate a wetting translucent behavior of graphene. However, little research has been done on the wetting dynamics of graphene-coated systems. Here, we simulate the wetting dynamics of water drops on free-standing graphene layers using a molecular dynamics framework. We employ the extended simple point charge (SPC/E) model to simulate the water drops. Our simulations are validated against the experimental results of water drop contact angles on graphite. Unlike many existing MD studies, we obtain the results starting from a physical consideration of spherical water drops. We observe the half power law for the spreading dynamics, i.e.,  $r \sim t^{1/2}$  ( $r$  is the spreading radius and  $t$  is the spreading time). Identical spreading laws have been identified for Lennard Jones (LJ) nanodroplets on non-layered surfaces; therefore, we establish that the change in the nature of the substrate (non-layered to 2D) and the liquid (LJ to water) does not alter the physics of wetting dynamics of nanodroplets.

**1:15PM B53.00011 Domain and rim growth kinetics in stratifying foam films**, YIRAN ZHANG, SUBINUER YILIXIATI, VIVEK SHARMA, University of Illinois at Chicago — Foam films are freely standing thin liquid films that typically consist of two surfactant-laden surfaces that are ~5 nm – 10 micron apart. Sandwiched between these interfacial layers is a fluid that drains primarily under the influence of viscous and interfacial forces, including disjoining pressure. Interestingly, a layered ordering of micelles inside the foam films (thickness <100 nm) leads to a stepwise thinning phenomena called stratification, which results in a thickness-dependent variation in reflected light intensity, visualized as progressively darker shades of gray. Thinner, darker domains spontaneously grow within foam films. During the initial expansion, a rim forms near the contact line between the growing thinner domain and the surrounding region, which influences the dynamics of domain growth as well as stratification. Using newly developed interferometry digital imaging optical microscopy (IDIOM) technique, we capture the rim evolution dynamics. Finally, we also develop a theoretical model to describe both rim evolution and domain growth dynamics.

**1:27PM B53.00012 Drop formation, pinch-off dynamics and liquid transfer of simple and complex fluids**, JELENA DINIC, VIVEK SHARMA, University of Illinois at Chicago — Liquid transfer and drop formation processes underlying jetting, spraying, coating, and printing – inkjet, screen, roller-coating, gravure, nanoimprint hot embossing, 3D – often involve formation of unstable columnar necks. Capillary-driven thinning of such necks and their pinchoff dynamics are determined by a complex interplay of inertial, viscous and capillary stresses for simple, Newtonian fluids. Micro-structural changes in response to extensional flow field that arises within the thinning neck give rise to additional viscoelastic stresses in complex, non-Newtonian fluids. Using FLOW-3D, we simulate flows realized in prototypical geometries (dripping and liquid bridge stretched between two parallel plates) used for studying pinch-off dynamics and influence of microstructure and viscoelasticity. In contrast with often-used 1D or 2D models, FLOW-3D allows a robust evaluation of the magnitude of the underlying stresses and extensional flow field (both uniformity and magnitude). We find that the simulated radius evolution profiles match the pinch-off dynamics that are experimentally-observed and theoretically-predicted for model Newtonian fluids and complex fluids.

**1:39PM B53.00013 Simulations of high and low viscosity micro-scale droplets splashing on a dry surface**, ARNOUT BOELEN, ANDRZEJ LATKA, JUAN DE PABLO, University of Chicago — When a droplet hits a dry surface at atmospheric pressure with a high enough impact velocity, it splashes and breaks apart into many smaller droplets. However, when the ambient gas pressure is reduced, splashing is suppressed. This is contrary to intuition, which suggests a more violent splash should occur at lower gas densities due to reduced drag forces. Although splashes of high and low viscosity liquids visually look very different, they also obey the pressure effect. In this study the effect of viscosity on splashing is investigated, to get a better understanding of the pressure effect in general. Simulation results are presented comparing splashing of low viscosity ethanol with high viscosity silicone oil in air. The droplets are several hundred microns large. The simulations are 2D, and are performed using a Volume Of Fluid approach. The contact line is described using the Generalized Navier Boundary Condition. Both the gas phase and the liquid phase are assumed to be incompressible. The results of the simulations show good agreement with experiments, including reproduction of the pressure effect, and suggest that the same scaling laws that apply to lamella formation in simple drop deposition, also apply to splashing droplets.

**1:51PM B53.00014 Dynamics of Wetting and Wicking on Rough Surfaces**, DION ANTAO, DANIEL PRESTON, SOLOMON ADERA, YANGYING ZHU, EVELYN WANG, Massachusetts Institute of Technology — Micro/nano engineering of surfaces to enhance the performance of phase-change heat transfer processes has recently gained wide interest. Interfacial phenomena at the micro/nanoscale play an important role in defining the dynamic wetting and wicking characteristics of the surfaces. Here we report experiments that characterize the dynamic wetting and wicking processes on microstructured silicon surfaces. We investigated cylindrical micropillar arrays in a square pattern with various diameter, pitch, and height to characterize key interfacial behavior over a wide range of surface roughness. The experiments were performed by dipping the microstructured sample vertically into a reservoir of de-ionized water and the spreading dynamics were captured with a high speed camera. We observed that both wetting and wicking exhibit a power law dependence on time, however they occur at different time scales. The instantaneous (~10-100 ms) wetting behavior occurs due to the interfacial tensions, and the resultant force acting at the three-phase contact line. The longer time scale (>100 ms) wicking behavior results from the balance of the capillary pressure generated within the microstructure and the viscous pressure loss from flow through the micropillar array. We develop analytical models to predict these different time scale behavior and compare them to experimental results. This work provides insight into key dynamic processes affecting micro/nanostructure enhanced phase-change heat transfer devices.

**11:15AM B54.00001 Experimental evidence of  $\alpha \rightarrow \beta$  phase transformation in SiC quantum dots and their size-dependent luminescence**, XIAOXIAO GUO, Department of Physics, Southeast University, DEJIAN DAI, Department of Physics, Southeast University, Nanjing 211189, PR China, BAOLU FAN, Department of Physics, Southeast University, JIYANG FAN, Department of Physics, Southeast University, Nanjing 211189, PR China — Silicon carbide (SiC) quantum dots (QDs) have attracted great interest due to their wide application in photonics, optoelectronics, and life sciences. SiC is an outstanding wide-bandgap semiconductor for applications in high power, high temperature, and high frequency electronic devices owing to its superior physical and mechanical properties. As a wide-bandgap semiconductor, SiC has over 250 crystalline structures, and some polytypes have been found in the presolar meteorites. Phase transformation can occur among different SiC polytypes under extreme conditions such as high pressure or high temperature. It remains unknown whether phase transformation can occur under normal conditions. We demonstrate that the  $\alpha \rightarrow \beta$  phase transformation can occur at ambient temperature and pressure in nanoscale SiC. The microstructural characterization and light absorption and emission spectroscopy demonstrate the occurrence of this phase transformation. It is found that the quantum-confinement luminescence dominates in larger SiC QDs and the surface-defect luminescence dominates in ultrasmall SiC QDs. The rare phenomenon of photon absorption accompanied by emission or absorption of multiple phonons has been observed, demonstrating the indirect-bandgap nature of the SiC QDs.

**11:27AM B54.00002 Two-photon absorption in 3-100nm diameter Silicon nanocrystals in solution**, BRANDON FUREY<sup>1</sup>, MICHAEL DOWNER<sup>2</sup>, YIXUAN YU<sup>3</sup>, BRIAN KORGEL<sup>4</sup>, University of Texas at Austin — Silicon nanocrystals (nc-Si) exhibit efficient photoluminescence (PL) that has applications in non-toxic bio-imaging. Two-photon absorption (TPA) is an important process for exciting PL in the tissue transparency spectral window, but absolute TPA coefficients have not been measured as a continuous function of nc size or excitation wavelength. Previous TPA studies have focused on nc-Si embedded in an oxide matrix or on porous Si surfaces at selected discrete wavelengths [1]. However, recently free standing, ligand-stabilized nc-Si with diameters ranging from 3 to 100 nm that are soluble in liquids, including water, and suitable for bio-imaging have become available [3]. We will present calibrated TPA spectra for free standing nc-Si over a wide range of nc diameters, based on measurements with tunable femtosecond laser pulses. We will compare indirect TPA measurements based on collection and detection of PL with direct TPA measurements based on attenuation of the incident beam. [1] P. Zhang, Z. Zhang, K. Chen et al., Nanoscale Res. Lett. 9 (28), 1 (2014) [2] C.M. Hessel, J. Wei, B. Korgel et al., Chem. Mater. 24 (2), 393 (2012)

**11:39AM B54.00003 ABSTRACT WITHDRAWN —**

**11:51AM B54.00004 Stimulated emission and lasing from all-inorganic perovskite quantum dots**, HANDONG SUN, YUE WANG, Nanyang Technological University, XIAOMING LI, ZENG HAIBO, Nanjing University of Science and Technology — We present superior optical gain and lasing properties in a new class of emerging quantum materials, the colloidal all-inorganic cesium lead halide perovskite quantum dots (IPQDs) ( $\text{CsPbX}_3$ ,  $X = \text{Cl, Br, I}$ ). Our result has indicated that such material system show combined merits of both colloidal quantum dots and halide perovskites. Low-threshold and ultrastable stimulated emission was demonstrated under atmospheric condition. The flexibility and advantageous optical gain properties of these  $\text{CsPbX}_3$  IPQDs were manifested by demonstration of an optically pumped micro-laser. The nonlinear optical properties including the multi-photon absorption and resultant photoluminescence of the  $\text{CsPbX}_3$  nanocrystals were investigated. A large two-photon absorption cross-section of up to  $\sim 1.2105 \text{ GM}$  is determined from 9 nm-sized  $\text{CsPbBr}_3$  nanocrystals. Moreover, low-threshold frequency-upconverted stimulated emission by two-photon absorption was observed from the thin films of close-packed  $\text{CsPbBr}_3$  nanocrystals. We further realize the three-photon pumped stimulated emission in green spectra range from colloidal IPQD.

**12:03PM B54.00005 Control of Photo- and Electro-generated Excited States of Colloidal Quantum Dots**, XIAOGANG PENG, Zhejiang Univ — Colloidal semiconductor nanocrystals (quantum dots) as solution-processible photo- and electro-excited emitters are promising and may impact many industrial sectors. Both photoluminescence and electroluminescence are based on generation and relaxation of the excited states. Thus, properties of excited states should be the key for design, synthesis, understanding, and applications of emitters. Specifically, as promising emissive materials, colloidal quantum dots rely heavily on their excited-state properties, instead of solely the ground-state properties.

**12:15PM B54.00006 Self-assembled single-mode micro-lasers of "giant" CdSe/CdS core/shell quantum dots**, CHEN LIAO, JIAYU ZHANG, Advanced Photonic Center, Southeast University — So-called giant quantum dots (g-QDs) as optical gain media have attracted much attention due to their near elimination of nonradiative Auger effects. In the present work, phase-pure wurtzite CdSe/CdS core/shell QDs with controlled shell thickness are successfully synthesized, and the threshold of amplified spontaneous emission (ASE) of the films of this series of QDs is measured. The threshold of ASE is decreased dramatically with the CdS shell growth towards 11 monolayers (MLs) ( $21 \mu\text{J}/\text{cm}^2$ ), but increased with the further shell growth. The effects of the overlap degree of electron and hole wave functions, surface states, and absorption cross-section are discussed to explain the ASE properties of the QDs. Moreover, the low-threshold gain of the CdSe/CdS core/shell (11 MLs) g-QDs is exploited to fabricate micro-lasers solely by deposition of small droplets of QDs solution onto glass substrates. The evaporation dynamics of the droplets are governed by the coffee-ring effect which leads to the formation of well defined micron-size rings. The self-assembled coffee-ring micro-lasers display single-mode operation and a very low threshold of  $3 \mu\text{J}/\text{cm}^2$ . Herein, an innovative, simple and reliable method to produce micro-lasers based on CdSe/CdS g-QDs is presented.

**12:27PM B54.00007 Red shift in the photoluminescence of colloidal carbon quantum dots induced by photon reabsorption**, WENXIA ZHANG, JIYANG FAN, Department of Physics, Southeast University, Nanjing 211189, Peoples Republic of China, DEPARTMENT OF PHYSICS, SOUTHEAST UNIVERSITY, NANJING 211189, PEOPLES REPUBLIC OF CHINA TEAM — We synthesize the colloidal carbon/graphene quantum dots 1-9 nm in diameter through a novel alkaline-assisted method and deeply studied their photoluminescence properties. Surprisingly, the luminescence properties of a fixed collection of carbon dots can be systematically changed as the concentration varies. A model based on photon reabsorption is proposed which explains well the experiment. Infrared spectral study indicates that the surfaces of the carbon dots are totally terminated by three bonding-types of oxygen atoms, which result in their ultra-high hydrophilicity. Our result clarifies the mystery of distinct emission colors in carbon dots and indicates that photon reabsorption can strongly affect the luminescence properties of colloidal nanocrystals. This mechanism can be generalized to help understand the complex luminescence properties of other colloidal quantum dots. and should be seriously considered, otherwise, distinct conclusions may be drawn if different concentrations of quantum dots have been utilized in studying their luminescence properties.

**12:39PM B54.00008 Tunable Emission in Inverted Type-I CdS/CdSe Core/Crown Semiconductor Nanoplatelets**, PEDRO LUDWIG HERNANDEZ-MARTINEZ<sup>1</sup>, Nanyang Technological University, SAVAS DELIKANLI, BURAK GUZELTURK<sup>2</sup>, TALHA ERDEM, YUSUF KELESTEMUR, MURAT OLUTAS, MEHMET ZAFER AKGUL, Bilkent University, HILMI VOLKAN DEMIR<sup>3</sup>, Nanyang Technological University — In this work, we present the tunable optical properties of an inverted Type-I core/crown nanoplatelet heterostructure. We show that the emission peak of the resulting CdS/CdSe hetero-nanoplatelets can be tuned continuously between the peak emission wavelengths of the core only CdS nanoplatelets (421 nm) and CdSe nanoplatelets (515 nm). In these inverted Type-I nanoplatelets, the unique continuously tunable emission is enabled by adjusting the lateral width of the CdSe crown, around the core CdS nanoplatelet. As a proof-of-concept, we generate white light by using color conversion concept with CdS/CdSe hetero-nanoplatelets, which have finely tuned thin crowns. This results in a color rendering index of 80.

**12:51PM B54.00009 Nonradiative Auger recombination of biexcitons in CdSe/CdS core-shell nanocrystal quantum dots**, ROMAN VAXENBURG, George Mason University, Fairfax, VA 22030, USA, ANNA RODINA, Ioffe Institute, St. Petersburg, 194021, Russia, EFRAT LIFSHITZ, Technion Israel Institute of Technology, Haifa, 32000, Israel, ALEXANDER EFROS, Naval Research Laboratory, Washington, DC 20375, USA — Semiconductor nanocrystals are known for their applicative potential as light-emitting components in lasers and LEDs, as well as light absorbers in solar cells. The performance of these nanocrystal-based devices, however, strongly depends on the dissipative nonradiative Auger recombination. The study of dynamics of the Auger processes is therefore of key importance in connection with the performance of nanocrystals devices. Here we report on a theoretical study of the Auger recombination dynamics of biexcitons in CdSe/CdS core-shell nanocrystals. Biexcitons can decay by the Auger process via negative or positive trion recombination channels. We study the dependence of the rate of each one of these channels on the angular momentum of the initial biexciton state, nanocrystal geometry, and temperature. We observe that the overall dependence of the rates of both channels is strongly oscillating with nanocrystal geometry, indicating large differences in the Auger rates in nanocrystals of similar size. We find that the rate of the negative trion channel is independent of the initial biexciton angular momentum and is generally slower than the rate of the positive trion channel, which, in contrast, is sensitive to the biexciton angular momentum. Further, we demonstrate that by variation of temperature the Auger rate can be varied across a wide range of values.

**1:03PM B54.00010 Dangling Bond Magnetic Polaron in CdSe nanocrystals**, ALEXANDER EFROS, Naval Research Lab, ANNA RODINA, Ioffe Physico-Technical Institute, RAS — In this work we study theoretically the effect of the spins of the surface dangling bonds on the PL of CdSe nanocrystals (NCs). [1] We show that spins of dangling bonds open new recombination channels for the dark exciton recombination which is connected with flip-flip and flip-flop spin-assisted recombination of the dark exciton. Calculations show that at low temperatures the interaction between dangling bonds and NC excitons leads to the dynamical polarization of the dangling bond spins along the anisotropic axis following by the formation of a dangling bond magnetic polaron. An increase of the temperature, or of the external magnetic field perpendicular to the anisotropic axis, destroys the polaron state. This results in a shift of the transition energy and an increase of its recombination rate. Thus thermal depolarization of the polaron state may explain the small activation energies observed in the temperature dependences of the exciton lifetimes in CdSe NCs. The exchange interaction of the electron spin with spins of the surface dangling bonds explains also radiative recombination of the dark excitons in nanowires, nanorods and nanoplatelets. [1] A. Rodina and A.I. Efros, Nano Lett. v. 15, 4214-4222 (2015)

**1:15PM B54.00011 Superradiance in Spherical Layered Nanostructures**, SERGUEI GOUPALOV, Jackson State Univ — We propose a design of a spherically symmetric nanostructure consisting of alternate concentric semiconductor and dielectric layers. The exciton states in different semiconductor layers of such a structure interact via the common electro-magnetic field of light. We show that, if the exciton states in  $N$  semiconductor layers are in resonance with one another, then superradiant states can emerge under optical excitation of such a structure. We discuss the conditions under which superradiance can be observed and show that they strongly depend on the valence-band structure of the semiconductor layers.

**1:27PM B54.00012 Macrocrystals of Colloidal Quantum Dots in Anthracene: Exciton Transfer and Polarized Emission**, ZELIHA SORAN-ERDEM, TALHA ERDEM, Bilkent University, PEDRO LUDWIG HERNANDEZ-MARTINEZ<sup>1</sup>, Nanyang Technological University, MEHMET ZAFER AKGUL, Bilkent University, NIKOLAI GAPONIK, TU Dresden, HILMI VOLKAN DEMIR<sup>2</sup>, Nanyang Technological University — We systematically investigate the exciton energy transfer from anthracene host (donor) to quantum dots (acceptor) in a centimeter-scale macrocrystal of nonpolar colloidal quantum dots incorporated into anthracene. The decrease in photoluminescence lifetime of the donor anthracene indicate a strong energy transfer with increasing quantum dot concentration in the macrocrystals. In addition, anisotropic emission from the isotropic quantum dots in anthracene macrocrystals was observed. The quantum dots inside the anthracene host acquired a polarization ratio of  $\sim 1.5$  at 0 degree collection angle, and this increases to  $\sim 2.5$  at the collection angle of 60 degree. Finally, a proof-of-concept application of these excitonic macrocrystals as tunable color converters was employed in light-emitting diodes.

**1:39PM B54.00013 Optical Properties of the Defect State Luminescence of Zn<sub>2</sub>SnO<sub>4</sub> Nanowires**<sup>1</sup>, BAICHHABI YAKAMI, UMA PAUDYAL, SHASHANK NANDYALA, GAURAB RIMAL, University of Wyoming, JASON K. COOPER, Lawrence Berkeley National Laboratory, JIAJUN CHEN, University of New Orleans, TEYU CHIEN, WENYONG WANG, JON M PIKAL, University of Wyoming, DEPARTMENT OF ELECTRICAL AND COMPUTER ENGINEERING TEAM, DEPARTMENT OF PHYSICS AND ASTRONOMY TEAM — Nanowires (NWs) are a promising option for sensitized solar cells, sensors & display technology. Most of the work thus far has focused on binary oxides for these NWs, but ternary oxides have advantages in additional control of optical and electronic properties. Here we report on the diffuse reflectance, Low Temperature (LT) and Room Temperature (RT) photoluminescence (PL), PL excitation and Time Resolved PL (TRPL) of Zinc Tin Oxide (ZTO) NWs grown by Chemical Vapor Deposition. Our results show two broad peaks centered at 640 nm & 450 nm. The complex emission spectra was studied by Time Resolved Emission Spectroscopy (TRES) and Intensity dependent PL. The intensity dependent TRPL shows that 640 nm states decay much slower than the 450 nm states. We propose an energy band model for the NWs containing donor and acceptor states in the band gap with the associated transitions between these states that are consistent with our results. The effect of annealing in air and vacuum is carried out to study the origin of defect states in these NWs. .

**1:51PM B54.00014 Photoluminescence of Sequential Infiltration Synthesized ZnO nanostructures.**<sup>1</sup> , LEONIDAS OCOLA, Argonne Natl Lab, DAVID GOSZTOLA, ANGEL YANGUAS-GIL, Argonne National Laboratory, AINE CONNOLLY, Vassar College — We have investigated a variation of atomic layer deposition (ALD), called sequential infiltration synthesis (SiS), as an alternate method to incorporate ZnO and other oxides inside polymethylmethacrylate (PMMA) and other polymers. Energy dispersive spectroscopy (EDS) results show that we synthesize ZnO up to 300 nm inside a PMMA film. Photoluminescence data on a PMMA film shows that we achieve a factor of 400X increase in photoluminescence (PL) intensity when comparing a blank Si sample and a 270 nm thick PMMA film, where both were treated with the same 12 alternating cycles of H<sub>2</sub>O and diethyl zinc (DEZ). PMMA is a well-known ebeam resist. We can expose and develop patterns useful for photonics or sensing applications first, and then convert them afterwards into a hybrid polymer-oxide material. We show that patterning does indeed affect the photoluminescence signature of native ZnO. We demonstrate we can track the growth of the ZnO inside the PMMA polymer using both photoluminescence and Raman spectroscopy and determine the point in the process where ZnO is first photoluminescent and also at which point ZnO first exhibits long range order in the polymer.

**2:03PM B54.00015 X-ray Analysis of Self-assembled Nano-Dielectrics** , LI ZENG, Northwestern University, RICCARDO TURRISI, University of Milano-Bicocca, JONATHAN EMERY, MARK HERSAM, TOBIN MARKS, MICHAEL BEDZYK, Northwestern University — Organic thin-film transistors (OTFTs) are viewed as the new generation thin-film transistors (TFT) for future low-cost, printable, flexible electronics. A class of materials called self-assembled nano-dielectrics (SAND) with phosphoric acid-based-electron (PAE) building blocks sandwiched between ultrathin layers of high-*k* inorganic oxide materials has been synthesized. These materials show exceptional large capacitance, insulating properties, and are also suitable for ambient atmosphere fabrication. The hybrid nature of these materials combines the distinct properties of both the organic and inorganic components and can be incorporated into the low-operating voltage semiconductor-based OTFT. Despite the great performance and flexibility of SANDs, fundamental aspects of dielectric behavior remain unexplored. Particularly, the behaviors of the Br counteranions that exist within PAE building blocks are poorly understood. Therefore, long-period X-ray Standing Wave (LP-XSW), which is a powerful technique sensitive to heavy atom distributions, was used to characterize SAND deposited on synthetic Si/Mo multilayer substrates. The elemental distributions of Br and reference elements were extracted from the analysis of XSW data. These accurate measurements are important for better understanding of counteranions distributions, charge transportation, dipole-semiconductors interactions, and future device modeling and engineering.

**Session B55 DBIO: Complex Microbial Communities** Hilton Baltimore Holiday Ballroom 6 - Jeff Gore, Massachusetts Institute of Technology

**11:15AM B55.00001 Evolution of Metabolic Dependency**<sup>1</sup> , WENYING SHOU, Fred Hutchinson Cancer Research Center — Microbes are often found to have lost their ability to make essential metabolites (auxotrophs) and instead rely on other individuals for these metabolites. How might metabolic dependency evolve to be so common? When microbes live inside a host (endosymbionts), amply host metabolites support auxotrophic endosymbionts. If the host transmits only a small number of endosymbionts to its offspring, then auxotrophic endosymbionts can rise to high frequency simply by chance. On the other hand, auxotrophs have also been observed in abundant free-living bacteria found in ocean water where nutrient supply is low. How might auxotrophs rise to an appreciable frequency in a large population when nutrient supply is low? We have found commonly-encountered conditions that facilitate the evolution of metabolic dependency. Metabolic interactions can in turn shape spatial organization of microbial communities (Momeni et al. (2013) eLife 2, 00230; Momeni et al. (2013) eLife 2, 00960; Estrela and Brown (2013) PLoS Comput Biol 9, e1003398; Muller et al. (2014) PNAS 111, 1037-1042). Rapid evolution of metabolic dependency can contribute to the complexity of microbial communities.

<sup>1</sup>Evolution of metabolic dependency

**11:51AM B55.00002 Visualizing the population dynamics of microbial communities in the larval zebrafish gut**<sup>1</sup> , RAGHUVeer PARTHASARATHY, The University of Oregon — In each of our digestive tracts, trillions of microbes representing hundreds of different species colonize local environments, reproduce, and compete with one another. The resulting ecosystems influence many aspects their hosts development and health. Little is known about how gut microbial communities vary in space and time: how they grow, fluctuate, and respond to various perturbations. To address this and investigate microbial colonization of the vertebrate gut, we apply light sheet fluorescence microscopy to a model system that combines a realistic *in vivo* environment with a high degree of experimental control: larval zebrafish with defined subsets of commensal bacterial species. Light sheet microscopy enables three-dimensional imaging with high resolution over the entire intestine, providing visualizations that would be difficult or impossible to achieve with other techniques. Quantitative analysis of image data enables measurement of bacterial abundances and distributions. I will describe this approach and focus especially on recent experiments in which a colonizing bacterial species is challenged by the invasion of a second species, which leads to the decline of the first group. Imaging reveals dramatic population collapses that differentially affect the two species due to their different biogeographies and morphologies. The collapses are driven by the peristaltic motion of the zebrafish intestine, indicating that the physical activity of the host environment can play a major role in mediating inter-species competition. role in mediating inter-species competition.

**12:27PM B55.00003 Forming Stable Complex Communities: Random vs. Evolved Interactions** , DAVID KESSLER, Bar Ilan Univ — We examine the problem of constructing a stable complex community of competing species. We first investigate the case of a randomly generated set of interactions and investigate the different regimes. Here, May showed that if the interactions are not very weak, the system typically does not a steady-state with all species present. We show from simulation that the system typically goes to a non-steady state for interaction strengths above an order 1 multiple of the critical May strength. When demographic stochasticity is added, the system typically jumps from one invadable state to another. For extremely strong competition however, the system does revert to one of a number of steady state. Our model contains, as special cases, the celebrated neutral island theories of Wilson-MacArthur and Hubbell. Moreover, we show that slight deviations from perfect neutrality may lead to each of the phases, as the Hubbell point appears to be quadracritical. If, however, the system is allowed to evolve its set of interactions, each new species inheriting its interactions from its parent species, then the system can produce an interaction matrix which is capable of supporting a large number ( $\sim 100$ ) of coexisting species. The key to evolutionary success turns out to be how the child species interacts with its parent.

**1:03PM B55.00004 Adaptive landscapes: Top-down and bottom-up perspectives** , BENJAMIN KERR, University of Washington — Sewall Wright introduced the metaphor of the adaptive landscape, a map from genotype to fitness, more than 80 years ago to help describe his view of adaptive evolution. This metaphor has been immensely popular and has been used in a variety of incarnations. However, a systematic study of the genotype-fitness map presents significant problems. The space of possible genotypes is vast, and the mapping is likely dependent on both environment and the composition of genotypes in a population. In this talk, I will discuss some of these problems and present experimental strategies for uncovering features of adaptive landscapes. In particular, I will discuss how population structure can be used as an experimental variable to elucidate landscape topography and how a combination of experimental evolution and genetic engineering can reveal important landscape features in changing environments. I will also present some potential applications of this work to the problem of antibiotic resistance and potential implications for evolutionary rescue in the face of global climate change. For some of these topics, the classic notion of the adaptive landscape must itself be adapted; however, I propose that there are fruitful ways to continue to apply this metaphor.

**1:39PM B55.00005 Principles of Virus-Microbe Dynamics: From Ecology to Evolution and Back Again** , JOSHUA WEITZ, Georgia Institute of Technology — Viruses are ubiquitous in the environment and can function like microbial predators, regulating the density and diversity of microbes present in a community. However, efforts to understand the dynamics of complex virus-microbe communities remain in their infancy. In this talk, I present examples of the interplay between evolutionary and ecological dynamics arising due to virus-microbe interactions. I begin by introducing canonical models of virus-microbe population dynamics in the context of observed oscillations of *E. coli* and associated phage. I then present a series of examples in which novel features observed in time series data arising from phage interactions with *E. coli* and *V. cholerae* can be understood when considering both population and evolutionary dynamics together. I conclude by presenting our recent efforts to extend the results of laboratory experiments to an environmental context, with significantly higher diversity of both viruses and microbes. Despite this increase in diversity, I show how network theoretic methods can reveal common principles underlying the dynamic coexistence of complex virus and host communities. Building on these findings, I describe new efforts to infer who infects whom directly from time series of multi-strain communities.

**2:30PM C1.00001 Frustrated Magnetism and Superconductivity in the Iron Chalcogenides<sup>1</sup>** ,

QIMIAO SI, Rice Univ — While studies in the early stage on the iron-based superconductors (FeSCs) focused on the iron pnictides, considerable efforts in the more recent past have also been directed towards iron chalcogenides. These studies are giving us renewed hope for even higher transition temperatures in the iron-based materials. In this talk, I will discuss several theoretical issues on the microscopic physics of the iron chalcogenides that teach us much about the overall physics of the FeSCs. One is the proposal we made on the orbital selective Mott phase [1], for which considerable evidence has come from ARPES [2] and other experiments. The second issue concerns magnetism, in particular the correlation-induced magnetic frustration effect. A major puzzle arises in bulk FeSe, which shows a structural phase transition similar to that seen in the iron pnictides but, unlike the latter, does not exhibit any static antiferromagnetic order. We studied the effect of magnetic frustration associated with the bilinear-biquadratic spin-exchange interactions [3]. Based on the derived phase diagram, we proposed that the structural transition in FeSe originates from an Ising-nematic order of an antiferro-quadrupolar phase. Within this picture, we have predicted that the collective modes of this quadrupolar state show  $(\pi, 0)$  magnetic fluctuations, which have since been verified by inelastic neutron scattering experiments [4]. These results considerably expand on the notion [5] regarding the importance of the bad-metal behavior, and provide a substantially broadened perspective on the magnetic and nematic correlations in the FeSCs. Finally, implications of the frustrated magnetism for superconductivity [5] will also be discussed. References: [1] R. Yu and Q. Si, Phys. Rev. Lett. 110, 146402 (2013). [2] M. **3:06PM C1.00002 On nematicity, magnetism and superconductivity in FeSe<sup>1</sup>** , ANNA BÖHMER, Ames

Laboratory, U.S. Department of Energy, Iowa State University, Ames, Iowa 50011 — FeSe is unique among iron-based superconductors, notably regarding the interrelationships of structure, magnetism, and superconductivity. At ambient pressure, FeSe exhibits a tetragonal-to-orthorhombic (nematic) phase transition at  $T_s = 90$  K, similar to other iron-based materials, but unlike them, no long-range magnetic order. One consequence is the unique possibility to study the in-plane resistivity anisotropy, arguably the most investigated nematic property, without interfering effects from the Fermi surface reconstruction induced by antiferromagnetic order. Recent findings pose the question whether nematicity in FeSe is driven by magnetic fluctuations, as often assumed in other iron-based systems. In particular, magnetic fluctuations, which are prominent at low temperatures, are not observed above  $T_s$  in FeSe by NMR [1,2], even though indicated by inelastic neutron scattering. The pressure-temperature phase diagram, recently obtained in new comprehensiveness using vapor-grown single crystals [3], shows that the structural transition is suppressed at 2 GPa and a new, likely magnetic phase is stabilized above 0.8 GPa, where  $T_c$  has a local maximum. Various theoretical scenarios have been proposed to explain this nematic transition far away from the magnetic order. Surprisingly, the degree of the orthorhombic distortion does not decrease below the superconducting transition at  $T_c = 8$  K, suggesting that nematic and superconducting channels do not compete [4]. Our new results on the superconducting state under pressure, show a non-monotonic pressure dependence of the upper critical field, which is well explained by the Fermi surface evolution. Further, we have successfully detwinned FeSe crystals and measured the in-plane resistivity anisotropy and elastoresistivity coefficients and compared them with model calculations of inelastic scattering from spin fluctuations. **3:42PM C1.00003 What Makes the  $T_c$  of FeSe/SrTiO<sub>3</sub> so High ?<sup>1</sup>**, DUNG-HAI LEE, Department of Physics, University of California, Berkeley — Raising the superconducting transition temperature to a point where applications are practical is one of the most important challenges in science. In the history of high  $T_c$  superconductivity there are two landmark events: the discovery of copper-oxide superconductor in 1986, and the discovery of iron-based superconductor in 2006. For the Fe-based superconductors the record of  $T_c$  was 55 K [1] until 2012. In the interface system composed of an one unit cell thick FeSe film grown on the TiO<sub>2</sub> terminated (001) surface of SrTiO<sub>3</sub> an anomalously large superconducting-like energy gap was seen by scan tunneling microscopy for [2]. Later ARPES works show the gap opening temperature can reach nearly the liquid nitrogen boiling temperature [3-7]. More recently several FeSe-related bulk and thin film high  $T_c$  systems have been discovered. This talk reviews some of the recent experimental [7] and theoretical [8] progresses in the study of the mechanism for high temperature superconductivity in this interface system. It offers the author's personal view of why  $T_c$  is so high and how to further increase it [910]. References:

**4:18PM C1.00004 What makes the nematic phase of FeSe different than other iron-based superconductors?**<sup>1</sup>, RAFAEL FERNANDES, University of Minnesota — Most iron-based superconductors display, in their normal state, a transition to a magnetic stripe state that is either accompanied or preceded by a tetragonal-to-orthorhombic transition. The proximity between these two transitions has led to the proposal that they correspond to a two-stage melting of the magnetic stripe state, resulting in a vestigial orthorhombic-paramagnetic nematic phase. Despite the success of this scenario to describe many iron-based materials, the simplest of them, FeSe, displays a high-temperature nematic transition but no long-range magnetic order. Interestingly, in its monolayer form, FeSe displays the highest  $T_c$  of all iron-based materials, raising the question of whether the nematic state of its bulk form could be related to the superconducting state of its monolayer form. In this talk, we investigate theoretically the microscopic origin of the nematic phase of FeSe. By extending the standard RPA formalism, we compare the orbital-order susceptibility and the spin-driven nematic susceptibility of a generic multi-orbital Hubbard model. We find that the former cannot in general drive the nematic transition, and that high-energy magnetic fluctuations play a fundamental role in stabilizing the nematic state in the absence of long-range magnetic order. Focusing on FeSe, we identify two features that distinguish it from all other iron-based materials: a very small Fermi energy and a large degeneracy of the magnetic ground state. We show that both effects enhance the nematic transition temperature at the same time as they suppress the magnetic transition. These results may explain why, in FeSe, the onset of nematic order does not require strong magnetic fluctuations, in contrast to other iron-based materials. Finally, we discuss how the interplay between magnetic fluctuations and small Fermi energy in FeSe can lead to the emergence of different types of Pomeranchuk instabilities, and discuss their experimental manifestations.

**4:54PM C1.00005 Tuning the electronic structure of bulk FeSe with chemical pressure using quantum oscillations and angle resolved photoemission spectroscopy (ARPES)**, AMALIA COLDEA, University of Oxford — FeSe is a unique and intriguing superconductor which can be tuned into a high temperature superconducting state using applied pressure, chemical intercalation and surface doping. In the absence of magnetism, the structural transition in FeSe is believed to be electronically driven, with the orbital degrees of freedom playing an important part [1]. This scenario supports the stabilization of a nematic state in FeSe, which manifests as a Fermi surface deformation in the presence of strong interactions, as detected by ARPES [1]. Another manifestation of the nematicity is the enhanced nematic susceptibility determined from elastoresistance measurements under applied strain [1]. Isovalent Sulphur substitution onto the Selenium site constitutes a chemical pressure, which subtly modifies the electronic structure of FeSe, suppressing the structural transition without inducing high temperature superconductivity [3]. I will present the evolution of the electronic structure with chemical pressure in FeSe, as determined from quantum oscillations [1,2] and ARPES studies [3] and I will discuss the suppression of the nematic electronic state and the role of electronic correlations. Experiments were performed at high magnetic field facilities in Tallahassee, Nijmegen and Toulouse and Diamond Light Source, UK. This work is mainly supported by EPSRC, UK (EP/I004475/1, EP/I017836/1) and I acknowledge my collaborators from Refs. [1-3]. [1] Phys. Rev. B **91**, 155106 (2015); [2] Phys. Rev. **2:30PM C2.00001 Creating and Probing Graphene Electron Optics with Local Scanning Probes<sup>1</sup>**, JOSEPH STROSCIO, Center for Nanoscale Science and Technology, NIST, Gaithersburg, MD 20899 — Ballistic propagation and the light-like dispersion of graphene charge carriers make graphene an attractive platform for optics-inspired graphene electronics where gate tunable potentials can control electron refraction and transmission. In analogy to optical wave propagation in lenses, mirrors and metamaterials, gate potentials can be used to create a negative index of refraction for Veselago lensing and Fabry-Pérot interferometers. In circular geometries, gate potentials can induce whispering gallery modes (WGM), similar to optical and acoustic whispering galleries [1] albeit on a much smaller length scale. Klein scattering of Dirac carriers plays a central role in determining the coherent propagation of electron waves in these resonators. In this talk, I examine the probing of electron resonators in graphene confined by linear and circular gate potentials with the scanning tunneling microscope (STM). The tip in the STM tunnel junction serves both as a tunable local gate potential, and as a probe of the graphene states through tunneling spectroscopy. A combination of a back gate potential,  $V_g$ , and tip potential,  $V_b$ , creates and controls a circular pn junction that confines the WGM graphene states. The resonances are observed in two separate channels in the tunneling spectroscopy experiment: first, by directly tunneling into the state at the bias energy  $eV_b$ , and, second, by tunneling from the resonance at the Fermi level as the state is gated by the tip potential. The second channel produces a fan-like set of WGM peaks, reminiscent of the fringes seen in planar geometries by transport measurements. The WGM resonances split in a small applied magnetic field, with a large energy splitting approaching the WGM spacing at 0.5 T. These results agree well with recent theory on Klein scattering in graphene electron resonators [2]. [1]. Y. Zhao, J. Wyrick, F. D. Natterer, J. F. **3:06PM C2.00002 Electronic Veselago lensing in graphene PN junctions.**, CORY DEAN, Columbia University — Ballistic electrons in a uniform 2D electron gas (2DEG) behave in close analogy to light propagating through an optical medium. In the absence of impurity scattering, electrons follow straight-line trajectories, while the associated de Broglie wavelength can give rise to interference and diffraction. Here we present measurements of ballistic graphene devices in which a graphite gate is used to realize an atomically-smooth junction. We demonstrate unambiguous signatures of negative refraction across a PN junction, paving the way for electron optics inspired by Veselago lensing. Comparison with theoretical simulations reveals the importance of the junction profile towards this effort. Opportunities for future device designs that may take advantage of these effects will be discussed.

**4:18PM C2.00004 Observation of the hydrodynamic Dirac fluid and the breakdown of the Wiedemann-Franz law in graphene<sup>1</sup>**, KIN CHUNG FONG, Raytheon BBN Technology — Interactions between particles in quantum many-body systems can lead to collective behavior described by hydrodynamics. One such system is the electron-hole plasma in graphene near the charge neutrality point which can form a strongly coupled Dirac fluid. This charge neutral plasma of quasi-relativistic fermions is expected to exhibit a substantial enhancement of the thermal conductivity, due to decoupling of charge and heat currents within hydrodynamics. Employing high sensitivity Johnson noise thermometry, we report the breakdown of the Wiedemann-Franz law in graphene, with a thermal conductivity an order of magnitude larger than the value predicted by Fermi liquid theory. This result is a signature of the Dirac fluid, and constitutes direct evidence of collective motion in a quantum electronic fluid. This research is performed in collaboration with J. Crossno, J. K. Shi, K. Wang, X. Liu, A. Harzheim, A. Lucas, S. Sachdev, P. Kim, T. Taniguchi, K. Watanabe, and T. A. Ohki.

**4:54PM C2.00005 Negative local resistance due to viscous electron backflow in graphene**, DENIS BANDURIN, School of Physics and Astronomy, University of Manchester, Manchester M13 9PL, UK — Theoretical and experimental studies of systems in which particles undergo frequent mutual collisions date back to more than two centuries ago. Transport in such systems is described by hydrodynamic theory that was found very successful in explaining the response of classical liquids and gases to external fields. It has been argued for a long time that collective behavior of charge carriers in solids can be also described by hydrodynamic approach. However, there has been almost no direct evidence to hydrodynamic electron transport so far. This is because the conditions at which the hydrodynamic effects become observable are very strict: the electron-electron scattering length should provide the shortest spatial scale in the problem. First of all, this requires ultra clean systems where the scattering at impurities is diminished. Second, the electron-phonon scattering rate should be smaller than that of electron-electron scattering. Due to weak electron-phonon coupling high mobility graphene devices offer an ideal system to study electron hydrodynamics. To amplify the hydrodynamic effects we employed a special measurement geometry. The idea is that in case of hydrodynamic electron flow, vortices emerge in the spatial electric current distribution near the current injection contact. That results in a development of a negative voltage drop at the nearby contacts. We were able to detect such negative signal over the range of temperatures when the electronic system is in a hydrodynamic regime. Finally, we performed a rheological study of electron liquid in graphene. The electron viscosity was found to be an order of magnitude larger than that of honey which is in good agreement with many-body calculation.

**2:30PM C3.00001 Electrical switching of an antiferromagnet<sup>1</sup>**, TOMAS JUNGWIRTH, Institute of Physics, Academy of Sciences of the Czech Republic and University of Nottingham UK — Louis Néel pointed out in his Nobel lecture that while abundant and interesting from theoretical viewpoint, antiferromagnets did not seem to have any applications. Indeed, the alternating directions of magnetic moments on individual atoms and the resulting zero net magnetization make antiferromagnets hard to control by tools common in ferromagnets. Strong coupling would be achieved if the externally generated field had a sign alternating on the scale of a lattice constant at which moments alternate in AFMs. However, generating such a field has been regarded unfeasible, hindering the research and applications of these abundant magnetic materials. We have recently predicted that relativistic quantum mechanics may offer staggered current induced fields with the sign alternating within the magnetic unit cell which can facilitate a reversible switching of an antiferromagnet by applying electrical currents with comparable efficiency to ferromagnets. Among suitable materials is a high Néel temperature antiferromagnet, tetragonal-phase CuMnAs, which we have recently synthesized in the form of single-crystal epilayers structurally compatible with common semiconductors. We demonstrate electrical writing and read-out, combined with the insensitivity to magnetic field perturbations, in a proof-of-concept antiferromagnetic memory device. References: [1] J. **3:06PM C3.00002 Interconnections between magnetic state and transport currents in anti-ferromagnetic  $\text{Sr}_2\text{IrO}_4$** , MAXIM TSOI, The University of Texas at Austin — Interconnections between magnetic state and transport currents in ferromagnetic (F) heterostructures are the basis for spintronic applications, e.g. tunneling magnetoresistance and spin-transfer torque phenomena provide a means to read and write information in magnetic memory devices like STTMRAM. Similar interconnections were proposed [1] to occur in systems where F-components are replaced with antiferromagnets (AFM). We demonstrated experimentally the existence of such interconnections in antiferromagnetic Mott insulator  $\text{Sr}_2\text{IrO}_4$ : first, we found [2] a very large anisotropic magnetoresistance (AMR) which can be used to monitor (read) the magnetic state of AFM; second, we demonstrated [3] the feasibility of reversible resistive switching driven by high-density currents/high electric fields which can be used for writing in AFM memory applications. These results support the feasibility of AFM spintronics where antiferromagnets are used in place of ferromagnets. This work was supported in part by C-SPIN, one of six centers of STARnet, a Semiconductor Research Corporation program, sponsored by MARCO and DARPA, and by NSF grants DMR-1207577, DMR-1265162 and DMR-1122603. **3:42PM C3.00003 Spin-Hall effects in metallic antiferromagnets.**<sup>1</sup>, WEI ZHANG, Argonne National Laboratory — Materials possessing new parameters for efficient and tunable spin Hall effects are being explored, among which antiferromagnets have become one of the most promising candidates. Two distinct properties of antiferromagnets are the microscopic spin magnetic moment ordering and the intrinsic anisotropy. Thus the natural question arises whether these two unique features of antiferromagnets can become new degrees of freedom for tuning their spin Hall effects. We performed experimental studies using spin pumping and inverse spin Hall detection on prototypical CuAu-I-type metallic antiferromagnets, PtMn, IrMn, PdMn, and FeMn, in which we observed increasing spin Hall effects for the alloys with heavier elements included<sup>2</sup>. In particular, PtMn shows a large spin Hall effect that is comparable to Pt. We also demonstrated that the spin transfer torques from the antiferromagnets are large enough to excite ferromagnetic resonance of an adjacent ferromagnetic layer. We conclude that the sign and magnitude of the spin Hall effects in these antiferromagnets are determined by the atomic spin-orbit coupling of the heavy elements (e.g. Pt and Ir) as well as the large spin magnetic moments of Mn. In addition, by using epitaxial growth, we investigated the influence of the different crystalline and magnetic orientations on the anisotropic spin Hall effects of these antiferromagnets. Most of the experimental results were further corroborated by first-principles calculations, which determine the intrinsic spin Hall effect contribution and suggest pronounced anisotropies. Thus metallic antiferromagnets may become an active component for manipulating spin dependent transport properties in spintronic concepts<sup>3</sup>.

**4:18PM C3.00004 Spin Transport by Collective Spin Excitations**<sup>1</sup>, P CHRIS HAMMEL, Ohio State University — We report studies of angular momentum transport in insulating materials. Our measurements reveal efficient spin pumping from high wavevector  $k$  spin waves in thin film  $\text{Y}_3\text{Fe}_5\text{O}_{12}$  (YIG): spin pumping is independent of wavevector up to  $k \sim 20 \mu\text{m}^{-1}$  [1]. Optical detection of YIG FMR by NV centers in diamond reveals a role for spin waves in this insulator-to-insulator spin transfer process [2]. Spin transport is typically suppressed by insulating barriers, but we find that fluctuating antiferromagnetic correlations enable efficient spin transport at nm-scale thicknesses in insulating antiferromagnets, even in the absence of long-range order, and that the spin decay length increases with the strength of the antiferromagnetic correlations [3,4]. **4:54PM C3.00005 Mechanism of spin current transfer through antiferromagnetic dielectrics**, VASYL TYBERKEVYCH, Oakland University — The mechanisms of spin current (SC) transfer are well-studied in both metallic systems, where SC is carried mostly by spin-polarized electrons, and in ferromagnetic (FM) dielectrics, where propagating spin waves (magnons) are responsible for the spin transfer. The possibility of SC transfer through *antiferromagnetic dielectrics* (AFMD) is much less investigated, although recent experimental studies by H. Wang *et al.* [H. Wang *et al.*, Phys. Rev. Lett. 113, 097202 (2014)] demonstrated extraordinary high efficiency of SC transfer in tri-layer FM-AFMD-Platinum (YIG-NiO-Pt) systems measured by the inverse spin Hall effect (ISHE). Perhaps the most unexpected result of these studies was that, with the increase of the thickness of the AFMD layer, the ISHE voltage, first, *increased*, and, then, exponentially decayed with the characteristic decay length of  $\lambda \sim 10$  nm. Moreover, the excitation frequency, equal to the ferromagnetic resonance (FMR) frequency of the YIG layer, was rather low compared to the frequencies of the antiferromagnetic resonance in the AFMD, which rules out the eigenmodes of the AFMD layer as potential carriers of the spin current. Here we propose a possible mechanism of SC transfer through the AFMD with a biaxial anisotropy, which explains all previous experimental findings and opens a new way of manipulating spin currents using anisotropic AFMD materials. We show, that spin current can be carried by *evanescent* AFMD modes non-resonantly excited at the FM-AFMD interface. The decay length of the evanescent modes is defined by the AFMD anisotropy and determines the SC penetration depth into the AFMD. Furthermore, the anisotropy of the AFMD leads to the coupling between the spin subsystem and the crystal lattice of the AFMD, which makes possible exchange of angular momentum between these subsystems. We demonstrate that, under certain realistic conditions, the angular momentum flows from the lattice to the spin subsystem, in which case the AFMD layer acts as a *spin current amplifier*. The enhancement or the suppression of the spin current by the AFMD lattice depends on the phase shift between the two evanescent AFMD modes and, thus, can be controlled by the method of excitation.

**Session C4 DCOMP DPOLY FIAP: Bridging Time and Length Scales: From Nano Assemblies to Bio-Polymers** Ballroom IV - Dvora Perahia, Clemson University

**2:30PM C4.00001 Going up in time and length scales in modeling polymers**, GARY S. GREEST, Sandia National Laboratories — Polymer properties depend on a wide range of coupled length and time scales, with unique macroscopic viscoelastic behavior stemming from interactions at the atomistic level. The need to probe polymers across time and length scales and particularly computational modeling is inherently challenging. Here new paths to probing long time and length scales including introducing interactions into traditional bead-spring models and coarse graining of atomistic simulations will be compared and discussed. Using linear polyethylene as a model system, the degree of coarse graining with two to six methylene groups per coarse-grained bead derived from a fully atomistic melt simulation were probed. We show that the degree of coarse graining affects the measured dynamic. Using these models we were successful in probing highly entangled melts and were able reach the long-time diffusive regime which is computationally inaccessible using atomistic simulations. We simulated the relaxation modulus and shear viscosity of well-entangled polyethylene melts for scaled times of 500 s. Results for plateau modulus are in good agreement with experiment. The long time and length scale is coupled to the macroscopic viscoelasticity where the degree of coarse graining sets the minimum length scale instrumental in defining polymer properties and dynamics. Results will be compared to those obtained from simple bead-spring models to demonstrate the additional insight that can be gained from atomistically inspired coarse grained models. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energys National Nuclear Security Administration under contract DE-AC04-94AL85000.

**3:06PM C4.00002 Multi-scale modelling and dynamics**, FLORIAN MLLER-PLATHE, Technische Universitt Darmstadt, Germany, and Princeton University USA — Moving from a fine-grained particle model to one of lower resolution leads, with few exceptions, to an acceleration of molecular mobility, higher diffusion coefficient, lower viscosities and more. On top of that, the level of acceleration is often different for different dynamical processes as well as for different state points. While the reasons are often understood, the fact that coarse-graining almost necessarily introduces unpredictable acceleration of the molecular dynamics severely limits its usefulness as a predictive tool. There are several attempts under way to remedy these shortcoming of coarse-grained models. On the one hand, we follow bottom-up approaches. They attempt already when the coarse-graining scheme is conceived to estimate their impact on the dynamics. This is done by excess-entropy scaling. On the other hand, we also pursue a top-down development. Here we start with a very coarse-grained model (dissipative particle dynamics) which in its native form produces qualitatively wrong polymer dynamics, as its molecules cannot entangle. This model is modified by additional temporary bonds, so-called slip springs, to repair this defect. As a result, polymer melts and solutions described by the slip-spring DPD model show correct dynamical behaviour. Read more: "Excess entropy scaling for the segmental and global dynamics of polyethylene melts", E. Voyiatzis, F. Müller-Plathe, and M.C. Böhm, Phys. Chem. Chem. Phys. **16**, 24301–24311 (2014). [DOI: 10.1039/C4CP03559C] "Recovering the Reptation Dynamics of Polymer Melts in Dissipative Particle Dynamics Simulations via Slip-Springs", M. Langeloth, Y. Masubuchi, M. C. Böhm, and F. Müller-Plathe, J. Chem. Phys. **138**, 104907 (2013). [DOI: 10.1063/1.4794156].

**3:42PM C4.00003 Role of Ionic Clusters in Dynamics of Ionomer Melts: From Atomistic to Coarse Grained Simulations<sup>1</sup>**, ANUPRIYA AGRAWAL, Research Assistant Professor, Washington University in St. Louis — Ionomers, polymers decorated with ionizable groups, have found application in numerous technologies where ionic transport is required. The ionic groups associate into random clusters resulting in substantial effect on structure, dynamics and transport of these materials. The effects of topology, size and dynamics of these aggregates however remain an open question. Here we probe cluster formation correlated with polymer dynamics through a model system of randomly sulfonated polystyrene (SPS) melts with molecular dynamics (MD) simulations over a broad time and length scales ranging from that within the ionic clusters through polymer segmental dynamics to the motion of the entire molecules. The cluster evolution was probed by fully atomistic studies. We find ladder-like aggregates that transform to globule-like with increasing the dielectric constant of media for sodium neutralized SPS. With increasing dielectric constant, the size of the aggregates decrease and their number increases. Concurrently, the mobility of the polymer increases. The counterion radius and valency affect both morphology and dynamics as is evident in the calculated static and dynamic structure factors. It is further manifested in the results of viscosity obtained through non-equilibrium molecular dynamics technique. Finally, to access larger length scales a three bead coarse-grained model to describe sulfonated styrene that we have developed will be discussed in view of the outstanding challenges in ionic polymers.

**4:18PM C4.00004 Protein free energy landscapes from long equilibrium simulations**, STEFANO PIANA-AGOSTINETTI, D.E. Shaw Research — Many computational techniques based on molecular dynamics (MD) simulation can be used to generate data to aid in the construction of protein free energy landscapes with atomistic detail. Unbiased, long, equilibrium MD simulations—although computationally very expensive—are particularly appealing, as they can provide direct kinetic and thermodynamic information on the transitions between the states that populate a protein free energy surface. It can be challenging to know how to analyze and interpret even results generated by this direct technique, however. I will discuss approaches we have employed, using equilibrium MD simulation data, to obtain descriptions of the free energy landscapes of proteins ranging in size from tens to thousands of amino acids.

**4:54PM C4.00005 Electrostatic Interactions and Self-Assembly in Polymeric Systems<sup>1</sup>**, ANDREY DOBRYNIN, Univ of Akron — Electrostatic interactions between macroions play an important role in different areas ranging from materials science to biophysics. They are main driving forces behind layer-by-layer assembly technique that allows self-assembly of multilayer films from synthetic polyelectrolytes, DNA, proteins and nanoparticles. They are responsible for complexation and reversible gelation between polyelectrolytes and proteins. In this talk, using results of the molecular dynamics simulations and analytical calculations, I will demonstrate what effect electrostatic interactions, counterion condensation and polymer solvent affinity have on a collapse of polyelectrolyte chain in a poor solvent conditions for the polymer backbone, on complexations and reversible gelation between polyelectrolytes and polyampholytes (unstructured proteins), on microphase separation transitions in spherical and planar charged brushes, and on a layer-by-layer assembly of charged nanoparticles and linear polyelectrolytes on charged surfaces.

**Session C5 GMAG DMP: Frustrated Magnetism: Theory** 301 - Gang Chen, Fudan University

**2:30PM C5.00001 Functional renormalization group - a new approach to frustrated quantum magnetism**, JOHANNES REUTHER, Freie Universitaet Berlin — The experimental and theoretical investigation of quantum spin systems has become one of the central disciplines of contemporary condensed matter physics. From an experimental viewpoint, the field has been significantly fueled by the recent synthesis of novel strongly correlated materials with exotic magnetic or quantum paramagnetic ground states. From a theoretical perspective, however, the numerical treatment of realistic models for quantum magnetism in two and three spatial dimensions still constitutes a serious challenge. This particularly applies to frustrated systems, which complicate the employment of established methods. This talk intends to propagate the pseudofermion functional renormalization group (PFFRG) as a novel approach to determine large size ground state correlations of a wide class of spin Hamiltonians. Using a diagrammatic pseudofermion representation for quantum spin models, the PFFRG performs systematic summations in all two-particle fermionic interaction channels, capturing the correct balance between classical magnetic ordering and quantum fluctuations. Numerical results for various frustrated spin models on different 2D and 3D lattices are reviewed, and benchmarked against other methods if available.

**3:06PM C5.00002 Filling constraints for spin-orbit coupled insulators in symmorphic and non-symmorphic crystals**, HARUKI WATANABE, Massachusetts Institute of Technology, HOI CHUN PO, ASHVIN VISHWANATH, UC Berkeley, MICHAEL ZALATEL, Station Q — We determine conditions on the filling of electrons in a crystalline lattice to obtain the equivalent of a band insulator - a gapped insulator with neither symmetry breaking nor fractionalized excitations. We allow for strong interactions, which precludes a free particle description. Previous approaches that extend the Lieb-Schultz-Mattis argument invoked spin conservation in an essential way, and cannot be applied to the physically interesting case of spin-orbit coupled systems. Here we introduce two approaches, the first an entanglement based scheme, while the second studies the system on an appropriate flat Bieberbach manifold to obtain the filling conditions for all 230 space groups. These approaches only assume time reversal rather than spin rotation invariance. The results depend crucially on whether the crystal symmetry is symmorphic. Our results clarify when one may infer the existence of an exotic ground state based on the absence of order, and we point out applications to experimentally realized materials. Extensions to new situations involving purely spin models are also mentioned.

**3:18PM C5.00003 Quantum Dimer Model: Phase Diagrams**, GARRY GOLDSTEIN, Cambridge University, CLAUDIO CHAMON, Boston university, CLAUDIO CASTELNOVO, Cambridge University — We present new theoretical analysis of the Quantum Dimer Model. We study dimer models on square, cubic and triangular lattices and we reproduce their phase diagrams (which were previously known only numerically). We show that there are several types of dimer liquids and solids. We present preliminary analysis of several other models including doped dimers and planar spin ice, and some results on the Kagome and hexagonal lattices.

**3:30PM C5.00004 Characterizing excitation statistics in fractionalized phases through spectral functions**, SIDDHARDH C. MORAMPUDI, FRANK POLLMANN, Max Planck Institute for the Physics of Complex Systems, Dresden, Germany, ARI M. TURNER, Johns Hopkins University, Baltimore, USA — Characterizing topologically ordered phases of matter involves identifying the statistics of their emergent anyonic excitations. We show that the exchange statistics of excitations show characteristic signatures in experimentally relevant spectral functions. Drawing motivation from models of gapped quantum spin liquids and fractional Chern insulators which possess fractionalized anyonic excitations, we consider a model with gapped two particle and three particle abelian anyonic excitations. We show that the low energy part of spectral functions can show a robust behaviour from which the statistics of the excitations can be obtained.

**3:42PM C5.00005 From Möbius aromaticity to gapped spin liquids**, CHENG-CHIEN CHEN, Argonne National Laboratory, LUKAS MUECHLER, TITUS NEUPERT, Princeton University, JOSEPH MACIEJKO, University of Alberta, ROBERTO CAR, Princeton University — Motivated by the concept of Mobius aromatics in organic chemistry, the Hubbard model on ring-shaped molecules has been shown previously to support a fragile Mott insulator (FMI) ground state, which is distinct from a conventional insulator through its nontrivial transformation properties under point-group symmetry operations. In this talk, we discuss two-dimensional lattices of weakly-coupled FMI molecules belonging to multi-dimensional irreducible representations of the molecular point group. The low-energy effective Hamiltonians map onto quantum compass models with broken spin SU(2) symmetry. On the triangular lattice, the ground state develops long-range magnetism, which corresponds to a charge-ordered state of the molecules. On the honeycomb lattice, interestingly, we find a non-degenerate gapped spin-liquid ground state that preserves all spatial symmetries but transforms nontrivially under point-group operations. Our microscopic model therefore realizes an intrinsically interacting fermionic symmetry protected topological (SPT) phase.

**3:54PM C5.00006 Tetrahedral Spin Crystal to a Chiral Spin Liquid: Frustration-induced quantum melting**, ARUN PARAMAKANTI, CIARAN HICKEY, University of Toronto, LUKASZ CINCIO, Perimeter Institute, ZLATKO PAPIC, University of Leeds — Motivated by the recent interest in interacting topological phases, we study the Haldane-Hubbard model which is shown to host a Mott insulating state with chiral tetrahedral magnetic texture. Frustration-induced melting of this spin crystal leads to a chiral spin liquid. We discuss the properties of these phases, and the Chern-Simons-Higgs theory of the intervening exotic quantum critical point.

**4:06PM C5.00007 Symmetric tensor networks and practical simulation algorithms to sharply identify classes of quantum phases distinguishable by short-range physics<sup>1</sup>**, YING RAN, SHENGHAN JIANG, Boston College — Phases of matter are sharply defined in the thermodynamic limit. One major challenge of accurately simulating quantum phase diagrams of interacting quantum systems is due to the fact that numerical simulations usually deal with the energy density, a local property of quantum wavefunctions, while identifying different quantum phases generally rely on long-range physics. In this paper we construct generic fully symmetric quantum wavefunctions under certain assumptions using a type of tensor networks: projected entangled pair states, and provide practical simulation algorithms based on them. We find that quantum phases can be organized into crude classes distinguished by short-range physics, which is related to the fractionalization of both on-site symmetries and space-group symmetries. Consequently, our simulation algorithms, which are useful to study long-range physics as well, are expected to be able to sharply determine crude classes in interacting quantum systems efficiently. Examples of these crude classes are demonstrated in half-integer quantum spin systems on the kagome lattice. Limitations and generalizations of our results are discussed.

**4:18PM C5.00008 Numerical studies of AKLT valence bond solids in one, two and three dimensions**, KEOLA WIERSCHEM, KEVIN BEACH, The University of Mississippi — The fixed-point valence bond solids of Affleck, Kennedy, Lieb and Tasaki (the so-called AKLT states) have become archetypes of symmetry protected topological order. These states are constructed by first placing  $M$  valence bonds on each pair of neighboring lattice points, and then symmetrizing the  $Mz$  resulting spin-1/2 degrees of freedom at each lattice site into a combined spin- $S$  degree of freedom with  $2S = Mz$  (where  $M$  is the multiplicity of the AKLT state and  $z$  is the lattice coordination number). Using Monte Carlo sampling of the AKLT wavefunctions in the loop gas framework, we directly calculate correlation functions and energy gap estimators for these states in one, two and three dimensions. We also study the behavior of the so-called strange correlator, which has been proposed as a measure of symmetry protected topological order.

**4:30PM C5.00009 Theory of supersymmetry “protected” topological phases of isostatic lattices and highly frustrated magnets**, MICHAEL LAWLER, Binghamton University — I generalize the theory of phonon topological band structures of isostatic lattices to highly frustrated antiferromagnets. I achieve this with a discovery of a many-body supersymmetry (SUSY) in the phonon problem of balls and springs which also applies to geometrically frustrated magnets. The Witten index of the SUSY model, when restricted to the single body problem (meaningful for linearized phonons), is then shown to be the Calladine-Kane-Lubensky index of mechanical structures that forms the cornerstone of the phonon topological band structure theory. “Spontaneous supersymmetry breaking” is then identified as the need to gap all modes in the bulk to create the topological state. The many-body SUSY formulation shows that the topology is not restricted to a band structure problem but extends to systems of coupled bosons and fermions that are in principle also realizable in solid state systems. The analogous supersymmetry of the magnon problem turns out to be particularly useful for highly frustrated magnets with the kagome family of antiferromagnets an analog of topological isostatic lattices. Thus, a solid state realization of the theory of phonon topological band structure may be found in highly frustrated magnets. However, our results show that this topology is protected not

**4:42PM C5.00010 Non-Kondo Mechanism of Resistivity Minimum in Frustrated Itinerant Magnets**, CRISTIAN BATISTA, T-Division and CNLS, Los Alamos National Laboratory, ZHENTAO WANG, Department of Physics and Astronomy, Rice University, KIPTON BARROS, T-Division and CNLS, Los Alamos National Laboratory, GIA-WEI CHERN, Department of Physics, University of Virginia — Frustration can induce novel phenomena in the transport properties of itinerant magnets. The "amount of frustration" is typically quantified by the  $|\Theta_{CW}|/T_C$  ratio. A large value of this ratio corresponds to a broad temperature regime  $T_C < T < \Theta_{CW}$ , where the spins are in spin liquid state, i.e., the magnetic structure factor is not flat, as in the gas ( $T > \Theta_{CW}$ ) state and it does not contain Bragg peaks, as in the ordered or "solid" state at  $TT_C$ . We demonstrate that when interaction between magnetic moments is mediated by the conduction electrons, the electronic resistivity increases upon lowering temperature, due to enhanced scattering rate for  $k \leq 2k_F$ . To illustrate this phenomenon we consider a triangular Kondo lattice model with classical local moments. By using both analytical and numerical methods, we unambiguously demonstrate that the electronic resistivity grows upon lowering temperature inside the spin liquid regime. This growth necessarily leads to a resistivity minimum when electron-electron and electron-phonon scattering are included. We note that the origin of this resistivity minimum is radically different from the well-known minimum induced by the Kondo effect.

**4:54PM C5.00011 Vortex Crystals with Chiral Stripes in Itinerant Magnets**, RYO OZAWA, Dept. of Appl. Phys., Univ. of Tokyo, SATORU HAYAMI, KIPTON BARROS, Theoretical Division and CNLS, Los Alamos National Lab., GIA-WEI CHERN, Dept. of Phys., Univ. of Virginia, YUKITOSHI MOTOME, Dept. of Appl. Phys., Univ. of Tokyo, CRISTIAN D. BATISTA, Theoretical Division and CNLS, Los Alamos National Lab. — Noncoplanar spin textures in itinerant magnets are generating increasing interest because of the associated spin Berry phase, which induces a tremendous effective magnetic field on the itinerant electrons. Such noncoplanar spin textures appear frequently in itinerant magnets, even with vanishingly small spin-orbit coupling. We explore a generic condition for noncoplanar spin ordering, with a focus on "frustration" in itinerant magnets, that is characterized by multiple global maxima in the magnetic susceptibility. In a simple square Kondo lattice model, we find that a noncoplanar vortex-antivortex crystal with a one-dimensional modulation of spin scalar chirality becomes stable in a wide range of electron filling fraction [1]. The unexpected result is obtained by careful analyses of higher-order terms in the perturbative expansion in terms of the Kondo exchange coupling and the degree of noncoplanarity, as well as numerical simulation based on the Langevin and stochastic Landau-Lifshitz-Gilbert dynamics with the kernel polynomial method. [1] R. Ozawa, S. Hayami, K. Barros, G.-W. Chern, Y. Motome, and C. D. Batista, preprint (arXiv:1510.06830).

**5:06PM C5.00012 Lifting mean field degeneracies in anisotropic spin systems<sup>1</sup>**, YURIY SIZYUK, NATALIA PERKINS, Univ of Minn - Minneapolis, PETER WOLFLE, Karlsruhe Institute of Technology — We propose a method for calculating the fluctuation contribution to the free energy of anisotropic spin systems with generic bilinear superexchange magnetic Hamiltonian based on the Hubbard-Stratonovich transformation. We show that this contribution splits the set of mean field degenerate states with rotational symmetry, and chooses states with the order parameter directed along lattice symmetric directions as the true ground states. We consider the simple example of Heisenberg-compass model on cubic lattice to show that depending on the relative strength of the compass and Heisenberg interactions the spontaneous magnetization is pinned to either one of the cubic directions or one of the cubic body diagonals with a intermediate phase in between where the minima and maxima of the free energy interchange.

**2:30PM C6.00001 Exploring 360 domain walls in ferromagnetic nanostructures using circular magnetic fields<sup>1</sup>**, ANANDAKUMAR SARELLA, F. I. KAYA, K. E. AIDALA, Mt Holyoke Coll — Ferromagnetic nanostructures can exhibit intriguing magnetic states, such as the metastable 360 domain wall (DW), in which two 180 DWs combine to form a nearly flux closed state in sufficiently thin structures. These composite structures have potential to maximize storage densities due to their minimal stray fields. We study a straightforward method to nucleate 360 DWs in nanorings, nanowires, using in-plane circular fields, as if from a current carrying wire passing through the substrate in close proximity to the nanostructures. Our simulations, using OOMMF, predict that the vortex state of a ring with appropriate geometry will reverse from CW to CCW through an intermediate state consisting of pairs of 360 DWs. We examine the dependence of the switching field and intermediate states on geometric properties such as the diameter, thickness, and width of the ring. Using the local circular field, we can also nucleate 360 DWs in nanowires, pinning the location of the DWs at notches spaced as close as 100 nm apart, suggesting high density storage. We are currently studying these structures experimentally using AFM/MFM. We generate the circular field by passing current through AFM tip and image the resulting magnetic states with MFM.

**2:42PM C6.00002 Quantitative X-Ray Magnetic Microscopy: from parallel stripe domains to buried topological defects<sup>1</sup>**, MARIA VELEZ, C. BLANCO-ROLDAN, C. QUIROS, F. VALDES-BANGO, L. M. ALVAREZ-PRADO, J. I. MARTIN, J. M. ALAMEDA, Universidad de Oviedo-CINN, SPAIN, A. HIERRO-RODRIGUEZ, U. Porto, Portugal, M. DUCH, N. TORRAS, J. ESTEVE, IMB - CNM, CSIC, SPAIN, A. SORRENTINO, R. VALCARCEL, E. PEREIRO, S. FERRER, Alba Synchrotron, SPAIN — Magnetic transmission X-ray microscopy (TXM) is a powerful imaging technique that can produce element specific images of magnetic domains with nanometric lateral resolution. Here we present a novel imaging method in which the angular dependence of the magnetic contrast in a series of high resolution TXM images is used to obtain quantitative descriptions of the magnetization (canting angles and sense). This has been applied first to analyze parallel stripe domains in weak perpendicular anisotropy ferromagnetic NdCo<sub>5</sub> layers of different thickness, and in NdCo<sub>5</sub>/Permalloy bilayers. Then, our method has been used to identify complex topological defects (merons or 1/2 skyrmions) in a NdCo<sub>5</sub> film that are only partially replicated by the Permalloy overlayer [1]. Meron propagation in trilayers (across the thickness) and in hexagonal networks (across bifurcations) will be discussed in terms of their topological characteristics (chirality and polarity). [1] C. Blanco-Roldan et al. Nature Communications 6 (2015) 8196

**2:54PM C6.00003 Soft x-ray ptychography studies of nanoscale magnetic and structural correlations in thin SmCo5 films<sup>1</sup>**, P. FISCHER, MSD LBNL Berkeley CA 94720, X. SHI, ALS LBNL Berkeley CA 94720, V. NEU, D. ELEFANT, IFW Dresden Germany, J.C.T. LEE, D.A. SHAPIRO, M. FARMAND, T. TYLISZCZAK, W. SHIU, S. MARCHESINI, S. ROY, S.D. KEVAN, ALS LBNL Berkeley CA 94720 — Soft x-ray ptychographic imaging was applied to probe an amorphous 50 nm thin SmCo5 film prepared by off-axis pulsed laser deposition and exhibiting a strong perpendicular magnetic anisotropy. Amplitude and phase contrast images, retrieved at photon energies near the cobalt L3 resonance, were used to identify and characterize magnetic and structural features with a spatial resolution of about 10 nm. Aside from the common magnetic labyrinth domain pattern, nanoscale structural inclusions were identified that are primarily located in close proximity to the magnetic domain walls. X-ray absorption spectroscopy suggests that these inclusions are nanocrystalline Sm2Co17 phases with nominally in-plane magnetic anisotropy. Our results indicate that x-ray ptychographic imaging enables fruitful studies of magnetic and structural correlations at length scales relevant to emerging magnetic and spintronic devices.

### **3:06PM C6.00004 Asymmetric and Stochastic Behavior in Magnetic Vortices Studied by Soft X-ray Microscopy**

<sup>1</sup>, MI-YOUNG IM, LBNL — Asymmetry and stochasticity in spin processes are not only long-standing fundamental issues but also highly relevant to technological applications of nanomagnetic structures to memory and storage nanodevices. Those nontrivial phenomena have been studied by direct imaging of spin structures in magnetic vortices utilizing magnetic transmission soft x-ray microscopy (BL6.1.2 at ALS). Magnetic vortices have attracted enormous scientific interests due to their fascinating spin structures consisting of circularity rotating clockwise ( $c = +1$ ) or counter-clockwise ( $c = -1$ ) and polarity pointing either up ( $p = +1$ ) or down ( $p = -1$ ). We observed a symmetry breaking in the formation process of vortex structures in circular permalloy (Ni<sub>80</sub>Fe<sub>20</sub>) disks. The generation rates of two different vortex groups with the signature of  $cp = +1$  and  $cp = -1$  are completely asymmetric. The asymmetric nature was interpreted to be triggered by intrinsic Dzyaloshinskii-Moriya interaction (DMI) arising from the spin-orbit coupling due to the lack of inversion symmetry near the disk surface and extrinsic factors such as roughness and defects. We also investigated the stochastic behavior of vortex creation in the arrays of asymmetric disks. The stochasticity was found to be very sensitive to the geometry of disk arrays, particularly interdisk distance. The experimentally observed phenomenon couldn't be explained by thermal fluctuation effect, which has been considered as a main reason for the stochastic behavior in spin processes. We demonstrated for the first time that the ultrafast dynamics at the early stage of vortex creation, which has a character of classical chaos significantly affects the stochastic nature observed at the steady state in asymmetric disks. This work provided the new perspective of dynamics as a critical factor contributing to the stochasticity in spin processes and also the possibility for the control of the intrinsic stochastic nature by optimizing the design of asymmetric disk arrays.

### **3:42PM C6.00005 Ultrasensitive Scanning Transmission X-ray Microscopy: Pushing the Limits of Time Resolution and Magnetic Sensitivity**

HENDRIK OHLDA, SLAC - Natl Accelerator Lab — Understanding magnetic properties at ultrafast timescales is crucial for the development of new magnetic devices. Samples of interest are often thin film magnetic multilayers with thicknesses in the range of a few atomic layers. This fact alone presents a sensitivity challenge in STXM microscopy, which is more suited toward studying thicker samples. In addition the relevant time scale is of the order of 10 ps, which is well below the typical x-ray pulse length of 50–100 ps. The SSRL STXM is equipped with a single photon counting electronics that effectively allows using a double lock-in detection at 476 MHz (the x-ray pulse frequency) and 1.28 MHz (the synchrotron revolution frequency) to provide the required sensitivity. In the first year of operation the excellent spatial resolution, temporal stability and sensitivity of the detection electronics of this microscope has enabled researchers to acquire time resolved images of standing as well as traveling spin waves in a spin torque oscillator in real space as well as detect the real time spin accumulation in non magnetic Copper once a spin polarized current is injected into this material. The total magnetic moment is comparable to that of a single nanocube of magnetic Fe buried under a micron of non-magnetic material.

### **4:06PM C6.00007 Magnetorheology of hybrid colloids measured by spin coating and classical rheometry.<sup>1</sup>**

RAHEEMA MUHAMMAD ASLAM, University of Navarra, Spain, KESHWAD SHAHRIVAR, JUAN DE VICENTE LVAREZ-MANZANEDA, University of Granada, Spain, WENCESLAO GONZALEZ-VIAS, University of Navarra, Spain — Hybrid colloids composed of micron-sized ferromagnetic and diamagnetic particles constitute a promising category of magnetorheological fluids with enhanced field-induced apparent yield stress. However, the physical mechanism explaining this stress enhancement is currently lacking. For the first time, we measure and compare the magnetic field-dependent viscosity of hybrid diluted colloids using spin-coating [] and magnetorheometry []. In the former technique, a magnetic field is applied during the spin coating of the colloidal suspension involving evaporation of the solvent. The viscosity of the colloidal suspension at applied field can be derived from the surface coverage of the dry spin-coated deposits and from the viscosity of the colloid at zero field. In the latter, its viscosity is measured with a torsional parallel plate magnetorheometer under uniaxial magnetic fields aligned in the gradient direction of a steady shearing flow. The experimental results under different conditions and the effect of each component on the magnetorheological properties of the resulting colloid will be discussed. [] M. Pichumani et al., Soft Matter, 2013, 9, 3220-3229 [] Juan de Vicente et al., Soft Matter, 2011, 7, 3701-3710

### **4:18PM C6.00008 Accuracy of MRI-based Magnetic Susceptibility Measurements**

STEPHEN RUSSEK, HANNAH ERDEVIG, KATHRYN KEENAN, KARL STUPIC, NIST - Boulder — Magnetic Resonance Imaging (MRI) is increasingly used to map tissue susceptibility to identify microbleeds associated with brain injury and pathologic iron deposits associated with neurologic diseases such as Parkinson's and Alzheimer's disease. Field distortions with a resolution of a few parts per billion can be measured using MRI phase maps. The field distortion map can be inverted to obtain a quantitative susceptibility map. To determine the accuracy of MRI-based susceptibility measurements, a set of phantoms with paramagnetic salts and nano-iron gels were fabricated. The shapes and orientations of features were varied. Measured susceptibility of 1.0 mM GdCl<sub>3</sub> solution in water as a function of temperature agreed well with the theoretical predictions, assuming Gd<sup>3+</sup> is spin 7/2. The MRI susceptibility measurements were compared with SQUID magnetometry. The paramagnetic susceptibility sits on top of the much larger diamagnetic susceptibility of water (-9.04 × 10<sup>-6</sup>), which leads to errors in the SQUID measurements. To extract out the paramagnetic contribution using standard magnetometry, measurements must be made down to low temperature (2K). MRI-based susceptometry is shown to be as or more accurate than standard magnetometry and susceptometry techniques.

**4:30PM C6.00009 Neutron interferometry with cold stage<sup>1</sup>**, TAI SIYA MINEEVA, Institute for Quantum Computing, M. ARIF, M.G. HUBER, National Institute of Standards and Technology, C.B. SHAHI, Tulane University, C.W. CLARK, Joint Quantum Institute, D.G. CORY, J. NSOFINI, D. SARENAC, D.A. PUSHIN, Institute for Quantum Computing — Neutron interferometry (NI) is amongst the most precise methods for characterizing neutron interactions by measuring the relative difference between two neutron paths, one of which contains a sample-of-interest. Because neutrons carry magnetic moment and are deeply penetrating, they are excellent probes to investigate properties of magnetic materials. The advantage of NI is its unique sensitivity which allows to directly measure magnetic and structural transitions in materials. Up to now NI has been sparingly used in material research due to its sensitivity to environmental noise. However, recent successes in implementing Quantum Error Correction principles lead to an improved NI design making it robust against mechanical vibrations. Following these advances, a new user facility at the National Institute for Standards and Technology was built to study condensed matter applications, biology and quantum physics. Incorporating cold sample stage inside NI is the first of its kind experiment which can be carried out on large range of temperatures down to 4K. Upon successful realization, it will open new frontiers to characterize magnetic domains, phase transitions and spin properties in a variety of materials such as, for example, iron-based superconductors and spintronic materials.

**4:42PM C6.00010 Relaxometry imaging of superparamagnetic magnetite nanoparticles at ambient conditions**, AMIT FINKLER, DOMINIK SCHMID-LORCH, THOMAS HÄBERLE, 3. Physikalisches Institut, Universität Stuttgart, FRIEDEMANN REINHARD, Technische Universität München, ANDREA ZAPPE, 3. Physikalisches Institut, Universität Stuttgart, MICHAEL SLOTA, 1. Physikalisches Institut, Universität Stuttgart, LAPO BOGANI, Department of Materials, University of Oxford, JÖRG WRACHTRUP, 3. Physikalisches Institut, Universität Stuttgart — We present a novel technique to image superparamagnetic iron oxide nanoparticles via their fluctuating magnetic fields. The detection is based on the nitrogen-vacancy (NV) color center in diamond, which allows optically detected magnetic resonance (ODMR) measurements on its electron spin structure. In combination with an atomic-force-microscope, this atomic-sized color center maps ambient magnetic fields in a wide frequency range from DC up to several GHz [1], while retaining a high spatial resolution in the sub-nanometer range [2]. We demonstrate imaging of single 10 nm sized magnetite nanoparticles using this spin noise detection technique. By fitting simulations (Ornstein-Uhlenbeck process) to the data, we are able to infer additional information on such a particle and its dynamics, like the attempt frequency and the anisotropy constant [3]. This is of high interest to the proposed application of magnetite nanoparticles as an alternative MRI contrast agent or to the field of particle-aided tumor hyperthermia. [1] E. Schäfer-Nolte et al., Phys. Rev. Lett. **113**, 217204 (2014) [2] P. Maletinsky et al., Nat. Nanotech. **7**, 320 (2012) [3] D. Schmid-Lorch et al., Nano Lett. **15**, 4942 (2015)

**4:54PM C6.00011 ABSTRACT WITHDRAWN —**

**5:06PM C6.00012 Measurements of magnetic spin excitations in Permalloy microstructures using nitrogen-vacancy magnetometry**, H.J. JASON LIU, SEUNGHA YOON<sup>1</sup>, ROBERT MCMICHAEL, Center for Nanoscale Science and Technology, National Institute of Standards and Technology — The magnetic properties of nitrogen-vacancy (NV) centers in diamond have enabled emerging applications in fields ranging from cell biology to quantum computing. An NV center is a lattice defect, which behaves like a spin-1 system. NV centers can be prepared in the  $m_z = 0$  state by excitation with green light, and the spin state can be detected by the center's fluorescence of red light. The Zeeman splitting of the  $m_z = 1$  state, combined with a spin coherence time that can approach 1 ms, makes the NV center a sensitive, atom-sized magnetometer. Recently, NV centers have been used to measure spin wave excitations and vortex core dynamics in a Permalloy microdisk. In this talk, we present current NV center measurements on Permalloy micro and nanostructures that build on previous work. Permalloy structures were fabricated on top of a microstrip antenna and the measurements were conducted on a home-built confocal microscope. Preliminary measurements show photoluminescence contrast of ~12% and field detectivity on the order of T/Hz<sup>1/2</sup>. This allows for fine field mapping of stray magnetic fields produced by micro and nanostructures, which are typically a few milliteslas in magnitude.

**2:30PM C7.00001 Guiding brine shrimp through mazes by solving reaction diffusion equations.**, KRISHMA SINGAL, FLAVIO FENTON, None — Excitable systems driven by reaction diffusion equations have been shown to not only find solutions to mazes but to also to find the shortest path between the beginning and the end of the maze. In this talk we describe how we can use the Fitzhugh-Nagumo model, a generic model for excitable media, to solve a maze by varying the basin of attraction of its two fixed points. We demonstrate how two dimensional mazes are solved numerically using a Java Applet and then accelerated to run in real time by using graphic processors (GPUs). An application of this work is shown by guiding phototactic brine shrimp through a maze solved by the algorithm. Once the path is obtained, an Arduino directs the shrimp through the maze using lights from LEDs placed at the floor of the Maze. This method running in real time could be eventually used for guiding robots and cars through traffic.

**2:42PM C7.00002 An Agent Based Model for Social Class Emergence**, XIAOXIANG YANG, DANIEL RODRIGUEZ SEGURA, FEI LIN, IRINA MAZILU, Washington and Lee University — We present an open system agent-based model to analyze the effects of education and the society-specific wealth transactions on the emergence of social classes. Building on previous studies, we use realistic functions to model how years of education affect the income level. Numerical simulations show that the fraction of an individuals total transactions that is invested rather than consumed can cause wealth gaps between different income brackets in the long run. In an attempt to incorporate the network effects, we also explore how the probability of interactions among agents depending on the spread of their income brackets affects wealth distribution.

**2:54PM C7.00003 Generation and characterization of high-density gas jets from a 150 micron diameter nozzle in air<sup>1</sup>** , LUKE HAHN, KEVIN BARTAS, YAN TAY, DONGHOON KUK, KI-YONG KIM, Univ of Maryland-College Park — This work characterizes argon and nitrogen gas jets in unconventional atmospheric pressure instead of the conventional vacuum pressure, and then compares the results directly to that of the conventional technique of creating gas jet targets. A Mach-Zehnder interferometer was used to estimate the number density of the gas jet, and a Rayleigh scattering setup was used to determine if either of the techniques formed atomic clusters and if so, estimating relative quantity. The diameter of the cylindrical nozzle used for is around 150  $\mu\text{m}$  with backing pressures ranging from 13 bars to 69 bars. The highest backing pressure gives us a maximum phase shift value of 9 rad, number density  $4.5 \cdot 10^{20} \text{ cm}^{-3}$ . Another characteristic property of these jets is the shock diamond formation due to the flows interaction with atmospheric air particles. The highest number density for a shock diamond was  $\sim 10^{20} \text{ cm}^{-3}$  which does not necessarily occur at higher backing pressure. Also, the distance from the first shock diamond to the nozzle orifice does increase with increasing backing pressure, consistent with a theory. This type of high-density, thin gas jets can be used as a laser target for creating dense plasmas and producing energetic particles and X-rays in the atmospheric conditions.

**3:06PM C7.00004 Combination Gravimetric/Volumetric Sorption Instrument for Energy Applications.** , DONALD BETHEA, JACOB BURRESS, Univ of South Alabama — The use of gaseous fuels such as hydrogen and methane (natural gas) will reduce emissions. Unfortunately, the storage of hydrogen and methane at room temperature is difficult because they are both supercritical gases, making the adoption of these fuels cumbersome. One means of overcoming the storage problem is to use physisorption-based systems which exploit the van der Waals interaction between the gas and a nanoporous material to compress the gases to near liquid densities. To measure the amount of gas in these materials, gravimetric or volumetric methods are employed. Gravimetric weighs the amount of gas and volumetric uses differences in gas pressures. Gravimetric systems typically have problems with buoyancy corrections. Volumetric systems normally have larger uncertainties that propagate through the isotherm. A modified system will be presented which allows for both gravimetric and volumetric gas sorption measurements. Additionally, the buoyancy corrections for the gravimetric measurements are significantly small and less than the uncertainties in the measurement. This apparatus can take measurements of most gases at room temperature and up to 200 bar.

**3:18PM C7.00005 Decoherence of nitrogen-vacancy defect spins in diamond from surface spins** , MICHAEL DOMINGUEZ, MICHAEL E. FLATT, Department of Physics and Astronomy, University of Iowa — In recent work[1,2], researchers measured the spin coherence time of intentionally-doped nitrogen-vacancy (NV) spin ensembles. The spin coherence times of these spins depends on their local environment, including their nearness to the surface of the material. We calculated the decoherence time of a deep spin within the material affected by the presence of a sheet of surface spins interacting with the deep spin through the dipolar interaction. These calculations describe the experimental measurements qualitatively, however quantitative agreement requires the assumption these spins extend deeper into the material from the surface layer. **3:30PM C7.00006 Electrostatic Simulation of Charge Trapping in Carbon Nanotube Vertical Organic Field Effect Transistors<sup>1</sup>** , JENNIFER CRAWFORD, ANDREW RINZLER, SELMAN HERSHFELD, Univ of Florida - Gainesville — The carbon nanotube vertical organic field effect transistor is a vertical sequence consisting of a gate electrode, gate dielectric, thin nanotube network source electrode, organic semiconducting channel and finally the drain electrode. The drain current is modulated by the gate voltage which varies a Schottky barrier between source and channel layers. Hysteresis in the current-voltage characteristic has been observed when a electret charge trapping layer is placed between the nanotube source and the gate dielectric. We provide a model for charge injection into a trapping layer placed in contact with the carbon nanotube film and solve self-consistently for the electrostatics and the occupancy of the traps. For a range of applied gate voltages the simulations demonstrate hysteresis of the carbon nanotubes' charge as a result of the electric field produced by the trapped charge. This affects the current by modulating the Schottky barrier.

**3:42PM C7.00007 Quantum correlations of magnetic impurities by a multiple electron scattering in carbon nanotubes** , DIDIER GAMBOA ANGULO, Universidad Autnoma de Yucatn, GUILLERMO CORDOURIER MARURI, ROMEO DE COSS GMEZ, Centro de Investigacin y de Estudios Avanzados del IPN — In this work we analyze the quantum correlations and polarizations states of magnetic impurities spins, when a multiple electron scattering was taken place. A sequence of non-correlated electrons interacts through scattering producing quantum correlation which will have an impact on the electronic transmission. We consider a short range Heisenberg interaction between ballistic electron and static impurities. We analyze the cases when the electron scattering is produce by one and two impurities, obtaining the electronic transmission rates. Concurrence and fidelity calculations are performed to obtain the level of quantum entanglement and polarization correlations. We also discuss the possible application of this model to metallic and semiconductor carbon nanotubes, which could have important implications on spintronics and quantum information devices.

**3:54PM C7.00008 Exact Diagonalization of a Quantum XXZ Model with Long-Range Interactions<sup>1</sup>** , JUSTIN A. WILLIAMS, DAVID A. SMITH, University of West Florida, C.C.-JOSEPH WANG, None, CHRISTOPHER N. VARNEY, University of West Florida — In recent years, rapid advancement has been made in using ultra-cold gases as quantum spin simulators, with two dimensional lattices becoming a rich target for exploring the exotic states and excitations of spin-1/2 systems on frustrated lattices. When the interaction in the system becomes long-ranged, the spins are frustrated by the long-range interaction. Consequently, the competition between the geometric frustration and the long-range interaction results in the the underlying orders present in the ground state being unclear. Here, we investigate the quantum dipolar XXZ model with exact diagonalization to characterize and contrast the ground state and excitations on square and triangular lattices to provide a baseline for comparison with experiments.

**4:06PM C7.00009 A Holographic c-Theorem for Schrodinger Spacetimes** , WEISHUN ZHONG, JAMES LIU, University of Michigan — We prove a c-theorem for holographic renormalization group flows in a Schrodinger spacetime that demonstrates that the effective radius  $L(r)$  monotonically decreases from the UV to the IR, where  $r$  is the bulk radial coordinate. This result assumes that the bulk matter satisfies the null energy condition, but holds regardless of the value of the critical exponent  $z$ . We also construct several numerical examples in a model where the Schrodinger background is realized by a massive vector coupled to a real scalar. The full Schrodinger group is realized when  $z=2$ , and in this case it is possible to construct solutions with constant effective  $z(r)=2$  along the entire flow.

**4:18PM C7.00010 The Configuration Space Symmetries in the Quantum Bouncer** , DAVID LOCKERBY, American University — We study a few-body particle system with contact interactions in a quantum bouncer potential well. In principle, the strength of the gravitational field can be extracted from the one-particle energy spectrum, but this is currently experimentally impractical. This project explores how varying the number of particles and tuning the particle interaction strength can improve measurement sensitivity. The analysis exploits the additional symmetries of configuration space that occur either in the unitary limit of contact interactions or when the bouncer potential is decorated with additional infinite delta-barriers.

**4:30PM C7.00011 Exploring Quantum Dynamics of Continuous Measurement with a Superconducting Qubit** , ARIAN JADBABAIE, NEDA FOROUZANI, DIAN TAN, KATER MURCH, Washington University, St. Louis — Weak measurements obtain partial information about a quantum state with minimal backaction. This enables state tracking without immediate collapse to eigenstates, of interest to both experimental and theoretical physics. State tomography and continuous weak measurements may be used to reconstruct the evolution of a single system, known as a quantum trajectory. We examine experimental trajectories of a two-level system at varied measurement strengths with constant unitary drive. Our analysis is applied to a transmon qubit dispersively coupled to a 3D microwave cavity in the circuit QED architecture. The weakly coupled cavity acts as pointer system for QND measurements in the qubits energy basis. Our results indicate a marked difference in state purity between two approaches for trajectory reconstruction: the Bayesian and Stochastic Master Equation (SME) formalisms. Further, we observe the transition from diffusive to jump-like trajectories, state purity evolution, and a novel, tilted form of the Quantum Zeno effect. This work provides new insight into quantum behavior and prompts further comparison of SME and Bayesian formalisms to understand the nature of quantum systems. Our results are applicable to a variety of fields, from stochastic thermodynamics to quantum control.

**4:42PM C7.00012 A simple table-top experiment demonstrating mechanical oscillation of a macroscopic object driven by radiation pressure.** , GRACE JESENSKY, DOMINIC DAMS, OLEKSIY KHOMENKO, WOO-JOONG KIM, Seattle Univ — We have implemented a Michelson's interferometer to demonstrate the resonant motion of a cm-sized cantilever due to radiation pressure of a laser diode (5 mW or less). The mechanical oscillation is found to be 2.454 (+/-0.003) kHz and is independently confirmed by dynamic force microscopy in which a piezoelectric transducer (PZT) is employed as a mechanical driver. We will discuss other applications, such as a wavelength meter and short-ranged force measurements, based on our simple table-top experiment.

**4:54PM C7.00013 ABSTRACT WITHDRAWN —**

**5:06PM C7.00014 Transient even and odd order nonlinearity of a YBCO transmission line<sup>1</sup>** , RICHARD HUIZEN, Grand Valley State University, STEPHEN REMILLARD, Hope College — Second (IMD2) and third (IMD3) order intermodulation distortions were found to exhibit dependencies on temperature and magnetic field. A carrier wave at the 890 MHz resonant frequency of the type-II  $\text{YBa}_2\text{Cu}_3\text{O}_{7-\delta}$  superconducting resonator circuit, with  $T_C = 89\text{K}$ , was introduced into the circuit via an electric coupling antenna. Two off-resonance probe signals were injected into the circuit via a separate magnetic coupling element. The combination of these three signals locally excited synchronous second and third order IMD. A static magnetic field was applied perpendicularly to the film which induced magnetic flux vortices in the sample. Upon removal of the static magnetic field, IMD2 and IMD3 exhibited distinct transient decay modes correlating to temperature. Between 85.0K and 87.5K, IMD3 decayed exponentially. Above 87.5K, IMD3 exhibited bounded exponential growth, while within a narrow temperature range around 87.5K, removal of a static magnetic field strongly suppressed IMD3. IMD2 exhibited exponential decay at all temperatures. Even and odd order microwave nonlinearities were thus shown to result from different, magnetically coupled, physical mechanisms.

**5:18PM C7.00015 Magnetic Levitation Experiments with the Electrodynamic Wheel<sup>1</sup>** , VINCENT CORDREY, ANGEL GUTARRA-LEON, NATHAN GAUL, WALERIAN MAJEWSKI, Northern VA Comm College — Our experiments explored inductive magnetic levitation using circular Halbach arrays with the strong variable magnetic field on the outer rim of the ring. Such a system is usually called an Electrodynamic Wheel (EDW). Rotating this wheel around a horizontal axis above a flat conducting surface should induce eddy currents in said surface through the variable magnetic flux. The eddy currents produce, in turn, their own magnetic fields which interact with the magnets of the EDW. We constructed two Electrodynamic Wheels with different diameters and demonstrated that the magnetic interactions produce both lift and drag forces on the EDW which can be used for levitation and propulsion of the EDW. The focus of our experiments is the direct measurement of lift and drag forces to compare with theoretical models using wheels of two different radii.

**Session C12 GSNP GSOF: Intrinsic Localized Modes: Recent Developments and Future Perspectives** 308 - David Campbell, Boston University

**2:30PM C12.00001 From Discrete Breathers to Many Body Localization and Flatbands** , SERGEI FLACH<sup>1</sup>, Center for Theoretical Physics of Complex Systems, Institute for Basic Science, Daejeon, South Korea — Discrete breathers (DB) and intrinsic localized modes (ILM) are synonymic dynamical states on nonlinear lattices - periodic in time and localized in space, and widely observed in many applications. I will discuss the connections between DBs and many-body localization (MBL) and the properties of DBs on flatband networks. A dense quantized gas of strongly excited DBs can lead to a MBL phase in a variety of different lattice models. Its classical counterpart corresponds to a 'nonergodic metal' in the MBL language, or to a nonGibbsian selftrapped state in the language of nonlinear dynamics. Flatband networks are lattices with small amplitude waves exhibiting macroscopic degeneracy in their band structure due to local symmetries, destructive interference, compact localized eigenstates and horizontal flat bands. DBs can preserve the compactness of localization in the presence of nonlinearity with properly tuned internal phase relationships, making them promising tools for control of the phase coherence of waves.

**3:06PM C12.00002 Recent advances in the physics of localized states** , YURI KIVSHAR<sup>1</sup>, Nonlinear Physics Center, Australian National University, Canberra, Australia — We will review several examples of the existence and generation of localized states in optics and metamaterials including weakly coupled optical waveguides and arrays of nonlinear “meta-atoms” in metamaterials. We will also mention some recent studies on an interplay of nonlinearity-induced energy localization and edge states in discrete systems appeared in the systems with nontrivial topology

<sup>1</sup>Also at the ITMO University, St. Petersburg, Russia

**3:42PM C12.00003 Shepherding intrinsic localized modes in micro-mechanical arrays** , ALBERT SIEVERS, Laboratory of Atomic and Solid State Physics, Cornell University, Ithaca, NY 14853 — The energy profiles of intrinsic localized modes (ILMs) in periodic physical lattices with nonlinear forces resemble those of localized vibrational modes at defects in a harmonic lattice but, like solitons, they can propagate; however, in contrast with solitons they loose energy as they move through the lattice - the more localized the excitation the faster the energy loss. One of our experimental studies with micro-mechanical arrays involves steady state locking of ILMs, and their interactions with impurities. By measuring the linear response spectra of a driven array containing an ILM both the dynamics of bifurcation transitions and the hopping of vibrational energy have been connected to the transition properties of soft modes. Recently the search for a completely mobile ILM has focused attention on minimizing the resonance interaction that occurs between the localized excitation and small amplitude plane wave modes. Via simulations we demonstrate that when more than one type of nonlinear force is present their Fourier components can often be designed to cancel against each other in the k-space region of the plane wave dispersion curve, removing the resonance. The end result is super-transmission for an ILM in a discrete physical lattice. Such an engineered, intrinsic, low loss channel may prove to be a useful property for other physical systems treated within a tight binding approximation. In collaboration with M. Sato.

**4:18PM C12.00004 Localized Modes in Granular Chains** , MASON PORTER, University of Oxford — Granular crystals are tightly-packed lattices (or more disordered arrangements) of solid particles that deform elastically when they contact each other. In the presence of precompression, they can exhibit breather solutions in the form of intrinsic localized modes and defect modes. I'll give an introduction to granular crystals and will then examine breathers in one-dimensional granular crystals (i.e., granular chains) in both models and experiments. I will give examples using both diatomic configurations and homogeneous configurations with defect particles. I will also consider disordered granular chains and discuss recent work on nonlinear Anderson localization and related phenomena in such systems.

**4:54PM C12.00005**

### **Intrinsic Localized Modes in Optical Photonic Lattices and Arrays**

<sup>1</sup> , DEMETRIOS CHRISTODOULIDES, CREOL-College of Optics and Photonics, UCF — Discretizing light behavior requires optical elements that can confine optical energy at distinct sites. One possible scenario in implementing such arrangements is to store energy within low loss high Q-microcavities and then allow photon exchange between such components in time. This scheme requires high-contrast dielectric elements that became available with the advent of photonic crystal technologies. Another possible avenue where such light discretization can be directly observed and studied is that based on evanescently coupled waveguide arrays. As indicated in several studies, discrete systems open up whole new directions in terms of modifying light transport properties. One such example is that of discrete solitons. By nature, discrete solitons represent self-trapped wavepackets in nonlinear periodic structures and result from the interplay between lattice diffraction (or dispersion) and material nonlinearity. In optics, this class of self-localized states has been successfully observed in both one- and two-dimensional nonlinear waveguide arrays. In recent years such photonic lattices have been implemented or induced in a variety of material systems, including those with cubic (Kerr), quadratic, photorefractive, and liquid-crystal nonlinearities. In all cases the underlying periodicity or discreteness can lead to new families of optical solitons that have no counterpart whatsoever in continuous systems. Interestingly, these results paved the way for observations in other physical systems obeying similar evolution equations like Bose-Einstein condensates. New developments in laser writing ultrashort femtosecond laser pulses, now allow the realization of all-optical switching networks in fully 3D environments using nonlinear discrete optics. Using this approach all-optical routing can be achieved using blocking operations. The spatio-temporal evolution of optical pulses in both normally and anomalously dispersive arrays can lead to novel schemes for mode-locking and pulse compression. A strong signature of discrete X-wave formation was also demonstrated in such structures. In the last few years, Anderson localization was unequivocally observed in array systems where the transition from ballistic transport to diffusive, and the cross-over to Anderson localization was studied as a function of disorder and nonlinearity. In recent studies synthetic lattices exhibiting parity-time (PT) symmetry were also considered. The interplay of gain and loss in this latter family of structures leads to counterintuitive characteristics and behavior such as non-reciprocal propagation and power oscillations. The realization of discrete array systems at sub-wavelength scales is another important direction that is nowadays intensively pursued. References 1. D. N. Christodoulides, F. Lederer, and Y. **2:30PM C13.00001 David Adler Lectureship Award in the Field of Materials Physics: Electrically Tunable Nanoantennas for Control of Absorption, Emission and Scattering<sup>1</sup>** , HARRY ATWATER, California Institute of Technology — Progress in understanding resonant subwavelength structures has fueled an explosion of interest in both fundamental processes and nanophotonic devices for imaging, sensing, solar energy conversion and thermal radiation control. Achieving electronic tunability of the optical properties is also an emerging opportunity to bring nanoscale resonators and antennas to life as dynamic objects. While the optical properties of photonic and plasmonic nanostructures are typically fixed at the time of fabrication, gated field effect tuning of the carrier density in conducting oxides and two-dimensional materials enables the optical dispersion of individual structures to be altered from dielectric to plasmonic, yielding active nano-antenna arrays with electrically tunable absorption, radiative emission and scattering properties.

**3:06PM C13.00002 Frank Isakson Prize for Optical Effects in Solids: Optical spectroscopy and mechanisms of superconductivity.** , DIRK VAN DER MAREL<sup>1</sup>, University of Geneva — By its very nature the phenomenon of superconductivity is intimately connected to the electrodynamics properties of a material, both in the normal and in the superconducting state. Optical spectroscopy and electrical transport -corresponding to the zero-frequency limit of the optical response- provide for this reason sensitive tools probing the collective response of a superconducting material. Optical spectroscopy can provide the real and imaginary parts of the optical conductivity of an electron liquid for all frequencies from radiowaves through infrared and visible up to the ultraviolet and even X-ray frequencies. Theory of the optical response is particularly well developed, leading among others to a number of sumrules, providing powerful tools for confronting experiment and theoretical models of superconducting pairing. In this talk examples of sumrules will be discussed relating to the kinetic energy and the Coulomb energy of the paired electrons, and experimental data of addressing these two energies will be presented. The basic understanding of pair formation in the conventional (i.e. BCS) model of superconductivity is, that electrons form pairs as a result of an attractive interaction. On general grounds one then expects the interaction energy to become reduced when the electrons form pairs, while at the same time their kinetic energy increases. Superconductivity is a stable state of matter provided that all contributions together result in a lowering of the total (interaction, kinetic plus other terms if relevant) lowering of energy. In this talk I will demonstrate that these two effects can be observed in the cuprate superconductors, that behave according to aforementioned trends for strongly overdoped cuprates, but that the observed effects have the opposite sign for underdoped and optimally doped cuprates. These observations compare favorably with published numerical calculations based on models of strong electron-electron correlation, not involving the vibrations of the lattice, and where the electron-electron interaction is purely repulsive.

<sup>1</sup>Invited talk because of the Frank Isakson Prize 2016

**3:42PM C13.00003 Frank Isakson Prize Talk: Superfluid and normal-fluid densities in the cuprate superconductors from infrared spectroscopy**<sup>1</sup> , D.B. TANNER, University of Florida — Measurements for a number of cuprate families of optical reflectance over a wide spectral range (far-infrared to ultraviolet) have been analyzed using Kramers-Kronig analysis to obtain the optical conductivity  $\sigma(\omega)$  and (by integration of the real part of the conductivity) the spectral weight of low- and mid-energy excitations. For the Kramers-Kronig analysis to give reliable results, accurate high-frequency extrapolations, based on x-ray atomic scattering functions, were used. When the optical conductivities of the normal and superconducting states are compared, a transfer of spectral weight from finite frequencies to the zero-frequency delta-function conductivity of the superconductor is seen. The strength of this delta function gives the superfluid density,  $\rho_s$ . In a clean metallic superconductor the superfluid density is essentially equal to the conduction electron density. The cuprates in contrast have only about 20% of the *ab*-plane low-energy spectral weight in the superfluid. The rest remains in finite-frequency, midinfrared absorption. In underdoped materials the superfluid fraction is even smaller. There are two ways to measure  $\rho_s$ , using either the partial sum rule for the conductivity or by examination of  $\sigma_2(\omega)$ . Comparison of these two estimates of the superfluid density shows that 98% of the *ab*-plane superfluid density comes from energies below 0.15 eV.

**4:18PM C13.00004 Richard L. Greene Dissertation Award in Experimental Condensed Matter or Materials Physics Talk: Ferromagnetic quantum criticality in YbNi<sub>4</sub>P<sub>2</sub>** , ALEXANDER STEPPKE, University of St. Andrews — In a number of strongly correlated electron systems quantum phase transitions can be observed by the suppression of antiferromagnetic order. In contrast the prototypical continuous quantum phase transition of a metallic ferromagnet is often preempted by a first-order transition or a superconducting state. We show that the Kondo lattice system YbNi<sub>4</sub>P<sub>2</sub> exhibits a ferromagnetically ordered phase with a very low Curie temperature of 0.15K. The compound can be tuned to a ferromagnetic quantum critical point by substitution of phosphorus by arsenic. With thermodynamic studies of specific heat, ac susceptibility and thermal expansion we show strong evidence for the ferromagnetic order and the quantum criticality in the YbNi<sub>4</sub>(P 1-x As x)<sub>2</sub> doping series and the existence of a ferromagnetic quantum critical point at zero applied field for small substitutions.

**4:54PM C13.00005 Richard L. Greene Dissertation Award in Experimental Condensed Matter or Materials Physics Talk: Towards single atom magnets** , SUSANNE BAUMANN, IBM Almaden Research Center — Magnetic anisotropy is a fundamental property of magnetic materials that governs the stability and directionality of their magnetization. At the atomic level, magnetic anisotropy originates from anisotropy in the orbital angular momentum (L) and the spin-orbit coupling that connects the spin moment of a magnetic atom to the spatial symmetry of its ligand field environment. Generally, the ligand field, that is necessary for the anisotropy, also quenches the orbital moment and reduces the total magnetic moment of the atom to its spin component. However, careful design of the coordination geometry of a single atom can restore the orbital moment while inducing uniaxial anisotropy, as we present here for single atoms deposited on top of a thin MgO film. Scanning tunneling spectroscopy and x-ray absorption spectroscopy measurements show a large magnetic anisotropy of 19 meV for iron and 58 meV for cobalt, as well as relaxation times of many milliseconds. These results offer a strategy, based on symmetry arguments and careful tailoring of the interaction with the environment, for the rational design of nanoscopic permanent magnets and single atom magnets.

**Session C14 FHP FPS: The Author in Dialogue: Steven Weinberg's 'To Explain the World'**

310 - Joseph D. Martin, Michigan State University

**2:30PM C14.00001 Reflections of a whig physicist** , STEVEN WEINBERG, Theory Group, Physics Department, University of Texas at Austin — I argue that a whig interpretation, keeping an eye on present knowledge and methods, is appropriate in the history of science.

**3:06PM C14.00002 Beller Lecture: Is Understanding the Past in Its Own Terms Understanding?** , DAVID WOOTTON, Professor of History at the University of York — History of Science is in a state of intellectual confusion symbolized by its hostility to what is called Whig history. The fundamental issue is whether it is legitimate to use hindsight in the writing of history. In this lecture I will defend retrospective history in three key respects: a) retrospection is generally a legitimate procedure in historical writing, primarily because historical outcomes are often unintended and unpredictable; b) retrospection is particularly legitimate where science is concerned because scientific development is path dependent; c) retrospection is particularly legitimate in history of science because science progresses, and progress can only be identified retrospectively. Defending retrospection is entirely compatible with recognizing that science is culturally specific; thus retrospection need not involve anachronism. See [www.inventionofscience.com](http://www.inventionofscience.com)

**3:42PM C14.00003 To Explain Copernicus: The Islamic Scientific and Religious Contexts** , F. JAMIL RAGEP, McGill University — No one seriously disputes the novelty of Copernicus's monumental decision to put the Earth in motion or its importance for the development of modern science. But that decision can appear quite different when viewed from the perspective of a modern scientist versus that of a contextualist historian. In his recent book *To Explain the World*, Prof. Weinberg places great store on what he calls aesthetic criteria for understanding Copernicus's choice. The historical record, however, is rather ambiguous on the matter, and if anything supports the view that Copernicus came to his aesthetic justifications (such as the beautiful ordering of the planets) after first reaching his heliocentric theory. So if not aesthetics, what did lead him to go against a two-millennium tradition that placed the Earth firmly in the center of the Cosmos? There are no doubt many factors; one of the most intriguing suggestions, well-argued by Noel Swerdlow, is that Copernicus was led to heliocentrism by his rather conservative desire to restore uniform, circular motion to the heavens and remove the irregularities of Ptolemaic astronomy. Swerdlow has also asserted that this has much to do with Islamic predecessors who were attempting to do the same thing, only within a geocentric framework. In this presentation, I will briefly summarize this Islamic scientific context and then explore the religious beliefs that led not only to the questioning of Ptolemaic scientific authority, including his alleged lack of observational diligence, but also ancient philosophical authority, the latter opening up possibilities for alternative cosmologies, at least one of which included the Earth's motion. Finally, evidence will be presented that connects these Islamic contexts with Copernicus's theories and justifications.

**4:18PM C14.00004 The Diagnosis of Error in Histories of Science** , WILLIAM THOMAS, History Associates, Inc. — Whether and how to diagnose error in the history of science is a contentious issue. For many scientists, diagnosis is appealing because it allows them to discuss how knowledge can progress most effectively. Many historians disagree. They consider diagnosis inappropriate because it may discard features of past actors' thought that are important to understanding it, and may have even been intellectually productive. Ironically, these historians are apt to diagnose flaws in scientists' histories as proceeding from a misguided desire to idealize scientific method, and from their attendant identification of deviations from the ideal as, *ipso facto*, a paramount source of error in historical science. While both views have some merit, they should be reconciled if a more harmonious and productive relationship between the disciplines is to prevail. In *To Explain the World*, Steven Weinberg narrates the slow but definite emergence of what we call science from long traditions of philosophical and mathematical thought. This narrative follows in a historiographical tradition charted by historians such as Alexandre Koyre and Rupert Hall about sixty years ago. It is essentially a history of the emergence of reliable (if fallible) scientific method from more error-prone thought. While some historians such as Steven Shapin view narratives of this type as fundamentally error-prone, I do not view such projects as *a priori* illegitimate. They are, however, perhaps more difficult than Weinberg supposes. In this presentation, I will focus on two of Weinberg's strong historical claims: that physics became detached from religion as early as the beginning of the eighteenth century, and that physics proved an effective model for placing other fields on scientific grounds. While I disagree with these claims, they represent at most an overestimation of vintage science's interest in discarding theological questions, and an overestimation of that science's ability to function at all reliably.

**Session C15 DCMP DMP: Graphene: Adatoms, Doping, and Magnetism** 314 - Olaf van 't Erve, Naval Research Laboratory

**2:30PM C15.00001 Proximity induced exchange interaction in graphene-YIG devices<sup>1</sup>** , JOHANNES CHRISTIAN LEUTENANTSMEYER, ALEXEY KAVERZIN, MAGDALENA WOJTASZEK, BART J. VAN WEES, University of Groningen, PHYSICS OF NANODEVICES TEAM — The proximity of two materials with radically different properties can give rise to a new physical phenomenon present only in the direct vicinity to the interface. Graphene is a perfect candidate for observing proximity effects as being ultimately thin and therefore ultimately sensitive for such interactions. Ferromagnetism is one of the desired properties for spintronics applications of graphene. It is absent in the pristine state, however, one can artificially induce magnetic ordering by bringing graphene in the proximity of ferrimagnetic insulating material, such as yttrium iron garnet (YIG). In this work we show that a monolayer of graphene placed on top of YIG adopts the exchange interaction induced by YIG and thus becomes ferromagnetic even at room temperatures. The proximity induced exchange interaction results in an effective magnetic field that influences directly the spin transport in graphene seen in a spin precession measurements. We are able to fit the measured Hanle dependences with extended solutions of Bloch diffusion equations and extract the value of the effective exchange field that is around 200 mT. Our findings open up a new route for creating novel all graphene in plane spin valve devices for spintronics applications.

**2:42PM C15.00002 Magneto-plasmons in graphene in a periodically modulated magnetic field** , YUXUAN JIANG, OWEN VAIL, JEREMY YANG, JAMEY GIGLIOTTI, Georgia Institute of Technology, Atlanta, GA, USA, CLAIRE BERGER, Georgia Institute of Technology, Atlanta, GA, USA/CNRS, Institut Néel, Grenoble, France, WALTER DE HEER, Georgia Institute of Technology, Atlanta, GA, USA, DMITRY SMIRNOV, National High Magnetic Field Laboratory, Tallahassee, FL, USA, ZHIGANG JIANG, Georgia Institute of Technology, Atlanta, GA, USA — We present infrared magneto-spectroscopy study of graphene in a periodically modulated magnetic field. Corrugated trenches are first patterned on SiC substrate using e-beam lithography and plasma etching. Multilayer epitaxial graphene is then grown over the trenches, forming a periodic structure. In the presence of an external magnetic field, the perpendicular component of the field is spatially modulated, and the modulation strength can be tuned by varying the trench packing density or the tilting angle of the field with respect to the substrate. Experimentally, enhanced absorption and salient deviations from single Lorentzian lineshape are observed, resulting from the periodic modulation. The deviated spectra can be well fitted by two Lorentzians, suggestive of the presence of two active modes. In addition, as the packing density of the trenches increases, the coupling between the corrugated graphene structures becomes stronger, resulting in a broadened spectrum.

**2:54PM C15.00003 Theory for disorder-induced magnetodrag in one-channel model for graphene<sup>1</sup>** , NAVNEETH RAMAKRISHNAN, DEREK HO, Center for Advanced 2D Materials, SHAFFIQUE ADAM, Yale-NUS College — Recent work has shown the presence of disorder induced magnetoresistance that persists far away from charge neutrality, even in effective one-band systems [1]. This effect manifests itself in the magnetic field dependence of Coulomb drag, an effect that existing theoretical treatments have not considered [2]. In the presence of disorder, we calculate the magnetodrag as a function of the parameters of the disorder distribution and compare our results with the available experimental data in graphene and 2D electron gases. We comment on the relevance of these results in explaining the large magnetodrag at charge neutrality in graphene.

**3:06PM C15.00004 Induced magnetism in exfoliated graphene via proximity effect with yttrium iron garnet thin films**, MARIO AMADO, YANG LI, ANGELO DI BERNARDO, Materials Science and Metallurgy, University of Cambridge, UK, ANTONIO LOMBARDO, ANDREA C. FERRARI, Cambridge Graphene Centre, University of Cambridge, UK, JASON ROBINSON, Materials Science and Metallurgy, University of Cambridge, UK — The recent discovery of the quantum anomalous Hall effect (QAHE) in magnetically doped topological insulators cooled below in the millikelvin regime represents breakthrough in the field of spintronics. Theoretically, the QAHE should occur in graphene proximity coupled to a ferromagnetic insulator but with the promise of much higher operating temperatures for practical applications. Hints of proximity-induced magnetism in graphene coupled to yttrium iron garnet (YIG) films have been reported although the QAHE remains unobserved; the lack of a fully developed plateau in graphene/YIG devices can be attributed to poor interfacial coupling and therefore a dramatically reduced magnetic proximity effect. Here we report the deposition and characterisation of epitaxial thin-films of YIG on lattice-matched gadolinium gallium garnet substrates by pulsed laser deposition. Pristine exfoliated graphene flakes transferred mechanically onto the YIG are reported alongside results that correlate the effects of YIG morphology on the electronic and crystal properties of graphene by electrical (low temperature magnetoresistance measurements in Hall-bar-like configuration) and optical (Raman) means.

**3:18PM C15.00005 The magnetic ratchet effect in bilayer graphene**, EDWARD MCCANN, NARJES KHEIRABADI, Physics Department, Lancaster University, Lancaster, LA1 4YB, UK, VLADIMIR FAL'KO, National Graphene Institute, The University of Manchester, Manchester, M13 9PL, UK — Experiments [1] have measured a magnetic ratchet effect for electrons in hydrogenated monolayer graphene, an effect in which a d.c. electric current is generated from an a.c. electric field in the presence of an in-plane magnetic field and spatial asymmetry. Here, we describe the theory of the magnetic ratchet effect in bilayer graphene. The Boltzmann kinetic equation [2,3] is used to relate the d.c. current to the scattering probability of electrons in bilayer graphene. Taking into account details of the low-energy band structure of bilayer graphene, including interlayer hopping parameters, we compare contributions arising from gate- and disorder-induced spatial asymmetry, illustrating that bilayer and multilayer graphenes are natural candidates for the study of non-linear transport effects. [1] C. Drexler et al, Nature Nanotechnology 8, 104 (2013). [2] V. I. Fal'ko, Sov. Phys. Solid State 31, 561 (1989). [3] S. A. Tarasenko, Phys. Rev. B 83, 035313 (2011).

**3:30PM C15.00006 Magnetic nanostructures on graphene**, XIAOJIE LIU, Center for Quantum Science and School of Physics, Northeast Normal University, Changchun, 130117, People's Republic of China., CAI-ZHUANG WANG, Ames Laboratory U. S. Department of Energy, and Department of Physics and Astronomy, Iowa State University, Ames, IA, 50011, U. S. A., HAI-QING LIN, Beijing Computational Science Research Center, Beijing 100084, China, MYRON HUPALO, Ames Laboratory U. S. Department of Energy, and Department of Physics and Astronomy, Iowa State University, Ames, IA, 50011, U. S. A., PATRICIA A. THIEL, Ames Laboratory U. S. Department of Energy, Department of Chemistry and Department of Materials Science and Engineering, Iowa State University, Ames, KAI-MING HO, MICHAEL C. TRINGIDES, Ames Laboratory U. S. Department of Energy, and Department of Physics and Astronomy, Iowa State University, Ames, IA, 50011, U. S. A. — The calculations also show that Fe clusters on graphene exhibit ferromagnetic order but have smaller magnetic moments compared to the corresponding free-standing clusters. By contrast, Mn clusters on graphene exhibit ferrimagnetic coupling and enhanced magnetic moment compared to their free-standing clusters. Adsorption of Fe and Mn nanostructures also induces magnetic moments in graphene, and the induced magnetic moment on each carbon atom in graphene is correlated with the distortion of the graphene lattice. The origin of the magnetic moment changes in the clusters upon adsorption can be attributed to the electron redistribution due to the interaction with graphene.

**3:42PM C15.00007 Understanding Magnetic Trimer Interactions in (Cr,Mn)-Substituted Graphene<sup>1</sup>**, JASON T. HARALDSEN, Department of Physics, University of North Florida, CHARLES B. CROOK, GREGORY HOCHINS, Department of Physics and Astronomy, James Madison University, JIAN-XIN ZHU, Theoretical Division and Center for Integrated Nanotechnologies, Los Alamos National Laboratory, COSTEL CONSTANTIN, Department of Physics and Astronomy, James Madison University, ALEXANDER V. BALATSKY, Institute for Materials Science, Los Alamos National Laboratory — We investigate the magnetic interactions within a graphene superlattice produced by three directly substituted transition-metal atoms (specifically chromium and manganese). Using a first principles approach, we calculate the electronic and magnetic properties for this system assuming an equilateral trimer configuration with varying atomic separations. Through an examination of the electronic band structure, density of states, and Millikan populations (magnetic moment) for each atom, we find that the presence of magnetic impurities establishes a distinct magnetic moment in the graphene lattice, where the interactions are dependent on the spatial and magnetic characteristic between the magnetic atoms and the carbon atoms, which leads to either ferromagnetic or antiferromagnetic behavior. Furthermore, we use magnetization mapping to show that the substituted atoms induce an overall magnetic moment in the graphene lattice, which may help guide the discussion on spintronic graphene.

**3:54PM C15.00008 Controlling Adatom Magnetism on Bilayer Graphene by External Field**, MUKUL KABIR, Indian Institute of Science Education and Research, Pune 411008, India, DHANI NAFDAY, TANUSRI SAHA-DASGUPTA, S. N. Bose National Centre for Basic Sciences, Kolkata 700098, India — We study the effect of external electric field on the magnetic properties of single Fe adatom and Fe dimer hosted on a bilayer graphene surface grown on a SiO<sub>2</sub> substrate within first-principles calculations. We find that electric field perpendicular to the bilayer graphene modulates the charge and spin-state of the single Fe adatom over a wide range. States ranging from  $3d^6$ ,  $S=2$  to  $3d^{10}$ ,  $S=0$  have been observed for Fe adatom, which may be inaccessible under normal condition. This would be of interest in the context of orbitally controlled Kondo effect. Further, for Fe-dimer, we find that a small electric field is able to tune the magnetic exchange coupling. Interestingly, we also observe an unusual magnetostructural coupling for Fe-dimer, which stabilizes a ferrimagnetic state over a fully compensated antiferromagnetic spin configuration.

**4:06PM C15.00009 Novel electronic properties of hydrogenated graphene: A first-principles calculation**, HONG-YAN LU, RUI WANG, SHIH-YANG LIN, C. S. TING, Texas Center for Superconductivity and Department of Physics, University of Houston, Houston, Texas 77204, USA — We studied the electronic properties of some new kinds of hydrogenated graphenes by first-principles calculations. The designed systems, depending on the position and concentration of the hydrogen atoms, may show interesting band structures that are different from that of the pure graphene. For example, we can obtain semiconductor of a gap about 3eV with flat valance and conduction bands, or semimetal with anisotropic Dirac cones in which the position of Dirac points are shifted from K points, or semimetal with flat band crossing the Dirac cone at the Dirac point. The consequences of these features will be presented. We are able to get good metal with considerable density of states at Fermi level. The phonon dispersions and spectra as well as the electron-phonon couplings of such metallic systems are currently being investigated by the first-principles calculation, their superconductivity transition temperatures  $T_c$  should thus be predictable by assuming the electron-phonon coupling as the pairing interaction. We expect that the phonon frequencies are quite large, and the  $T_c$  could be high for some of the metallic systems.

**4:18PM C15.00010 Peculiarity of Thiophene/Graphene interface for organic electronic applications**, SOURAYA GOUMRI-SAID, Al Faisal University — Interfacial study between thiophene molecule and graphene surface is investigated on the basis of density functional theory. The reported HOMO-LUMO energy gaps, adsorption energy as well as binding energy are showing the existence of intermolecular forces accumulated from the attractive van der Waals forces and Pauli repulsion forces. The interface's separation distance is varied from 1.00Å to 2.50Å. It is noted that, subsequently growing intermolecular forces are very sensitive even to a relatively small change in the interface's separation distance between the molecule and the surface. The electronic density of states, dense electrons population of the thiophene/graphene system is found to be at energy Fermi level with appearance of spin-polarization. A slight magnetic behaviour on thiophene molecule, accompanied by a decrease in the magnetization of graphene surface was observed in the presence of the molecule near to the surface.

**4:30PM C15.00011 Adsorption of Nitric Oxide on Carbon Vacancies in Graphene and its Impact on the Conductivity**, JORGE SOFO, SANGZI LIANG, Physics Department, The Pennsylvania State University, GUGANG CHEN, AVETIK HARUTYUNYAN, Honda Research Institute — The conductance of graphene in FET devices increases when exposed to NO with detection limits down to the part-per-quadrillion level. We explore a possible explanation for this phenomena assuming that NO chemisorbs to vacancies and eventually dissociates. We found that adsorption of NO in graphene vacancies is favorable by 5.3 eV. In order to evaluate the conductivity due to these impurities, we obtain a minimum tight binding model with a Wannier transformation of the Kohn-Sham orbitals obtained by DFT. We evaluate the conductivity using the Kubo-Greenwood formula and the kernel polynomial method. We consider vacancies, NO and N chemisorbed in the vacancies, and O as an adatom on graphene. We found that the conductivity stays the same when NO adsorbs into a vacancy, but it increases when the oxygen atom moves away from the nitrogen atom, either leaving or moving to other parts of the surface, with the former giving a larger increase in conductivity.

**4:42PM C15.00012 Using Single Adatoms to Sense Screening by Graphene Charge Carriers**, JONATHAN WYRICK, FABIAN NATTERER, Center for Nanoscale Science and Technology, NIST, YUE ZHAO, Center for Nanoscale Science and Technology, NIST; University of Maryland, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, NIKOLAI ZHITENEV, JOSEPH STROSCIO, Center for Nanoscale Science and Technology, NIST — As electronic devices approach the nanometer scale it becomes increasingly necessary to understand how small numbers of defects interact with one another and ultimately determine the behavior of a device. In the case of devices with graphene exposed at the surface, defects can be modelled and varied by depositing adatoms. We investigate how Co atoms adsorbed on graphene create and modify the electric potential experienced by graphene carriers using scanning tunneling microscopy and spectroscopy at low temperature. When an STM tip is brought into proximity to a biased graphene sample the electric field between tip and sample is screened by graphene's 2D electron gas, resulting in a local top-gating potential under the tip. This potential can be manipulated by varying a backgate voltage and the sample bias, and can be spatially characterized by imaging charging rings that form around defects when the potential changes their charge state. We find that defect charging rings lying near or even crossing adsorbed Co atoms become distorted and can form secondary charging rings around those atoms. To explain these effects we employ a charging model that incorporates a defect resonance, the screened tip potential, and modified screening in regions localized around Co atoms.

**4:54PM C15.00013 Transport measurement of Li doped monolayer graphene**, ALI KHADEMI, EBRAHIM SAJADI, PINDER DOSANJH, JOSHUA FOLK, Department of Physics and Astronomy, University of British Columbia, Vancouver, BC, V6T1Z1, Canada, ALEXANDER STHR, STIVEN FORTI, ULRICH STARKE, Max Planck Institute for Solid State Research, 70569 Stuttgart, Germany — Lithium adatoms on monolayer graphene have been predicted to induce superconductivity with a critical temperature near 8 K [1], and recent experimental evidence by ARPES indicates a critical temperature nearly that high [2]. Encouraged by these results, we investigated the effects of lithium deposited at cryogenic temperatures on the electronic transport properties of epitaxial and CVD monolayer graphene down to 3 K. The change of charge carrier density due to Li deposition was monitored both by the gate voltage shift of the Dirac point and by Hall measurements, in low and high doping regimes. In the high doping regime, a saturation density of  $210^{13} \text{ cm}^{-2}$  was observed independent of sample type, initial carrier density and deposition conditions. No signatures of superconductivity were observed down to 3 K. [1] G. Profeta, et al., Nat Phys 8, 131 (2012). [2] B. M. Ludbrook, et al., PNAS 112 (38), 11795–11799 (2015).

**5:06PM C15.00014 Phase transitions of monolayers on graphene**, JOSHUA KAHN, BORIS DZYUBENKO, OSCAR VILCHES, DAVID COBDEN, Department of Physics, University of Washington — We have studied physisorbed layers of monatomic and diatomic gases on graphene. We used devices in which few-layer graphene, ranging from monolayer to trilayer, is suspended across a trench between two platinum contacts and are cleaned by thermal and current annealing. We found that the density of adsorbates is revealed by the conductance, similar to the case with nanotubes. The conductance change for a monolayer can be large. On trilayer graphene the adsorbed gases can be seen to exhibit transitions between two-dimensional phases identical to those on bulk graphite, including incommensurate and commensurate solid, fluid and vapor and multiple layers. New features appear in the conductance at the boundaries of the commensurate phase of Kr. We are able to measure single-particle binding energies very accurately and see how it depends on thickness; investigate the effects of changing disorder by gradually current annealing; and search for new phases in the case of monolayer graphene where atoms adsorbed on both sides can interact. We can map out the 2d phase diagrams very quickly by ohmic heating, which gives nearly instantaneous control of the temperature.

**5:18PM C15.00015 Electronic transport experiments on osmium-adatom-decorated graphene**, JAMIE ELIAS, ERIK HENRIKSEN, Washington University in St. Louis — Monolayer graphene is theoretically predicted to inherit a spin-orbit coupling from a dilute coating of certain transition metal adatoms. To explore these predictions we have constructed a cryogenic probe capable of *in situ* thermal annealing of graphene followed immediately by electronic transport measurements and controlled deposition of sub-monolayer coatings of most any metal. Previously a light coating of indium on graphene was investigated, and found to transfer electrons to graphene and reduce the mobility although no evidence of an induced spin-orbit coupling was seen. We are now depositing osmium and tungsten on graphene devices. Our initial results show an unexpected hole-doping and a sizable increase in resistance of the sample. We will report our progress on characterizing these samples by electronic transport measurements.

Session C16 DCMP DMP: Scanning Tunneling Microscopy/Spectroscopy of Graphene 315 -  
Michael Lodge, University of Central Florida

**2:30PM C16.00001 Imaging nonlocal transport in graphene using scanning gate microscopy<sup>1</sup>**, MALCOLM CONNOLLY, ZIWEI DOU, University of Cambridge, SEI MORIKAWA, Institute of Industrial Science, University of Tokyo, SHU-WEI WANG, CHARLES SMITH, University of Cambridge, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, SATORU MASUBUCHI, TOMOKI MACHIDA, Institute of Industrial Science, University of Tokyo — Nonlocal transport measurements are designed to detect when charge injected by a current probe induces voltages far from the classical current path. While a range of exotic forces can induce nonlocal transport of Dirac fermions in graphene such as bandstructure topology [1], Zeeman spin Hall [2], and many-body interactions [3], it is important to understand the role of density fluctuations around the Dirac point where nonlocality can be most pronounced. We use scanning gate microscopy to image current flow and nonlocal signals directly in high-mobility graphene encapsulated by hexagonal boron nitride. Despite being located several mean-free paths from the current injector, Hall voltage probes parallel with current path display an order of magnitude larger nonlocal signal than expected around the Dirac point. SGM images captured at different carrier density are consistent with current spreading due to percolation. Such long range charge transport should be considered when designing devices and calculating the relaxation length of nonlocal currents. [1] R. V. Gorbachev, et al., Science, 346, 6208, 448-451 (2014) [2] D. A. Abanin, et al., Science, 332, 6027, 328-330 (2011) [3] D. A. Bandurin, arXiv:1509.04165 (2015)

**2:42PM C16.00002 New Approaches to Edge-Doping Graphene Nanoribbons**, DANIEL J. RIZZO, TOMAS MARANGONI, TING CAO, GIANG D. NGUYEN, HSIN-ZON TSAI, ARASH A. OMRANI, CHRISTOPHER BRONNER, TRINITY JOSHI, GRIFFIN F. RODGERS, WON-WOO CHOI, RYAN R. CLOKE, STEVEN G. LOUIE, FELIX R. FISCHER, MICHAEL F. CROMMIE, UC Berkeley, CROMMIE TEAM<sup>1</sup>, FISCHER TEAM<sup>2</sup>, LOUIE TEAM<sup>3</sup> — Graphene nanoribbons (GNRs) are narrow semiconducting strips of graphene that exhibit novel electronic and magnetic properties. New bottom-up fabrication techniques enable atomic-scale precision in GNR synthesis. The use of these techniques to reliably tune the position and size of GNR band gaps is an important challenge that also has relevance for the question of whether GNRs are viable for future nanotechnologies. We have used scanning tunneling microscopy (STM) and scanning tunneling spectroscopy (STS) to investigate how the geometry of heteroatom incorporation alters the electronic structure of bottom-up fabricated chevron-type GNRs. We find that the addition of nitrogen into the GNR edge via a five-membered ring yields a reduced band gap compared to the behavior of pristine, undoped chevron GNRs.

**2:54PM C16.00003 Scanning tunneling microscopy of atomically precise graphene nanoribbons exfoliated onto H:Si(100)**, ADRIAN RADOCEA, University of Illinois at Urbana-Champaign, MOHAMMAD MEHDI POUR, TIMOTHY VO, MIKHAIL SHEKHIREV, ALEXANDER SINITSKII, University of Nebraska - Lincoln, JOSEPH LYDING, University of Illinois at Urbana-Champaign — Atomically precise graphene nanoribbons (GNRs) are promising materials for next generation transistors due to their well-controlled bandgaps and the high thermal conductivity of graphene. The solution synthesis of graphene nanoribbons offers a pathway towards scalable manufacturing. While scanning tunneling microscopy (STM) can access size scales required for characterization, solvent residue increases experimental difficulty and precludes band-gap determination via scanning tunneling spectroscopy (STS). Our work addresses this challenge through a dry contact transfer method that cleanly transfers solution-synthesized GNRs onto H:Si(100) under UHV using a fiberglass applicator. The semiconducting silicon surface avoids problems with image charge screening enabling intrinsic bandgap measurements. We characterize the nanoribbons using STM and STS. For chevron GNRs, we find a 1.6 eV bandgap, in agreement with computational modeling, and map the electronic structure spatially with detailed spectra lines and current imaging tunneling spectroscopy. Mapping the electronic structure of graphene nanoribbons is an important step towards taking advantage of the ability to form atomically precise nanoribbons and finely tune their properties.

**3:06PM C16.00004 LT-STM/STS studies of clean armchair edge**<sup>1</sup>, ZHENG JU, WENHAN ZHANG, WEIDA WU, Department of Physics and Astronomy, Rutgers University, WEIDA WU TEAM — It was predicted and observed that the passivated zigzag edges of graphene host highly localized edge state [1]. This edge state is predicted to be spin-polarized, which is appealing for spintronic applications. In contrast, no edge state was expected at passivated armchair graphene edge. Here we report low temperature scanning tunneling microscopy and spectroscopy (STM/STS) studies of electronic properties of clean monoatomic step edges on cleaved surface of HOPG. Most of step edges are armchair edges, in agreement with previous STM results. We observed only  $(\sqrt{3} \times \sqrt{3})R30^\circ$  superstructure near armchair edges, which has been reported in previous STM studies [2, 3, 4]. On the other hand, no honeycomb superstructure was observed in our STM data. In addition, our STM results reveal an intriguing localized electronic state at clean armchair edges. Spectroscopic and spatial evolution of this edge state will be presented. [1] Fujita et al, JSPJ, 65, 1920, (1996). [2] Niimi et al, PRB, 73, 085421 (2006). [3] Giunta and Kelyt, J. Chem. Phys., 114, 1807 (2001). [4] Sakai, et al, PRB, 81, 235417(2010).

**3:18PM C16.00005 Exotic Charge Polarization near Dirac Cone Merging Transition in Graphene-based Systems**, NOAH WILSON, OWEN MYERS, TARAS LAKOBA, VALERI KOTOV, Univ of Vermont — Extreme strain in graphene yields a fascinating charge distribution around a Coulomb impurity. Graphene's band structure is characterized by gapless Dirac cones but can be made gapped by application of intense strain. The cones become increasingly elliptic continually merging, until the spectrum has an exotic, highly anisotropic, semi-Dirac, nature. This situation can also occur in various artificially engineered lattices. The unusual spectrum leads to an unconventional charge distribution around a Coulomb impurity. Crucially, unlike isotropic graphene, the polarization charge density exhibits long-range oscillatory tails far from the impurity. Such exotic behavior is due to the anisotropy of the polarization, and occurs even at zero chemical potential (i.e. unrelated to Friedel-type physics). The angular and radial functions are intrinsically coupled, hence a litany of distinct angular distributions is observed through multiple distance regimes. The density can approach infinity at angles where it was once close to zero, be negative all around the impurity, or have its polarity fluctuate along different directions. Thus our results could have important implications for STM experiments probing polarization charge around impurities in highly anisotropic Dirac systems.

**3:30PM C16.00006 Experimental Evidence of Giant Non-reciprocity of WGM Modes in Graphene**, YUE ZHAO, Dept. of Physics, South University of Science and Technology of China; Center for Nanoscale Science and Technology, NIST; Maryland Nanocenter, UMD, JONATHAN WYRICK, FABIAN NATTERER, Center for Nanoscale Science and Technology, NIST, JOAQUIN RODRIGUEZ-NIEVA, Dept. of Physics, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Material Science, Japan, LEONID LEVITOV, Dept. of Physics, Massachusetts Institute of Technology, NIKOLAI ZHITENEV, JOSEPH STROSCIO, Center for Nanoscale Science and Technology, NIST — Klein scattering in a circular graphene pn junction can lead to Whispering Gallery Mode(WGM) type resonances[1]. Utilizing the electrostatic potential induced by the probe of a scanning tunneling microscope, we create graphene electron resonators defined by circular pn junctions. These quasi-confined WGM states can be probed by tunneling spectroscopy measurements. With small applied magnetic fields, we observe a large energy splitting of the WGM states, displaying a manifestation of non-reciprocity due to Klein scattering of massless Dirac fermions in graphene [2].

**3:42PM C16.00007 The synthesis of planar sp<sup>2</sup>-bonded system from molecular building blocks**<sup>1</sup>, XIN ZHANG, HONG LUO, University at Buffalo, GONG GU, University of Tennessee, Knoxville — Biphenyl and pyrene molecules were deposited onto atomically flat Cu (100) surface as building blocks for the synthesis of planar, conjugated, sp<sup>2</sup>-bonded system. In situ STM observation confirmed the formation of highly-ordered lattice structure after annealing under UHV condition, as a result of the substrate-assisted dehydrogenation. The electronic properties of the system were examined by STS and will be presented.

<sup>1</sup>ONR N00014-15-1-2661

**3:54PM C16.00008 Tunneling spectroscopy in metal-hexagonal boron nitride-graphene structures<sup>1</sup>**, U. CHANDNI, Institute for Quantum Information and Matter and Department of Physics, California Institute of Technology, Pasadena, California 91125, USA, K. WATANABE, T. TANIGUCHI, National Institute for Materials Science, 1-1 Namiki, Tsukuba Ibaraki 305-0044, Japan, J. P. EISENSTEIN, Institute for Quantum Information and Matter and Department of Physics, California Institute of Technology, Pasadena, California 91125, USA — Tunneling spectroscopy provides a tool to probe the density of states of various electronic materials. Here, we report vertical tunneling transport in van der Waals heterostructures with hexagonal boron nitride (hBN) as a tunnel barrier between graphene (or graphite) and a metal (Cr/Au) electrode. We observe a strong suppression of tunneling at low biases, with a gap of about 130 meV in the dI/dV spectrum for metal-hBN-graphene (or graphite) structures. In the graphene devices, the finite zero-bias tunnel resistance was found to depend on the electron density of the graphene layer, while the gap remained unaffected. We also tested graphite-hBN-graphite junctions, in which the strong suppression of tunneling at low energies was found to be absent. We interpret the signatures in the context of phonon-mediated processes in such vertical heterostructures.

**4:06PM C16.00009 Modification of Electronic Surface States by Graphene Islands on Cu(111)<sup>1</sup>**, GRADY GAMBREL, The Ohio State University, SHAWNA HOLLEN, University of New Hampshire, STEVEN TJUNG, NANCY SANTAGATA, EZEKIEL JOHNSTON-HALPERIN, JAY GUPTA, The Ohio State University — The interaction of graphene with copper is of interest for graphene applications due to the frequent use of copper in the chemical vapor deposition (CVD) growth of graphene. We grew pristine graphene islands on Cu(111) by dissociating ethylene gas in an ultra high vacuum environment. In situ low-temperature scanning tunneling microscopy (STM) was used to measure the physical and electronic structure of the surface with atomic resolution, enabling us to compare the graphene-covered regions to bare Cu(111). We observed a shift of the Rydberg-like series of images potential states (IPS) to lower energies and a decrease in linewidth in graphene-covered regions, indicating a decrease in local work function and reduced coupling to the copper bulk states. In some cases, the first of these states were split, which may correspond to the dual Rydberg series which has been predicted for graphene. By measuring the dispersion of the Shockley surface state, we found that the band edge and effective mass are influenced by the graphene layer. We will extend these findings [SM Hollen, et al. Phys. Rev B 91, 195425 (2015)] to our study of in situ graphene devices and present preliminary STM and transport data with respect to gate voltage.

<sup>1</sup>Funding for this research was provided by the Center for Emergent Materials: an NSF MRSEC under award number DMR-0820414

**4:18PM C16.00010 Screening of a Coulomb Charge by Dirac Electrons in Graphene<sup>1</sup>**, JINHAI MAO, YUHANG JIANG, GUOHONG LI, Rutgers University, NJ, USA, D. MOLDOVAN, M. RAMEZANI MASIR, F. M. PEETERS, University of Antwerp, Belgium, EVA Y. ANDREI, Rutgers University, NJ, USA — Single-atom vacancies in graphene exhibit a rich variety of electronic phenomena ranging from mid-gap states to Kondo screening. Here we report on a new phenomenon showing that vacancies can host a positive charge which can be built up gradually by applying voltage pulses with the tip of a scanning tunneling microscope. The response of the conduction electrons to this charge, which is monitored with scanning tunneling and Landau level spectroscopy, and compared to numerical simulations, exhibits an unusual electron-hole asymmetry. On the p-doped side screening is weak. In this regime, as the charge is increased its interaction with the conduction electrons undergoes a transition into a regime where itinerant electrons are trapped in quasi-bound states (QBS) resembling an artificial atom. We observe the equivalent of the atomic 1S and 2S states as well as the emergence of a new satellite of the 1S state resulting from the broken sublattice symmetry at the vacancy site. In contrast, on the n-doped side screening is very efficient: as soon as the n-doped regime is entered the charge is screened and the QBS disappear. We show that the QBS are gate tunable and that the trapping mechanism can be turned on and off, providing a new mechanism to control electrons in graphene.

**4:30PM C16.00011 Computer simulation of STM images of vertical heterostructures of graphene/hexagonal boron nitride with intercalated atoms<sup>1</sup>**, GUNN KIM, JUNSU LEE, Sejong Univ — Using density functional theory, we did computational simulations of scanning tunneling microscopy of vertical graphene/hexagonal boron nitride heterostructures with an intercalated atom (Li, K, Cr, Mn, Co or Cu). A plane-wave basis set was employed with a kinetic energy of 400 eV. The form of the Perdew-Burke-Ernzerhof type was utilized for the exchange-correlation energy functional. To obtain the more accurate result, the van der Waals interaction was also considered. In the computer-simulated scanning tunneling microscopy (STM) images in the Tersoff-Hamann scheme, we demonstrated that the single impurity atom between Gr and hBN sheets is detectable. We observed three different STM patterns on the graphene side. These can be classified by group 1 (Li, Co, and Cu), group 2 (Cr and Mn), and group 3 (K), which have hexagonal, circular, and wide bright spot patterns around the impurity atom, respectively. Although Co and Cu are both in group 1, the Co atom shows stronger d orbital character than the Cu atom. Interestingly, in the case of the Co atom, the simulated STM images are quite different at bias voltages of -0.1 V and +0.1 V. While C  $p_z$ -Co  $d_{yz}$  hybridization occurs at the bias voltage of -0.1 V, C  $p_z$ -Co  $d_{xz}$  hybridization occurs at the bias voltage of +0.1 V.

**4:42PM C16.00012 Growth and analysis of polymorphic graphene with STM and LEEM-IV for applications in molecular self-assembly and organic electronics<sup>1</sup>**, MAXWELL GRADY, Univ of New Hampshire, TAISUKE OHTA, BOGDAN DIACONESCU, Sandia National Laboratory, ZHONGWEI DAI, KARSTEN POHL, Univ of New Hampshire — Graphene has aroused tremendous interest due to its remarkable electronic and mechanical properties, and is of interest for use in organic electronic devices such as organic photovoltaic cells. We present an analysis of a novel graphene system grown on Ru(0001) in the presence of atomic hydrogen and carbon vapor using STM and LEEM-IV. Structural studies completed with STM show a wide array of moire superlattice sizes ranging from 0.9 to 3.0 nm. Preliminary LEEM and LEEM-IV results confirm the presence of ordered graphene atop the Ru(0001) surface. Investigation using LEEM-IV provides information about the carbon layer thickness; also, micro-LEED-IV determines the precise atomic reconstruction of the interface region. In this regard, we believe the hydrogen present in the system to be interstitial at the carbon-ruthenium interface thus passivating the ruthenium surface, decoupling, and lifting the carbon layer from the substrate. The structural polymorphism displayed by this system is of interest for the study of directed self-assembly. Control over moire size can aid in future work using graphene as a template for self-assembled growth of organic electronics.

#### 4:54PM C16.00013 Scanning Tunneling Microscopy Studies of Crystalline Hydrogenation of Graphene Grown on Cu(111)<sup>1</sup>

, STEVEN J. TJUNG, GRADY A. GAMBREL, The Ohio State University, SHAWNA M. HOLLEN, University of New Hampshire, JAY A. GUPTA, The Ohio State University — Because of the sensitivity of 2D material surfaces, chemical functionalization can be exploited to tune the electronic structure of these materials. For example, hydrogen bonding to carbon atoms in graphene tunes the material from a semi-metal to a wide-gap insulator. We developed a method for a reproducible epitaxial growth of graphene on Cu(111) in the ultra-high vacuum chamber of a scanning tunneling microscope (STM). We find that hydrogen atoms can be bonded to the graphene in a nanoscale region using a novel field-emission process, whereby physisorbed H<sub>2</sub> is cracked in situ using the STM tip. This method produced crystalline surfaces of hydrogen-terminated graphene with 4.2Å lattice, which has proven difficult to produce using conventional atomic beam methods which typically produced disordered hydrogenation. Additionally, this hydrogenation process is reversible and we are able to recover the pristine graphene by H desorption during STM imaging at a high bias. STM images after the dehydrogenation process showed the same atomic lattice and Moiré pattern as the pristine graphene, with the exception of additional point defects. STM spectra show the suppression of the Cu surface state on the hydrogenated graphene, but the opening of a wide-gap was not observed.

#### 5:06PM C16.00014 Experimental Investigation of the Electronic Properties of Twisted Bilayer Graphene by STM and STS

, LONGJING YIN, JIABIN QIAO, WENXIAO WANG, WEIJIE ZUO, LIN HE, Beijing Normal Univ — The electronic properties of graphene multilayers depend sensitively on their stacking order. A twisted angle is treated as a unique degree of freedom to tune the electronic properties of graphene system. Here we study electronic structures of the twisted bilayers by scanning tunneling microscopy (STM) and spectroscopy (STS). We demonstrate that the interlayer coupling strength affects both the Van Hove singularities and the Fermi velocity of twisted bilayers dramatically. This removes the discrepancy about the Fermi velocity renormalization in the twisted bilayers and provides a consistent interpretation of all current data. Moreover, we report the experimental evidence for non-Abelian gauge potentials in twisted graphene bilayers by STM and STS. At a magic twisted angle, about 1.11, a pronounced sharp peak is observed in the tunnelling spectra due to the action of the non-Abelian gauge fields. Because of the effective non-Abelian gauge fields, the rotation angle could transfer the charge carriers in the twisted bilayers from massless Dirac fermions into well localized electrons, or vice versa, efficiently. This provides a new route to tune the electronic properties of graphene systems, which will be essential in future graphene nanoelectronics.

#### 5:18PM C16.00015 Ab initio study of friction of graphene flake on graphene/graphite or SiC surface<sup>1</sup>

, OGUZ GULSEREN, Bilkent University, CEREN TAYRAN, Gazi University, CEREN SIBEL SAYIN, Bilkent University — Recently, the rich dynamics of graphene flake on graphite or SiC surfaces are revealed from atomic force microscopy experiments. The studies toward the understanding of microscopic origin of friction are getting a lot of attention. Despite the several studies of these systems using molecular dynamics methods, density functional theory based investigations are limited because of the huge system sizes. In this study, we investigated the frictional force on graphene flake on graphite or SiC surfaces from pseudopotential planewave calculations based on density functional theory. In both cases, graphene flake (24 C) on graphite or SiC surface, bilayer flake is introduced by freezing the top layer as well as the bottom layer of the surface slab. After fixing the load with these frozen layers, we checked the relative motion of the flake over the surface. A minimum energy is reached when the flake is moved on graphene to attain AB stacking. We also conclude that edge reconstruction because of the finite size of the flake is very critical for frictional properties of the flake; therefore the saturation of dangling bonds with hydrogen is also addressed. Not only the symmetric configurations remaining parameter space is extensively studied. Supported by TUBITAK Project No: 114F162.

Session C17 DCMP: Charge Density Waves: Low Dimensional and Organic Conductors 316 - Eva Andrei, Rutgers University

#### 2:30PM C17.00001 Enhancement of charge ordering by dynamic electron-phonon interaction

, ANDREJ SINGER, Department of Physics, University of California San Diego, ERIC FULLERTON, Center for Memory and Recording Research, University of California San Diego, OLEG SHPYRKO, Department of Physics, University of California San Diego — Symmetry breaking and emergence of order is one of the most fascinating phenomena in condensed matter physics and leads to a plethora of intriguing ground states such as in antiferromagnets, Mott insulators, superconductors, and density-wave systems. Exploiting non-equilibrium dynamics of matter following ultrafast external excitation can provide even more striking routes to symmetry-lowered, ordered states, for instance, by accessing hidden equilibrium states in the free-energy landscape or dynamic stabilization of non-equilibrium states. This is remarkable because ultrafast excitation typically creates disorder, reduces the order parameter, and raises the symmetry. Here, we demonstrate for the case of antiferromagnetic chromium that moderate photo-excitation can transiently enhance the charge-density-wave (CDW) order by up to 30% above its equilibrium value, while strong excitation leads to an oscillating, large-amplitude CDW state that persists above the equilibrium transition temperature. Both effects result from dynamic electron-phonon interaction, which provides an efficient mechanism to selectively transform a broad excitation of the electronic order into a well defined, long-lived coherent lattice vibration. This mechanism may be exploited to transiently enhance the order parameter in other systems with coupled electronic and lattice orders. The data was collected at the x-ray free electron laser LCLS at SLAC.

#### 2:42PM C17.00002 Transport studies in the incommensurate charge density wave series RTe<sub>3</sub>

, PHILIP WALMSLEY, SIMON AESCHLIMANN, Stanford University, PAULA GIRALDO GALLO, NHMFL, Florida State University, IAN FISHER, Stanford University — The quasi-2D rare-earth tritelluride compounds (RTe<sub>3</sub>; R=La-Tm) are a model series in which to study incommensurate charge density waves (iCDWs), with the interplay between Fermi surface nesting and electron-phonon coupling forming an open and lively area of research. The slight orthorhombicity in the 2D Te bilayer that forms the Fermi surface favors a single-domain unidirectional iCDW along the c-axis, with a second, perpendicular unidirectional iCDW forming at lower temperatures in the heavier members (R=Tb-Tm). It remains unclear how the lower temperature iCDW disappears with rare earth substitution (chemical pressure) and whether there is an associated quantum phase transition. We present recent transport measurements that study the evolution of the two iCDWs as they are tuned across the enormous phase-space offered by these compounds, with a particular focus on the in-plane anisotropy and Fermi-surface geometry.

#### 2:54PM C17.00003 Magnetic properties of single crystalline HoTe<sub>3</sub>

, M.S. SONG, B.Y. KANG, K.K. CHO, B.K. CHO, Gwangju Inst of Sci & Tech — Charge density waves (CDWs) are in a broken ground state, driven by electronic instabilities in a low-dimensional system with a highly anisotropic electronic structure [1]. As one of the CDW materials, the RTe<sub>3</sub> (R = rare earth elements) compound is a quasi-two-dimensional system. Even if the magnetic properties of RTe<sub>3</sub> in light rare earth elements have been reported [2], magnetic and electronic information in heavy rare earth elements remains unknown. In this study, the magnetic properties of HoTe<sub>3</sub> were investigated and two ferromagnetic transitions were discovered along a direction perpendicular to the stacking axis while RTe<sub>3</sub>. An antiferromagnetic transition temperature was found at T<sub>N</sub> = 4.5 K for H // b and two ferromagnetic transitions were found at T<sub>c1</sub> = 3.5 K and T<sub>c2</sub> = 4.5 K for H ⊥ b.

**3:06PM C17.00004 Temperature-Dependent Studies of Charge Density Wave States in  $\text{TbTe}_3$**  , MICHAEL BOYER, AARON KRAFT, LING FU, BISHNU SHARMA, Clark University, IAN FISHER, Stanford University — We use temperature-dependent scanning tunneling microscopy (STM) to study charge density wave (CDW) states in  $\text{TbTe}_3$ .  $\text{TbTe}_3$  undergoes a bulk CDW transition near 335 K, though x-ray data shows evidence for CDW fluctuations up to 363 K.[1] Our STM measurements characterize the well-established, long-range, unidirectional CDW state ( $q_{\text{cdw}} = 0.71 \text{ c}^*$ ) at 300 K. Our temperature-dependent measurements above  $T_{\text{CDW}}$  show evidence for localized static CDW order which is consistent with x-ray detection of CDW fluctuations above  $T_{\text{CDW}}$ . Surprisingly, we also find evidence for localized static order associated with a second CDW along the a-axis, a CDW state which never establishes long-range coherence in the bulk of  $\text{TbTe}_3$  even at low temperatures. [1] Ru et al., PRB 77, 035114 (2008).

**3:18PM C17.00005 Doping-induced Charge-Density-Wave** , ATSUSHI NOMURA, KAZUHIKO YAMAYA, SHIGERU TAKAYANAGI, KOICHI ICHIMURA, TORU MATSUURA, SATOSHI TANDA, Hokkaido University, HOKKAIDO UNIVERSITY TEAM — Doping is a useful method for searching new characters in solids, as we can see in the discoveries of impurity semiconductors and high-temperature superconductors. If a Charge-Density-Wave (CDW) is induced in materials which do not exhibit a CDW, new CDW properties might be brought there.  $\text{TaSe}_3$  exhibits no CDW transition but a superconductivity transition at about 2 K while it has a quasi-one-dimensional chain structure as well as typical CDW conductors,  $\text{NbSe}_3$ ,  $\text{TaS}_3$ , and  $\text{NbS}_3$ . Therefore,  $\text{TaSe}_3$  is one of the suitable materials for the induction of a CDW by doping, and we tried to induce a CDW in  $\text{TaSe}_3$  by doping Cu. Cu concentration was determined by inductively coupled plasma atomic emission spectroscopy (ICP-AES). The high Cu concentration was consistent with the high value of residual resistance ( $R(4.5 \text{ K})/(R(280 \text{ K}) - R(4.5 \text{ K}))$ ). Single-crystal X-ray diffraction pattern (XRD) showed an expansion of the  $c$ -axis in Cu-doped  $\text{TaSe}_3$ . The temperature dependence of the resistivity showed the anomaly at 80-100 K in Cu-doped  $\text{TaSe}_3$ , which was never observed in pure  $\text{TaSe}_3$ . These results suggest that the Cu-doping induces a CDW. We will discuss the relation between the resistivity anomaly and superconductivity.

**3:30PM C17.00006 ABSTRACT WITHDRAWN —**

**3:42PM C17.00007 Observation of an Excitonic Sound Wave in  $\text{TiSe}_2$  with meV-resolution EELS** , ANSHUL KOGAR, MELINDA RAK, SEAN VIG, ALI HUSAIN, Univ of Illinois - Urbana, YOUNG IL JOE, NIST, PETER ABBAMONTE, Univ of Illinois - Urbana — The charge density wave (CDW) in  $\text{TiSe}_2$  has been attributed to an excitonic instability by many authors. In a conventional CDW material, there exists a soft phonon at the transition temperature, which, below the transition temperature, gives way to the phase and amplitude collective excitations of the CDW order parameter. In  $\text{TiSe}_2$ , a soft phonon has indeed been observed with inelastic X-ray scattering. In the 1960s, though, W. Kohn predicted that one of the signatures of an excitonic instability would be the presence of a soft electronic excitation which similarly gives way to an excitonic sound mode in the condensed phase. In this talk, I will present data showing that the  $\text{TiSe}_2$  exhibits a collective excitation consistent with the excitonic sound wave prediction, which emerges out of the normal phase plasmon. This provides strong evidence that excitonic correlations play a role in the CDW formation in  $\text{TiSe}_2$ . Hence, a more nuanced view of the charge density wave transition in  $\text{TiSe}_2$  is needed where both excitonic effects and electron-phonon coupling must be taken into consideration.

**3:54PM C17.00008 ABSTRACT WITHDRAWN —**

**4:06PM C17.00009 Decay of Bloch oscillations in the charge-density-wave ordered phase of an all electronic charge density wave state** , OLEG MATVEEV, Department of Physics, Georgetown University, Washington, DC , ANDRII SHVAIKA, Institute for Condensed Matter Physics of the National Academy of Sciences of Ukraine, Lviv, Ukraine, THOMAS DEVEREAUX, Geballe Laboratory for Advanced Materials, Stanford University, Stanford, CA, USA, JAMES FREERICKS, Department of Physics, Georgetown University, Washington, DC — The charge-density-wave phase of the Falicov-Kimball model displays a number of anomalous behavior including the appearance of subgap density of states as the temperature increases. These subgap states should have a significant impact on transport properties, particularly the nonlinear response of the system to a large dc electric field. Using the Kadanoff-Baym-Keldysh formalism, we employ nonequilibrium dynamical mean-field theory to exactly solve for this nonlinear response. We examine both the current and the order parameter of the conduction electrons as the ordered system is driven by a dc electric field.

**4:18PM C17.00010 Ground state in  $\kappa - (\text{BEDT} - \text{TTF})_2\text{Hg}(\text{SCN})_2\text{Br}$  studied by Raman Spectroscopy and Heat Capacity measurements<sup>1</sup>** , N. HASSAN, Johns Hopkins Univ, S. A. TURUNOVA, E.I. ZHILYAEVA, R.N. LYUBOVSKAYA, Institute of Problems of Chemical Physics, Chernogolovka, Russia, N. DRICHKO, Johns Hopkins Univ — Quasi-two-dimensional organic conductor  $\kappa - (\text{BEDT} - \text{TTF})_2\text{Hg}(\text{SCN})_2\text{Br}$  is a Mott insulator ( $T_c \approx 100 \text{ K}$ ) on a triangular lattice which makes it a potential spin liquid candidate. To elucidate its magnetic ground state we study heat capacity and Raman response of single crystals of this material. Our low temperature heat capacity measurements suggest a presence of a linear term in the temperature dependence, which might indicate the existence of gapless spinons. Vibrational Raman response indicates a presence of charge order fluctuations in the insulating state. The low-frequency Raman response is discussed in terms of fluctuations of paired electron crystal state [1]. [1] S. Dayal, R. T. Clay, H. Li, and S. Mazumdar, Phys. Rev. B 83, 245106 (2011)

**4:30PM C17.00011 ABSTRACT WITHDRAWN —**

**4:42PM C17.00012 Raman scattering in an anisotropic triangular spin lattice system** , HIDEO KISHIDA, YUTO NAKAMURA, KAZUSHI MIZUKOSHI, Nagoya University, YUKIHIRO YOSHIDA, Meijo University, GUNZI SAITO, Meijo University and Toyota Physical and Chemical Research Institute — Spin-disordered quantum phases in an anisotropic triangular spin lattice system,  $\kappa - (\text{BEDT} - \text{TTF})_2\text{B}(\text{CN})_4$ , were recently reported [1]. In this compound, the ratio of the two transfer integrals,  $t'/t$ , reaches 1.44 at 298 K and 1.80 at 100 K. Its optical conductivity in the infrared region is anisotropic. The temperature dependence of the optical anisotropy correlates with that of  $t'/t$ . From the experimentally evaluated optical anisotropy, we expect that the values of  $t'/t$  are larger than 1.80 in the lower temperature region. For this compound, we observe the polarization-dependent broad Raman scattering signals below  $600 \text{ cm}^{-1}$  at 10 K. In such a wavenumber region, we have observed the magnetic Raman signals in triangular spin lattice systems such as  $\kappa - (\text{BEDT} - \text{TTF})_2\text{X}$  [2] and  $\beta'$ -type  $\text{Pd}(\text{dmit})_2$  salts [3]. By comparison with them, we discuss the origin of the Raman signals observed for  $\kappa - (\text{BEDT} - \text{TTF})_2\text{B}(\text{CN})_4$ . [1] Y. Yoshida *et al.*, Nat. Phys. 11, 679 (2015). [2] Y. Nakamura *et al.*, J. Phys. Soc. Jpn. 83, 074708 (2014). [3] Y. Nakamura *et al.*, J. Phys. Soc. Jpn. 84, 044715 (2015).

**4:54PM C17.00013 Strong light-field effects in correlated organic conductors.** , SHINICHIRO IWAI, YOHEI KAWAKAMI, YOTA NAITOH, HIROTAKE ITOH, SUMIO ISHIHARA, Tohoku University, KENJI YONEMITSU, Chuo University — Optical responses of organic conductors have attracted much attentions, because they exhibit ultrafast solid-state phase transitions in the conducting and/or dielectric natures upon photo-excitations. In this decade, photoinduced melting of correlated insulators with clear charge gap have been extensively investigated. On the other hand, optical responses of correlated metal has not been studied well. Here, we describe a charge localization induced by the 9.3 MV/cm instantaneous electric field of a 1.5 cycle (7 fs) infrared pulse in an organic conductor  $\alpha$ -(bis[ethylenedithio]-tetrathiafulvalene)<sub>2</sub>I<sub>3</sub>. A large reflectivity change of 30 percent and a coherent charge oscillation along the time axis reflect the opening of the charge ordering gap in the metallic phase. This optical freezing of charges, which is the reverse of the photoinduced melting of electronic orders, is attributed to the 10 percent reduction of  $t$  driven by the strong, high-frequency electric field. Furthermore, the contribution of Coulomb repulsion will be discussed on the basis of the polarization dependence of the pump light and the theory.

**5:06PM C17.00014 Dielectric Properties of Organic Charge-Transfer Salts** , J. K. H. FISCHER, P. LUNKENHEIMER, S. KROHNS, Experimental Physics V, EKM, University of Augsburg, Augsburg, Germany, R. S. MANNA, Experimental Physics VI, EKM, University of Augsburg, Augsburg, Germany, B. HARTMANN, H. SCHUBERT, M. LANG, J. MÜLLER, Phys. Inst. Univ. Frankfurt, SFB/TR 49, Frankfurt, Germany, J. A. SCHLUETER, Materials Research, National Science Foundation, Arlington, Virginia, United States, C. MÉZIÈRE, P. BATAIL, Laboratoire MOLTECH, UMR 6200 CNRS-Université d'Angers, Bt. K, UFR Sciences, Angers, France, A. LOIDL, Experimental Physics V, EKM, University of Augsburg, Augsburg, Germany — The BEDT-TTF-based charge-transfer salts have attracted considerable attention due to their often intriguing dielectric properties. An example is  $\kappa$ -(BEDT-TTF)<sub>2</sub>Cu[N(CN)<sub>2</sub>]Cl. It was recently found to exhibit multiferroicity, for which a new electric-dipole driven mechanism was proposed [1]. The polar moment in this system was suggested to arise from the dimerization of the BEDT-TTF molecules, combined with charge order. Another interesting recent example is  $\alpha$ -(BEDT-TTF)<sub>2</sub>I<sub>3</sub>, which shows the signature of relaxor-ferroelectric behavior [2]. Here, we will present an overview of the dielectric properties of the above systems and provide new results on  $\kappa$ -(BEDT-TTF)<sub>2</sub>Hg(SCN)<sub>2</sub>Cl, which also seems to show relaxor-ferroelectric behavior in its charge-ordered state. In addition, we present measurements of  $\delta$ -(EDT-TTF-CONMe<sub>2</sub>)<sub>2</sub>Br. This compound lacks dimerization, but exhibits charge order already at room temperature. [1] P. Lunkenheimer *et al.*, Nat. Mater. **11**, 755 (2012). [2] P. Lunkenheimer *et al.*, Phys. Rev. B **91**, 245132 (2015).

**5:18PM C17.00015 Anisotropic transport and structure of single-crystal molybdenum bronze, Li<sub>0.33</sub>MoO<sub>3</sub>**<sup>1</sup> , SAEED MOSHFEHGYEGANEH, JOSHUA L. COHN, University of Miami, JOHN J. NEUMEIER, Montana State University — We present transport measurements (resistivity, thermopower, thermal conductivity) on single crystals of the quasi-one-dimensional (Q1D), small-gap semiconductor<sup>a</sup> Li<sub>0.33</sub>MoO<sub>3</sub> in the temperature range 150-500 K. The Q1D character of this material is reflected in  $T = 300$  K resistivity ratios,  $\rho_c:\rho_a:\rho_b \simeq 1:20:180$ , and extreme anisotropy in the Seebeck coefficient within the  $a-c$  planes,  $S_c - S_a \simeq 250 \mu\text{V/K}$ . A weak structural anomaly near  $T_s = 355$  K (0.001 Å expansions along  $c^*$  and  $b^*$  directions, comparable contraction along  $a^*$ ) is identified in the temperature-dependent lattice constants from x-ray diffraction, and is coincident with changes in the transport coefficients. Analysis of the transport data at  $T > T_s$  shows that an intrinsic semiconductor model can be applied to explain transport along the most conducting  $c$  axis, but along  $a$  and  $b^*$  the transport is better described by a non-adiabatic, small-polaron picture.

<sup>1</sup>This material is based upon work supported by the U.S. Department of Energy Office of Basic Energy Sciences grant DE-FG02-12ER46888 (Univ. Miami) and the National Science Foundation under grant DMR-0907036 (Mont. St. Univ.)

## Monday, March 14, 2016 2:30PM - 5:18PM – Session C18 GMAG DMP: Iridates I 317 - Deepak Singh, University of Missouri

**2:30PM C18.00001 Topological and unconventional magnetic states in transition metal oxides**<sup>1</sup> , GREGORY FIETE, University of Texas at Austin — In this talk I describe some recent work on unusual correlated phases that may be found in bulk transition metal oxides with strong spin-orbit coupling. I will focus on model Hamiltonian studies that are motivated by the pyrochlore iridates, though the correlated topological phases described may appear in a much broader class of materials. I will describe a variety of fractionalized topological phases protected by time-reversal and crystalline symmetries: The weak topological Mott insulator (WTMI), the TI\* phase, and the topological crystalline Mott insulator (TCMI). If time permits, I will also discuss closely related heterostructures of pyrochlore iridates in a bilayer and trilayer film geometry. These quasi-two dimensional systems may exhibit a number of interesting topological and magnetic phases.

<sup>1</sup>This work is generously funded by the ARO, DARPA, and the NSF.

**3:06PM C18.00002 Multipolar effects in Eu<sub>2</sub>Ir<sub>2</sub>O<sub>7</sub>** , YILIN WANG, XI DAI, Institute of Physics, Chinese Academy of Sci (CAS) — We use the density functional theory plus the rotationally invariant Hartree-Fock mean-field method to study the magnetic properties of the pyrochlore iridate material Eu<sub>2</sub>Ir<sub>2</sub>O<sub>7</sub> (5d<sup>5</sup>), where the crystal field splitting  $\Delta$ , spin-orbit coupling (SOC)  $\lambda$  and Coulomb interaction  $U$  of Ir atoms are all playing significant roles. We have constructed a  $t_{2g}$  Wannier tight-binding Hamiltonian and calculated the  $U$ - $\lambda$  phase diagram, from which we find a very stable all-in/all-out antiferromagnetic ground state for moderate SOC (0.2-0.5 eV). In this magnetic state, except for the dipole moments, we also find considerable multipolar moments (octupole) and large non-linear magnetic susceptibility. With strong enough SOC, the system reduces to a  $j_{eff} = \frac{1}{2}$  single band Hubbard model, and the ground state changes to another antiferromagnetic configuration without multipolar moments. Our results indicate that the coexisting multipolar order is crucial to stabilize the all-in/all-out state and contributes a lot to the non-linear magnetic susceptibility.

**3:18PM C18.00003 Resonant X-ray scattering studies of magnetic order and excitations in pyrochlore iridates.** , DESMOND MCMORROW, London Center Nanotechnology — The rare-earth pyrochlore iridates (R<sub>2</sub>Ir<sub>2</sub>O<sub>7</sub>, R=rare earth) have been proposed to host a number of exotic electronic states as a consequence of the existence of strong spin-orbit coupling of the Ir<sup>4+</sup> ion in the presence of significant electron correlations. Of crucial importance to understanding whether any of these states can be realized in practice is to determine the effective low-energy Hamiltonian describing the system. Here we report a comprehensive series of resonant X-ray experiments, both elastic (REXS) and inelastic (RIXS), which reveal the nature of the magnetic order and excitations in single crystals of Sm<sub>2</sub>Ir<sub>2</sub>O<sub>7</sub> and Nd<sub>2</sub>Ir<sub>2</sub>O<sub>7</sub>.

**3:54PM C18.00004 ABSTRACT WITHDRAWN —**

**4:06PM C18.00005 The interplay of ferromagnetic and antiferromagnetic exchanges in the 3d-5d transition metal oxides Sr<sub>2</sub>B<sub>2</sub>IrO<sub>6</sub> (B=Ni, Cu, Zn)** , KATHARINA ROLFS, EKATERINA POMJAKUSHINA, SANDOR TOT, VLADIMIR POMJAKUSHIN, KAZIMIERZ CONDER, Paul Scherrer Institute — In the field of strongly correlated electron systems significant attention has been drawn towards the study of compounds based on magnetic 4d and 5d transition metal (TM) oxides. The spin orbit coupling (SOC) within these systems becomes non-negligible compared to the crystal field energies and leads to new exotic ground states, such as the Mott insulating state in Sr<sub>2</sub>IrO<sub>4</sub>. In order to understand the influence of the SOC on the electronic ground state the focus also turned to mixed 3d-5d systems, which gives the possibility to disentangle SOC effects from common charge-spin-orbital physics, as it is present in pure 3d TMOs and could also introduce new properties. One group within these candidates is the group of Ir-based double perovskites A<sub>2</sub>B<sub>2</sub>IrO<sub>6</sub> (B=3d TM). While in a large number of insulating 3d TMOs, the superexchange interactions between magnetic ions being nearest neighbour is adequate to determine the magnetic order, the SOC of 5d elements can change the exchange topology. This is possibly the case for Sr<sub>2</sub>NiIrO<sub>6</sub>, Sr<sub>2</sub>CuIrO<sub>6</sub> and Sr<sub>2</sub>ZnIrO<sub>6</sub>. All compounds are high oxygen pressure compounds, which we successfully synthesised. The influence of the 3d metal on the magnetic properties will be discussed based on bulk magnetisation, transport measurements and neutron diffraction.

**4:18PM C18.00006 Magnetic Orders Proximal to the Kitaev Limit in Frustrated Triangular Systems: Application to Ba<sub>3</sub>IrTi<sub>2</sub>O<sub>9</sub>** , ANDREI CATUNEANU, Department of Physics and Center for Quantum Materials, University of Toronto, JEFFREY RAU, Department of Physics and Astronomy, University of Waterloo, HEUNG-SIK KIM, HAE-YOUNG KEE, Department of Physics and Center for Quantum Materials, University of Toronto — Frustrated transition metal compounds in which spin-orbit coupling (SOC) and electron correlation work together have attracted much attention recently. In the case of 5d transition metals, where SOC is large,  $j_{eff} = 1/2$  bands near the Fermi level are thought to encompass the essential physics of the material, potentially leading to a concrete realization of exotic magnetic phases such as the Kitaev spin liquid. We derive a spin model on a triangular lattice based on  $j_{eff} = 1/2$  pseudo-spins that interact via antiferromagnetic Heisenberg ( $J$ ) and Kitaev ( $K$ ) exchanges, and crucially, an anisotropic ( $\Gamma$ ) exchange. Our classical analysis of the spin model reveals that, in addition to small regions of 120°,  $Z_2$  / dual- $Z_2$  vortex crystal and nematic phases, the stripy and ferromagnetic phases dominate the  $J$ - $K$ - $\Gamma$  phase diagram. We apply our model to the 5d transition metal compound, Ba<sub>3</sub>IrTi<sub>2</sub>O<sub>9</sub>, in which the Ir<sup>4+</sup> ions form layered two-dimensional triangular lattices. By combining our ab-initio and classical analyses, we predict that Ba<sub>3</sub>IrTi<sub>2</sub>O<sub>9</sub> has a stripy ordered magnetic ground state.

**4:30PM C18.00007 Spin-Orbit Induced Emergent Magnetic Phases in Iridium Based Oxides<sup>1</sup>** , INDRA DASGUPTA, Department of Solid State Physics, Indian Association for the Cultivation of Science, Jadavpur, Kolkata 700032 — We shall present our results on the electronic structure of 6H perovskite type quaternary iridates Ba<sub>3</sub>M<sub>2</sub>Ir<sub>2</sub>O<sub>9</sub>, where Ir ions form structural dimers and non magnetic M provides a knob to tailor the valence of Ir. We shall first consider the d<sup>4.5</sup> insulator Ba<sub>3</sub>YIr<sub>2</sub>O<sub>9</sub> and explain the origin of the pressure induced magnetic transition to a spin-orbital liquid (SOL) state in this system. As a next example [2], we shall consider a pentavalent (d<sup>4</sup>) 6H perovskite iridate Ba<sub>3</sub>ZnIr<sub>2</sub>O<sub>9</sub> and argue that the ground state of this system is a realization of novel SOL state. Our results reveal that such a system provides a very close realization of the elusive J=0 state where Ir local moments are generated due to the comparable energy scales of the singlet-triplet splitting driven by spin-orbit coupling (SOC) and the superexchange interaction mediated by strong intra-dimer hopping, however substantial frustrated interdimer exchange interactions induce quantum fluctuations favoring SOL phase at low enough temperature. **4:42PM C18.00008 Orbital-selective singlet dimer formation and suppression of double exchange in 4d and 5d systems<sup>1</sup>** , SERGEY STRELTISOV, Institute of Metal Physics, GANG CAO, University of Kentucky, DANIEL KHOMSKII, University of Cologne — One of the main mechanisms of ferromagnetic ordering in conducting materials is the double exchange (DE). It is usually supposed in DE model that the Hund's coupling  $J_H$  is much larger than electron hopping  $t$ ; in this case one stabilizes the state with maximum spin per pair of ions, which finally leads to ferromagnetism in bulk systems. We show that in the dimerized 4d/5d transition metal oxides for which  $J_H$  is reduced and  $t$  is in contrast enhanced, another situation is possible, when formation of the spin-singlets on delocalized orbitals is more favorable. This leads to suppression of the DE and to a strong decrease of the total spin. The model calculations using the dynamical mean-field theory show that this effect survives even in the extended systems, not only for dimers. Such a situation is realized, e.g., in Y<sub>5</sub>Mo<sub>2</sub>O<sub>12</sub>, CrO<sub>2</sub> under pressure and in many other 4d/5d based materials. Another mechanism, which may suppress DE and which is also typical for 4d/5d compounds is the spin-orbit coupling (SOC). We show on the example of Ba<sub>5</sub>Allr<sub>2</sub>O<sub>11</sub>, that in this system it is the combination of molecular-orbital formation and SOC that strongly decreases magnetic moment on Ir.

**4:54PM C18.00009 Investigation of frustrated antiferromagnet on the honeycomb lattice with an applied field<sup>1</sup>** , SHENXIU LIU, Department of Physics, Stanford University, HONGCHEN JIANG, TOM DEVEREAUX, Stanford Institute of Materials and Energy Sciences, SLAC — Quantum spin-1/2 honeycomb XY antiferromagnet, or the equivalent hard-core boson system, with both nearest-neighbor J<sub>1</sub> and next-nearest-neighbor J<sub>2</sub> interactions is a representative frustrated system possibly hosting new phases of matter. Recent theoretical study suggests that this system may exhibit a series of incompressible states, which host fermionic elementary excitations rather than bosonic excitations, at small fixed filling factors or equivalent magnetic field strength. In this work, we will examine the theoretical prediction by directly studying the frustrated honeycomb J<sub>1</sub>-J<sub>2</sub> XY model, using unbiased grand canonical density-matrix renormalization group technique. By searching for magnetization plateaus with an applied magnetic field, we will ultimately determine the presence of these incompressible states as well as their properties. For a more comprehensive study, different variants of this model, including the honeycomb J<sub>1</sub>-J<sub>2</sub> Heisenberg antiferromagnet, will also be investigated.

**5:06PM C18.00010 Topological magnon bands in pyrochlore iridate thin films** , PONTUS LAURELL, GREGORY A FIETE, University of Texas at Austin — Thin films of pyrochlore iridates (A<sub>2</sub>Ir<sub>2</sub>O<sub>7</sub>) have previously been studied using weak-coupling techniques such as DFT and DMFT. Here we approach the systems from the strong coupling limit. Since the pyrochlore iridates most likely reside in the difficult to access intermediate coupling regime, a strong coupling study should offer a complementary viewpoint to existing studies. We carry out a variational mean field calculation of the magnetic ground state configurations. We show that the all-in/all-out state, known as the bulk ground state, is generically present in the triangular-Kagome-triangular trilayers. This state can also be found in bilayer films, in specific parameter regimes. A linear spin-wave analysis of the magnetic excitations is also carried out. It shows that when the magnetic order is in (or close to) the all-in/all-out state, the lowest magnon band acquires a non-zero Chern number, leading to the prediction that pyrochlore iridate thin films can host the magnon Hall effect.

Session C19 GMAG DMP: Epitaxial Engineering of Magnetic Oxide Thin Films 318 - Mark Huijben, University of Twente

**2:30PM C19.00001 Epitaxial Engineering of Domain Walls and Distortions in Ferrite Heterostructures.** , JULIA MUNDY, UC Berkeley — The defining feature of ferroics is the ability of an external stimulus—electric field, magnetic field, or stress—to move domain walls. These topological defects and their motion enables many useful attributes, e.g., memories that can be reversibly written between stable states as well as enhanced conductivity, permittivity, permeability, and piezoelectricity. Although methods are known to drastically increase their density, the placement of domain walls with atomic precision has until now evaded control. Here we engineer the location of domain walls with monolayer precision and exploit this ability to create a novel multiferroic in which ferroelectricity enhances magnetism at all relevant length scales. Starting with hexagonal  $\text{LuFeO}_3$ , a geometric ferroelectric with the greatest known planar rumpling, we introduce individual extra monolayers of FeO during growth to construct formula-unit-thick syntactic layers of ferrimagnetic  $\text{LuFe}_2\text{O}_4$  within the  $\text{LuFeO}_3$  matrix, i.e.,  $(\text{LuFeO}_3)_m/(\text{LuFe}_2\text{O}_4)_1$  superlattices. The severe rumpling imposed by the neighboring  $\text{LuFeO}_3$  drives the ferrimagnetic  $\text{LuFe}_2\text{O}_4$  into a simultaneously ferroelectric state and reduces the  $\text{LuFe}_2\text{O}_4$  spin frustration. This increases the magnetic transition temperature significantly—to 281 K for the  $(\text{LuFeO}_3)_9/(\text{LuFe}_2\text{O}_4)_1$  superlattice. Moreover,  $\text{LuFeO}_3$  can form charged ferroelectric domain walls, which we align to the  $\text{LuFe}_2\text{O}_4$  bilayers with monolayer precision. Charge transfers to these domain walls to alleviate the otherwise electrostatically unstable polarization arrangement, further boosting the magnetic moment. Our results demonstrate the utility of combining ferroics at the atomic-layer level with attention to domain walls, geometric frustration and polarization doping to create multiferroics by design.

**3:06PM C19.00002 Understanding the Interplay of Polar, Magnetic, and Electronic Order in Ferroic  $(\text{LuFeO}_3)_m/\text{LuFe}_2\text{O}_4$  Superlattices** , ALEJANDRO REBOLA, Cornell University, HENA DAS, Lawrence Berkeley National Laboratory, CRAIG FENNIE, Cornell University — Multiferroics are not only important from a technological point of view but also because of the rich and complex physics that results from the interplay between spin, charge and structural distortions. Hexagonal  $\text{LuFeO}_3$  has recently been understood theoretical and experimentally, and shown to be an improper structural ferroelectric directly analogous to the hexagonal manganites.  $\text{LuFe}_2\text{O}_4$  is structurally homologous to  $\text{LuFeO}_3$ —both are characterized by a  $\text{FeO}_5$  bipyramidal crystal field— but unlike the latter it exhibits a much larger magnetic moment and it is still a matter of debate whether it is ferroelectric. The double Fe-layer in  $\text{LuFe}_2\text{O}_4$  is thought to be charge ordered and highly frustrated, resulting in possible polar, non-polar or anti-polar charge arrangements. Here we first investigate the relation between different charge and magnetic orders and structural distortions in bulk  $\text{LuFe}_2\text{O}_4$  by DFT and Monte Carlo calculations. Then we concentrate on a system that combines both mechanisms—a structural improper ferroelectric and a charge frustrated polar structure— such as the  $(\text{LuFeO}_3)_m/\text{LuFe}_2\text{O}_4$  superlattices.

**3:18PM C19.00003 Strain-mediated control of orbital ordering planes in heteroepitaxial lanthanum manganite thin films** , YONG-JIN KIM, JIN HONG LEE, KAIST, TAE YEONG KOO, Pohang Accelerator Laboratory, Pohang University of Science and Technology, Pohang 790-784, Korea, CHAN-HO YANG, KAIST — Strain engineering which controls the misfit strain of heteroepitaxial thin films leads to distinctive physical properties in contrast to the intrinsic properties of unstrained bulk materials. Perovskite  $\text{LaMnO}_3$  (LMO) has attracted considerable attention due to strong coupling among the lattice, charge, spin and orbital degrees of freedom. Bulk LMO is known to be an A-type antiferromagnetic ( $T_N \sim 140$  K) Mott insulator, and its orbital ordering plane is established due to cooperative Jahn-Teller distortion below  $\sim 750$  K. Previous studies have focused on the orbital ordering planes of the bulk LMO but not researched on correlation between orbital planes and misfit strain. To figure out the strain dependence of orbital ordering planes, we have grown LMO thin films on four different substrates, i.e.,  $\text{DyScO}_3(110)$ ,  $\text{GaScO}_3(110)$ ,  $\text{SrTiO}_3(001)$ , and  $\text{LSAT}(001)$ , using the pulsed laser deposition technique. The films have been characterized by atomic force microscopy and x-ray diffraction. We have performed resonant x-ray scattering to identify orbital ordering plane on each film. We have found that orbital ordering planes can be modulated depending on the misfit strain.

**3:30PM C19.00004 Ferroelectric-ferromagnetic coupling in hexagonal  $\text{YMnO}_3$  film.**<sup>1</sup> , SHAOBO CHENG, MENGLEI LI, SHIQING DENG, SHANYONG BAO, PEIZHE TANG, WENHUI DUAN, JING MA, CEWEN NAN, JING ZHU, Tsinghua University — Simultaneously achieving ferroelectricity and ferromagnetism in a single phase material is an important research topic in recent decades. Here, we demonstrate that with the modulation of oxygen vacancies, the ferroelectric-ferromagnetic coupling can be realized in the typical hexagonal manganite:  $\text{YMnO}_3$ . The first-principles calculations are used to reveal the importance of oxygen vacancies on the alterations of magnetic behaviors for  $\text{YMnO}_3$ . In order to obtain net magnetic moments, the on-top oxygen vacancies of  $\text{MnO}_5$  clusters should be created, thus the initial 2D spin frustration structure of Mn ions will be broken. By growing  $\text{YMnO}_3$  film on  $\text{Al}_2\text{O}_3$  substrate, large in-plane compressive strain is induced, thus we can experimentally realize the on-top oxygen vacancies. With the help of SQUID and spherical aberration corrected TEM, the magnetic moments are experimentally measured and the correlations between the crystal structures and magnetic properties can be clearly understood. Our findings may pave a way for future applications of single phase multiferroic materials.

**3:42PM C19.00005 An oxygen-deficiency modulated multiferroic: Cobalt-substituted perovskite**<sup>1</sup> , JUAN MANUEL FLOREZ, Universidad Técnica Federico Santa María; Massachusetts Inst. of Tech. — In this work, we use density functional theory to model recently demonstrated room temperature ferromagnetism and ferroelectricity in polycrystalline and single crystal Cobalt-substituted  $\text{SrTiO}_3$  thin films ( $\text{SrTi}_{0.70}\text{Co}_{0.30}\text{O}_{3-d}$ ), deposited at different oxygen pressures to change their oxygen vacancy concentration. The modeling indicates an origin for both magnetism and electric polarization in the interactions between oxygen vacancies and the B-site cations. The magnetization saturation increases with the oxygen deficiency as a result of valence spin states changes, which depend on whether the oxygen octahedral of the respective local B-site cations are complete or not. On the other hand, a finite electric polarization appears as a result of a non-centrosymmetric distribution of different resulting local charges and such a polarization increases when the oxygen vacancies increase. Increasing of both order parameters, magnetic and ferroelectric, are analyzed respect to all possible Co-sites and O-vacancies distributions, showing that these results suggest a class of multiferroic materials with properties controlled by their oxygen stoichiometry. Agreement and discrepancies between experiments and modeling are discussed.

### 3:54PM C19.00006 Transport and Raman signatures of electron-doped $\text{SmNiO}_3$ thin films ,

KOUSHIK RAMADOSS, School of Materials Engineering, Purdue University, West Lafayette, IN 47907, NIRAJAN MANDAL<sup>1</sup>, Department of Physics, Purdue University, West Lafayette, IN 47907, YOU ZHOU, School of Engineering and Applied Sciences, Harvard University, Cambridge, MA 02138, YONG CHEN<sup>2</sup>, Department of Physics, Purdue University, West Lafayette, IN 47907, SHRIRAM RAMANATHAN, School of Materials Engineering, Purdue University, West Lafayette, IN 47907 — We report low temperature transport and Raman spectroscopy measurements of electron-doped  $\text{SmNiO}_3$  (SNO) thin films. It has been shown that pristine SNO films can be doped with electrons using hydrogen. Our transport measurements indicate a Coulomb interaction dominated variable range hopping (VRH) for electron-doped samples whereas the pristine films show a Mott type VRH mechanism at low temperatures. The electron-doped samples display a strong localization which can be correlated with the high spin state of  $\text{Ni}^{2+}$  ions. The spatial Raman map shows a remarkable shift of about  $167\text{ cm}^{-1}$  with electron doping thus serving as a spectroscopic tool to investigate hydrogen in our films. **References**

### 4:06PM C19.00007 Temperature dependent near field infrared microscopy of $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$ thin films<sup>1</sup> ,

PENG XU, TJ HUFFMAN, MM QAZILBASH, Department of Physics, College of William and Mary, INHAE KWAK, AMLAN BISWAS, Department of Physics, University of Florida —  $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3$  thin films are studied with apertureless, scattering-type near field microscopy at mid-infrared wavelength and varied temperatures. Spatial resolution of about 20 nm is achieved with our technique. The temperature-dependent resistivity shows a continuous second order phase transition between insulating and metallic phases. At most temperatures, near-field infrared microscopy reveals local persistent phase separation that is independent of temperature. It is possible that the local persistent phase separation is induced by strain inhomogeneity in the thin films. Remarkably, we also observe global time-dependent changes in the infrared near-field signal upon repeated scanning of the same microscopic area at a fixed temperature. This observation is consistent with time-dependent, fluctuating conductivity in the vicinity of a second order phase transition.

### 4:18PM C19.00008 Step-induced magnetic phase separation in $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3/\text{SrTiO}_3$ (100) thin films.<sup>1</sup> ,

IN HAE KWAK, AMLAN BISWAS, University of Florida, Department of Physics — We investigated thickness dependent magnetic anisotropy in  $\text{La}_{0.67}\text{Sr}_{0.33}\text{MnO}_3/\text{SrTiO}_3$  (100) (LSMO/STO) thin films using a combination of magnetic force microscopy (MFM) and magnetization measurements. Atomically smooth thin films of LSMO were grown on STO using pulsed laser deposition. The thin films showed step flow growth with unit cell step heights. MFM images of a 40 unit cell (u.c.)-thick film showed out-of-plane magnetic domain structure indicating bulk-like rhombohedral crystalline anisotropy. As the film thickness was decreased to 20 u.c., the MFM images showed signatures of step-induced uniaxial anisotropy. Hence, the magnetic domain structure shows that tensile strain from lattice mismatch weakens the rhombohedral crystalline anisotropy in LSMO. Magnetization vs. field,  $M(H)$  measurements for the 20 u.c. thick LSMO film revealed a clear in-plane uniaxial anisotropy with the direction along the steps being the easy axis and the coercive fields along the steps were consistently smaller than across the steps for a broad temperature range. Our combination of bulk and local magnetic measurements suggest that the microscopic origin of magnetic anisotropy is step-induced phase separation in the thinner films which are under higher tensile strain.

### 4:30PM C19.00009 Electronic and magnetic properties of quadruple manganite $\text{Ca}_{1-x}\text{Sr}_x\text{Mn}_7\text{O}_{12}$ films ,

AMANDA HUON, STEVEN MAY, Drexel University — We investigate the functional properties of epitaxial  $\text{Ca}_{1-x}\text{Sr}_x\text{Mn}_7\text{O}_{12}$  films to better understand the underlying physical phenomenon in this perovskite system. We utilize oxide molecular beam epitaxy to fabricate  $\text{Ca}_{1-x}\text{Sr}_x\text{Mn}_7\text{O}_{12}$  thin films. The epitaxial films were achieved through a two-step oxygen/ozone post-growth anneal. In parent  $x=0$  films, we find bulk-like electronic and magnetic properties including an abrupt increase in resistivity at 425 K due to a nominal charge ordering transition and a net magnetization below 43 K likely arising from helical magnetic order. Finally, we will present on how tuning the Sr concentration alters the electronic and magnetic properties, providing a means to control the phase transition temperatures. The results highlight the scientific opportunities in heterostructures based on quadruple manganites.

### 4:42PM C19.00010 Observation of a huge polaron gyrotropic response near room temperature in manganite thin films. ,

GERVASI HERRANZ, BLAI CASALS, RAFAEL CICHELERO, DAVID PESQUERA, MARIANO CAMPOY, FLORENCIO SANCHEZ, JOSEP FONTCUBERTA, Institut de Ciència de Materials de Barcelona ICMAB-CSIC, Campus UAB, 08193 Bellaterra, Spain, PABLO GARCIA FERNANDEZ, JAVIER JUNQUERA, Dept. Ciencias de la Tierra y Fs. de la Materia Condensada, U.de Cantabria, Av. de los Castros s/n, 39005 Santander, Spain — Magnetic materials induce rotation and ellipticity in the polarization of light. This phenomenon is exploited, e.g., to control the flux of light along optical fibers. In the pursuit for increased magneto-optic responses, strategies so far have been based on photonic or plasmonic effects. Here we uncover a novel physical mechanism by which the gyrotropic activity is hugely enhanced around the Curie temperature in optimally doped ferromagnetic manganites. This phenomenon is observed only for a narrow range of wavelengths and temperatures and is strongly dependent on the angle of incidence and polarization. We understand such an outstanding response as the result of the interplay between Jahn-Teller distortions and spin-orbit coupling in narrow-band manganites. The showcased material is  $\text{La}_{2/3}\text{Ca}_{1/3}\text{MnO}_3$ , for which the extraordinary gyrotropic response is seen near room temperature. This raises the possibility of optimizing the stoichiometric composition to drive the effect to higher temperatures. The observed phenomenon gives an added functionality –unseen previously in any manganite or other magnetic oxides– and puts a new perspective on the use of these materials for optical data storage and retrieval.

### 4:54PM C19.00011 The Manipulation of Electronic Phase Separation in Manganites. ,

LIFENG YIN, State Key Laboratory of Surface Physics and Department of Physics, Fudan University, Shanghai 200433, China — The Electronic Phase Separation (EPS) is a common phenomenon in strongly correlated systems where two or more electronic phases coexist owing to a delicate balance of competition between these phases. A model system is  $(\text{La}_{5/8-y}\text{Pr}_y)\text{Ca}_{3/8}\text{MnO}_3$  (LPCMO), a colossal magnetoresistance (CMR) manganite that is known for its large-scale EPS. Since the transport and magnetic properties depend sensitively on EPS, it is crucial to manipulate the EPS domains, especially for the applications of CMR manganites in multifunctional electronic and spintronic devices. Through the broken symmetry induced edge states, we can control the nucleation and growth of ferromagnetic metallic domains, thus the spatial distribution of EPS domains in turn. When the Pr doping is chemical ordered, we found the size of EPS domains will be one order of magnitude smaller. Furthermore, the EPS phenomena can be fully eliminated by the spatial confinement when the sample size is smaller than 500nm. These findings could help to understand the origin of large-scale EPS in LPCMO.

**5:06PM C19.00012 Enhanced magnetization in ultrathin manganite layers via structural “delta-doping” of octahedral rotations**<sup>1</sup>, EUN JU MOON, Drexel University, BRIAN J. KIRBY, National Institute of Standards and Technology, STEVEN J. MAY, Drexel University — The design of rotations and distortions of the corner-shared  $BO_6$  octahedra has emerged as an exciting platform to control electronic or magnetic behavior in  $ABO_3$  perovskite heterostructures. Recent work has shown that purely structural effects can be used to spatially confined magnetism in oxide heterostructures and point to the design of rotational gradients as routes to realize novel electronic or ferroic states in oxide superlattices [Nat. Comm. **5**, 5710 (2014)]. Here, we demonstrate a structural “delta doping” approach for controlling magnetism in ultrathin layers within isovalent manganite superlattices. Polarized neutron reflectivity and temperature dependent magnetization measurements are used to correlate enhanced magnetization with local regions of suppressed octahedral rotations in the heterostructures.

**5:18PM C19.00013 Ultrafast structural dynamics of  $LaVO_3$  thin films grown by hybrid molecular beam epitaxy**, MATTHEW BRAHLEK, JASON LAPANO, VLADIMIR STOICA, LEI ZHANG, HAI-TIAN ZHANG, HIROFUMI AKAMATSU, CRAIG EATON, VENKATRAMAN GOPALAN, Pennsylvania State University, JOHN FREELAND, HAIDAN WEN, Argonne National Lab, ROMAN ENGEL-HERBERT, Pennsylvania State University —  $LaVO_3$ , with a partially full d-shell is expected to be metallic, but due to electron-electron interactions a gap emerges and the ground state is a Mott insulator. Such effects are a strong function of the bonding geometry, and particularly the V-O-V bond angle. Controlling these structural effects on the ultrafast time scale can lead to control over the underlying electronic ground state. Here we report the ultrafast structural dynamics of 25 and 50 nm thick  $LaVO_3$  thin films grown by the hybrid molecular beam epitaxy technique on  $SrTiO_3$  when excited across the bandgap by 800 nm light. Using time-resolved x-ray diffraction on the 100 ps time scale at Sector 7 of the Advanced Photon Source, we directly measured the structural changes with atomic accuracy by monitoring integer Bragg diffraction peaks and find a large out-of-plane strain of 0.18% upon optical excitation; the recovery time is ~1 ns for the 25 nm film and ~2 ns for the 50 nm film, consistent with the thermal transport from the film to the substrate. Further, we will discuss the response of the oxygen octahedral rotation patterns indicated by changes of the half-order diffraction peaks. Understanding such ultrafast structural deformation is important for optimizing optical excitations to create new metastable phases starting from a Mott insulator. This work was supported by the Department of Energy under Grant DE-SC0012375, and DE-AC02-06CH11357.

**2:30PM C20.00001 A DMC study on FePc electronic state**, TOM ICHIBHA, KENTA HONGO, RYO MAEZONO, Japan Adv Inst of Sci and Tech — We performed fixed-node DMC calculations on an isolated FePc [Iron(II) Phthalocyanine] using CASSCF nodal surfaces, getting its ground state,  $^3A_{2g} [d_{z^2}^2 d_{xz, yz}^2 d_{xy}^2]$ . Virial ratios for each state are achieved to be within 0.042% around 2.0. Recent studies [1] are proposing a mixed state with  $^3E_g(b)$  and  $^3B_{2g}$  as the ground state, while past ab-initio calculations [2] are predicting  $^3A_{2g}$  or  $^3E_g(a)$ , giving still controversial arguments even within isolated/no-LS coupling model. Under  $D_{4h}$  ligand field parameter space, ( $10Dq$ ,  $D_t$ ,  $D_s$ ), the state,  $^3A_{2g}$ , is reported to be possible as a ground state [3], while it is not when we restrict the space into 2-dim sub-space corresponding to more specified symmetry as in FePc with plane square alignment of neighboring N to Fe ('superposition model' [4]). Our optimized geometry also satisfies the same symmetry, and hence appears to be contradicting to the ligand theory[4]. [1] J. Fernández-Rodríguez *et al.*, Phys. Rev. B **91**, 214427 (2015). [2] K. Nakamura *et al.*, Phys. Rev. B **85**, 235129 (2012). [3] P.S. Miedema *et al.*, J. Phys.: Conf. Ser. **190**, 012143 (2009). [4] M.D. Kuzmin *et al.*, J. Chem. Phys. **138**, 244308 (2013).

**2:42PM C20.00002 An effective model for  $LaTiO_3$  using first principles quantum Monte Carlo**, KIEL WILLIAMS, LUCAS WAGNER, Univ of Illinois - Urbana — The rare earth perovskites have long been of interest due in part to the interplay of their geometries and electronic properties. The perovskite  $LaTiO_3$  in particular is an antiferromagnetic insulator with a small 0.2 eV band gap that displays the GdFeO<sub>3</sub> distortion at ambient pressure. We apply a new technique[1] to derive an effective model for  $LaTiO_3$  as a function of the distortion. Since this technique treats one and two-body degrees of freedom on an equal footing, we use it to evaluate the evolution of effective model parameters with changes in the lattice. We will report on the progress in assessing whether the insulating nature is due to the distortion, or vice versa. [1] Changlani, Zheng, and Wagner J. Chem. Phys. **143**, 102814 (2015).

**2:54PM C20.00003 A new constraint DFT technique for self-consistent determination of  $U$  values**, TOMOYUKI HAMADA<sup>1</sup>, Hitachi, Ltd. Research and Development Group, TAKAHISA OHNO<sup>2</sup>, National Institute of Materials Science — A new constraint density functional (DFT) technique workable in combination with the projector augmented wave (PAW) and pseudopotential (PP) methods was developed. This technique calculates the effective on-site-interaction parameter,  $U_{eff}$ , of correlated electrons of materials, self-consistently, by using the DFT+U method. The  $U_{eff}$  determined by this technique has a clear physical meaning in that it determines the electronic structures of strongly correlated electronic systems (SCESs) and *vice versa*. The technique was used to determine the  $U_{eff}$  of correlated electrons of hexagonal neodymium sesquioxide ( $h-Nd_2O_3$ ) and orthorhombic iron oxide ( $\alpha-FeO$ ) in the antiferromagnetic states, and it was shown to be effective for this purpose. The newly developed constraint DFT technique enables first principles DFT+U PAW and PP calculations of SCESs free from any empirical parameters, which are more reliable than the DFT+U PAW and PP calculations of them using empirical  $U_{eff}$ s.

**3:06PM C20.00004 Electronic and structural properties of  $M_3(HITP)_2$  ( $M = Ni, Cu$  and  $Co$ ) metal-organic frameworks**, ORLANDO SILVEIRA, HELIO CHACHAM, SIMONE ALEXANDRE, Federal University of Minas Gerais — Theoretical and experimental works have demonstrated that electrical and structural properties of metal-organic frameworks (MOF) can be significantly changed by the identity of the metal center, leading to a potential strategy for tuning the selectivity of the material toward different types of technological applications. In this work, we use first principle calculations to investigate the electronic properties of 2D MOF  $M_3(HITP)_2$  ( $M$  is Ni, Cu and Co and HITP = 2,3,6,7,10,11 hexaiminotriphenylene). Our results show that for  $M=Ni$  and  $Co$ , the structures are perfect planar and there is a full charge delocalization in the 2D plane of stacking due to the predominance of  $\pi - \pi$  bonding. The band structure for  $M = Ni$  shows that this material is a semiconductor with an indirect band gap of 132 meV, whilst for  $M = Co$  the band structure shows that this material is a ferromagnetic semiconductor with a direct band gap of 386 meV for spin down and an indirect band gap of 246 meV for spin up. For  $M=Cu$ , the material is a metal and adopts a distorted structure due to a different hybridization of the metal atom in comparison with its counterparts. We also propose a tight binding model that can represent the electronic structure near the Fermi level of this family of MOF.

**3:18PM C20.00005 Band structure of correlated  $\text{Sr}_2\text{RuO}_4$  using DFT+DMFT**, OLIVIER GINGRAS, MICHEL CT, Univ of Montreal, ANDR-MARIE TREMBLAY, Univ of Sherbrooke — The discovery of superconductivity in the cuprates stimulated investigations on materials sharing similar structural properties. Ruthenates, including  $\text{Sr}_2\text{RuO}_4$  became of great interest since they were found to be unconventional superconductors, possibly *p*-wave, at sufficiently low temperature. A lot of experimental data was acquired and analyzed over the past decade. Of particular interest is the discrepancy between the calculated and measured effective masses. In this presentation, we will present DFT+DMFT calculations as implemented in the ABINIT program to compute the electronic structure of  $\text{Sr}_2\text{RuO}_4$ .

**3:30PM C20.00006 A general optimization method applied to a vdW-DF functional for water**, MICHELLE FRITZ, JOSE M. SOLER, Universidad Autnoma de Madrid, MARIVI FERNÁNDEZ-SERRA, Stony Brook University — In particularly delicate systems, like liquid water, ab initio exchange and correlation functionals are simply not accurate enough for many practical applications. In these cases, fitting the functional to reference data is a sensible alternative to empirical interatomic potentials. However, a global optimization requires functional forms that depend on many parameters and the usual trial and error strategy becomes cumbersome and suboptimal. We have developed a general and powerful optimization scheme called data projection onto parameter space (DPPS) and applied it to the optimization of a van der Waals density functional (vdW-DF) for water. In an arbitrarily large parameter space, DPPS solves for vector of unknown parameters for a given set of known data, and poorly sampled subspaces are determined by the physically-motivated functional shape of ab initio functionals using Bayes' theory. We present a new GGA exchange functional that has been optimized with the DPPS method for 1-body, 2-body, and 3-body energies of water systems and results from testing the performance of the optimized functional when applied to the calculation of ice cohesion energies and ab initio liquid water simulations. We found that our optimized functional improves the description of both liquid water and ice when compared to other versions of GGA exchange.

**3:42PM C20.00007 Solvated ions as defects in liquid water: A first-principles perspective<sup>1</sup>**, ERIC SCHWEGLER, TUAN ANH PHAM, Lawrence Livermore Natl Lab, MARCO GOVONI, GIULIA GALLI, Institute for Molecular Engineering-The University of Chicago, and Argonne National Laboratory — Understanding the electronic properties of solvated ions is crucial in order to control and engineer aqueous electrolytes for a wide variety of emerging energy and environmental technologies, including photocatalytic water splitting. In this talk, we present a strategy to evaluate electronic energy levels of simple solvated ions in aqueous solutions, using a combination of first-principles molecular dynamics simulations and many-body perturbation theory within the GW approximation. We considered  $\text{CO}_3^{2-}$ ,  $\text{HCO}_3^-$ ,  $\text{NO}_3^-$ ,  $\text{NO}_2^-$  ions and we show that by analogy to defects in semiconductors, these solvated ions may be classified as deep or shallow defects in liquid water. In particular  $\text{CO}_3^{2-}$  and  $\text{NO}_2^-$  ions behave as shallow defects, while  $\text{HCO}_3^-$  and  $\text{NO}_3^-$  as deep ones. We also show that the inclusion of many-body corrections constitutes significant improvement over conventional density functional theory calculations, yielding satisfactory agreement with photoemission experiments.

**3:54PM C20.00008 Evaluation of Hamaker coefficients using Diffusion Monte Carlo method**, RYO MAEZONO, KENTA HONGO, School of Information Science, JAIST, Japan — We evaluated the Hamaker's constant for Cyclohexasilane to investigate its wettability, which is used as an ink of 'liquid silicon' in 'printed electronics'. Taking three representative geometries of the dimer coalescence (parallel, lined, and T-shaped), we evaluated these binding curves using diffusion Monte Carlo method. The parallel geometry gave the most long-ranged exponent,  $\sim 1/r^6$ , in its asymptotic behavior. Evaluated binding lengths are fairly consistent with the experimental density of the molecule. The fitting of the asymptotic curve gave an estimation of Hamaker's constant being around 100 [zJ]. We also performed a CCSD(T) evaluation and got almost similar result. To check its justification, we applied the same scheme to Benzene and compared the estimation with those by other established methods, Lifshitz theory and SAPT (Symmetry-adopted perturbation theory). The result by the fitting scheme turned to be twice larger than those by Lifshitz and SAPT, both of which coincide with each other. It is hence implied that the present evaluation for Cyclohexasilane would be overestimated.

**4:06PM C20.00009 Exploring Reaction Mechanism on Generalized Force Modified Potential Energy Surfaces (G-FMPES) for Diels-Alder Reaction**, SANJIV JHA, Univ of Southern Mississippi, KATIE BROWN, Auburn University, GOPINATH SUBRAMANIAN, Univ of Southern Mississippi — We apply a recent formulation for searching minimum energy reaction path (MERP) and saddle point to atomic systems subjected to an external force. We demonstrate the effect of a loading modality resembling hydrostatic pressure on the trans to cis conformational change of 1,3-butadiene, and the simplest Diels-Alder reaction between ethylene and 1,3-butadiene. The calculated MERP and saddle points on the generalized force modified potential energy surface (G-FMPES) are compared with the corresponding quantities on an unmodified potential energy surface. Our study is performed using electronic structure calculations at the HF/6-31G\*\* level as implemented in the AIMS-MOLPRO code. Our calculations suggest that the added compressive pressure lowers the energy of cis butadiene. The activation energy barrier for the concerted Diels-Alder reaction is found to decrease progressively with increasing compressive pressure.

**4:18PM C20.00010 Fast molecular dynamics simulations using high-order forces and nonlocal operators in real space<sup>1</sup>**, GRADY SCHOFIELD, N. SCOTT BOBBITT, JAMES R. CHELIKOWSKY, Univ of Texas, Austin — We present a new modification to the finite-difference based real space pseudopotential density functional theory method as implemented in the code PARSEC. By using a high-order treatment of the nonlocal pseudopotential terms in the Hamiltonian, as well as integration performed during post-processing the wave functions, we improve the accuracy of total energy and interatomic forces. We perform molecular dynamics simulations for several systems, including organic molecules and small clusters. We demonstrate significant reduction in energy drift owing to the accuracy of our improved force calculations. Furthermore, the reduction in numerical noise as atoms move over the grid permits a larger grid spacing than would be possible with a conventional discretization.

<sup>1</sup>This work is supported by the DOE through the SciDAC program funded by ASCR and BES under award number DE-SC0008877. Computations were performed on machines at TACC.

**4:30PM C20.00011 Real-space pseudopotential methods for calculating the vibrational Stark tuning rate<sup>1</sup>**, BENJAMIN GARRETT, JAMES CHELIKOWSKY, University of Texas at Austin — We introduce a real-space method based on pseudopotentials constructed within density functional theory for computing the vibrational Stark effect. With wave functions defined in real space and cluster boundary conditions, convergence is controlled solely by the grid spacing. Moreover, charged systems can be incorporated without a compensating background charge. Real space methods also have the advantage that neither polarization functions nor supercells are required to simulate external electric fields. We illustrate this method by calculating the Stark tuning rates of small carbonyls and nitriles. The use of high-order integration techniques allow for a coarser (less expensive) grid spacing. Perturbative methods for determining the tuning rate will also be discussed.

<sup>1</sup>We acknowledge support from the U.S. Department of Energy from grant DE-FG02-06ER46286.

**4:42PM C20.00012 Unbiased QM/MM approach using accurate multipoles from a linear scaling DFT calculation with a systematic basis set**, STEPHAN MOHR, Barcelona Supercomputing Center, CEA Grenoble, LUIGI GENOVESE, CEA Grenoble, LAURA RATCLIFF, Argonne Leadership Computing Facility, MICHEL MASELLA, CEA Saclay — The quantum mechanics/molecular mechanics (QM/MM) method is a popular approach that allows to perform atomistic simulations using different levels of accuracy. Since only the essential part of the simulation domain is treated using a highly precise (but also expensive) QM method, whereas the remaining parts are handled using a less accurate level of theory, this approach allows to considerably extend the total system size that can be simulated without a notable loss of accuracy. In order to couple the QM and MM regions we use an approximation of the electrostatic potential based on a multipole expansion. The multipoles of the QM region are determined based on the results of a linear scaling Density Functional Theory (DFT) calculation using a set of adaptive, localized basis functions, as implemented within the BigDFT software package. As this determination comes at virtually no extra cost compared to the QM calculation, the coupling between QM and MM region can be done very efficiently. In this presentation I will demonstrate the accuracy of both the linear scaling DFT approach itself as well as of the approximation of the electrostatic potential based on the multipole expansion, and show some first QM/MM applications using the aforementioned approach.

**4:54PM C20.00013 Large-scale All-electron Density Functional Theory Calculations using Enriched Finite Element Method<sup>1</sup>**, BIKASH KANUNGO, VIKRAM GAVINI, Univ of Michigan - Ann Arbor — We present a computationally efficient method to perform large-scale all-electron density functional theory calculations by enriching the Lagrange polynomial basis in classical finite element (FE) discretization with atom-centered numerical basis functions, which are obtained from the solutions of the Kohn-Sham (KS) problem for single atoms. We term these atom-centered numerical basis functions as enrichment functions. The integrals involved in the construction of the discrete KS Hamiltonian and overlap matrix are computed using an adaptive quadrature grid based on gradients in the enrichment functions. Further, we propose an efficient scheme to invert the overlap matrix by exploiting its *LDL* factorization and employing spectral finite elements along with Gauss-Lobatto quadrature rules. Finally, we use a Chebyshev polynomial based acceleration technique to compute the occupied eigenspace in each self-consistent iteration. We demonstrate the accuracy, efficiency and scalability of the proposed method on various metallic and insulating benchmark systems, with systems ranging in the order of 10,000 electrons. We observe a 50-100 fold reduction in the overall computational time when compared to classical FE calculations while being commensurate with the desired chemical accuracy.

<sup>1</sup>We acknowledge the support of NSF (Grant No. 1053145) and ARO (Grant No. W911NF-15-1-0158) in conducting this work.

**5:06PM C20.00014 Ultrafast Response of the Hubbard Model: Non-adiabatic TDDFT+DMFT versus Non-equilibrium DMFT Solution<sup>1</sup>**, SHREE RAM ACHARYA, University of Central Florida, VOLODYMYR TURKOWSKI, TALAT S. RAHMAN, Department of Physics, University of Central Florida — We study the ultrafast response of electrons in the one-band Hubbard model to an external laser-pulse perturbation by using the Non-adiabatic Time-Dependent Density Functional Theory + Dynamical Mean-Field Theory (TDDFT+DMFT) approach. The corresponding exchange-correlation kernel (XC) is obtained from the DMFT charge susceptibility by using the Quantum Monte Carlo solver for the impurity problem. Detailed analysis of the time-dependent excited charge density, the Fermi distribution function, and the spatially nonhomogeneous response (metallic domain growth), is performed for different values for the carrier density and local Coulomb repulsion. We compare the results with the corresponding non-equilibrium DMFT solutions, and demonstrate that non-adiabaticity (frequency-dependence) of the XC kernel is important in order to reproduce the non-equilibrium DMFT solution. Also, from the numerical results for the charge susceptibility, we obtain an approximate analytical expression for the XC kernel. Using this kernel, we reveal possible types of "elementary" excitations and the dynamics of metallic domain growth in the case of the one-band Hubbard model. Possible generalization of the approach to the multi-orbital case is discussed.

**5:18PM C20.00015 Improving Boundary Conditions for Electronic Structure Calculations**, G. A. BENESH, Baylor University, ROGER HAYDOCK, University of Oregon — Boundary conditions imposed on a local system joined to a much larger substrate system routinely introduce unphysical reflections that affect the calculation of electronic properties such as energies, charge densities, and densities of states. These problems persist in atomic cluster, slab, and supercell calculations alike. However, wave functions in real, physical systems do not reflect at artificial boundaries. Instead, they carry current smoothly across the surface separating the local system from the underlying medium. Haydock and Nex have derived a non-reflecting boundary condition that works well for discrete systems [Phys. Rev. B 75, 205121 (2006)]. Solutions satisfying their maximal breaking of time-reversal symmetry (MBTS) boundary condition carry current away from the boundary at a maximal rate—in much the same way as exact wave functions in physical systems. The MBTS approach has now been extended to studies employing continuous basis functions. In model systems, MBTS boundary conditions work well for calculating wave functions, eigenenergies, and densities of states. Results are reported for an Al(001) surface. Comparisons are made with slab calculations, embedding calculations, and experiment.

Session C21 GMAG DMP: Magnetic Chains and Kondo Effects 320 - Christopher Landee, Clark University

**2:30PM C21.00001 Magnetic Behavior of quasi-1D-Ferromagnetic Fe Chains in Metallo-Organic Superlattices<sup>1</sup>**, C. MONTON, Univ of Texas, San Antonio, A. C. BASARAN, I. VALMIANSKI, Univ California, San Diego, T. GREDIG, California State University, Long Beach, D. ALTBIR, V. L. CARVALHO-SANTOS, Universidad de Santiago de Chile, IVAN K. SCHULLER, Univ California, San Diego — We report structural and magnetic properties of metallo-organic iron-phthalocyanine (FePc) / metal-free-phthalocyanine (H2Pc) superlattices. H2Pc is a weak diamagnetic molecule in which, instead of a metal ion, two hydrogen atoms occupy the center of the molecule. Due to molecular stacking, the divalent Fe(II) ion of FePc forms quasi one-dimensional (1D) chains. These Fe chains can be oriented either parallel or perpendicular to the substrate based on the choice of the substrate. These quasi-1D chains exhibit two magnetic regimes: ferromagnetic-like order below 5K, and nontraditional paramagnetic order (nonlinear behavior with decreasing saturation intensity with temperature) between 5 and 40 K. We have found that reducing the average Fe chains length from 70 to 7 Fe ions substantially increases the coercive field. We discuss the magnetic behavior of quasi-1D Fe chains as a function of the chains length and we correlate the observed magnetic behavior with structural information obtained from x-ray diffraction and Monte Carlo based micromagnetic simulations.

**2:42PM C21.00002 Spin Liquid Ground State in the Frustrated  $J_1$ - $J_2$  Zigzag Chain System  $\text{BaTb}_2\text{O}_4$** , A.A. ACZEL, Oak Ridge National Laboratory, L. LI, University of Tennessee, V.O. GARLEA, Oak Ridge National Laboratory, J.-Q. YAN, University of Tennessee and Oak Ridge National Laboratory, F. WEICKERT, V.S. ZAPF, R. MOVSHOVICH, M. JAIME, Los Alamos National Laboratory, P.J. BAKER, Rutherford Appleton Laboratory, V. KEPPENS, D. MANDRUS, University of Tennessee — We have investigated polycrystalline samples of the zigzag chain system  $\text{BaTb}_2\text{O}_4$  with magnetic susceptibility, heat capacity, neutron powder diffraction, and muon spin relaxation ( $\mu\text{SR}$ ). No magnetic transitions are observed in the bulk measurements, while neutron diffraction reveals the presence of low-temperature, short-range, intrachain magnetic correlations between  $\text{Tb}^{3+}$  ions.  $\mu\text{SR}$  indicates that these correlations are dynamic, as no signatures of static magnetism are detected by the technique down to 0.095 K. These combined findings provide strong evidence for a spin liquid ground state in  $\text{BaTb}_2\text{O}_4$ .

**2:54PM C21.00003 Study of magnetic and magnetocaloric properties of monoclinic and triclinic spin chain  $\text{CoV}_2\text{O}_6$** , MOUMITA NANDI, PRABHAT MANDAL, Saha Institute of Nuclear Physics, 1/AF Bidhannagar Kolkata, India — We have investigated magnetic and magnetocaloric properties of both monoclinic and triclinic phases of  $\text{CoV}_2\text{O}_6$  from magnetization and heat capacity measurements. Conventional and inverse magnetocaloric effects have been observed in both phases of  $\text{CoV}_2\text{O}_6$ . For a field change from 0 to 7 T, maximum values of magnetic entropy change and adiabatic temperature change reach  $11.8 \text{ J kg}^{-1} \text{ K}^{-1}$  and 9.5 K respectively for monoclinic  $\text{CoV}_2\text{O}_6$  while the corresponding values reach  $12.1 \text{ J kg}^{-1} \text{ K}^{-1}$  and 13.1 K for triclinic  $\text{CoV}_2\text{O}_6$ . Particularly for triclinic  $\text{CoV}_2\text{O}_6$ , the magnetocaloric parameters are quite large in low or moderate field range. Apart from this, we have constructed magnetic phase diagram of monoclinic  $\text{CoV}_2\text{O}_6$  where field-induced complex magnetic phases appear below a certain critical temperature 6 K when external magnetic field is applied along crystallographic easy axis.

**3:06PM C21.00004 Entanglement properties of the bond alternating Heisenberg chain with general integer spins**, SHOHEI MIYAKOSHI, Chiba Univ, SATOSHI NISHIMOTO, IFW Dresden, TU Dresden, YUKINORI OTHA, Chiba Univ — Symmetry protected topological (SPT) phases are a gapped phase under a given symmetry. Unless any symmetries that protect the SPT phases are broken, the SPT phases can be distinguished from each other. Recently, it was pointed out that the entanglement spectrum of the many-body state characterizes such SPT phases. In particular, the degeneracy of the entanglement spectrum reflects the corresponding symmetries and edge states of the system. Motivated by recent studies of the SPT phases, we study the bond-alternating Heisenberg model with general integer spins and clarify the entanglement properties of the ground state using the density matrix renormalization group method. In particular, this model has the intermediate phase at  $S > 1$  due to the bond alternation. The entanglement properties of this phase in the case of  $S > 2$  have not been studied sufficiently because of the numerical difficulties under an extremely small spin-gap situation. We studied the case of  $S = 1, 2, 3$  using the antiperiodic boundary condition. Under the antiperiodic boundary condition, we found that the doubly degenerate spectra which characterize the intermediate phase can be observed in the entanglement spectrum. We will also discuss the effect of the single-ion uniaxial anisotropy.

**3:18PM C21.00005 Finite temperature dynamics of spin-1/2 chains with symmetry breaking interactions<sup>1</sup>**, SALVATORE R. MANMANA, ALEXANDER C. TIEGEL, THOMAS PRUSCHKE, Institute for Theoretical Physics, University of Goettingen, ANDREAS HONECKER, LPTM, Université de Cergy-Pontoise — I will discuss recent developments for flexible matrix product state (MPS) approaches to calculate finite-temperature spectral functions of low-dimensional strongly correlated quantum systems. The main focus will be on a Liouvilian formulation. The resulting algorithm does not specifically depend on the MPS formulation, but is applicable for any wave function based approach which can provide a purification of the density matrix, opening the way for further developments of numerical methods. Based on MPS results for various spin chains, in particular systems with Dzyaloshinskii-Moriya interactions caused by spin-orbit coupling and dimerized chains, I will discuss how symmetry breaking interactions change the nature of the finite-temperature dynamic spin structure factor obtained in ESR and neutron scattering experiments.

**3:30PM C21.00006 Magnetic Spin Relaxation Probed with Sweep Speed Dependent Coercivity<sup>1</sup>**, THOMAS GREDIG, MATTHEW BYRNE, Department of Physics and Astronomy, California State University Long Beach — The magnetic spin relaxation of finite-length iron chains has been investigated in iron phthalocyanine thin films by means of sweep speed dependence on magnetic coercivity. The  $\text{Fe(II)}$  ions are embedded in a carbon matrix and molecules self-assemble during vacuum sublimation, so that the  $\text{Fe(II)}$  cores form well-separated chains of 1.3 nm and tunable chain lengths within the polycrystalline thin film. The average length of the chains is controlled through deposition variables and ranges from 30 nm to 300 nm. The coercivity strongly increases with chain length in this regime. This may be an interesting experimental realization of a low-dimensional finite-sized Ising model. The coercivity dependence on chain length and sweep speed is described with an Ising model based on Glauber dynamics.

**3:42PM C21.00007 ANISOTROPIC PHASE DIAGRAM OF THE FRUSTRATED SPIN CHAIN  $\beta\text{-TeVO}_4$** , F. WEICKERT, M JAIME, N HARRISON, B. L. SCOTT, Los Alamos Natl Lab, A. LEITMAE, L. HEINMAA, R STERN, O JANSON, NICPB Tallinn, Estonia, H. BERGER, EPFL, Lausanne, Switzerland, H ROSNER, MPI CPfS, Dresden, Germany, A. A. TSIRLIN, Augsburg University, Germany — We will present experimental as well as theoretical data on  $\beta\text{-TeVO}_4$  a candidate for the  $J_1$ - $J_2$  chain model with ferromagnetic  $J_1 \sim 18 \text{ K}$  and antiferromagnetic  $J_2 \sim 48 \text{ K}$  coupling constants. The  $T - H$  magnetic phase diagram is revealed by measurements of the magnetization, specific heat, magnetostriction, and thermal expansion on oriented single crystals at temperatures between 0.5 K and 50 K and in magnetic fields up to 50 T. The high field data were taken in a capacitor bank-driven pulsed magnet at NHMFL – LANL and complemented with measurements in a superconducting magnet. Our comprehensive study allows for the first time a detailed mapping of the phase diagram in both directions,  $H \parallel ab$  and  $H \parallel c$ . We find clear evidence for 5 different phases including full polarization of the magnetic moments above 23 T that is only weakly dependent on the crystal orientation. Surprisingly, the phase boundary at the saturation field splits into two distinct lines below 5 K. The magnetic phases occurring at fields below 10 T show significant magnetic anisotropy between  $H \parallel ab$  and  $H \parallel c$ . The nature of the different phases and regions in  $\beta\text{-TeVO}_4$  is still far from being understood, but our results will stimulate further research on this interesting model compound.

**3:54PM C21.00008 Unusual features of magnetism in transition-metal-doped phthalocyanines**  $C_{32}H_{16}N_8TM$  (TM = Mn, Fe, Co, Ni, Cu), ZHENGJUN WANG, MOHINDAR S. SEEHRA, Department of Physics and Astronomy, West Virginia University — Transition-metal-doped phthalocyanines (TMPc), semiconductors with potential optoelectronic applications [1], are planar molecules with the TM atom at the center bound to four N atoms and forming a linear chain along the monoclinic b-axis. Because of this symmetry, the ground states of TMPc often violate the Hund's rules; e.g. the  $S = 3/2$  state for  $d^5$  Mn(II) in  $\beta$ -MnPc,  $S = 1/2$  state for the  $d^7$  Co(II) in  $\beta$ -CoPc, and  $S=0$  for Ni(II) in NiPc. The magnetic properties of TMPc are also affected by the stack angle  $\delta$  between the orientation of the molecular plane and the b-axis,  $\delta$  being 65(45) for  $\alpha$  ( $\beta$ ) phase [2]. For  $\beta$ -CoPc, our M vs. T data fits well with the Bonner-Fisher model for  $S = 1/2$  AFM Heisenberg linear chain [3] yielding the  $Co^{2+}$ - $Co^{2+}$  exchange constant  $J/k_B = -1.5$  K. For  $\beta$ -MnPc, a long-presumed ferromagnet with  $T_C \approx 9$  K [4], our magnetic studies show it to be an Ising chain magnet with Arrhenius magnetic relaxation governed by  $J/k_B = 2.6$  K and the zero-field splitting  $D/k_B = 8.3$  K. In  $\beta$ -MnPc, the absence of  $\lambda$ -type peak in specific heat and no peaks in ac susceptibilities near the quoted  $T_C \approx 9$  K confirms the absence of long range order (LRO). Instead we argue that LRO is absent in  $\beta$ -MnPc as  $D > J$  makes the spins in a chain parallel but canted with respect to spins in neighboring chains. [1]G. Mattioli et al, Phys. Rev. Lett. 101, 126805 (2008); [2]Z. Wang et al, IEEE Trans. Mag. 51, 2700104(2015); [3]J. Bonner & M. Fisher, Phys. Rev. 135, A640 (1964); [4]Y. Taguchi et al, J. Magn. Magn. Mater. 301, 1229 (2007).

**4:06PM C21.00009 Heat transport in spin chains with weak spin-phonon coupling<sup>1</sup>**, ALEXANDER CHERNYSHEV, University of California, Irvine, ALEXANDER ROZHKOV, Institute for Theoretical and Applied Electrodynamics, Russian Academy of Sciences, Russia — We propose that the heat conductivity by 1D spin excitations in  $S = 1/2$  Heisenberg spin chains can be quantitatively described within the bosonization framework, in which large-momentum scattering of spin excitations is due to optical phonons with the spin-phonon couplings that are well within the physical bounds. Our theory provides an excellent fit to the data from the systematic experimental thermal conductivity studies in the high-quality single-crystalline large- $J$  spin-chain cuprates that have recently become available. Our description of the spin-phonon scattering is also in accord with a physically intuitive picture of phonons playing the role of thermally-populated weak impurities for the fast spin excitations. Our approach stands out from previous considerations that require large coupling constants to explain the data and thus imply a spin-Peierls transition, absent in real materials.

**4:18PM C21.00010 Spin dynamics in critical regime of the spin-1/2 XXZ chain**, WANG YANG, JIANDA WU, CONGJUN WU, University of California San Diego — The spin-1/2 Heisenberg XXZ chain is one of the most well-studied quantum integrable models. Although its eigenstates and spectrum are solvable through Bethe ansatz, even understanding its zero temperature spin dynamics remains a challenge. In the axial anisotropic regime, by tuning longitudinal magnetic field, the system undergoes a quantum phase transition, entering into the critical regime. Recent experiments provided some evidences for understanding spin dynamics in the critical regime. Here we investigate the spin dynamics in this regime by form factor methods. Our results can be directly compared with experiments on relevant materials.

**4:30PM C21.00011 First principles electron transport simulations in the Kondo regime**, IVAN RUNGGER, National Physical Laboratory, MIŁOS RADONJIC, WILHELM APPELT, LIVIU CHIONCEL, University of Augsburg, ANDREA DROGHETTI, Universidad del País Vasco — When magnetic atoms, molecules or thin films are brought into contact with metals the electron-electron interaction leads to the appearance of the correlated Kondo state at low temperatures. In this talk we will present results for the electronic structure and conductance in the Kondo regime of recent STM and break junction experiments for stable radical molecules<sup>1</sup>, which correspond to spin half molecular magnets. We will outline the methodological approach to evaluate the conductance of such systems from first principles, as implemented in the Smeagol electron transport code<sup>2</sup>. The method combines the density functional theory (DFT) with Anderson impurity solvers within the continuum time quantum Monte Carlo (CTQMC) and numerical renormalization group (NRG) approaches.

**4:42PM C21.00012 Cobalt on silicene/ZrB<sub>2</sub>: an intriguing Kondo system**, TOBIAS GILL, BEN WARNER, HENNING PRSER, UCL, UK, ANTOINE FLEURENCE, YUKIKO YAMADA-TAKAMURA, JAIST, Japan, CYRUS HIRJIBEHEDIN, UCL, UK — Magnetic atoms placed upon metallic substrates have been used as prototypical systems for the investigation of the fundamentals of atomic-scale magnetism. Often these magnetic impurities undergo the Kondo effect, in which the magnetic moment of the impurity is collectively screened by a cloud of conduction electrons forming a many-body singlet ground state. Here we present results for individual Co adatoms on the silicene/ZrB<sub>2</sub> surface. Unlike on metallic surfaces, Co atoms exhibit a distinct energy-dependent change in the spatial distribution of their electronic states when imaged with scanning tunneling microscopy. At low biases around the Fermi level, the Co atoms exhibit a two-lobe structure that is oriented along one of three equivalent directions in the plane and that is revealed by scanning tunneling spectroscopy to result from a Kondo resonance centered upon each lobe. This spatially anisotropic Kondo resonance is reminiscent of the orbital states of magnetic atoms on semiconductor surfaces or of the spatially distributed Kondo resonances seen for magnetic molecules on metallic surfaces, and is a result of the interaction between a magnetic impurity and the unusual electronic structure of the silicene/ZrB<sub>2</sub> surface.

**4:54PM C21.00013 ABSTRACT WITHDRAWN —**

**5:06PM C21.00014 Sub-molecular modulation of a 4f driven Kondo resonance by surface-induced asymmetry**, BEN WARNER, FADI EL HALLAK, UCL, NICOLAE ATODIRESEI, Forschungszentrum Juelich, PHILIPP SEIBT, HENNING PRUSER, UCL, VASILE CACIUC, Forschungszentrum Juelich, MICHAEL WATERS, U. of Nottingham, ANDREW J. FISHER, UCL, STEFAN BLUGEL, Forschungszentrum Juelich, JORIS VAN SLAGEREN, U. of Stuttgart, CYRUS F. HIRJIBEHEDIN, UCL — Coupling between a magnetic impurity and an external bath can give rise to many-body quantum phenomena, including Kondo and Hund's Impurity states in metals, and Yu-Shiba-Rusinov states in superconductors. While advances have been made in probing the magnetic properties of d-shell impurities on surfaces, the confinement of f orbitals makes them much more difficult to access directly. Here we show that a 4f driven Kondo resonance can be modulated spatially by asymmetric coupling between a metallic surface and a molecule containing a 4f-like moment. Strong hybridisation of dysprosium double-decker phthalocyanine (DyPc<sub>2</sub>) with Cu(001) induces Kondo screening of the central magnetic moment. Misalignment between the symmetry axes of the molecule and the surface induces asymmetry in the molecule's electronic structure, spatially mediating electronic access to the magnetic moment through the Kondo resonance. This work demonstrates the important role that molecular ligands play in mediating electronic and magnetic coupling and in accessing many-body quantum states.

**5:18PM C21.00015 Revealing the Atomic Site-Dependent g Factor within a Single Magnetic Molecule via the Extended Kondo Effect<sup>1</sup>**, SHIXUAN DU, Institute of Physics, Chinese Academy of Sciences — Control over charge and spin states at the single molecule level is crucial not only for a fundamental understanding of charge and spin interactions but also represents a prerequisite for development of molecular electronics and spintronics. In this talk, I will talk about the extended spin distribution in space beyond the central Mn ion, and onto the non-magnetic constituent atoms of the MnPc molecule. This extended spin distribution results in an extended Kondo effect, which can be explained by spin polarization induced by symmetry breaking of the molecular framework, as confirmed by DFT calculations. Measuring the evolution of the Kondo splitting with applied magnetic fields at different atomic sites, we find a spatial variation of the g-factor within a single molecule for the first time. The existence of atomic site-dependent g-factors can be attributed to specific molecular orbitals distributed over the entire molecule. This work not only open up a new opportunity for quantum information recording, but also provide a new route to explore the internal electronic and spin structure of complex molecules, hard to achieve otherwise. (L.W. Liu et al., Phys. Rev. Lett. 2015, 114, 126601. In collaboration with Liwei Liu, Kai Yang, Yuhang Jiang, Li Gao, Qi Liu, Boqun Song, Wende Xiao, Haitao Zhou, Hongjun Gao in CAS, Min Ouyang in MU, and A.H. Castro Neto in SNU.)

**Session C22 DCOMP: Electrons, Phonons, and Electron-Phonon Scattering II** 321 - David Broido, Boston College

**2:30PM C22.00001 Controlling electron-phonon scattering with metamaterial plasmonic structures**, KRZYSZTOF KEMPA, XUEYUAN WU, JIANTAO KONG, DAVID BROIDO, Boston College — Electron-plasmon scattering can be faster than electron-phonon scattering. While in metals plasmons occur in the UV range, phonons dominate behavior at much lower frequencies (far IR range), and this typically decouples these phenomena. In metamaterial plasmonic structures, however, plasma effects can be tuned down to the far IR range, allowing for their interference with phonons. It was recently shown, that such interference can protect hot electron energy induced in a solar cell, from dissipation into heat [1]. In this work we explore the possibility of using such an effect to control the electron-phonon interaction and transport in semiconductors. We demonstrate, that this could lead to a novel path to enhancing the electrical and thermal conductivities and the thermoelectric figure of merit. [1] Hot electron plasmon-protected solar cell, J. Kong, A.H. Rose, C. Yang, J. M. Merlo, M.J. Burns, M. Naughton, and K. Kempa, Opt. Express 23, A1087-A1095 (2015) doi:10.1364/OE.23.0A1087

**2:42PM C22.00002 Temperature-dependence of electron bands in wurtzite GaN, including non-adiabatic (Polaron) contributions<sup>1</sup>**, JEAN PAUL NERY, JIAN LIU, P. B. ALLEN, Stony Brook University — We study the temperature dependence of the band gap of wurtzite structure GaN [1]. Virtual interband electron-phonon scattering is accounted properly by adiabatic (Allen-Heine-Cardona) theory. The correct way to avoid an unphysical divergence, is to use a non-adiabatic treatment for intraband scattering by small  $q$  polar optical phonons [2,3]. This is equivalent to including Fröhlich polaron effects. The  $T = 0$  zero-point weak-coupling polaron shift ( $-\alpha\hbar\omega$ ) is well known, but finite  $T$  effects are less studied. We also calculate the  $T$  dependence of the band mass (both polaron and adiabatic contributions). We compare results from an *ab-initio* density-functional approach with those obtained starting from the traditional Fröhlich Hamiltonian approach. [1] M. Cardona and Kremer, Thin Solid Films 571, 680 (2014). [2] S. Poncé *et al.*, The Journal of Chemical Physics 143, 102813 (2015) [3] C. Verdi and F. Giustino, Phys. Rev. Lett. 115, 176401 (2015)

**2:54PM C22.00003 Anti-ferromagnetism enables electron-phonon coupling in iron-based superconductors**, SINISA COH, MARVIN L. COHEN, STEVEN G. LOUIE, UC Berkeley and Lawrence Berkeley National Laboratory — We show that a generic form of an anti-ferromagnetic wavefunction opens strong electron-phonon coupling channels in the iron-based superconductors. In the non-magnetic state these channels exist locally on a single iron atom, but are cancelled out between two iron atoms in the primitive unit cell. Our findings are mostly based on symmetry and are relevant for any iron-based superconductor. This work was supported by NSF Grant No. DMR15-1508412 and the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by the DOE at Lawrence Berkeley National Laboratory's NERSC facility.

**3:06PM C22.00004 Acoustic Faraday rotation in Weyl semimetals**, DONGHAO LIU, JUNREN SHI, Peking Univ — We investigate the phonon problems in Weyl semimetals, from which both the phonon Berry curvature and the phonon Damping could be obtained. We show that even without a magnetic field, the degenerate transverse acoustic modes could also be split due to the adiabatic curvature. In three dimensional case, acoustic Faraday rotation shows up. And furthermore, since the attenuation procedure could distinguish the polarized mode, single circularly polarized acoustic wave could be realized. We study the mechanism in the novel time reversal symmetry broken Weyl semimetal. New effects rise because of the linear dispersion, which give enlightenment in the measurement of this new kind of three-dimensional material.

**3:18PM C22.00005 Strong enhancement of s-wave superconductivity near a quantum critical point of  $(\text{Ca}_{1-x}\text{Sr}_x)_3\text{Ir}_4\text{Sn}_{13}$  and  $(\text{Ca}_{1-x}\text{Sr}_x)_3\text{Rh}_4\text{Sn}_{13}$ <sup>1</sup>**, ELVEZIO MORENZONI, PABITRA BISWAS, ZURAB GUGUCHIA, RUSTEM KHASANOV, MANUEL CHINOTTI, JONAS KRIEGER, Paul Scherrer Institut, L LI, KEFENG WANG, CEDOMIR PETROVIC, Brookhaven National Laboratory, EKATERINA POMJAKUSHINA, Paul Scherrer Institut — We report microscopic studies by muon spin rotation as a function of pressure of the  $(\text{Ca}_{1-x}\text{Sr}_x)_3\text{Ir}_4\text{Sn}_{13}$  and  $(\text{Ca}_{1-x}\text{Sr}_x)_3\text{Rh}_4\text{Sn}_{13}$  cubic compounds, which display superconductivity and a structural phase transition associated with the formation of a charge density wave (CDW)[1]. In  $\text{Ca}_3\text{Ir}_4\text{Sn}_{13}$  we find a strong enhancement of the superfluid density and a dramatic increase of the pairing strength above a pressure of  $\approx 1.6$  GPa giving direct evidence of the presence of a quantum critical point separating a superconducting phase coexisting with CDW from a pure superconducting phase [2]. The superconducting order parameter in both phases has the same s-wave symmetry. Similar behavior is found in the other family. In spite of the conventional phonon-mediated BCS character of these weakly correlated 3-4-13 systems, the dependence of the effective superfluid density on the critical temperature put these compounds in the “Uemura” plot close to unconventional superconductors. These systems exemplify that conventional BCS superconductors can also display characteristics of unconventional superconductors. [1] S.K. Goh et al. Phys. Rev. Lett. 114, 097002 (2015). [2] P.K. Biswas et al., Phys. Rev. B (2015).

**3:30PM C22.00006 Ambient Pressure Structural Quantum Critical Point in the Phase Diagram of  $(\text{Ca}_x\text{Sr}_{1-x})_3\text{Rh}_4\text{Sn}_{13}$** <sup>1</sup>, SWEE K. GOH, Department of Physics, The Chinese University of Hong Kong, D. A. TOMPSETT, Imperial College London, P. J. SAINES, University of Oxford, H. C. CHANG, University of Cambridge, T. MATSUMOTO, M. IMAI, K. YOSHIMURA, Kyoto University, F. M. GROSCHE, University of Cambridge — The quasiskutterudite superconductor  $\text{Sr}_3\text{Rh}_4\text{Sn}_{13}$  features a pronounced anomaly in electrical resistivity at  $T^* \sim 138$  K. The anomaly is caused by a second-order structural transition, which can be tuned to 0 K by applying physical pressure and chemical pressure via the substitution of Ca for Sr. A broad superconducting dome is centered around the structural quantum critical point. Detailed analysis of the tuning parameter dependence of  $T^*$  as well as insights from lattice dynamics calculations strongly support the existence of a structural quantum critical point at ambient pressure when the fraction of Ca is 0.9 ( $x_c=0.9$ ). This establishes the  $(\text{Ca}_x\text{Sr}_{1-x})_3\text{Rh}_4\text{Sn}_{13}$  series as an important system for exploring the physics of structural quantum criticality and its interplay with the superconductivity, without the need of applying high pressures. Refs: Swee K. Goh *et al.*, Phys. Rev. Lett. 114, 097002 (2015); Wing Chi Yu *et al.*, Phys. Rev. Lett. (in press, 2015)

**3:42PM C22.00007 Pressure-enhanced superconductivity in A15-type Nb<sub>3</sub>Ge via increased Fermi surface nesting**<sup>1</sup>, RYAN STILLWELL, JASON JEFFRIES, SCOTT MCCALL, ZSOLT JENEI, SAM WEIR, Lawrence Livermore Natl Lab, YOGESH VOHRA, University of Alabama at Birmingham — The A15-type superconductors are the most widely used superconductors in industrial applications yet the physics behind maximizing the superconducting transition temperature is still not completely understood. The highest transition temperatures found to date have recently been reported for high-pressure hydride materials and it is believed that they too are BCS-type phonon-mediated superconductors, just like the A15-type superconductors. Understanding the electron-phonon coupling has therefore been brought front stage in the search to understand the mechanisms for optimizing high-temperature superconductors. Using a multi-faceted suite of high-pressure techniques we found that Nb<sub>3</sub>Ge has an isostructural phase transition at high pressure that correlates directly with a bandstructure change seen in high-pressure magnetotransport measurements. Our results suggest that A15-type superconductivity is not only phonon-mediated but that the degree of Fermi surface nesting is a controlling parameter for maximizing the superconducting transition temperature.

**3:54PM C22.00008 Strong Coupling Superconductivity in the Vicinity of the Structural Quantum Critical Point in  $(\text{Ca}_x\text{Sr}_{1-x})_3\text{Rh}_4\text{Sn}_{13}$** <sup>1</sup>, WING CHI YU, YIU WING CHEUNG, Department of Physics, The Chinese University of Hong Kong, PAUL J. SAINES, Department of Chemistry, University of Oxford, MASAKI IMAI, TAKUYA MATSUMOTO, CHISHIRO MICHIOKA, KAZUYOSHI YOSHIMURA, Department of Chemistry, Kyoto University, SWEE K. GOH, Department of Physics, The Chinese University of Hong Kong — The family of the superconducting quasiskutterudites  $(\text{Ca}_x\text{Sr}_{1-x})_3\text{Rh}_4\text{Sn}_{13}$  features a structural quantum critical point at  $x_c = 0.9$ , around which a dome-shaped variation of the superconducting transition temperature  $T_c$  is found. In this talk, we present the specific heat data for the normal and the superconducting states of the entire series straddling the quantum critical point. Our analysis indicates a significant lowering of the effective Debye temperature on approaching  $x_c$ , which we interpret as a result of phonon softening accompanying the structural instability. Furthermore, a remarkably large enhancement of  $2\Delta/k_B T_c$  and  $\Delta C/\gamma T_c$  beyond the Bardeen-Cooper-Schrieffer values is found in the vicinity of the structural quantum critical point. Reference: Wing Chi Yu *et al.* Phys. Rev. Lett. (in press, 2015)

**4:06PM C22.00009 Investigation of the superconducting and normal state properties of the filled-skutterudite system  $\text{PrPt}_4\text{Ge}_{12}$  via chemical substitution.**<sup>1</sup>, INHO JEON, KEVIN HUANG, DUYGU YAZICI, NORAVEE KANCHANAVATEE, BENJAMIN D. WHITE, SOOYOUNG JANG, NAVEEN POUSE, M. BRIAN MAPLE, University of California, San Diego, PEI-CHUN HO, California State University Fresno — We report a systematic chemical substitution study on the unconventional superconductor system  $\text{PrPt}_4\text{Ge}_{12}$ , which Sb ions are substituted for Ge. Polycrystalline samples of  $\text{PrPt}_4\text{Ge}_{12-x}\text{Sb}_x$  up to  $x = 5$  were synthesized and investigated by means of x-ray diffraction, electrical resistivity, magnetic susceptibility, and specific heat measurements. We observed a suppression of superconductivity with increasing Sb substitutions and evidence for a weak “rattling” mode associated with the Pr ions, characterized by a value of  $\Theta_E \sim 60$  K. As part of a systematic study of the effect of various elemental substitutions on the properties of  $\text{PrPt}_4\text{Ge}_{12}$ , measurements of the superconducting and normal state properties of the  $\text{Pr}_{1-x}\text{Eu}_x\text{Pt}_4\text{Ge}_{12}$  system are currently being performed. This work was supported by the U. S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Grant No. DE-FG02-04-ER46105 (characterization and physical properties measurements), and the National Science Foundation under Grant No. DMR 1206553 (low-temperature measurements).

**4:18PM C22.00010 First principles study of the electron-phonon coupling on the light-actinides Ac-Th alloy: effect of spin-orbit coupling**<sup>1</sup>, OMAR DE LA PEÑA SEAMAN, ROMEO DE COSS-MARTINEZ, PAOLA GONZALEZ-CASTELAZO, Institute of Physics (IFUAP), Benemerita Universidad Autonoma de Puebla (BUAP), ROLF HEID, KLAUS-PETER BOHNEN, Institute of Solid State Physics (IFP), Karlsruher Institute of Technology (KIT) — We have studied the electronic, lattice dynamics, and electron-phonon (e-ph) properties of the  $\text{Ac}_{1-x}\text{Th}_x$  actinide alloy. This system have been studied within the framework of density functional perturbation theory, using a mixed-basis pseudopotential method and the virtual crystal approximation (VCA) for modeling the alloy. The electronic density of states (DOS), the full-phonon dispersion as well as the Eliashberg spectral function ( $\alpha^2 F(\omega)$ ) and the electron-phonon coupling ( $\lambda$ ) parameter have been calculated with and without the inclusion of spin-orbit coupling (SOC). For Ac the observed effects of SOC on  $\alpha^2 F(\omega)$  are very minor. However, as Th-content increases on the alloy the SOC influence is more important. Such evolution has its roots on a continuous increase of density of states at the Fermi level ( $N(E_F)$ ) difference between schemes, as well as a steady hardening of the SOC full phonon dispersion. The evolution of  $\lambda$  as a function of Th-content for both schemes is presented and discussed on the light of SOC effects on the electronic and vibrational properties.

**4:30PM C22.00011 Truncated phase-space approach to polaron response**<sup>1</sup>, DRIES SELS, Boston Univ — A method is presented to obtain the linear response coefficients of a system coupled to a bath. The method is based on a systematic truncation of the Liouville equation for the reduced distribution function in the Weyl representation. Explicit expressions for the conductivity of the Frhlich polaron are obtained, and the discrepancy between the Kadanoff and the Feynman-Hellwarth-Iddings-Platzman mobility is elucidated. We argue why both approaches require a correction. Finally, we show how due to the system-bath coupling, the external perturbation induces a retarded internal field which dynamically screens the external force. Whereas the effect on the dc-mobility is of second order, dynamical properties such as the effective mass and the optical absorption are modified in first order.

**4:42PM C22.00012 First-Principles Calculation of forces and phonons in solid**, ZHENHUA NING, WILLIAM SHELTON, Louisiana State University — We have developed a multiple scattering theory approach to calculate Hellmann-Feynman forces and phonons via the calculation of the force constant and dynamical matrix. To demonstrate the accuracy and validity of our approach we compare with the ELK code, which is a full potential Linear Augmented Plane Wave (FLAPW) based method. As we will show our forces and phonon dispersion curves are in good agreement with the FLAPW code. This work lays the foundation for developing a first principles approach for calculation of phonons in substitutionally disordered materials.

**4:54PM C22.00013 Phonon and magnon dispersions of incommensurate spin ladder compound  $\text{Sr}_{14}\text{Cu}_{24}\text{O}_{41}$** <sup>1</sup>, XI CHEN, Univ of Texas, Austin, DIPANSHU BANSAL, Oak Ridge National Lab, SEAN SULLIVAN, JIANSHI ZHOU, Univ of Texas, Austin, OLIVIER DELAIRE, Oak Ridge National Lab, LI SHI, Univ of Texas, Austin — There are a variety of compounds consisting of two or more interpenetrating sublattices with lattice periods incommensurate at least along one crystal axis. One example is spin ladder compound  $\text{Sr}_{14}\text{Cu}_{24}\text{O}_{41}$  consisting of incommensurate spin ladder and spin chain sublattices. It has been predicted that unique phonon modes occur in these compounds due to the relative motion of the sublattices. In the low-wavelength limit, there is only one longitudinal acoustic mode due to the rigid translation of both sublattices. In addition, one extra pseudo-acoustic mode is present due to relative sliding motions of the two sublattices. Although the theoretical aspects of the lattice dynamics of incommensurate compounds have been studied, there have been few experimental investigations on their phonon dynamics. In this work, single crystals of  $\text{Sr}_{14}\text{Cu}_{24}\text{O}_{41}$  are grown by the traveling solvent floating zone method. The phonon dispersion of  $\text{Sr}_{14}\text{Cu}_{24}\text{O}_{41}$  is studied through inelastic neutron scattering measurements in order to better understand its phonon dynamics. In addition, its magnon dispersion is investigated and correlated to the large directional magnon thermal conductivity. The measurements reveal a wealth of intriguing features on phonons and magnons in the spin ladder compound.

**5:06PM C22.00014 High Temperature Superconductivity at High Pressures for  $\text{H}_3\text{SixP}(1-x)$ ,  $\text{H}_3\text{PxS}(1-x)$  and  $\text{H}_3\text{ClxS}(1-x)$** <sup>1</sup>, DIMITRIOS PAPACONSTANTOPOULOS, FUDONG FAN, George Mason Univ, MICHAEL MEHL, Naval Research Lab — Recent experimental and computational works have established the occurrence of superconducting temperatures,  $T_c$ , around 200K at corresponding 200GPa pressures in hydrogen-based sulfur compounds. In this work we have investigated the effects of phosphorus and chlorine substitutions of sulfur on  $T_c$ , as well as the effect of hydrogen vacancies. In addition, we have explored the superconductivity-relevant parameters in the  $\text{H}_3\text{SixP}(1-x)$  system. In executing this work we have used the virtual-crystal-approximation and performed a systematic set of LAPW calculations for many different concentrations of the sulfur component. From the densities of states and the scattering phase-shifts at the Fermi level, we calculated electron-ion matrix elements and estimated the electron-phonon coupling constants for different concentrations as well as  $T_c$ . We find that the high values of  $T_c$  correlate with the position of the Fermi level with respect to peaks (van Hove singularities) in the density of electronic states of these materials.

<sup>1</sup>US Department of Energy

**5:18PM C22.00015 Effect of van Hove singularities on high- $T_c$  superconductivity in H3S**, WATARU SANO, Department of applied physics, University of Tokyo, TAKASHI KORETSUNE, RIKEN Center of Emergent Matter Science, TERUMASA TADANO, Department of applied physics, University of Tokyo, RYOSUKE AKASHI, Department of physics, University of Tokyo, RYOTARO ARITA, RIKEN Center of Emergent Matter Science — One of interesting open questions for the high- $T_c$  superconductivity in sulfur hydrides is why some of the H3S phases under high pressures are so special. Recently, it has been pointed out that the presence of the van Hove singularities (vHs) around the Fermi level is crucial. Interestingly, such vHs are always absent in H2S, for which  $T_c$  is estimated to be much lower. Although there have been quantitative calculations of  $T_c$  based on the Migdal-Eliashberg theory, the effect of the vHs on the superconductivity is yet to be fully understood. This is because the energy dependence of the density of states (DOS) has been neglected to simplify the Eliashberg equation. In this study, we perform a calculation beyond the constant DOS approximation. In contrast with the conventional calculations, this approach with a sufficiently large number of Matsubara frequencies enables us to calculate  $T_c$  self-consistently without introducing the empirical pseudo Coulomb potential. We show that the constant DOS approximation seriously overestimates (underestimates)  $T_c$  by ~60 K (~10 K) for H3S (H2S). We then consider the effect of the anharmonicity of the phonon and the energy shift due to the zero-point motion. Eventually,  $T_c$  is estimated to be 180 K for H3S and 35 K for H2S, which successfully explains the pressure dependence of  $T_c$  observed in the experiment.

## Monday, March 14, 2016 2:30PM - 5:42PM –

Session C23 DMP: Acoustic, Thermal, and Photonic Metamaterial Concepts 322 - Matthew Sheldon, Texas AM University

**2:30PM C23.00001 Photonic hypercrystals**, EVGENII NARIMANOV, Purdue University — We introduce a new universality class of artificial optical media - the photonic hypercrystals. These hyperbolic metamaterials with a periodic spatial variation of dielectric permittivity on a subwavelength scale, combine the features of optical metamaterials and photonics crystals within the same medium.

**3:06PM C23.00002 A Metasurface Anti-reflection Coating for Enhancing Surface Plasmon-Polariton of Metallic Hole Array.**, KHAGENDRA BHATTARAI, Department of Physics, University of South Florida, Tampa, FL 33620, USA, JIYEON JEON, JUN KIM, Korea Research Institute of Standards and Science, Daejeon, 305-340, Korea, ZAHYUN KU, Air Force Research Laboratory, Dayton, OH 45433, USA, SANG JUN LEE, Korea Research Institute of Standards and Science, Daejeon, 305-340, Korea, JIANGFENG ZHOU, Department of Physics, University of South Florida, Tampa, FL 33620, USA, USA COLLABORATION, KRISS, KOREA COLLABORATION, AFRL, USA COLLABORATION — We demonstrate a metasurface made of metallic disk resonator array as an anti-reflection (AR) coating to enhance (reduce) the transmission (reflection) through metal hole array (MHA). Our result show that the simulated (measured) transmission at the first order surface plasmon-polariton (SPP) resonance is increased up to 82 % ( 88%) compared to uncoated MHA. The electric field of the surface wave is also enhanced by 33%. Using an effective medium theory, we show that the metasurface operates at off-resonance wavelengths and can be understood as a thin film that exhibits high effective permittivity (~30) with very low loss (loss tangent ~0.005). Thus we reveal the mechanism of the metasurface AR coating as the traditional thin film AR coating. With tunable effective permittivity, our structure provides great flexibility to achieve AR coating for general substance at any wavelength.

**3:18PM C23.00003 Hybrid graphene/dielectric metasurfaces for enhanced transmission modulation**, CHRISTOS ARGYROPOULOS, University of Nebraska-Lincoln — All-dielectric silicon based metasurfaces are powerful platforms to enhance light-matter interactions at nanoscale regions. Their low-loss nature, CMOS processing compatibility and increased damage threshold promise to outperform the functionalities of the recently established plasmonic metallic metasurfaces. In our talk, we will demonstrate ways to hybridize all-dielectric metasurfaces with graphene in order to obtain new electro-optical devices. In particular, a hybrid graphene/dielectric metasurface design will be presented to achieve tunable and modulated transmission at near-infrared (near-IR) frequencies (C. Argyropoulos, *Optics Express*, vol. 23, No. 18, pp. 23787-23797, 2015). The proposed all-dielectric metasurface is composed of periodically arranged pairs of asymmetric silicon nanobars, which can sustain trapped magnetic resonances with a sharp Fano-type transmission signature. One-atom-thick graphene is placed over this dielectric metasurface and strong transmission modulation is obtained at near-IR telecom wavelengths as the doping level of graphene is increased. The enhanced in-plane fields along the all-dielectric metasurface strongly interact with the tunable properties of graphene. This leads to strong coupling between the incoming radiation and graphene. Several new integrated nanophotonic components are envisioned based on the proposed device, such as efficient electro-optical transmission modulators.

**3:30PM C23.00004 Nonlinear light-matter interactions in engineered optical media<sup>1</sup>**, NATALIA LITCHINITSER, University at Buffalo, The State University of New York — In this talk, we consider fundamental optical phenomena at the interface of nonlinear and singular optics in artificial media, including theoretical and experimental studies of linear and nonlinear light-matter interactions of vector and singular optical beams in metamaterials. We show that unique optical properties of metamaterials open unlimited prospects to “engineer” light itself. Thanks to their ability to manipulate both electric and magnetic field components, metamaterials open new degrees of freedom for tailoring complex polarization states and orbital angular momentum (OAM) of light. We will discuss several approaches to structured light manipulation on the nanoscale using metal-dielectric, all-dielectric and hyperbolic metamaterials. These new functionalities, including polarization and OAM conversion, beam magnification and de-magnification, and sub-wavelength imaging using novel non-resonant hyperlens are likely to enable a new generation of on-chip or all-fiber structured light applications. The emergence of metamaterials also has a strong potential to enable a plethora of novel nonlinear light-matter interactions and even new nonlinear materials. In particular, nonlinear focusing and defocusing effects are of paramount importance for manipulation of the minimum focusing spot size of structured light beams necessary for nanoscale trapping, manipulation, and fundamental spectroscopic studies. Colloidal suspensions offer as a promising platform for engineering polarizabilities and realization of large and tunable nonlinearities. We will present our recent studies of the phenomenon of spatial modulational instability leading to laser beam filamentation in an engineered soft-matter nonlinear medium. Finally, we introduce so-called virtual hyperbolic metamaterials formed by an array of plasma channels in air as a result of self-focusing of an intense laser pulse, and show that such structure can be used to manipulate microwave beams in a free space.

<sup>1</sup>This work was supported by the Army Research Office Awards (W911NF-15-1-0146, W911NF-11-1-0297).

**4:06PM C23.00005 Broadband non-unity magnetic permeability in planar hyperbolic metamaterials**, GEORGIA THEANO PAPADAKIS, DAGNY FLEISCHMAN, ARTUR R. DAVOYAN, KRISHNAN THYAGARAJAN, HARRY A. ATWATER, Caltech — Metal/dielectric heterostructures with extreme anisotropy and topologically nontrivial dispersion are of fundamental and applied interest due to unique optical and opto-electronic properties. Here we demonstrate that, surprisingly, such systems exhibit a broadband non-unity magnetic response. Typically the electromagnetic properties of such metal-dielectric stacks are deduced from effective medium theories for unbounded, i.e., infinite in size periodic arrangements (c.f., Maxwell-Garnett approximation). In this talk, we show that this description is incomplete for metamaterials with finite number of layers. We demonstrate that a few-layer metal-dielectric metamaterial exhibits a non-unity magnetic permeability across the whole visible spectrum. The response can be diamagnetic or paramagnetic depending on the type of the terminating layers: metallic or dielectric, with non-resonant magnetic permeability that can be engineered to attain values as low as -2 or as high as 2. We have developed a theoretical model that explains the underlying mechanism. We further experimentally validate non-unity effective permeability in the optical range of frequencies. Ag/SiO<sub>2</sub> and Ge-based metamaterials fabricated with electron beam evaporation are characterized by ellipsometric measurements and also phase and amplitude of transmittance/reflectance. These results open pathways for creating broadband subwavelength magnetic structures in the visible regime.

**4:18PM C23.00006 Microscopic model of the nonlocal response of metamaterial plasmonic structures**, JIANTAO KONG, KRZYSZTOF KEMPA, Boston College — Nonlocal effects are generally omitted in typical approaches to calculating the electromagnetic response of the metamaterial plasmonic structures. In some situations, however, where the electron momenta far exceed those of photons, nonlocal corrections are essential. In this work, we investigate simple models of the nonlocal dielectric functions, based on the d-function formalism of Feibelman [1,2], and assess their validity by comparing with experiments. We show, that the applicability of the commonly used hydrodynamic approximation is very limited, since it often strongly overestimates the nonlocal response. [1] Feibelman, *Prog. Surf. Sci.* 12, 287 (1982); *Phys. Rev. B* 40, 2752 (1989) [2] Liebsch, *Phys. Rev. B* 48, 15 (1993)

**4:30PM C23.00007 Semiconductor Hyperbolic Metamaterials for the Mid-Infrared**, DONGXIA WEI, University of Delaware, CHRISTIAN HARRIS, Lincoln University, CORY BOMBERGER, JING ZHANG, JOSHUA ZIDE, STEPHANIE LAW, University of Delaware — Hyperbolic metamaterials have shown great promise for controlling light in the visible spectral range. However, moving metamaterials to the infrared is not just a matter of scaling geometries, but also of choosing new materials with appropriate optical properties. We demonstrate infrared hyperbolic metamaterials with optical properties tunable across the mid-infrared created from semiconductor superlattices grown by molecular beam epitaxy. The metamaterials are made of alternating subwavelength layers of metal (doped semiconductor) and dielectric (undoped semiconductor). By tuning the doping density, layer thicknesses, and metal:dielectric thickness ratio, we can control the onset and bandwidth of metamaterial behavior across the infrared. Our materials exhibit low optical losses as well as high sample uniformity and sharp interfaces. Transmission and reflection properties of the samples are studied by Fourier transform infrared spectroscopy and modeled with effective medium theory. We will also show the results from a beam optics experiment which demonstrates that our materials exhibit negative refraction.

**4:42PM C23.00008 Semiconductor-based mid-IR metamaterials: experimental and theoretical studies**, ANDREY SEMICHAEVSKY, CHRISTIAN HARRIS, Lincoln University (PA), DONGXIA WEI, STEPHANIE LAW, University of Delaware — All-semiconductor (III-V) metamaterials (MTM) for the infrared (IR) can be applied to superlensing and optical cloaking [1]. 1-D metallic-semiconductor superlattices can be designed to have hyperbolic dispersion due to the choice of their effective permittivity tensor components. In this paper we go beyond the effective-medium theories and provide a detailed analysis of how the choice of doping levels and layer thicknesses in the InAs - InAs:Si will affect the reflectance of the MTM superlattice in the IR. In order to do that, four metamaterial samples with various doping profiles were grown by MBE and characterized using FTIR. For the same samples we performed full-wave calculations of the wavelength- and angle-resolved reflectance. Our numerical model is suitable for 1-D inhomogeneous lossy dispersive media and is capable of accounting for an arbitrary doping profile and the quantum mechanical tunneling of electrons in the heterostructure. Experimental and theoretical results for the reflectance of IR metamaterial structures are compared. [1] S. Law, C. Roberts, T. Kilpatrick, L. Yu, T. Ribaud, E. A. Shaner, V. Podolskiy, and D. Wasserman, *Phys. Rev. Letters*, **112**, 017401, 2014.

**4:54PM C23.00009 Broadband enhanced transmission of acoustic waves through serrated metal gratings**, DONG-XIANG QI, REN-HAO FAN, YU-QIANG DENG, RU-WEN PENG, MU WANG, Nanjing Univ, JIANGNAN UNIVERSITY COLLABORATION — In this talk, we present our studies on broadband properties of acoustic waves through metal gratings. We have demonstrated that serrated metal gratings, which introduce gradient coatings, can give rise to broadband transmission enhancement of acoustic waves. Here, we have experimentally and theoretically studied the acoustic transmission properties of metal gratings with or without serrated boundaries. The average transmission is obviously enhanced for serrated metal gratings within a wide frequency range, while the Fabry-Perot resonance is significantly suppressed. An effective medium hypothesis with varying acoustic impedance is proposed to analyze the mechanism, which was verified through comparison with finite-element simulation. The serrated boundary supplies gradient mass distribution and gradient normal acoustic impedance, which could efficiently reduce the boundary reflection. Further, by increasing the region of the serrated boundary, we present a broadband high-transmission grating for wide range of incident angle. Our results may have potential applications to broadband acoustic imaging, acoustic sensing and new acoustic devices. References: [1] Dong-Xiang Qi, Yu-Qiang Deng, Di-Hu Xu, Ren-Hao Fan, Ru-Wen Peng, Ze-Guo Chen, Ming-Hui Lu, X. R. Huang and Mu Wang, Appl. Phys. **5:06PM C23.00010 Manipulate acoustic waves by impedance matched acoustic metasurfaces<sup>1</sup>**, YING WU, King Abdullah Univ of Sci & Tech (KAUST), JUN MEI, South China University of Technology, RASHA ALJAHDALI, King Abdullah Univ of Sci & Tech (KAUST) — We design a type of acoustic metasurface, which is composed of carefully designed slits in a rigid thin plate. The effective refractive indices of different slits are different but the impedances are kept the same as that of the host medium. Numerical simulations show that such a metasurface can redirect or reflect a normally incident wave at different frequencies, even though it is impedance matched to the host medium. We show that the underlying mechanisms can be understood by using the generalized Snell's law, and a unified analytic model based on mode-coupling theory. We demonstrate some simple realization of such acoustic metasurface with real materials. The principle is also extended to the design of planar acoustic lens which can focus acoustic waves.

<sup>1</sup>Manipulate acoustic waves by impedance matched acoustic metasurfaces

**5:18PM C23.00011 Simulation and Experimental Realization of a Nano-scale Thermal Cloak.**, XUE BAI, NUS Graduate School for Integrative Sciences and Engineering, National University of Singapore, Kent Ridge 119620, Republic of Singapore., XIANGFAN XU, Center for Phononics and Thermal Energy Science, School of Physical Science and Engineering, Tongji University, 200092, Shanghai, China., BAOWEN LI, Department of Mechanical Engineering, University of Colorado, Boulder, Colorado 80309, USA, XUDONG CHEN, JOHN T. L. THONG, Department of Electrical and Computer Engineering, National University of Singapore, 4 Engineering Drive 3, Republic of Singapore — Manipulation of heat flow at microstructures plays an important role in modern industry, especially for electronic and optoelectronic devices, for their performance and reliability are highly temperature dependent. Analogous to the invisible cloak in transformation optics, the thermal cloak can hide objects from heat and realize isothermal region in transformation thermodynamics. However, due to the macro-scale thermal properties may not be suitable for nano-materials, the realization of the nano-scale thermal cloak highly relies on the thermal transport in nanostructures. Here, we report our recent work of the realization of nano-scale thermal cloak based on the thermal property study of nano-materials via a spatially resolved thermal resistance measurement technique. The simulation and experiment verified its maintenance of isothermal region and heat protection capabilities. This work may provide a new way to manipulate heat transport in nano-scale devices..

**5:30PM C23.00012 Microscopic Model of the Nonlocal Response of Metamaterial Plasmonic Structures II**, ALEXANDER SHVONSKI, KRZYSZTOF KEMPA, Boston College — Nonlocal effects are generally omitted in typical approaches to calculating the electromagnetic response of metamaterial plasmonic structures. In some situations, however, where the electron momenta far exceed those of photons, nonlocal corrections are essential. In this work, we calculate the nonlocal plasmonic response of a microscopic model of a metamaterial plasmonic structure by employing the random phase approximation, and the self-consistent ground Lang-Kohn states. We compare our results with experiment, and various simple models, including the hydrodynamic approximation.

323 - Maxim Sukharev, Arizona State University

**2:30PM C24.00001 Ultrafast Single and Multiexciton Energy Transfer in Semiconductor Nanoplatelets<sup>1</sup>**, RICHARD SCHALLER, Argonne National Laboratory & Northwestern University — Photophysical processes such as fluorescence resonance energy transfer (FRET) enable optical antennas, wavelength down-conversion in light-emitting diodes (LEDs), and optical bio-sensing schemes. The rate and efficiency of this donor to acceptor transfer of excitation between chromophores dictates the utility of FRET and can unlock new device operation motifs including quantum-funnel solar cells and reduced gain thresholds. However, the fastest reported FRET time constants involving spherical quantum dots (QDs) (0.12-1 ns), do not outpace biexciton Auger recombination (0.01-0.1 ns), which impedes multiexciton-driven applications including electrically-pumped lasers and carrier-multiplication-enhanced photovoltaics. Precisely controlled, few-monolayer thick semiconductor nano-platelets with tens-of-nanometer diameters exhibit intense optical transitions and hundreds-of-picosecond Auger recombination, but heretofore lack FRET characterizations. We examine binary CdSe NPL solids and show that inter-plate FRET (~6-23 ps, presumably for co-facial arrangements) can occur 15-50 times faster than Auger recombination and demonstrate multiexcitonic FRET, making such materials ideal candidates for advanced technologies.

**3:06PM C24.00002 Spontaneous emission enhancement of colloidal CdSe nanoplatelets.**, ZHILI YANG, University of Maryland, College Park, MATTHEW PELTON, University of Maryland, Baltimore, EDO WAKS, University of Maryland, College Park — Colloidal CdS /CdSe/CdS nanoplatelets synthesized recently are high efficient nano-emitters and gain media for nanoscale lasers and other nonlinear optical devices. They are characterized as quantum well structure due to energy gap difference between core CdSe and shell CdS, of which the luminescent wavelength could be tuned precisely by their thickness of growth. However, the influence of environment on the material's optical properties and further enhancement of the emission to implement nanoscale systems remains to be investigated. Here we demonstrate spontaneous emission rate enhancement of these CdSe nanoplatelets coupled to a photonic crystal cavity. We show clearly the photoluminescent spectrum modification of the nanoplatelets emission and an averaged Purcell enhancement factor of 3.1 is achieved when they are coupled to carefully-designed nanobeam photonic crystal cavities compared to the ones on unpatterned surface in our experiment of lifetime measurement. Also the phenomenon of cavity quality factor increasing is observed when increasing intensity of pumping, which attributes to saturable absorption of the nanoplatelets. Our success in enhancement of emission from these nanoplatelets here paves the road to realize actual nanoscale integrated systems such as ultra-low threshold micro-cavity lasers.

### 3:18PM C24.00003 Interfacial charge separation and trapping in composite photocatalysts<sup>1</sup>

DINKO CHAKAROV, Chalmers Univ of Tech — We explore the phenomena of interfacial charge separation and trapping in composite metal-semiconductor systems and the interaction (energy and charge exchange) between optically excited nanoparticles and the surrounding medium. Disc-shaped copper nanoparticles (Cu NPs) were fabricated by hole-mask colloidal lithography on bare and thin titania film covered fused silica substrates. The dynamics of Cu oxide formation around the NPs were studied in water by localized surface plasmon resonance (LSPR) spectroscopy. We found that the oxidation rate is strongly enhanced under UV irradiation when the NPs are on the surface of the titania film, in comparison to NPs deposited on an inert fused silica substrate. The reason is sought in the ability of TiO<sub>2</sub> to create hydroxyl radicals with strong oxidative potential in water under UV irradiation and the charge transfer at the interface between the Cu NPs and the TiO<sub>2</sub>. The results demonstrate the potential of using LSPR spectroscopy to monitor the oxidation of Cu NPs in situ and in different environments.

### 3:30PM C24.00004 Fluorescence of semiconductor nanocrystals coupled to optical Tamm

**cavities**<sup>1</sup>, FU FENG, Institut Des Nanosciences de Paris, PASCALE SENELLART TEAM<sup>2</sup>, BENOIT DUBERTRET TEAM<sup>3</sup>, AGNES MAITRE TEAM<sup>4</sup> — We describe here the photoluminescence properties of a layer of colloidal CdSe/CdS fluorescent nanocrystals embedded in such a Tamm cavity. Spectral and angular analysis of fluorescence shows that the nanocrystals emission is into the Tamm states; the emission dispersion relation for disks of various diameters shows the effect of the Tamm states lateral confinement. We also combined spatial and angular emission analysis and showed that the direction of emission is not the same for different points on a disk: emission from the left (resp. right) portion of the cavity is directed mostly in the left (resp. right) direction, in agreement with our numerical simulations. Our measurement scheme constitutes a probe of the Tamm state electric field phase gradient inside the cavity.

### 3:42PM C24.00005 Measuring Exciton Migration in Conjugated Polymer Films with Ultrafast Time Resolved Stimulated Emission Depletion Microscopy

, SAMUEL PENWELL, UC Berkeley — Conjugated polymers are highly tunable organic semiconductors, which can be solution processed to form thin films, making them prime candidates for organic photovoltaic devices. One of the most important parameters in a conjugated polymer solar cell is the exciton diffusion length, which depends on intermolecular couplings, and is typically on the order of 10 nm. This mean exciton migration can vary dramatically between films and within a single film due to heterogeneities in morphology on length scales of 10's to 100's nm. To study the variability of exciton diffusion and morphology within individual conjugated polymer films, we are adapting stimulated emission depletion (STED) microscopy. STED is typically used in biology with sparse well-engineered fluorescent labels or on NV-centers in diamond. I will, however, describe how we have demonstrated the extension of STED to conjugated polymer films and nanoparticles of MEH-PPV and CN-PPV, despite the presence of two photon absorption, by taking care to first understand the material's photophysical properties. We then further adapt this approach, by introducing a second ultrafast STED pulse at a variable delay. Excitons that migrate away from the initial subdiffraction excitation volume during the ps-ns time delay, are preferentially quenched by the second STED pulse, while those that remain in the initial volume survive. The resulting effect of the second STED pulse is modulated by the degree of migration over the ultrafast time delay, thus providing a new method to study exciton migration. Since this technique utilizes subdiffraction optical excitation and detection volumes with ultrafast time resolution, it provides a means of spatially and temporally resolving measurements of exciton migration on the native length and time scales. In this way, we will obtain a spatiotemporal map of exciton distributions and migration that will help to correlate the energetic landscape to film morphology at the nanoscale.

### 4:18PM C24.00006 How Microstructure Defines Function in Organic Conjugated Materials:

**Insights from Modelling**, YOANN OLIVIER, University of Mons, Laboratory for Chemistry of Novel Materials, Place du Parc 20, Mons, Belgium — Organic conjugated materials have attracted an increasing interest over the years for their use in organic opto- electronic devices such as light-emitting diodes, solar cells, or field- effect transistors as a result of their low cost, light weight and ease of processing from solution. The improvement of the device performances requires a deep understanding of the electronic processes taking place in these devices down to the molecular scale. Especially, the way organic conjugated molecules or polymer chains organize in the solid state appears as a critical parameter to control in order to fine tune the materials electronic and photophysical properties. In our laboratory, we have developed a multi-faceted modeling scheme that encompasses classical molecular dynamics, quantum-chemistry, non-adiabatic quantum dynamics and kinetic Monte Carlo simulations to assess multiple fundamental opto- electronic processes occurring in conjugated materials used in devices. Here, we will more specifically review work dealing with the modeling of charge transport in conjugated polymers as well as singlet fission and exciton transport in small molecules. In all cases, we will highlight how these processes are sensitive to the relative arrangement of the materials at the nanoscale.

### 4:54PM C24.00007 Probing surface recombination velocities in semiconductors using two-photon microscopy

, BENOIT GAURY, Maryland Nanocenter, University of Maryland, College Park. CNST, National Institute of Standards and Technology, PAUL HANEY, National Institute of Standards and Technology — We propose an analysis of the diffusion problem related to the two-photon time-resolved photoluminescence microscopy technique. We are considering a model of excess carrier diffusion in three dimensions, with recombination that is first order in carrier density (ie valid in low injection regime) and various boundary conditions that will apply to different use of the technique. First, we study a single planar boundary with enhanced recombination (parameterized with a recombination velocity). This planar boundary may represent the exposed sample surface, or any deep subsurface structure, such as a grain boundary or materials interface. Next, we assume the diffusion to be bounded by two parallel planes parameterized with different recombination velocities. This may apply to thin films where the diffusion length is higher than the sample thickness, or when the carrier generation volume axially spans the entire film. Finally, we investigate diffusion in a sphere where the spherical surface plays the role of a closed grain boundary. For all these cases we give analytical solutions for the three-dimensional diffusion problem for an excitation of arbitrary spatial or time dependence. We believe the solutions and scalings to be simple enough to enable convenient data fitting.

### 5:06PM C24.00008 Direct measurement of non-equilibrium phonon occupations in femtosecond laser heated Au films

, TYLER CHASE, MARIANO TRIGO, ALEXANDER REID, RENKAI LI, THEODORE VECCHIONE, XIAOZHE SHEN, STEPHEN WEATHERSBY, RYAN COFFEE, NICK HARTMANN, DAVID REIS, XIJIE WANG, HERMANN DÜRR, SLAC - Natl Accelerator Lab — We use ultrafast electron diffraction to detect the temporal evolution of phonon populations in femtosecond laser-excited ultrathin single-crystalline gold films. From the time-dependence of the Debye-Waller factor we extract a 4.7 ps time-constant for the increase in mean-square atomic displacements. We show from the increase of the diffuse scattering intensity that the population of phonon modes near the X and K points in the Au fcc Brillouin zone grows with timescales of 2.3 and 2.9 ps, respectively, faster than the Debye-Waller average. We find that thermalization continues within the initially non-equilibrium phonon distribution after 10 ps. The observed momentum dependent timescale of phonon populations is in contrast to what is usually predicted in a two-temperature model.

**5:18PM C24.00009 Time-resolved spectroscopy at surfaces and adsorbate dynamics: insights from a model-system approach**, EMIL BOSTRÖM, ANDERS MIKKELSEN, CLAUDIO VERDOZZI, Lund University — We introduce a finite-system, model description of the initial stages of femtosecond laser induced desorption at surfaces. Using the exact many-body time evolution and also results from a novel time-dependent DFT description for electron-nuclear systems, we analyse the competition between several surface-response mechanisms and electronic correlations in the transient and longer time dynamics under the influence of dipole-coupled fields. Our model allows us to explore how coherent multiple-pulse protocols impact desorption in a variety of prototypical experiments.

**2:30PM C25.00001 Ultrafast studies of coexisting electronic order in cuprate superconductors**, JAMES HINTON, UC San Diego, ERIC THEWALT, UC Berkeley, LBNL, ZHANYBEK ALPICHSEV, MIT, AARON STERNBACH, ALEX MCLEOD, UC San Diego, L. JI, MIKE VEIT, CHELSEY DORROW, University of Minnesota, JAKE KORALEK, SLAC, LBNL, XUDONG XHAO, Jilin University, NEVEN BARISIC, CEA Saclay, ALEXANDER KEMPER, North Carolina State University, LBNL, NUH GEDIK, MIT, MARTIN GREVEN, University of Minnesota, DIMITRI BASOV, UC San Diego, JOE ORENSTEIN, UC Berkeley, LBNL — The cuprate family of high temperature superconductors displays a variety of electronic phases which emerge when charge carriers are added to the antiferromagnetic parent compound. These electronic phases are characterized by subtle differences in the low energy electronic excitations. Ultrafast time-resolved reflectivity (TRR) provides an ideal tool for investigating the cuprate phase diagram, as small changes in the electronic structure can produce significant contrast in the non-equilibrium reflectivity. Here we present TRR measurements of cuprate superconductors, focusing on the model single-layer cuprate  $\text{HgBa}_2\text{CuO}_{4+\delta}$ . We observe a cusp-like feature in the quasiparticle lifetime near the superconducting transition temperature  $T_c$ . This feature can be understood using a model of coherently-mixed charge-density wave and superconducting pairing. We propose extending this technique to the nanoscale using ultrafast scattering scanning near-field microscopy (u-SNOM). This will allow us to explore how these electronic phases coexist and compete in real-space.

**2:42PM C25.00002 Probing broken symmetry states in cuprate superconductors with polarization-sensitive infrared spectroscopy**<sup>1</sup>, ALOK MUKHERJEE, MUMTAZ MURAT ARIK, JUNGRYEOL SEO, JOHN CERNE, University at Buffalo, HAO ZHANG, KE JUN XU, JOHN Y. T. WEI, University of Toronto, N.P. ARMITAGE, Johns Hopkins University, T. KIRZHNER, G. KOREN, Technion-Israel Institute of Technology — The nature of the pseudogap state in high-temperature superconducting (HTS) cuprates has drawn a lot of attention in the past two decades. A fundamental question is whether the pseudogap is a distinct phase with its own broken symmetries. Recent optical studies in the near-IR (800 meV) [1] and THz (2-6 meV) [2] ranges have observed symmetry breaking in the pseudogap state of HTS cuprates, suggesting that the pseudogap is a distinct phase. To probe the spectral character of this broken symmetry, we have performed infrared/visible Faraday and Kerr effect measurements at zero magnetic field and various temperatures on a series of HTS cuprate thin films, grown epitaxially by pulsed laser-ablated deposition. We will present and discuss our data, primarily complex Faraday/Kerr angle as a function of energy (0.1-3 eV), temperature (10-300K) and sample orientation with respect to the incident light polarization. 1. Xia, J et.al PRL 100, 127002 (2008). 2. Lubashevsky, Y et.al PRL 112, 147001 (2014) .

**2:54PM C25.00003 Optical anisotropy of a cuprate high  $T_c$  superconductor**<sup>1</sup>, LIUYAN ZHAO, California Institute of Technology, CARINA BELVIN, Wellesley College, RUIXING LIANG, WALTER HARDY, DOUG BONN, University of British Columbia, PETER ARMITAGE, Johns Hopkins University, DAVID HSIEH, California Institute of Technology — Evidence for a symmetry breaking phase transition across the pseudogap temperature  $T^*$  of cuprate high- $T_c$  superconductors has been reported in several experiments. For example, resonant ultrasound spectroscopy reveals a discontinuous change in the normal mode frequencies of the lattice across  $T^*$  while spin-flip neutron scattering shows time reversal symmetry breaking across  $T^*$ . Recent THz spectroscopy measurements also suggest the loss of mirror symmetries in the vicinity of  $T^*$ . Optical anisotropy is in principle sensitive to the point group symmetries of a crystal and is highly complementary to the aforementioned techniques. I will present our progress in measuring and understanding the optical anisotropy of  $\text{YBa}_2\text{Cu}_3\text{O}_y$  in the vicinity of its pseudogap transition temperature.

<sup>1</sup>Optical anisotropy of a cuprate high  $T_c$  superconductor

**3:06PM C25.00004 Elucidating the driving force of superconductivity increase in compressed optimally doped  $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+x}$** , XIAO-JIA CHEN, Center for High Pressure Science and Technology Advanced Research, Shanghai 201203, China, VIKTOR STRUZHNIKIN, Geophysical Laboratory, Carnegie Institution of Washington, Washington, DC 20015, JIAN-BO ZHANG, Center for High Pressure Science and Technology Advanced Research, Shanghai 201203, China, ALEXANDER GAVRILIUK, Institute of Crystallography, Russian Academy of Sciences, Moscow 119333, Russia, ALEXANDER GONCHAROV, HO-KWANG MAO, Geophysical Laboratory, Carnegie Institution of Washington, Washington, DC 20015, HAI-QING LIN, Beijing Computational Science Research Center, Beijing 100089, China, GENDA GU, Brookhaven National Laboratory, NY 11973 — An optimally doped cuprate  $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+x}$  is as a perfect model system to explore the mechanism of superconductivity by applying pressure as one can avoid complicated competing orders in the underdoped regime and explore pure intrinsic effects rather than secondary effects related to change in the carrier concentration. Here, by carefully examining the collected high-pressure Raman spectra at low temperatures, we have observed an enhanced two-magnon mode and connected this to the observed 10 K increase in  $T_c$  (reaching more than 100 K for the first time) in the optimally doped  $\text{Bi}_2\text{Sr}_2\text{CaCu}_2\text{O}_{8+x}$  upon compression clearly delineating the effect of pressure-induced charge transfer that must suppress  $T_c$  for this optimally doped sample. Our finely designed experiments offer the direct and convincing evidence for identifying the magnetic fluctuations as the pairing interaction in cuprate superconductors.

**3:18PM C25.00005 Time domain THz studies of thin film spinel superconductor  $\text{LiTi}_2\text{O}_4$** <sup>1</sup>, EVAN JASPER, M.T. WARREN, T.T. MAI, J. BRANGHAM, R. VALDÉS AGUILAR, Department of Physics, The Ohio State University. Columbus OH 43210, J. M. SHIN, I. TAKEUCHI, R.L. GREENE, University of Maryland — Recent advances in growth of high-quality crystalline thin films of the only known spinel superconductor (SC)  $\text{LiTi}_2\text{O}_4$  have allowed the discovery of an anomalous anisotropic magnetoresistance in its normal state [1]. We have used time domain terahertz spectroscopy, a contactless transport measurement, to determine the ac conductivity of  $\text{LiTi}_2\text{O}_4$  and to examine the BCS nature of the superconducting state. We obtained the temperature dependence of the SC gap as well as the London penetration depth, and also found a hint of a second gap. We will discuss and compare these results in terms of the known dc transport properties [1]. [1] K. Jin, et al. Nature Communications, 6, 7183, 2015.

**3:30PM C25.00006 Superconductivity-induced changes in density-density correlation function enabled by Umklapp processes**, WEI-CHENG LEE, Binghamton Univ — Motivated by the midinfrared scenario for high-temperature superconductivity proposed by Leggett, the effects of Umklapp processes on the density-density correlation function in the presence of long-range Coulomb interaction have been investigated. We show that because Umklapp processes enable scatterings that conserve total momentum only up to an integer times the reciprocal wave vector, significant amounts of spectral weight in the plasmonic excitations at long wavelength are transferred into lower frequency around the midinfrared regime. We further find that regardless of the gap symmetry, superconductivity generally suppresses the Umklapp scatterings due to the nature of Cooper pairs. This suppression is unique for the superconductivity due to the interplay between electron pairing and the odd parity of the matrix elements associated with Umklapp channels, which usually does not occur in other known competing orders. Specific predictions for the experimental signatures in optical conductivity and electron energy loss spectroscopy will be discussed.

**3:42PM C25.00007 New Method for Imaging Gap Nodal Structure of Unconventional Superconductors through the Anisotropic Nonlinear Meissner Effect<sup>1</sup>**, SEOKJIN BAE, YUEWEN TAN, RAHUL GOGNA, NATHAN MENDELSON, Univ of Maryland-College Park, STEVEN REMILLARD, Hope College, STEVEN ANLAGE, Univ of Maryland-College Park — We present a new measurement method which can be used to image gap nodal structure of superconductors whose pairing symmetry is unknown. This method utilizes photoresponse from a microwave resonance of the superconducting sample perturbed by a scanned laser spot. For an epitaxial or single crystal sample, the anisotropy of this photoresponse is directly related to that of gap function via the non-linear Meissner coefficient, so the gap nodal directions can be inferred from the photoresponse image. The significant advantage of the presented method over previous spiral or lumped circuit resonator methods is that it does not require a complicated lithographic patterning process which often degrades superconductivity or introduces defect-dominant photoresponse and hence limits one from testing various kinds of materials. The validity of the method is confirmed both by HFSS simulation and experiments on unpatterned superconducting thin films. Photoresponse images from example unconventional superconductors will be also presented and discussed.

Title: New Method for Imaging Gap Nodal Structure of Unconventional Superconductors through the Anisotropic Non-

**3:54PM C25.00008 Imaging the Anisotropic Non-linear Meissner Effect Range<sup>1</sup>**, YUEWEN TAN, SEOKJIN BAE, STEVEN ANLAGE, Univ of Maryland, College Park — The anisotropic non-linear superconductors, which gives information about gap nodal structure, has been observed by measurements of anisotropic photoresponse to about 3 Kelvin.[1] Since the anisotropy of photoresponse originates from the non-linear Meissner effect coefficient, and the dependence for the photoresponse at temperatures below  $0.1T_c$ , [2] it will be interesting to measure photoresponse in that range. We will use a scanning laser microscope around a dilution refrigerator, and plan to measure photoresponse of unconventional superconductors in the millikelvin range. Reference: [1] A. P. Zhuravel, B. G. Ghamsari, C. Kurter, P. Jung, S. Remillard, J. Abrahams, A. V. Lukashenko, "Imaging the Anisotropic Nonlinear Meissner Effect in Nodal  $YBa_2Cu_3O_{7-\delta}$  Thin-Film Superconductors" Phys. **4:06PM C25.00009 Examining the low energy electrodynamics of the superconductor-insulator transition in the potential topological superconductor  $Tl_4(Tl_{1-x}Sn_x)Te_3$ <sup>1</sup>**, N. J. LAURITA, K. A. ARPINO, S. M. KOOPAYEH, T. M. MCQUEEN, N. P. ARMITAGE, Institute for Quantum Matter, Johns Hopkins University — The search for an intrinsic single crystal topological superconductor is one of the most dynamic areas of modern condensed matter physics. One of the best candidates of such a material is  $Tl_5Te_3$  ( $T_c = 2.3K$ ), which previous ARPES measurements have shown possesses a Dirac cone within its superconducting gap. However, the fundamental nature of superconductivity, i.e. the superconducting order parameter, in  $Tl_5Te_3$  remains unknown. Additionally, it has been shown that  $Tl_5Te_3$  undergoes a superconducting-insulator transition upon doping with Sn. With no band parity inversion expected in the fully Sn doped compound one expects a topological superconductor - trivial insulator transition, the nature of which is also unknown. In this work we use highly sensitive microwave cavity perturbation measurements, a direct probe of the superfluid density, to study the low energy electrodynamics of superconductivity in  $Tl_5Te_3$  and its corresponding superconductor-insulator transition upon Sn doping.

**4:18PM C25.00010 Characterizing phase transitions in known materials with Magnetic Field Modulated Microwave Spectroscopy (MFMMS)<sup>1</sup>**, JAMES WAMPLER, Dept. of Physics, Center for Advanced Nanoscience, Univ. of California, JUAN GABRIEL RAMIREZ, Dept. of Physics, Universidad de los Andes, Bogot, Colombia, ALI BASARAN, Dept. of Physics, Gebze Technical Univ, IVAN SCHULLER, Dept. of Physics, Center for Advanced Nanoscience, Univ. of California — We have previously introduced Magnetic Field Modulated Microwave Spectroscopy (MFMMS), a sensitive and selective technique used to identify electromagnetic phase transitions in homogenous and inhomogeneous materials. By scanning the temperature, we can detect the phase transitions of a material. In standard operation, samples are placed in a microwave cavity with a resonance frequency of 9.4 GHz. A 100 kHz modulation field with 15 Oe amplitude and an optional DC field are applied while temperature is scanned. [1,2,3]. Here we will discuss different methods to further characterize phase transitions by scanning DC field while temperature is fixed. Since the response of different phase transitions to the applied field is varied, DC field scans can help to distinguish and reveal the origin of the transition. We have investigated many known superconducting and other reference materials and will compare the results in these different materials. 1. J. G. Ramirez, A. C. Basaran *et al.*, *Rep. Prog. Phys.* **77**, 093902 (2014). 2. S. Guénon *et al.*, *Scientific Reports* **4**, 7333 (2014). 3. S. Guénon *et al.*, *arxiv:1509.04452*, manuscript submitted.

**4:30PM C25.00011 Progress towards a Hybrid Superconducting Microwave Cavity for Axion Searches<sup>1</sup>**, GIANPAOLO CAROSI, Lawrence Livermore National Laboratory, ADMX COLLABORATION, ADMX-HF COLLABORATION — Axions are a well motivated dark matter candidate and can be detected by their resonant conversion into photons using a microwave resonant cavity in an axial magnetic field. This is the basis of both the ADMX and ADMX-HF experiments. The predicted axion-photon conversion power is extremely small ( $< 10^{-22}$  W) and is directly related to the quality factor ( $Q$  = resonant frequency over bandwidth) of the microwave cavity. To date copper cavities have been used with  $Q \sim 10^5$  at frequencies of 1 GHz. As one scales to higher frequencies this  $Q$  degrades substantially. Superconducting cavities can regularly be made with  $Q > 10^9$  but would in general be driven normal in the high magnetic field of ADMX and ADMX-HF ( $> 8$  T). Here we describe progress of R&D efforts to make and test hybrid cavities with regular copper endcaps and thin-film superconducting barrels, produced with NbTiN RF sputtering, which are designed to maintain RF superconducting properties in the presence of a strong axial magnetic field at low temperatures ( $< 1$  K).

<sup>1</sup>Supported by DOE Grants DE-FG02-97ER41029, DE-FG02-96ER40956, DE-AC52-07NA27344, DE-AC03-76SF00098, NSF Grant 1067242, and the Livermore LDRD program.

**4:42PM C25.00012 Anomalous gap edge dissipation in disordered superconductors at the brink of localization**, BING CHENG, LIANG WU, NICHOLAS LAURITA, Johns Hopkins Univ, HARKIRAT SINGH, PRATAP RAYCHAUDHURI, Tata Institute of Fundamental Research, NORMAN ARMITAGE, Johns Hopkins Univ — In highly disordered conventional superconductors, it is frequently found that the optical conductivity presents an anomalous additional conductivity below the superconducting gap  $2\Delta$  even as  $T$  approaches zero. According to Bardeen-Cooper-Schrieffer theory and Matthis-Bardeen (MB) formula, no dissipation state should exist below  $2\Delta$  at  $T=0$  K. To resolve this problem, we studied a number of NbN superconducting films by time-domain terahertz spectroscopy. We found an extra conductivity beyond the predictions of MB theory begin to show up even at medium disorder level. With increasing disorder level, more and more optical spectral weights are moved to in-gap region ( $\omega < 2\Delta$ ). By using a self-consistent Abrikosov-Gorkov model, we found, disorder acts as a pairing breaking factor, which blurs the region around the gap edge and introduces dissipative states into the original gap region ( $\omega < 2\Delta$ ) in the optical conductivity. Our results show that the collective modes of superconductivity are not necessary to explain the extra dissipative states in disordered superconductors.

**4:54PM C25.00013 Extreme and Local 3rd Harmonic Response of Niobium (Nb) Superconductor<sup>1</sup>**, BAKHROM ORIPOV, Univ of Maryland-College Park, TAMIN TAI, Oak Ridge National Laboratory, STEVEN ANLAGE, Univ of Maryland-College Park — Superconducting Radio Frequency (SRF) cavities are being widely used in new generation particle accelerators. These SRF cavities are based on bulk Nb. Based on the needs of the SRF community to identify defects on Nb surfaces, a novel near-field magnetic microwave microscope was successfully built using a magnetic writer from a conventional magnetic recording hard-disk drive<sup>1</sup>. This magnetic writer can create an RF magnetic field, localized and strong enough to drive Nb into the vortex state. This probe enables us to locate defects through scanning and mapping of the local electrodynamic response in the multi-GHz frequency range. Recent measurements have shown that 3rd harmonic nonlinear response is far more sensitive to variations in input power and temperature than linear response, thus we mainly study the 3rd harmonic response. Moreover, the superconductor is usually the only source for nonlinear response in our setup, thus there is less chance of having noise or background signal. Understanding the mechanism responsible for this non-linear response is important for improving the performance of SRF cavities. Besides Nb we also study various other superconductors such as MgB2 and the cuprate Bi-Sr-Ca-Cu-O (BSCCO) for potential applications in SRF cavities.

<sup>1</sup>This work is funded by US Department of Energy through grant DE-SC0012036T and CNAM.

**5:06PM C25.00014 Observation of Raman active phonon with Fano lineshape in quasi-one-dimensional superconductor  $K_2Cr_3As_3$** , W.-L. ZHANG, H. LI, X. DAI, H.W. L, Y.-G. SHI, J.L. LUO, JIANGPING HU, P. RICHARD, H. DING, Chinese Academy of Sci (CAS), EXTREME CONDITION TEAM, CONDENSED MATTER THEORY TEAM — We study the polarization-resolved phononic Raman scattering in the recent discovered quasi-one-dimensional superconductor  $K_2Cr_3As_3$ . With support from first-principles calculations, we characterize several phonons, among which one mode has a Fano lineshape, indicative of an electron-phonon coupling. While the common expectation of an electron-phonon coupling is the conventional superconducting mechanism, we show that this mode is related to the in-plane Cr vibration, which modulates the exchange coupling between the first nearest Cr neighbors. Our result support the presence of magnetic fluctuations coupled to the electrons *via* the lattice. We acknowledge MOST (2010CB923000, 2011CBA001000, 2011CBA00102, 2012CB821403 and 2013CB921703), NSFC (11004232, 11034011/A0402, 11234014, 11274362 and 11474330) of China and by the Strategic Priority Research Program (B) of the Chinese Academy of Sciences, Grant No. XDB07020100.

**5:18PM C25.00015 Superconducting pairing in resonant inelastic X-ray scattering**, YIFEI SHI, University of Virginia, DAVID BENJAMIN, EUGENE DEMLER, Harvard University, ISRAEL KLICH, University of Virginia — We develop a method to study the effect of the superconducting transition on resonant inelastic X-ray scattering (RIXS) signal in superconductors with an order parameter with an arbitrary symmetry within a quasiparticle approach. As an example, we compare the direct RIXS signal below and above the superconducting transition for  $p$ -wave type order parameters. For a  $p$ -wave order parameter with a nodal line, we show that, counterintuitively, the effect of the gap is most noticeable for momentum transfers in the nodal direction. This phenomenon may be naturally explained as a type of nesting effect.

Session C26 DMP: 2D Devices: Low-dimensional Properties and Contacts 325 - Doug Strachan, University of Kentucky

**2:30PM C26.00001 Electron Transport Simulations of 4-Terminal Crossed Graphene Nanoribbons Devices<sup>1</sup>**, PEDRO BRANDIMARTE, CFM CSIC-UPV/EHU and DIPC, Spain, NICK R. PAPIOR, DTU Nanotech, Denmark, MADS ENGELUND, CFM CSIC-UPV/EHU and DIPC, Spain, ARAN GARCIA-LEKUE, THOMAS FREDERIKSEN, DIPC and IKERBASQUE, Spain, DANIEL SÁNCHEZ-PORTAL, CFM CSIC-UPV/EHU and DIPC, Spain — Recently, it has been reported theoretically a current switching mechanism by voltage control in a system made by two perpendicular 14-armchair graphene nanoribbons (GNRs) [1]. In order to investigate the possibilities of using crossed GNRs as ON/OFF devices, we have studied their electronic and transport properties as function structural parameters determining the crossing. Our calculations were performed with TranSIESTA code [2], which has been recently generalized to consider  $N \geq 1$  arbitrarily distributed electrodes at finite bias. We find that the transmission along each individual GNR and among them strongly depends on the stacking. For a  $60^\circ$  rotation angle, the lattice matching in the crossing region provokes a strong scattering effect that translates into an increased interlayer transmission. [1] K. Masum Habib and R. Lake, Phys. Rev. B 86, 045418 (2012); [2] M. Brandbyge et al, Phys. Rev. B 65, 165401 (2002).

**2:42PM C26.00002 Spatially Mapping Dirac Fermions in a Graphene Quantum Dot**, JUWON LEE, DILLON WONG, JAIRO VELASCO JR, Univ of California - Berkeley, JOAQUIN RODRIGUEZ-NIEVA, MIT, SALMAN KAHN, Univ of California - Berkeley, PHONG VO, MIT, HSIN-ZON TSAI, Univ of California - Berkeley, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, ALEX ZETTL, FENG WANG, Univ of California - Berkeley, LEONID LEVITOV, MIT, MICHAEL CROMMIE, Univ of California - Berkeley — Quantum confinement in graphene is important for tuning and exploiting graphene's electronic, spin, and optical properties. Here we present a novel technique for creating gate-tunable graphene quantum dots that are fully exposed and compatible with surface characterization tools. Using scanning tunneling microscopy (STM), we are able to spatially visualize and characterize the electronic structure of these gate-tunable graphene quantum dots. The quantum interference patterns observed in this way can be compared to the predictions of the Dirac equation, thus providing new insight into the behavior of confined ultra-relativistic Dirac fermions.

**2:54PM C26.00003 Imaging Quantum Confinement in Multiple Graphene Quantum Dots**, DILLON WONG, JAIRO VELASCO, JUWON LEE, Univ of California - Berkeley, JOAQUIN RODRIGUEZ-NIEVA, Massachusetts Institute of Technology, SALMAN KAHN, Univ of California - Berkeley, PHONG VO, Massachusetts Institute of Technology, HSINZON TSAI, Univ of California - Berkeley, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, ALEX ZETTL, FENG WANG, Univ of California - Berkeley, LEONID LEVITOV, Massachusetts Institute of Technology, MICHAEL CROMMIE, Univ of California - Berkeley — Quantum dots provide a useful means for controlling the electronic and spin degrees of freedom of mesoscale and nanoscale materials. Here we demonstrate a new method for fabricating interacting graphene quantum dots that is compatible with electrostatic gating and visualization by way of scanning tunneling microscopy (STM). Using this new technique we have created and spatially characterized systems of two or more interacting quantum dots. Our results show that it is possible to engineer electronic wave functions in graphene with a high degree of spatial control.

**3:06PM C26.00004 Probing electric properties at the boundary of planar 2D heterostructure**, JEWOOK PARK, Oak Ridge National Laboratory — The quest for novel two-dimensional (2D) materials has led to the discovery of hybridized 2D atomic crystals. Especially, planar 2D heterostructure provides opportunities to explore fascinating electric properties at abrupt one-dimensional (1D) boundaries reminiscent to those seen in the 2D interfaces of complex oxides. By implementing the concept of epitaxy to 2D space, we developed a new growth technique to epitaxially grow hexagonal boron nitride (hBN) from the edges of graphene, forming a coherent planar heterostructure [1]. At the interface of hBN and graphene, a polar-on-nonpolar 1D boundary can be formed which is expected to possess peculiar electronic states associated with the polarity of hBN and edge states of graphene. Scanning tunneling microscopy and spectroscopy (STM/S) measurements revealed an abrupt 1D zigzag oriented boundary, with boundary states about 0.6 eV below or above the Fermi level depending on the termination of the hBN at the boundary [2]. The boundary states are extended along the boundary and exponentially decay into the bulk of graphene and hBN. Combined STM/S and first-principles theory study not only disclose spatial and energetic distribution of interfacial state but also reveal the origin of boundary states and the effect of the polarity discontinuity at the interface. By probing electric properties at the boundary in the atomic scale, planar 2D heterostructure is demonstrated as a promising platform for discovering emergent phenomena at the 1D interface in 2D materials. This research was conducted at the Center for Nanophase Materials Sciences, which is a DOE Office of Science User Facility. 1 L. Liu and J. Park et al., *Science* **343**, 163 (2014). 2 J. Park and J. K. Lee et al., *Nature Commun.* **5**, 5403 (2014).

**3:42PM C26.00005 Electronic Transport of Encapsulated WSe<sub>2</sub> Fabricated by Pick-up of Pre-patterned hBN**, YAFANG YANG, Massachusetts Institute of Technology, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science, Japan, PABLO JARILLO-HERRERO, Massachusetts Institute of Technology, MIT TEAM — We report high quality WSe<sub>2</sub> devices encapsulated between two hexagonal boron nitride (hBN) flakes using a pick-up method with etched hBN flakes. Previous work on graphene has shown that sample disorder can be greatly reduced via isolation from charge impurities in the substrate by means of encapsulation. However, the effect of encapsulation still remains unknown for dichalcogenides devices. Besides, the quality of contact to TMDs is also a critical factor limiting the transport performance of such devices. To measure the transport properties of dichalcogenide devices as a function of temperature, low resistance electrical contacts must be made to the material. To achieve this, we encapsulate few-layer WSe<sub>2</sub> in hexagonal boron nitride that has been patterned to allow ionic liquid doping of the contact region. This technique simultaneously protects the WSe<sub>2</sub> surface above and below, resulting in the highest mobility few-layer WSe<sub>2</sub> devices reported to date.

**3:54PM C26.00006 Influence of Metal Contacts on Graphene Transport Characteristics and Its Removal with Nano-carbon Interfacial Layer**, AKINOBU KANDA, YU ITO, KENTA KATAKURA, HIROKI SONODA, SHOMA HIGUCHI, University of Tsukuba, HIKARI TOMORI, PRESTO-JST and University of Tsukuba, YOUTI OOTUKA, University of Tsukuba — Graphene is a promising candidate for the next-generation electronic material. While considerable effort has been devoted to achieve higher mobility in graphene films, relatively little attention has been paid to the effect of metal contacts, which are indispensable to the electric devices. At a graphene/metal interface, mainly due to the difference in work functions, carriers are injected from the metal to graphene. The resulting shift of local Dirac point is not limited at the graphene/metal interface but extends into the graphene channel. This carrier doping affects more significantly the performance of graphene field effect devices with shorter channel, as well as may conceal Dirac physics at the graphene/metal interface. Here, we experimentally investigate the channel length dependence of graphene transport properties in a wide gate-voltage range and extract the effect of metal contact. Several metal species are investigated. We reveal the origin of electron-hole asymmetry and the effect of the chemical interaction between graphene and metal, and derive the effective work function of graphene (4.93 eV). Furthermore, we succeed in reducing the influence of metal contact by inserting a thin nano-carbon layer (amorphous carbon or multilayer graphene (MLG)) at the interface.

**4:06PM C26.00007 Atomically Thin One-Dimensional Contacts to Two-Dimensional Semiconductors**, MARCOS GUIMARAES, Kavli Institute at Cornell, Cornell University, Ithaca, New York 14853, USA, HUI GAO, KIBUM KANG, Department of Chemistry and Chemical Biology, Cornell University, Ithaca, New York 14853, USA, DANIEL RALPH, Department of Physics, Cornell University, Ithaca, New York 14853, USA, JIWOONG PARK, Department of Chemistry and Chemical Biology, Cornell University, Ithaca, New York 14853, USA — Two dimensional van der Waals materials, including graphene and transition metal dichalcogenides (TMDs), are promising candidates for atomically thin circuitry. However, electrical contacts to semiconducting TMDs made using metal electrodes (e.g. Ti, Au) show high contact resistances ( $\geq 50 \text{ k}\Omega\cdot\mu\text{m}$ ). This makes it difficult to study and utilize the intrinsic properties of TMD materials, and the 3D metal contacts add significant thickness to the final devices. Here we report one-dimensional, atomically-thin, lateral contacts between graphene and monolayer TMDs with low contact resistance. The graphene/TMD lateral heterostructures are mechanically strong, and the structural and electronic properties of each individual material are well preserved after the growth processes. The interface between graphene and MoS<sub>2</sub> shows a much lower resistance (below  $20 \text{ k}\Omega\cdot\mu\text{m}$ ) than conventional metal contacts despite its atomic thickness and one dimensionality. Our devices exhibit linear I-V characteristics and very weak temperature dependence down to 77 K, confirming the ohmic properties of our contacts. By studying graphene/WS<sub>2</sub> devices fabricated in a similar way we show that our method is universal and can be expanded to other two-dimensional semiconducting TMDs.

**4:18PM C26.00008 High-Performance WSe<sub>2</sub>, MoS<sub>2</sub>, and MoSe<sub>2</sub> Transistors Enabled by a New Contact Strategy**, HSUN JEN CHUANG, BHIM CHAMLAGAIN, Wayne State University, MICHAEL KOEHLER, The University of Tennessee, MEEGHAGE MADUSANKA PERERA<sup>1</sup>, Wayne State University, JIAQIANG YAN, Oak Ridge National Laboratory, DAVID MANDRUS, The University of Tennessee, DAVID TOMNEK, Michigan State University, ZHIXIAN ZHOU, Wayne State University — Fabrication of high-performance transistors of transition metal dichalcogenides (TMDs) including WSe<sub>2</sub>, MoS<sub>2</sub>, and MoSe<sub>2</sub> has been a major challenge in 2D electronics. The performance of current metal-contacted TMDs is limited by the presence of a significant Schottky barrier in most cases. Here we introduce a new strategy for fabricating low-resistance ohmic contacts to a variety of TMDs. We demonstrate low contact resistance  $\approx 0.3 \text{ k}\Omega\mu\text{m}$ , high on/off ratios up to  $>10^9$ , and high drive currents exceeding  $320 \mu\text{A } \mu\text{m}^{-1}$  in few-layer WSe<sub>2</sub> field-effect transistors (FETs). These favorable characteristics are combined with a two-terminal field-effect hole mobility  $\mu_{\text{FE}} \approx 2 \times 10^2 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$  at room temperature, which increases to  $>2 \times 10^3 \text{ cm}^2 \text{ V}^{-1} \text{ s}^{-1}$  at cryogenic temperatures. We observe a similar performance also in MoS<sub>2</sub> and MoSe<sub>2</sub> FETs. \*We acknowledge the partial support by NSF grant number DMR-1308436 and the WSU Presidential Research Enhancement Award.

**4:30PM C26.00009 Niobium disulfide as a edge-contact electrode of transition metal dichalcogenides(TMDC) semiconductor.**, HUNYOUNG BARK, JINHWAN LEE, JAEHYUCK JUNG, Sungkyunkwan Univ, CHANGGU LEE, peterlee@skku.edu, GRAPHENE ENGINEERING LAB TEAM — Two dimensional ultrathin transition metal dichalcogenides(TMDC) semiconductor is considered as a promising candidate for future flexible and transparent electronic devices. However, direct metal contact to two dimensional ultrathin transition metal dichalcogenides(TMDC) semiconductor forms a schottky contact, which suppress electrical performance like electron mobility. Here, we suggest edge contact method using niobium disulfide for low contact resistance. Niobium disulfide is a two dimensional transition metal dichalcogenides(TMDC) conductor and has a similar atomic structure with other two dimensional transition metal dichalcogenides(TMDC) semiconductors. Niobium disulfide forms a covalent bonding with transition metal dichalcogenides(TMDC) semiconductor instead of van der Waals bonding which occurred in conventional metal contact methods. Covalent bonding between transition metal dichalcogenides(TMDC) semiconductor and niobium disulfide decrease a contact resistance. Therefore, niobium disulfide electrode device shows improved device performance compared with conventional metal electrode device due to low contact resistance.

**4:42PM C26.00010 One-Dimensional Electrical Contact to Molybdenum Disulfide**, ZHENG YANG, CHANGHO RA, SKKU Advanced Institute of Nano Technology, FAISAL AHMED, SKKU Mechanical Engineering Department, DAEYEONG LEE, MINSUP CHOI, XIAOCHI LIU, DESHUN QU, WON JONG YOO, SKKU Advanced Institute of Nano Technology, NANO DEVICE PROCESSING LAB TEAM — Molybdenum disulfide (MoS<sub>2</sub>) is one of the promising two-dimensional materials for future application in nano electronics, which has high carrier mobility, very good stability under atmosphere, proper band gap, etc. However, its application to electronic switching devices is hindered by Fermi level pinning at metal-MoS<sub>2</sub> interfaces. Here, we experimentally demonstrate one-dimensional electrical contact to MoS<sub>2</sub> formed via controllable plasma etching. We fabricated Al/MoS<sub>2</sub> FET (n-type), Mo/MoS<sub>2</sub> FET (n-type), and Pd/MoS<sub>2</sub> FET (ambipolar). For Mo/MoS<sub>2</sub> FET (n-type), on/off current ratio is around  $10^8$  and mobility is around  $104 \text{ cm}^2/(\text{Vs})$ . By contrast, for Pd/MoS<sub>2</sub> FET (ambipolar), on/off current ratio is around  $10^8$ , hole mobility is ranged from 350 to  $650 \text{ cm}^2/(\text{Vs})$ , and the mean free path of holes at 9K is around 23 nm. All the measured mobilities are evaluated by using two-terminal field-effect configuration. We can also achieve complementary logic gates with intrinsic MoS<sub>2</sub>/metal one-dimensional electrical contact.

**4:54PM C26.00011 Engineering MoS<sub>2</sub> contact with graphene electrodes under electrostatic doping**, EN-MIN SHIH, REBECA RIBEIRO-PALAU, GHIDEWON AREFE, YOUNG-DUCK KIM, JIA LI, JAMES HONE, CORY DEAN, Columbia University — Semiconductor transition metal dichalcogenides (TMDs) are 2D semiconductors that host attractive transport properties such as unconventional quantum Hall effect and spin-valley physics. However, metal contacts typically result in a Schottky barrier, making it difficult to access fundamental properties of the intrinsic charge transport. In this report, we utilize graphene electrodes to achieve ohmic contact to MoS<sub>2</sub> monolayer and bilayer. Our devices are fully encapsulated by boron-nitride, which reduces the disorders from Si/SiO<sub>2</sub> substrate, and benefit from a dual-gate geometry, which allow us to independently dope the MoS<sub>2</sub> channel and graphene contact regions. The transition from non-ohmic to ohmic contacts is studied as a function of graphene doping and the MoS<sub>2</sub> carrier density. Our results reveal the operational range of these new devices, and provide new insight into future device design.

**5:06PM C26.00012 WSe<sub>2</sub> heterostructures with p-type multi-layer graphene contacts**, GHIDEWON AREFE, NATHAN FINNEY, Columbia University, DONGJEA SEO, Yonsei University, YOUNG DUCK KIM, DAMIEN CHANG, XU CUI, Columbia University, KYUNG NAM KANG, Stevens Institute of Technology, SAHNG-KYOON JERNG, SEUNG HYUN CHUN, Sejong University, EUI-HYEOK YANG, Stevens Institute of Technology, JAMES HONE, Columbia University — Recent advances in 2D material research have opened up new opportunities to study fundamental physics and to imagine new applications for this advanced class of materials. 2D tungsten diselenide (WSe<sub>2</sub>) is a transition metal dichalcogenide (TMDC) semiconductor that is intrinsically p-type with great potential for advanced opto-electronic applications. WSe<sub>2</sub> monolayers grown by CVD and highly p-doped PECVD multilayer graphene are used to construct 2D heterostructure p-type field effect transistors as a platform to study the potential for applications and novel physical phenomena. P-type graphene is being used to overcome the challenge of making good electrical contact to WSe<sub>2</sub> that is Ohmic at low temperatures and to allow for the construction of an entirely 2D heterostructure. Electrical transport and novel optical effects will be studied in these WSe<sub>2</sub> heterostructures that are fully encapsulated in hexagonal boron nitride (h-BN) in order to show greatly improved environmental stability and high mobility at low temperature due to the suppression of extrinsic scattering effects such as charge impurities, surface polar optical phonons, and absorbents from air.

**5:18PM C26.00013 Doping, strain engineering, and interlayer interaction in bilayer hexagonal boron nitride sheets<sup>1</sup>**, SUSUMU SAITO, YOSHITAKA FUJIMOTO, Tokyo Inst of Tech - Tokyo — We study electronic properties of bilayer hexagonal boron nitride (h-BN) sheets with different stacking sequences in the framework of the density-functional theory. The bulk h-BN material usually takes the so-called AA (or AA') stacking, corresponding to the "non-polar" bilayer h-BN sheet. On the other hand, the rhombohedral BN takes the ABC stacking, and the corresponding bilayer sheet has "upper" and "lower" layers which are not equivalent with each other. Interestingly, the energetics of stacking sequences for bilayer h-BN sheets is found to be different from that for bulk h-BN materials. We report that strain engineering for bilayer h-BN sheets can possess much wider possibilities than that for monolayer h-BN due to the modification of the interlayer interaction. We also study the substitutional C doping into bilayer h-BN sheets, and report the energetics and the strain effect for these C-doped sheets. Finally we discuss the similarities and differences between bilayer h-BN sheets and double-wall h-BN nanotubes.

**Session C27 DCMP: Heavy Fermion Compounds: Experiment and Theory** 326 - Sheng Ran, University of California, San Diego

### 2:30PM C27.00001 Global phase diagram and single particle excitations in Kondo insulators

, QIMIAO SI, Rice University, JEDEDIAH PIXLEY, Condensed Matter Theory Center and Joint Quantum Institute, Department of Physics, University of Maryland, RONG YU, Department of Physics, Renmin University of China, SILKE PASCHEN, Institute of Solid State Physics, Vienna University of Technology — Motivated by quantum criticality in Kondo insulators [1] tuned by pressure or doping we study the effects of magnetic frustration and the properties of the single particle excitations in a Kondo lattice model [2]. Focusing on the Kondo insulating limit we study the Shastry-Sutherland Kondo lattice and determine the zero temperature phase diagram, which incorporates a valence bond solid, antiferromagnet, and Kondo insulating ground states, with metal-to-insulator quantum phase transitions. We argue that this phase diagram is generic and represents a “global” phase diagram of Kondo insulators in terms of quantum fluctuations and the Kondo interaction. We then focus on the momentum distribution of single particle excitations within the Kondo insulating ground state. We show how features of the Fermi-surface of the underlying conduction electrons appear in the Kondo insulating phase. Lastly, we discuss the implications of our results for quantum criticality in Kondo insulators [1] as well as for the recent de Haas-von Alphen measurements in the Kondo insulator SmB<sub>6</sub> [3,4]. [1] Q. Si and S. Paschen, *physica status solidi (b)* 250, 425 (2013). [2] J. H. Pixley, et. al., arXiv:1509.02907 (2015). [3] B. Tan et al, *Science* 349, 287 (2015). [4] G. Li et al, *Science* 346, 1208 (2014).

### 2:42PM C27.00002 Probing the Kondo State using Terahertz Radiation

, CHRISTOPH WETLI, Department of Materials, ETH Zurich, JOHANN KROHA, Institute of Physics, Bonn University, CORNELIUS KRELLNER, KRISTIN KLIEMT, Institute of Physics, Goethe University Frankfurt, OLIVER STOCKERT, MPI for Chemical Physics of Solids, Dresden, HILBERT V. LOEHNEISEN, Institute of Solid State Physics, Karlsruhe Institute of Technology, MANFRED FIEBIG, Department of Materials, ETH Zurich — The appearance of quantum critical phase transitions is boosting the interest in the field of Kondo-lattice systems. After intense research over the last decades, experimental insights have been mainly gained by measuring the specific heat capacity or the magnetic susceptibility and relating them to the increase of the effective mass. Lately, it has been demonstrated that ARPES experiments allow direct access to the electrons contributing to the Kondo-lattice effect, but with some experimental restrictions. We will show that THz radiation is a powerful and highly accurate alternative for investigating the approach to the coherent Kondo-state of heavy-fermion systems. Photons in the THz range directly couple to the electronic heavy quasiparticles causing the Kondo-singlet behavior. Additionally, this technique allows studying Kondo-state dynamics on the picosecond time scale. We report lifetime measurements of excited Kondo singlets for the two crystalline rare earth heavy-fermion systems CeCu<sub>6</sub> and YbRh<sub>2</sub>Si<sub>2</sub>, where the lifetimes scale inversely proportional to the Kondo-temperature. THz spectroscopy thus gives a very different perspective towards the Kondo-lattice effect, with the unique ability to combine temporal resolution and possible measurements in magnetic field.

### 2:54PM C27.00003 Quantum oscillations near a metallic quantum critical point

, ARKADY SHEKHTER, NHMFL, Tallahassee FL — Quantum criticality is a pervasive origin of new physics in metals, such as the linear-in-temperature resistivity observed in multiple classes of unconventional superconductors. One of the most direct probes of quantum critical metals is the quantum oscillation technique, which provides Fermi surface geometry information, as well as quasiparticle masses and lifetimes. Recent quantum oscillation experiments in high temperature superconductors show a suppression of the quantum oscillation amplitude with doping. This has been interpreted as an enhancement of the quasiparticle effective mass approaching a critical doping—in strong support of a quantum critical origin of their phase diagrams. We suggest that rather than a pure mass enhancement, the aforementioned quantum oscillation experiments indicate the increasing role of quantum fluctuation modes in the thermodynamics, contributing to the suppression of the quantum oscillation amplitude with temperature. We show that attempt to calculate the temperature dependent amplitude of quantum oscillations in the anomalous metals results in a violation of the third law of thermodynamics unless non-quasiparticle effects are considered.

### 3:06PM C27.00004 Emergence of anisotropic heavy fermions in antiferromagnetic Kondo lattice CeIn<sub>3</sub> revealed by photoemission

, YUN ZHANG, Department of Engineering Physics, Tsinghua University, Beijing 100084, China, HAIYAN LU, XIEGANG ZHU, SHIYONG TAN, QIYUN CHEN, WEI FENG, DONGHUA XIE, LIZHU LUO, WEN ZHANG, XINCHUN LAI, Science and Technology on Surface Physics and Chemistry Laboratory, Mianyang 621907, China, DONGLAI FENG TEAM, HUIQIU YUAN TEAM — One basic concept in heavy fermions systems is the entanglement of localized spin state and itinerant electron state. It can be tuned by two competitive intrinsic mechanisms, Kondo effect and Ruderman-Kittel-Kasuya-Yosida interaction, with external disturbances. The key issue regarding heavy fermions properties is how the two mechanisms work in the same phase region. To investigate the relation of the two mechanisms, the cubic antiferromagnetic heavy fermions compound CeIn<sub>3</sub> was investigated by soft x-ray angle resolved photoemission spectroscopy. The hybridization between f electrons and conduction bands in the paramagnetic state was observed directly, providing compelling evidence for Kondo screening scenario and coexistence of two mechanisms. The hybridization strength shows slight and regular anisotropy in K space, implying that the two mechanisms are competitive and anisotropic. This work illuminates the concomitant and competitive relation between the two mechanisms and supplies some evidences for the anisotropic superconductivity of CeIn<sub>3</sub>.

### 3:18PM C27.00005 Global phase diagram of the Ising-anisotropic Kondo lattice

, EMILIAN M NICA, Rice University, KEVIN INGERSANT, University of Florida, QIMIAO SI, Rice University — In recent years, a significant amount of work has been dedicated to understanding heavy-fermion quantum criticality. What has emerged is a proposed global phase diagram [1] meant to capture the interplay between Kondo singlet formation, magnetic ordering and intrinsic fluctuations associated with the quantum-mechanical nature of the local moments. Using an Extended Dynamical Mean-Field Theory (EDMFT) approach, we study a prototypical Ising-anisotropic Kondo lattice model in the presence of a transverse field that provides a way of controlling the quantum fluctuations of the local moments. We show that the transverse field opens up a line of continuous transitions directly from an antiferromagnetic phase with Kondo destruction (and, hence, a small Fermi surface) to a paramagnetic heavy-fermion state (with a large Fermi surface). We show that the critical scaling characteristics along this line are the same as for the previously studied zero-transverse field case, indicating the robustness of the Kondo-destruction scenario with respect to enhanced quantum fluctuations. General implications of our results for the global phase diagram and heavy-fermion quantum criticality will be discussed. [1] “Kondo Destruction and Quantum Criticality in Kondo Lattice Systems,” Q. Si, J. H. Pixley, E. Nica, S. J. Yamamoto, P. Goswami, R. Yu, and S. Kirchner, *J. Phys. Soc. Jpn.* **83**, 061005 (2014).

### 3:30PM C27.00006 Spin wave spectrum in CeRhIn<sub>5</sub> under applied magnetic fields

, DAVID FOBES, S.-Z. LIN, Los Alamos National Lab, NM, USA, N.J. GHIMIRE, Argonne National Lab, IL, USA, F. RONNING, E.D. BAUER, J.D. THOMPSON, C.D. BATISTA, Los Alamos National Lab, NM, USA, G. EHLERS, Oak Ridge National Lab, TN, USA, M. JANOSCHEK, Los Alamos National Lab, NM, USA — The phase diagram of CeRhIn<sub>5</sub> is in many ways a prototypical example of a heavy fermion superconductor; it is a heavy fermion antiferromagnet that can be tuned to a quantum critical point (QCP) via pressure, around which unconventional superconductivity emerges. Closer inspection reveals unusual behavior however; the interplay between magnetism and unconventional superconductivity is atypical, and electrical transport behavior and changes in the Fermi surface at the QCP are not in agreement with the prototypical spin-density-wave-type scenario. This is supported by our previous measurements of the spin wave spectrum at ambient pressure replicated by a simple frustrated  $J_1 - J_2$  model based on localized Ce 4f electrons. We show that the addition of magnetic anisotropy and Zeeman terms to our Anisotropic Next-Nearest Neighbor Ising (ANNNI) model Hamiltonian quantitatively describes the spin wave spectrum under the application of magnetic field as obtained by neutron scattering, and reproduces the experimental magnetic phase diagram. Finally, this model predicts that the magnetic ordering vector should change logarithmically as a function of temperature across the high-field incommensurate-to-commensurate phase boundary, in agreement with our latest neutron diffraction results.

**3:42PM C27.00007 An efficient continuous-time quantum Monte Carlo impurity solver in Kondo Regime**, CHANGMING YUE, YILIN WANG, Institute of Physics, Chinese Academy of Science, XI DAI, Beijing National Laboratory for Condensed Matter Physics, and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China — An efficient continuous-time quantum Monte Carlo impurity solver with high acceptance ratio at low temperature is developed to study the strongly correlated heavy-fermion materials. In this solver, the imaginary time evolution operator for the high energy multiplets, which decays very rapidly with time, is approximated by a  $\delta$  function, and as a result the virtual charge fluctuations of  $f^n \rightarrow f^{n\pm 1}$  are all included without applying Schrieffer-Wolff transformation explicitly. As benchmarks, our algorithm perfectly reproduces the results for both Coqblin-Schrieffer and Kondo lattice models obtained by ct- $J$  method developed by Junya Otsuki et al. Furthermore, it allows us to study low energy physics of heavy-fermion materials directly without fitting the exchange coupling  $J$  in the Kondo model. As an example, we test our solver on CeCoIn<sub>5</sub>, the famous heavy fermion material within the framework of LDA+DMFT to obtain its quasi-particle spectrum.

**3:54PM C27.00008 Investigation of quantum criticality in the new heavy fermion compound Ce<sub>2</sub>PdAl<sub>7</sub>Ge<sub>4</sub>**, ERIC BAUER, N. A. WAKEHAM, D. KIM, N. J. GHIMIRE, F. RONNING, R. MOVSHOVICH, J. D. THOMPSON, Los Alamos National Laboratory — Ce-based intermetallic compounds exhibit a variety of interesting ground states including magnetic order, heavy fermion behavior, unconventional superconductivity, and non-Fermi liquid behavior. When magnetic order is suppressed to  $T = 0$  K, or quantum critical point, by chemical substitution, pressure, or magnetic field, a dome of unconventional superconductivity is often found. Close to the quantum critical point, non-Fermi liquid temperature dependencies of the thermodynamic and transport properties are observed. Recently, a new family of tetragonal Ce<sub>2</sub>MAI<sub>7</sub>Ge<sub>4</sub> (M=Co, Ni, Pd, Ir) compounds was discovered. While the Ce<sub>2</sub>MAI<sub>7</sub>Ge<sub>4</sub> (M=Co, Ir, Ni) materials order magnetically between  $T_m = 0.8 - 1.6$  K, Ce<sub>2</sub>PdAl<sub>7</sub>Ge<sub>4</sub> exhibits non-Fermi liquid behavior at low temperature. Here, we discuss the quantum criticality in Ce<sub>2</sub>PdAl<sub>7</sub>Ge<sub>4</sub>.

**4:06PM C27.00009 Fermiology Of Ce<sub>2</sub>Rh<sub>3</sub>Ge<sub>5</sub>**, MARK WARTENBE, FSU — The competition between localized and delocalized f electrons in heavy fermion materials produces a wide variety of interesting physical phenomena. Among these compounds is Ce<sub>2</sub>Rh<sub>3</sub>Ge<sub>5</sub>. This heavy-fermion system undergoes an antiferromagnetic transition below 4K and exhibits an angle dependent magnetic phase transition around 25 tesla. In addition, RF conductivity measurements in pulsed field (65T) have revealed quantum oscillations. Temperature dependence at fixed angle indicates relatively heavy effective masses of values ranging from  $\sim 3m_e$  on up to  $\sim 10m_e$ . This indicates that the narrow f-electron density of states is partially hybridized close to the Fermi energy, but also places strict cryogenic constraints upon the measurement ( $^3\text{He}$  temperatures are required). Fermi surface calculations have produced complex figures which lend validation to such rich behavior. Presented are updated measurements including magnetization and revised theoretical calculations..
