**2:30PM P33.00001 Molecular dynamics simulations for the study of optical properties in conjugated semiconducting molecules**, JACK WILDMAN, JEAN-CHRISTOPHE DENIS, PETER REPIŠČÁK, MARTIN J. PATERSON, IAN GALBRAITH, Heriot-Watt University — Conformational disorder of conjugated polymers strongly influences their optical and electronic properties. Molecular Dynamics (MD) simulations can provide a quantitative understanding of these effects. Given the ever-expanding range of molecules with potential for device applications, it is critical to systematically establish accurate MD parameters for such simulations. We present an experimentally verified, general and optimised procedure, based on a computationally inexpensive methodology for generating the required MD parameters for conjugated molecules. By combining a large sample (~1000) of MD generated conformations with DFT calculations for the resulting electronic states we can explore the influence of conformational disorder on the optical properties. Using this scheme, we determine the effect of conformational variation on both linear and two-photon absorption spectra in a number of different conjugated semiconducting oligomers. Our results indicate that, while there exists significant inhomogeneous broadening in the linear absorption, there is only a weak conformational influence on the two-photon absorption spectrum.

**2:42PM P33.00002 Directed self-assembly of  $\pi$ -conjugated oligopeptides for supramolecular electronics.**, BO LI, SONGSONG LI, YUECHENG ZHOU, University of Illinois at UrbanaChampaign, JOHN TOVAR, Johns Hopkins University, WILLIAM WILSON, Harvard University, CHARLES SCHROEDER, University of Illinois at UrbanaChampaign — The directed mesoscale engineering of nanoscale building blocks holds enormous promise to catalyze a revolution in new functional materials for advanced electronics. Bio-inspired systems can play a key role in this effort due to their inherent “programmable” function. In this work, oligopeptide with defined flanking sequences was appended to  $\pi$ -conjugated units, thereby directing their assembly processes in a designed manner. By utilizing custom-designed microfluidic devices and controlled acid vapor diffusion, the self-assembly rate was directed and precisely tuned. Notably, the kinetics was found to play a key role in the morphology of self-assembled  $\pi$ -conjugated oligopeptides. The influence of flanking peptide sequences and  $\pi$ -conjugated core-core interactions on the self-assembly nanostructure was systematically investigated. Importantly, the electronic properties of the synthetic peptide assembly was explored by integration as the active layer of a field effect transistor. The presented study offers insights to the design and fabrication of supramolecular electronics.

**2:54PM P33.00003 In-situ observation of dynamic processes during organic semiconductor thin film deposition and strain-stabilization of metastable states**, YANG LI, JING WAN, Department of Physics and Materials Science Program, University of Vermont, DETLEF-M. SMILGIES, Cornell High Energy Synchrotron Source, Cornell University, NICOLE BOUFFARD, Microscopy Imaging Center, College of Medicine, University of Vermont, RICHARD SUN, Angstrom Sun Technologies Inc., RANDALL HEADRICK, Department of Physics and Materials Science Program, University of Vermont — In-situ optical spectromicroscopy in reflection mode is used to study the growth mechanisms and thermal stability of 6,13- bis(trisopropylsilyl)ethynyl-pentacene (TIPS-pentacene) thin films. The results show that the films form in a supersaturated state before transforming to a solid film. Molecular aggregates are observed by optical spectroscopy in this supersaturated region corresponding to subcritical nuclei in the crystallization process. During deposition on a heated substrate, a progressive blue shift of optical absorption peaks of the solid film is observed at higher deposition temperatures due to a continuous thermally driven change of the crystalline packing. As crystalline films are cooled to ambient temperature they become strained although cracking of thicker films is observed, which allows the strain to partially relax. Below a critical thickness of 30 nm, cracking is not observed and the films are constrained to the lattice constants corresponding to the temperature at which they were deposited. An high averaged hole mobility about  $2\text{ cm}^2\text{V}^{-1}\text{s}^{-1}$  is obtained for strained TIPS-pentacene thin films deposited at 135C.

**3:06PM P33.00004 Transient phases during crystallization of solution-processed organic thin films<sup>1</sup>**, JING WAN, YANG LI, JEFFERY ULBRANDT, Department of Physics, University of Vermont, DETLEF-M SMILGIES, Cornell High Energy Synchrotron Source, JONATHAN HOLLIN, ADAM WHALLEY, Department of Chemistry, University of Vermont, RANDALL HEADRICK, Department of Physics, University of Vermont — We report an in-situ study of 2,7-diethyl[1]benzothieno[3,2-b][1]benzothiophene ( $\text{C}_8$ -BTBT) organic semiconductor thin film deposition from solution via hollow pen writing, which exhibits multiple transient phases during crystallization. Under high writing speed (25 mm/s) the films have an isotropic morphology, although the mobilities range up to  $3.0\text{ cm}^2/\text{V}\cdot\text{s}$ . To understand the crystallization in this highly non-equilibrium regime, we employ in-situ microbeam grazing incidence wide-angle X-ray scattering combined with optical video microscopy at different deposition temperatures. A sequence of crystallization was observed in which a layered liquid-crystalline (LC) phase of  $\text{C}_8$ -BTBT precedes inter-layer ordering. For films deposited above 80°C, a transition from LC phase to a transient crystalline state that we denote as Cr1 occurs after a temperature-dependent incubation time, which is consistent with classical nucleation theory. After an additional  $\approx 0.5\text{s}$ , Cr1 transforms to the final stable structure Cr2. Based on these results, we demonstrate a method to produce large crystalline grain size and high carrier mobility during high-speed processing by controlling the nucleation rate during the transformation from the LC phase.

**3:18PM P33.00005 Critical Role of Processing on the Thermoelectric Performance of Doped Semiconducting Polymers**, SHRAYESH PATEL, UC Santa Barbara - Materials Research Lab, ANNE GLAUDELL, MICHAEL CHABINYC, UC Santa Barbara - Materials Department — The ability to convert excess waste heat into useable energy can significantly help meet the global energy demands. One may capture this waste heat through thermoelectrics devices. In a thermoelectric material, the charge carriers transport both electrical current and heat. Consequently, under a temperature difference ( $\Delta T$ ), a carrier concentration gradient results in a voltage ( $\Delta V$ ), which is related to the Seebeck coefficient,  $\alpha = -\Delta V / \Delta T$ . One of the challenges lies in finding materials that simultaneously have low thermal conductivity ( $\kappa$ ), high electrical conductivity ( $\sigma$ ), and high Seebeck coefficient ( $\alpha$ ). Conjugated semiconducting polymers can potentially meet this demand due to their inherent low thermal conductivity and high electrical conductivity through sufficient doping. Here, we report on the critical role of thermal processing on the enhancement of thermoelectric properties of conjugated polymer thin films. These films were doped using three different mechanisms: acid (toluene sulfonic acid), charge transfer ( $F_4$ TCNQ), and vapor (fluorinated-alkyl trichlorosilane). These thermoelectrics properties will be correlated to the structural and morphological properties of the doped thin-films through various synchrotron X-ray scattering techniques. Lastly, to further elucidate the charge transport mechanism driving the thermoelectric performance, we report on the temperature-dependent measurements of both the Seebeck coefficient and electrical conductivity.

**3:30PM P33.00006 Influence of Molecular Shape on Molecular Orientation and Stability of Vapor-Deposited Organic Semiconductors**, DIANE M. WALTERS, NOAH D. JOHNSON, M. D. EDIGER, University of Wisconsin-Madison — Physical vapor deposition is commonly used to prepare active layers in organic electronics. Recently, it has been shown that molecular orientation and packing can be tuned by changing the substrate temperature during deposition, while still producing macroscopically homogeneous films. These amorphous materials can be highly anisotropic when prepared with low substrate temperatures, and they can exhibit exceptional kinetic stability; films retain their favorable packing when heated to high temperatures. Here, we study the influence of molecular shape on molecular orientation and stability. We investigate disc-shaped molecules, such as TCTA and m-MTDATA, nearly spherical molecules, such as Alq<sub>3</sub>, and linear molecules covering a broad range of aspect ratios, such as p-TTP and BSB-Cz. Disc-shaped molecules have preferential horizontal orientation when deposited at low substrate temperatures, and their orientation can be tuned by changing the substrate temperature. Alq<sub>3</sub> forms stable, amorphous films that are optically isotropic when vapor deposited over a broad range of substrate temperatures. This work may guide the choice of material and deposition conditions for vapor-deposited films used in organic electronics and allow for more efficient devices to be fabricated.

**3:42PM P33.00007 Selective crystallization of conjugated polymers into nanowires from graphene coated surfaces.**, DANIEL ACEVEDO-CARTAGENA, JIAXIN ZHU, Univ of Mass - Amherst, ELVIRA TRABANINO, None, EMILY PENTZER, Case Western Reserve University, TODD EMRICK, ALEJANDRO BRISEO, Univ of Mass - Amherst, STEPHEN NONNENMANN, RYAN HAYWARD, Univ of Mass, Amherst — Solution-based crystallization of conjugated polymers offers a scalable and attractive route to develop hierarchical structures for organic electronic devices, especially solar cells. The introduction of well-defined nucleation sites into metastable supersaturated solutions provides a way to regulate the crystallization behavior, and therefore the morphology of the material. We focus on metastable solutions of poly(3-hexylthiophene) (P3HT) dissolved in mixtures of m-xylene, a marginal solvent, and chlorobenzene, a good solvent. Appropriate levels of supersaturation are identified to suppress homogenous nucleation of crystals at room temperature, while allowing for crystallization on heterogeneous nucleation sites. We show that in these metastable solutions, P3HT selectively crystallizes on graphene-coated surfaces. Through in situ atomic force microscopy, we confirm that nanowires grow vertically in a face-on orientation from highly oriented pyrolytic graphite and graphene. Moreover, this method can be successfully extended to other conjugated polymers with superior electronic properties, such as poly[2,5-bis(3-tetradecylthiophen-2-yl)thieno[3,2-b] thiophene]. Therefore, this method is a promising route to improve the performance of organic electronics.

**3:54PM P33.00008 Surface induced alignment for semiflexible polymers**, WENLIN ZHANG, ENRIQUE GOMEZ, SCOTT MILNER, Pennsylvania State University — The interfacial structure of semiflexible polymers can largely affect the overall performance of applications, such as organic electronics. Due to backbone stiffness, semiflexible polymers, including conjugated polymers, tend to align parallel to an impenetrable surface. The segmental alignment near the wall creates a quadrupolar aligning field, which can interact with the polymer backbones and enhance the chain alignment. In the present work, we combine molecular dynamic (MD) simulations and a lattice version of self-consistent field theory (SCFT) to investigate the surface induced alignment for semiflexible polymers. Using MD simulations of bead-spring chains, we demonstrate that the thickness of the aligned layer is about a persistence length  $L_p$  for semiflexible polymers in the isotropic phase. Using the SCFT lattice model, we predict that the amplitude and range of the alignment increase with increasing nematic coupling, quantified by the nematic coupling constant  $\alpha$ . The impenetrable surface acts as a perturbation on the chain alignment, and the nematic coupling  $\alpha$  amplifies the perturbation. By comparing the SCFT results for chains near an impenetrable surface to MD simulations, we can also qualitatively estimate  $\alpha$  for semiflexible polymers.

**4:06PM P33.00009 Revealing molecular order inside and between PBTTT nanoribbons through the polarized X-ray scattering**, BRIAN COLLINS, Washington State University, DEAN DELONGCHAMP, National Institute of Standards and Technology — Electronic and optical properties of conjugated polymers emerge not only through molecular architecture, but also through hierarchical ordering from the molecular to the mesoscale. Characterizing aspects of that ordering critical to properties can be challenging, however. For example, local molecular orientation within and connectivity between ordered structures is considered paramount for charge transport in conjugated polymer films. While some of these aspects can be imaged with state-of-the-art microscopy measurements, true statistical measurements of molecular order and connectivity remain elusive due to the low levels of crystalline packing that limit diffractive and other techniques capable of statistical analysis. Recently, we demonstrated how resonant scattering with polarized soft X-rays (PSoXS) is sensitive to molecular orientation and that such measurements could be used to locate sources and types of ordering within larger nanostructures on a statistical basis. Here we combine forward simulation and measurements of PSoXS on PBTTT nanoribbon films to extract critical information such as the average level of molecular alignment within nanoribbon structures and the level of connectivity between ribbons that promote the dominant charge transport mechanisms in these films. Further development of PSoXS will enable crucial insight into internal molecular order within organic materials tied to optical and electronic properties and how to control these properties for use in novel devices.

**4:18PM P33.00010 Charge Transport in Conjugated Block Copolymers**, BRANDON SMITH, THINH LE, YOUNGMIN LEE, ENRIQUE GOMEZ, Penn State University — Interest in conjugated block copolymers for high performance organic photovoltaic applications has increased considerably in recent years. Polymer/fullerene mixtures for conventional bulk heterojunction devices, such as P3HT:PCBM, are severely limited in control over interfaces and domain length scales. In contrast, microphase separated block copolymers self-assemble to form lamellar morphologies with alternating electron donor and acceptor domains, thereby maximizing electronic coupling and local order at interfaces. Efficiencies as high as 3% have been reported in solar cells for one block copolymer, P3HT-PFTBT, but the details concerning charge transport within copolymers have not been explored. To fill this gap, we probed the transport characteristics with thin-film transistors. Excellent charge mobility values for electron transport have been observed on aluminum source and drain contacts in a bottom gate, bottom contact transistor configuration. Evidence of high mobility in ordered PFTBT phases has also been obtained following thermal annealing. The insights gleaned from our investigation serve as useful guideposts, revealing the significance of the interplay between charge mobility, interfacial order, and optimal domain size in organic block copolymer semiconductors.

**4:30PM P33.00011 Selective crystallization of regioregularity controlled polythiophene for enhancing mechanical stability and electronic performance.** , HYEONG JUN KIM, KAIST, HOJEONG YU, POSTECH, JAE HAN KIM, JIN-SUNG KIM, TAEK SOO KIM, KAIST, JOON HAK OH, POSTECH, BUMJOON KIM, KAIST — Considering the many potential applications of organic electronics in portable electronic devices, it is of great importance to develop an electro-active material that possesses mechanical stability and high electronic performance. Coexistence of both properties, however, is very difficult to achieve because good electronic performance is associated with long conjugation length, and high crystallinity often results in stiffness and brittleness. Herein, we utilize P3HT with two different regioregularities: high RR (98%) P3HT has high electronic properties but poor mechanical resilience, and low RR P3HT (68%) exhibits high elasticity and ductility but poor electronic performance. Selective crystallization of high RR P3HT induced by solution assembly allows construction of percolated networks of high RR P3HT nanowires (NWs) embedded in low RR P3HT matrix. Only 5 wt% high RR P3HT is required to reach a hole mobility comparable to that of high RR P3HT, and high RR NWs embedded in film exhibits 20 times higher elongation at break. Selective self-assembly allows us to overcome the fragile nature of highly crystalline conjugated polymers without losing their electronic properties.

**4:42PM P33.00012 Regio regularity effects on chain mobility and entanglement for poly(3-hexylthiophene)<sup>1</sup>** , RENXUAN XIE, ENRIQUE GOMEZ, Department of Chemical Engineering, Penn State University at University Park, RALPH COLBY, Department of Materials Science and Engineering, Penn State University at University Park — Poly(3-hexylthiophene-2,5-diyl) (P3HT) is a conjugated polymer that can serve as the active layer in a variety of electronic devices. However, its glass transition temperature ( $T_g$ ) and entanglement molecular weight ( $M_e$ ) are still in dispute. These parameters are essential for estimating the density of tie chains, which are hypothesized to limit the bulk charge transport. A wide range of molecular weights of both regiorandom (RRa) and regioregular (RRe) P3HT were studied by oscillatory shear rheology. Coupled with the molecular weight distribution from GPC,  $M_e$  was extracted by fitting the linear viscoelastic data of multiple MW samples using BoB software. Furthermore, two  $T_g$ 's were identified for both RRe and RRa P3HT.  $T_g$  corresponds to the segmental motion and follows Flory-Fox equation well for various MWs with  $2\text{ C} < T_g < 14\text{ C}$ , yielding high MW limit of  $T_{g\infty} = 21\text{ C}$ . RRe has a larger  $M_e$  than RRa, which might originate from their different  $T_{gPE}$  corresponding to the side chain packing. So, further investigation on their packing lengths via dilute solution light scattering will be crucial to understand entanglement in these semiflexible polymers.

**4:54PM P33.00013 Controlling the out-of-plane orientation of solution-processed organic semiconductor crystals** , XIAOSHEN BAI, Department of Chemical Engineering and Materials Science, Stevens Institute of Technology, MEGAN HAND, Mechanical Engineering, Stevens Institute of Technology, JACK LY, ALEJANDRO BRISENO, Department of Polymer Science and Engineering, University of Massachusetts, Amherst, STEPHANIE LEE, Department of Chemical Engineering and Materials Science, Stevens Institute of Technology — We demonstrate the ability to control out-of-plane orientation of small-molecule bis(triisopropylsilyl)ethynyl pyranthrene (TIPS-PY) crystals drop cast from the solution phase onto SiO<sub>2</sub> substrates. By tuning solvent-molecule interactions through the incorporation of varying amounts of an anti-solvent during drop casting, we observed a systematic change in the crystal morphology from cross-shaped crystals to needle like crystals using optical microscopy and scanning electron microscopy. 2-D x-ray diffraction experiments revealed that this change in crystal morphology corresponded to a change in the crystallographic orientation of the crystals, from one in which the (100) plane is parallel to the substrate surface to one in which the (001) plane is parallel to the substrate surface. Tuning molecule-substrate interactions by modifying the surface energy of the underlying substrate was also found to affect the observed crystal orientation. Because organic semiconductor crystals display large charge transport anisotropies along different crystallographic directions, it is expected that the out-of-plane charge mobility will depend on the TIPS-PY crystal orientation.

**5:06PM P33.00014 Birefringence and Enhanced Stability in Stable Organic Glasses<sup>1</sup>** , TIANYI LIU, ANNEMARIE EXARHOS, KEVIN CHENG, TIEZHENG JIA, PATRICK WALSH, JAY KIKKAWA, ZAHRA FAKHRAAI, Univ of Pennsylvania — Stable glasses can be prepared by physical vapor depositing organic molecules onto a cold substrate at slow rates. These glasses have many exceptional properties such as high thermal stability, high density, and birefringence. Regardless of the molecular shape or intermolecular interactions, birefringence has been observed in various stable glasses produced at low temperatures (below 80% of the molecule's glass transition temperature,  $T_g$ ). Here we prepare stable glasses of an organic molecule, 9-(3,5-di(naphthalen-1-yl)phenyl)anthracene, that possesses a nearly isotropic shape and intrinsic fluorescence. Ellipsometry is used to show that all stable glasses prepared in the temperature range from 73%  $T_g$  to 97%  $T_g$  show positive birefringence. Angle- and polarization- dependent photoluminescence measurements show isotropic molecular orientation in these optically birefringent glasses. Furthermore, the values of birefringence are strongly correlated with the enhanced density, implying a general origin of the observed anisotropy in stable glasses. This correlation can elucidate the role of packing in the formation of such high-density glasses.

**5:18PM P33.00015 Traversing the polymorphic landscape through tuning molecule-molecule, molecule-substrate and molecule-solvent interactions** , GEOFFREY PURDUM, Dept. of Chemical and Biological Engineering, Princeton University, THOMAS GESSNER, R. THOMAS WEITZ, BASF SE, GMV 67056, Germany, YUEH-LIN LOO, Dept. of Chemical and Biological Engineering, Princeton University — As subtle changes in the crystalline packing motif of molecular semiconductors can have a large impact on charge transport, a thorough understanding of the accessibility of polymorphs in thin films is needed. Using a series of core-chlorinated naphthalene tetracarboxylic diimides, we demonstrate that the choice of the alkyl substituents at the imide functionalities, as well as the choice of substrate and post-deposition processing conditions, tune the relative strengths of molecule-molecule, molecule-substrate and molecule-solvent interactions, providing a handle over polymorphic selection. We access the triclinic polymorph of NTCDI-CH<sub>2</sub>C<sub>3</sub>F<sub>7</sub> in thermally evaporated thin films; solvent-vapor annealing induces a reversible transformation to its monoclinic polymorph. The addition of a fluoromethylene group in the alkyl substituent increases molecule-molecule interactions and, accordingly, improves the stability of its triclinic polymorph; this derivative does not undergo a polymorphic transformation with any of the post-deposition conditions we have explored.

**2:30PM P34.00001 Thermodynamics, morphology, and kinetics of early- stage self-assembly of pi-conjugated oligopeptides<sup>1</sup>** , BRYCE THURSTON, Univ of Illinois - Urbana, JOHN TOVAR, Johns Hopkins University, ANDREW FERGUSON, Univ of Illinois - Urbana — Synthetic oligopeptides containing  $\pi$ -conjugated cores self-assemble novel materials with attractive electronic and photophysical properties. All-atom, explicit solvent molecular dynamics simulations of Asp-Phe-Ala-Gly-OPV3-Gly-Ala-Phe-Asp peptides were used to parameterize an implicit solvent model to simulate self-assembly. At low-pH conditions, peptides assemble into  $\beta$ -sheet-like stacks with strongly favorable monomer association free energies of  $\Delta F \approx -25k_B T$ . Aggregation at high-pH produces disordered aggregates destabilized by Coulombic repulsion between negatively charged Asp termini. We model simulations of hundreds of monomers as a continuous-time Markov process. We infer transition rates between different aggregate sizes and microsecond relaxation times for early-stage assembly. Our data suggests a hierarchical model of assembly in which peptides coalesce into small clusters over tens of nanoseconds followed by structural ripening and diffusion limited aggregation on longer time scales. This work provides new molecular-level understanding of early-stage assembly, and a means to study the impact of peptide chemistry upon the thermodynamics, assembly kinetics, and morphology of the supramolecular aggregates.

**2:42PM P34.00002 Bridging Length Scales to Study Self-Assembly and Self-Organization** , BRYAN KAYE, DANIEL NEEDLEMAN, Harvard University — A variety of proteins can assemble into large polymers as an integral part of their biological function. Studying the biochemistry and biophysics of polymer formation often involves time-resolvable measurements of the amount of polymer. Non-invasive measurements of polymer can be divided into two categories: short (spectroscopy) and large (microscopy) length scale measurements. Microscopy-based estimates of polymer amount are often dependent on spatial non-uniformity of polymer, whereas spectroscopy-based estimates of polymer amount are often based on models that are difficult to test. Here we show how both large and small length scale measurements can be combined to validate the assumptions behind both measurements while incorporating both measurements to make more accurate estimates of polymer amount. We utilize this approach with two-photon microscopy and FRET to measure the amount of tubulin (monomer) in microtubules (polymer) in order to study microtubule nucleation in cell extracts. In addition, this approach may be useful to study a wide variety of polymers, including actin filaments, viruses, lipid membranes, and other protein aggregates.

**2:54PM P34.00003 Creating Ordered Antibody Arrays with Antibody-Polymer Conjugates.** , XUEHUI DONG, ALLIE OBERMEYER, BRADLEY OLSEN, Massachusetts Institute of Technology — Antibodies are a category of functional proteins that play crucial roles in the immune system and have been widely applied in the area of cancer therapeutics, targeting delivery, signal detection, and sensors. Due to the extremely large size and lack of specific functional groups on the surface, it is challenging to functionalize antibodies and manipulate the ordered packing of antibodies in an array with high density and proper orientation, which is critical to achieve outstanding performance in materials. In this work, we demonstrate an efficient and facile approach for preparing antibody-polymer conjugates with two-step sequential “click” reaction to form antibody-polymer block copolymers. Highly ordered nanostructures are fabricated based on the principles of block copolymer self-assembly. The nanostructures are studied with both small angle X-ray scattering (SAXS) and transmission electron microscopy (TEM). Lamellae with alternating antibody domain and polymer domain are observed with an overall domain size of  $\sim 50$  nm. The nanostructure not only increases the packing density and promotes proper orientation of the antibody, but also provides possible channel to facilitate substrate transportation and improves the stability of the antibody.

**3:06PM P34.00004 Self-assembly of Artificial Actin Filaments** , CHRISTOPHER GROSENICK, SHENG FENG CHENG, Virginia Polytechnic Institute and State University — Actin Filaments are long, double-helical biopolymers that make up the cytoskeleton along with microtubules and intermediate filaments. In order to further understand the self-assembly process of these biopolymers, a model to recreate actin filament geometry was developed. A monomer in the shape of a bent rod with vertical and lateral binding sites was designed to assemble into single or double helices. With Molecular Dynamics simulations, a variety of phases were observed to form by varying the strength of the binding sites. Ignoring lateral binding sites, we have found a narrow range of binding strengths that lead to long single helices via various growth pathways. When lateral binding strength is introduced, double helices begin to form. These double helices self-assemble into substantially more stable structures than their single helix counterparts. We have found double helices to form long filaments at about half the vertical binding strength of single helices. Surprisingly, we have found that triple helices occasionally form, indicating the importance of structural regulation in the self-assembly of biopolymers.

**3:18PM P34.00005 Intermediate-filaments: from disordered building blocks to well-ordered cells.** , MICHA KORNREICH, ETI MALKA-GIBOR, ADI LASER-AZOGUI, OFER DORON, RAM AVINERY, Tel Aviv University, HARALD HERRMANN, German Cancer Research Center, Heidelberg, ROY BECK, Tel Aviv University — In the past decade it was found that  $\approx 50\%$  of human proteins contain long disordered regions, which play significant functional roles. As these regions lack a defined 3D folded structure, their ensemble conformations can be studied using polymer physics statistical-mechanics arguments. We measure the structure and mechanical response of hydrogels composed of neuronal intermediate filaments proteins. In the nervous system, these proteins provide cells with their mechanical support and shape, via interactions of their long, highly charged and disordered protein chains. We employ synchrotron small-angle X-ray scattering and various microscopy techniques to investigate such hydrogels from the nano- to the macro-scale. In contrast to previous polymer physics theories and experiments, we find that shorter and less charged chains can promote network expansion. The results are explained by intricate interactions between specific domains on the interacting chains, and also suggest a novel structural justification for the changing protein compositions observed during neuronal development. We address the following questions: Can protein disorder have an important role in cellular architecture? Can structural disorder in the micro-scale induce orientational and translational order on the macro-scale? How do the physical properties of disordered protein regions, such as charge, length, and hydrophobicity, modulate the cellular super-structure?

**3:30PM P34.00006 The effect of local melting of DNA on DNA loop formation** , JIYOUN JEONG, HAROLD KIM, Georgia Inst of Tech — Statistical mechanics of double-stranded DNA (dsDNA) is well described by the wormlike chain model (WLC) which assumes a harmonic bending potential. Such smooth bending potential may no longer be valid for large bending angles to form small loops ( $<100$  bp). Instead, DNA may rely on rare structural transitions such as local melting (opening) of base pairs to lower the energetic cost. In theory, open base pairs called bubbles can increase the looping probability of short DNA molecules by a few orders of magnitude, but a robust experimental validation of this theoretical prediction is lacking. Here, we investigated the correlation between local melting probability and looping dynamics of dsDNA using single-molecule fluorescence resonance energy transfer (FRET). We designed two groups of short DNA molecules with low and high melting probabilities around their center and measured their looping and unlooping rates in equilibrium. Our data allow rigorous tests of meltable wormlike chain (MWLC) models at short length scales for setting ranges of acceptable free energy cost of bubble formation and flexibility values of a bubble.

**3:42PM P34.00007 Effect of Backbone Design on Hybridization Thermodynamics of Oligo-nucleic Acids: A Coarse-Grained Molecular Dynamics Simulation Study**, AHMADREZA F. GHOBADI, Department of Chemical and Biomolecular Engineering, University of Delaware, Newark DE 19716, ARTHI JAYARAMAN, Department of Chemical and Biomolecular Engineering, Department of Material Science and Engineering, University of Delaware, Newark DE 19716 — DNA hybridization is the basis of various bio-nano technologies, such as DNA origami and assembly of DNA-functionalized nanoparticles. A hybridized double stranded (ds) DNA is formed when complementary nucleobases on hybridizing strands exhibit specific and directional hydrogen bonds through canonical Watson-Crick base-pairing interactions. In recent years, the need for cheaper alternatives and significant synthetic advances have driven design of DNA mimics with new backbone chemistries. However, a fundamental understanding of how these backbone modifications in the oligo-nucleic acids impact the hybridization and melting behavior of the duplex is still lacking. In this talk, we present our recent findings on impact of varying backbone chemistry on hybridization of oligo-nucleic acid duplexes. We use coarse-grained molecular dynamics simulations to isolate the effect of strand flexibility, electrostatic interactions and nucleobase spacing on the melting curves for duplexes with various strand sequences and concentrations. Since conjugation of oligo-nucleic acids with polymers serve as building blocks for thermo-responsive polymer networks and gels, we also present the effect of such conjugation on hybridization thermodynamics and polymer conformation.

**3:54PM P34.00008 Pore Diameter Dependence and Segmental Dynamics of Poly-Z-L-lysine and Poly-L-alanine Confined in 1D Nanocylindrical Geometry**, EYLUL TUNCEL, TOBB UET, YASUHIITO SUZUKI, Max Planck Institute for Polymer Research, AGATHAGGELOS IOSSIFIDIS, University of Ioannina, MARTIN STEINHART, University of Osnabruck, HANS-JURGEN BUTT, Max Planck Institute for Polymer Research, GEORGE FLOUDAS, University of Ioannina, HATICE DURAN, TOBB UET — Structure formation, thermodynamic stability, phase and dynamic behaviors of polypeptides are strongly affected by confinement. Since understanding the changes in these behaviors will allow their rational design as functional devices with tunable properties, herein we investigated Poly-Z-L-lysine (PZLL) and Poly-L-alanine (PALa) homopolypeptides confined in nanoporous alumina containing aligned cylindrical nanopores as a function of pore size by differential scanning calorimetry (DSC), Fourier Transform Infrared Spectroscopy, Solid-state NMR, X-ray diffraction, Dielectric spectroscopy(DS). Bulk PZLL exhibits a glass transition temperature ( $T_g$ ) at about 301K while PZLL nanorods showed slightly lower  $T_g$  (294K). The dynamic investigation by DS also revealed a decrease (4K) in  $T_g$  between bulk and PZLL nanorods. DS is a very sensitive probe of the local and global secondary structure relaxation through the large dipole to study effect of confinement. The results revealed that the local segmental dynamics, associated with broken hydrogen bonds, and segmental dynamics speed-up on confinement.

**4:06PM P34.00009 Effects of spermine binding on Taxol-stabilized microtubules**, SHENGFENG CHENG, CHOLA REGMI, Virginia Polytechnic Institute and State University — Previous studies have shown that polyamines such as spermine present in cells at physiological concentrations can facilitate the polymerization of tubulins into microtubules (MTs). A recent experiment demonstrates that in the presence of high-concentration spermine, Taxol-stabilized MTs undergo a shape transformation into inverted tubulin tubules (ITTs), the outside surface of which corresponds to the inside surface of a regular MT. However, the molecular mechanism underlying the shape transformation of MTs into ITTs is unclear. We perform all atom molecular dynamics simulations on Taxol-stabilized MT sheets containing two protofilaments surrounded by spermine ions. The spermine concentration is varied from 0 to 25mM to match the range probed experimentally. We identify important spermine binding regions on the MT surface and the influence of the spermine binding on the structure and dynamics of MTs. In contrast to Taxol, our results show that spermine binding seems to decrease the flexibility of tubulin proteins, resulting in weaker tubulin-tubulin contacts and promoting the bending of protofilaments into curved protofilaments, inverted rings, and eventually inverted tubules.

**4:18PM P34.00010 Tuning the entropic spring to dictate order and functionality in polymer conjugated peptide biomaterials**, SINAN KETEN, Northwestern University — Hybrid peptide-polymer conjugates have the potential to combine the advantages of natural proteins and synthetic polymers, resulting in biomaterials with improved stability, controlled assembly, and tailored functionalities. However, the effect of polymer conjugation on peptide structural organization and functionality, along with the behavior of polymers at the interface with biomolecules remain to be fully understood. This talk will summarize our recent efforts towards establishing a modeling framework to design entropic forces in helix-polymer conjugates and polymer-conjugated peptide nanotubes to achieve hierarchical self-assembling systems with predictable order. The first part of the talk will discuss how self-assembly principles found in biology, combined with polymer physics concepts can be used to create artificial membranes that mimic certain features of ion channels. Thermodynamics and kinetics aspects of self-assembly and how it governs the growth and stacking sequences of peptide nanotubes will be discussed, along with its implications for nanoscale transport. The second part of the talk will review advances related to modeling polymer conjugated coiled coils at relevant length and time scales. Atomistic simulations combined with sampling techniques will be presented to discuss the energy landscapes governing coiled-coil stability, revealing cascades of events governing disassembly. This will be followed by a discussion of mechanisms through which polymers can stabilize small proteins, such as shielding of solvents, and how specific peptide sequences can reciprocate by altering polymer conformations. Correlations between mechanical and thermal stability of peptides will be discussed. Finally, coarse-grained simulations will provide insight into how the location of polymer attachment changes entropic forces and higher-level organization in helix bundle assemblies. Our findings set the stage for a materials-by-design capability towards dictating complex topologies of polymer-peptide conjugate systems.

**4:54PM P34.00011 Thermal Properties of Silk Fibroin Using Fast Scanning Calorimetry<sup>1</sup>**, PEGGY CEBE, BENJAMIN PARTLOW, DAVID KAPLAN, Tufts University, ANDREAS WURM, EVGENY ZHURAVLEV, CHRISTOPH SCHICK, University of Rostock — We performed fast scanning chip-based calorimetry of silk protein using the Mettler Flash DSC1. We suggest the methodology by which to obtain quantitative information on the very first scan to high temperature, including the melting endotherm of the beta pleated sheets. For proteins, this first scan is the most important one, because the crystalline secondary structural features, the beta pleated sheets, melt after the first heating and cannot be thermally reintroduced. To obtain high quality data, the samples must be treated to drying and enthalpy relaxation sequences. The heat flow rates in heating and cooling must be corrected for asymmetric heat losses. We evaluate methods to obtain an estimate of the sample mass, finally choosing internal calibration using the known heat capacity increment at the glass transition. We report that even heating at rates of 2000 K/s, thermal degradation of silk cannot be totally avoided, though it can be minimized. Using a set of nineteen samples, we successfully determine the liquid state heat capacity of silk as:  $C_p^{liquid}(T) = (1.98 \pm 0.06) \text{ J/gK} + T(6.82 \pm 1.4) \times 10^{-4} \text{ J/gK}^2$ . Methods for estimation of the sample mass will be presented and compared.

**5:06PM P34.00012 Long-term Controlled Drug Release from bi-component Electrospun Fibers**, SHANSHAN XU, ZIXIN ZHANG, QINGHUA XIA, CHARLES HAN, Chinese Academy of Sci (CAS) — Multi-drug delivery systems with timed programmed release are hard to be produced due to the complex drug release kinetics which mainly refers to the diffusion of drug molecules from the fiber and the degradation of the carrier. This study focused on the whole life-time story of the long-term drug releasing fibrous systems. Electrospun membrane utilizing FDA approved polymers and broad-spectrum antibiotics showed specific drug release profiles which could be divided into three stages based on the profile slope. With throughout morphology observation, cumulative release amount and releasing duration, releasing kinetics and critical factors were fully discussed during three stages. Through changing the second component, approximately linear drug release profile and a drug release duration about 13 days was prepared, which is perfect for preventing post-operative infection. The addition of this semi-crystalline polymer in turn influenced the fiber swelling and created drug diffusion channels. In conclusion, through adjusting and optimization of the blending component, initial burst release, delayed release for certain duration, and especially the sustained release profile could all be controlled, as well as specific anti-bacterial behavior could be obtained.

**5:18PM P34.00013 Correlation Between Chain Architecture and Hydration Water Structure in Polysaccharides** , MICHAEL GROSSUTTI, JOHN DUTCHER, University of Guelph — The physical properties of confined water can differ dramatically from those of bulk water. Hydration water associated with polysaccharides provides a particularly important example of confined water, with differences in polysaccharide structure providing different spatially confined environments for water adsorption. We have used attenuated total reflection infrared (ATR-IR) spectroscopy to investigate the structure of hydration water in films of three different polysaccharides under controlled relative humidity (RH) conditions. We compare the results obtained for films of highly branched, monodisperse phytyglycogen nanoparticles to those obtained for two unbranched polysaccharides, hyaluronic acid (HA) and chitosan. We find similarities between water structuring in the two linear polysaccharides, and significant differences for phytyglycogen. In particular, the phytyglycogen nanoparticles exhibited high network water connectivity, and a large increase in the fraction of multimer water clusters with increasing RH, whereas the water structure for HA and chitosan was found to be insensitive to changes in RH. These measurements provide unique insight into the relationship between the chain architecture and hydration of polysaccharides.

**2:30PM P35.00001 Old and new news about single-photon sensitivity in human vision<sup>1</sup>** , PHILIP NELSON, University of Pennsylvania — It is sometimes said that “our eyes can see single photons,” when in fact the faintest flash of light that can reliably be reported by human subjects is closer to 100 photons. Nevertheless, there is a sense in which the familiar claim is true. Experiments conducted long after the seminal work of Hecht, Schlaer, and Pirenne in two distinct realms, those of human psychophysics and single-cell physiology, now admit a more precise conclusion to be drawn about our visual apparatus. Finding a single framework that accommodates both kinds of result is a nontrivial challenge, and one that sets severe quantitative constraints on any model of dim-light visual processing. I will present one such model and compare it to a recent experiment.

**2:42PM P35.00002 Matching tutors and students: effective strategies for information transfer between circuits** , TIBERIU TESILEANU, CUNY - Graduate Center, VIJAY BALASUBRAMANIAN<sup>1</sup>, University of Pennsylvania, BENEC OLVECKY, Harvard University — Many neural circuits transfer learned information to downstream circuits: hippocampal-dependent memories are consolidated into long-term memories elsewhere; motor cortex is essential for skill learning but dispensable for execution; anterior forebrain pathway (AFP) in songbirds drives short-term improvements in song that are later consolidated in pre-motor area RA. We show how to match instructive signals from tutor circuits to synaptic plasticity rules in student circuits to achieve effective two-stage learning. We focus on learning sequential patterns where a timebase is transformed into motor commands by connectivity with a ‘student’ area. If the sign of the synaptic change is given by the magnitude of tutor input, a good teaching strategy uses a strong (weak) tutor signal if student output is below (above) its target. If instead timing of tutor input relative to the timebase determines the sign of synaptic modifications, a good instructive signal accumulates the errors in student output as the motor program progresses. We demonstrate song learning in a biologically-plausible model of the songbird circuit given diverse plasticity rules interpolating between those described above. The model also reproduces qualitative firing statistics of RA neurons in juveniles and adults.

**2:54PM P35.00003 Sensory stimuli reduce the dimensionality of cortical activity** , LUCA MAZZUCATO, ALFREDO FONTANINI, GIANCARLO LA CAMERA, State Univ of NY- Stony Brook — Neural ensembles in alert animals generate complex patterns of activity. Although cortical activity unfolds in a space whose dimension is equal to the number of neurons, it is often restricted to a lower dimensional subspace. Dimensionality is the minimal number of dimensions that accurately capture neural dynamics, and may be related to the computational tasks supported by the neural circuit. Here, we investigate the dimensionality of neural ensembles from the insular cortex of alert rats during periods of ‘ongoing’ (spontaneous) and stimulus-evoked activity. We find that the dimensionality grows with ensemble size, and does so significantly faster during ongoing compared to evoked activity. We explain both results using a recurrent spiking network with clustered architecture, and obtain analytical results on the dependence of dimensionality on ensemble size, number of clusters, and pair-wise noise correlations. The theory predicts a characteristic scaling with ensemble size and the existence of an upper bound on dimensionality, which grows with the number of clusters and decreases with the amount of noise correlations. To our knowledge, this is the first mechanistic model of neural dimensionality in cortex during both spontaneous and evoked activity.

**3:06PM P35.00004 Patterns in nature shape human visual perception.** , ANN HERMUNDSTAD, University of Pennsylvania — The statistical regularities of natural signals are known to shape the first stages of sensory processing. In the visual system, an efficient representation of light intensity begins in retina, where statistical redundancies are removed via spatiotemporal decorrelation. Much less is known, however, about the efficient representation of complex features in higher visual areas. I will discuss how the central visual system, operating with different goals and under different constraints, makes efficient use of resources to extract meaningful features from complex visual stimuli.

**3:42PM P35.00005 Nonlinear Bayesian cue integration explains the dynamics of vocal learning<sup>1</sup>** , BAOHUA ZHOU, SAMUEL SOBER, ILYA NEMENMAN, Emory University — The acoustics of vocal production in songbirds is tightly regulated during both development and adulthood as birds progressively refine their song using sensory feedback to match an acoustic target. Here, we perturb this sensory feedback using headphones to shift the pitch (fundamental frequency) of song. When the pitch is shifted upwards (downwards), birds eventually learn to compensate and sing lower (higher), bringing the experienced pitch closer to the target. Paradoxically, the speed and amplitude of this motor learning decrease with increases in the introduced error size, so that birds respond rapidly to a small sensory perturbation, while seemingly never correcting a much bigger one. Similar results are observed broadly across the animal kingdom, and they do not derive from a limited plasticity of the adult brain since birds can compensate for a large error as long as the error is imposed gradually. We develop a mathematical model based on nonlinear Bayesian integration of two sensory modalities (one perturbed and the other not) that quantitatively explains all of these observations. The model makes predictions about the structure of the probability distribution of the pitches sung by birds during the pitch shift experiments, which we confirm using experimental data.

<sup>1</sup>This work was supported in part by James S. McDonnell Foundation Grant 220020321, NSF Grant IOS/1208126, NSF Grant IOS/1456912 and NIH Grants R01NS084844.

**3:54PM P35.00006 Neurocontrol in sensory cortex<sup>1</sup>**, JASON RITT, Boston University, ANIRBAN NANDI, Washington University, St. Louis, JOSEPH SCHROEDER, Boston University, SHINUNG CHING, Washington University, St. Louis — Technology to control neural ensembles is rapidly advancing, but many important challenges remain in applications, such as design of controls (e.g. stimulation patterns) with specificity comparable to natural sensory encoding. We use the rodent whisker tactile system as a model for active touch, in which sensory information is acquired in a closed loop between feedforward encoding of sensory information and feedback guidance of sensing motions. Motivated by this system, we present optimal control strategies that are tailored for underactuation (a large ratio of neurons or degrees of freedom to stimulation channels) and limited observability (absence of direct measurement of the system state), common in available stimulation technologies for freely behaving animals. Using a control framework, we have begun to elucidate the feedback effect of sensory cortex activity on sensing in behaving animals. For example, by optogenetically perturbing primary sensory cortex (SI) activity at varied timing relative to individual whisker motions, we find that SI modulates future sensing behavior within 15 msec, on a whisk by whisk basis, changing the flow of incoming sensory information based on past experience.

**4:06PM P35.00007 Dynamical encoding of looming, receding, and focussing.** <sup>1</sup>, ANDRE LONGTIN, STEPHEN ELISHA CLARKE, LEONARD MALER, University of Ottawa, CENTER FOR NEURAL DYNAMICS COLLABORATION — This talk will discuss a non-conventional neural coding task that may apply more broadly to many senses in higher vertebrates. We ask whether and how a non-visual sensory system can focus on an object. We present recent experimental and modeling work that shows how the early sensory circuitry of electric sense can perform such neuronal focusing that is manifested behaviorally. This sense is the main one used by weakly electric fish to navigate, locate prey and communicate in the murky waters of their natural habitat. We show that there is a distance at which the Fisher information of a neuron's response to a looming and receding object is maximized, and that this distance corresponds to a behaviorally relevant one chosen by these animals. Strikingly, this maximum occurs at a bifurcation between tonic firing and bursting. We further discuss how the invariance of this distance to signal attributes can arise, a process that first involves power-law spike frequency adaptation. The talk will also highlight the importance of expanding the classic dual neural encoding of contrast using ON and OFF cells in the context of looming and receding stimuli.

**4:18PM P35.00008 Songbird Respiration is Controlled by Multispike Patterns at Millisecond Temporal Resolution<sup>1</sup>**, CAROLINE HOLMES, KYLE SRIVASTAVA, Emory University, MICHEL VELLEMA, COEN ELEMANS, University of Southern Denmark, ILYA NEMENMAN, SAMUEL SOBER, Emory University — Although the importance of precise timing of neural action potentials (spikes) is well known in sensory systems, approaches to motor control have focused almost exclusively on firing rates. Here we examined whether precise timing of spikes in multispike patterns has an effect on the motor output in the respiratory system of the Bengalese finch, a songbird. By recording from single motor neurons and the muscle fibers they innervate in freely behaving birds, we find that the spike trains are significantly non-Poisson, suggesting that the precise timing of spikes is tightly controlled. We further find that even a one millisecond shift of an individual spike in a multispike pattern predicts a significantly different air sac pressure. Finally, we provide evidence for the causal relation between precise spike timing and the motor output in this organism by stimulating the motor system with precisely timed patterns of electrical impulses. We observe that shifting a single pulse by as little as two milliseconds elicits differences in resulting air sac pressure. These results demonstrate that the precise timing of spikes does play a role in motor control.

**4:30PM P35.00009 The primary visual cortex in the neural circuit for visual orienting<sup>1</sup>**, LI ZHAOPING, University College London — The primary visual cortex (V1) is traditionally viewed as remote from influencing brain's motor outputs. However, V1 provides the most abundant cortical inputs directly to the sensory layers of superior colliculus (SC), a midbrain structure to command visual orienting such as shifting gaze and turning heads. I will show physiological, anatomical, and behavioral data suggesting that V1 transforms visual input into a saliency map to guide a class of visual orienting that is reflexive or involuntary. In particular, V1 receives a retinotopic map of visual features, such as orientation, color, and motion direction of local visual inputs; local interactions between V1 neurons perform a local-to-global computation to arrive at a saliency map that highlights conspicuous visual locations by higher V1 responses. The conspicuous location are usually, but not always, where visual input statistics changes. The population V1 outputs to SC, which is also retinotopic, enables SC to locate, by lateral inhibition between SC neurons, the most salient location as the saccadic target. Experimental tests of this hypothesis will be shown. Variations of the neural circuit for visual orienting across animal species, with more or less V1 involvement, will be discussed.

**4:42PM P35.00010 Distributed multisensory integration in a recurrent network model through supervised learning**, HE WANG, K. Y. MICHAEL WONG, Hong Kong University of Science and Technology — Sensory integration between different modalities has been extensively studied. It is suggested that the brain integrates signals from different modalities in a Bayesian optimal way. However, how the Bayesian rule is implemented in a neural network remains under debate. In this work we propose a biologically plausible recurrent network model, which can perform Bayesian multisensory integration after trained by supervised learning. Our model is composed of two modules, each for one modality. We assume that each module is a recurrent network, whose activity represents the posterior distribution of each stimulus. The feedforward input on each module is the likelihood of each modality. Two modules are integrated through cross-links, which are feedforward connections from the other modality, and reciprocal connections, which are recurrent connections between different modules. By stochastic gradient descent, we successfully trained the feedforward and recurrent coupling matrices simultaneously, both of which resembles the Mexican-hat. We also find that there are more than one set of coupling matrices that can approximate the Bayesian theorem well. Specifically, reciprocal connections and cross-links will compensate each other if one of them is removed. Even though trained with two inputs, the network's performance with only one input is in good accordance with what is predicted by the Bayesian theorem.

**4:54PM P35.00011 Learning tinnitus<sup>1</sup>**, J. LEO VAN HEMMEN, Physik Department, TU Munich — Tinnitus, implying the perception of sound without the presence of any acoustical stimulus, is a chronic and serious problem for about 2% of the human population. In many cases, tinnitus is a pitch-like sensation associated with a hearing loss that confines the tinnitus frequency to an interval of the tonotopic axis. Even in patients with a normal audiogram the presence of tinnitus may be associated with damage of hair-cell function in this interval. It has been suggested that homeostatic regulation and, hence, increase of activity leads to the emergence of tinnitus. For patients with hearing loss, we present spike-timing-dependent Hebbian plasticity (STDP) in conjunction with homeostasis as a mechanism for "learning" tinnitus in a realistic neuronal network with tonotopically arranged synaptic excitation and inhibition. In so doing we use both dynamical scaling of the synaptic strengths and altering the resting potential of the cells. The corresponding simulations are robust to parameter changes. Understanding the mechanisms of tinnitus induction, such as here, may help improving therapy.

- Randy Kamien, University of Pennsylvania

**2:30PM P36.00001 Directed self-assembly of colloidal particles onto the chemically anchoring patterned surface in a nematic liquid crystal**, XIAO LI, JULIO ARMAS-PÉREZ, JUAN HERNANDEZ-ORTIZ, JUAN DE PABLO, PAUL NEALEY, University of Chicago — The defects assisted assembly of colloidal particles works are more focused on the defects created in the bulk or the interface of nematic liquid crystal, which usually observe a group of particles spontaneously forming a chain or aggregating over the defects. The confining surface with specific 3D sculptured structures, such as pyramid or zig-zag grooves, offers the opportunity to isolate the trapped particles into certain position. Here, we explore a new method to direct self-assemble the colloidal particles through manipulating defects on the 2D geometry confined anchoring surface. Since the director of the preferred planar orientation of LCs could be manipulated by the pattern geometry and dimension, the topological defects could be engineered based on multi-stable orientation by designed 2D geometry pattern of different controllable direction at sub-micrometer dimension. We demonstrate that the designed one single middle straight stripe with disjoint two groups of straight stripe array on both side of the middle stripe as 45 angle of different orientation director could control the distortion of the disjoint gap space thus acting as defects template to trap the colloidal particles directed self-assembly at the designed positions. Through anchoring distribution on the pattern areas, geometry design of pattern, and also the external electric field applied on the system, those defects areas could be generate, erase, resume or even correct.

**2:42PM P36.00002 Self-assembly and separation of nematic colloids through photo-patterned molecular orientation<sup>1</sup>**, CHENHUI PENG, YUBING GUO, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, Kent, OH 44242, USA, CHRISTOPHER CONKLIN, JORGE VIALS, School of Physics and Astronomy and Minnesota Supercomputing Institute, University of Minnesota, Minneapolis, MN 55455, USA, SERGIJ SHYANOVSKII, QI-HUO WEI, OLEG LAVRETOVICH, Liquid Crystal Institute and Chemical Physics Interdisciplinary Program, Kent State University, Kent, OH 44242, USA, OLEG D. LAVRETOVICH TEAM, JORGE VIALS COLLABORATION — Design and control of particles self-assembly is an important theme in colloidal science. Dispersions of colloids in a nematic liquid crystal (LC) show a diversity of self-assembled structures guided by long-range interactions. Here we describe a versatile approach to control colloidal structures through surface-patterned molecular orientation and dynamic processes of LC-enabled electrokinetics (LCEK). In presence of the electric field, the surface-imprinted pattern of molecular orientation triggers LCEK flows which transport the colloidal aggregates to specified locations. The aggregation is directed by the director gradients. Colloids that differ in surface anchoring or shape are guided into different areas of the cell, thus being sorted. The dynamic approach to control colloidal systems through LCEK in cells with patterned director field opens the opportunities in the microfluidic and lab on a chip applications.

**2:54PM P36.00003 Directed Self-assembly of Colloidal Particles on a Blue Phase I Interface<sup>1</sup>**, JOSE MARTINEZ-GONZALEZ, YE ZHOU, MONIRO SADAT SADATI, Univ of Chicago, NICHOLAS ABBOTT, University of Wisconsin, JUAN DE PABLO, Univ of Chicago — Blue phases are liquid states of matter with a highly ordered defect structure which confers unique properties among complex fluids. In this work, a free energy model of chiral liquid crystals is used to consider the self-assembly of colloids and nanoparticles on the interface of a Blue Phase I. It is shown that the crystalline defect structure of the blue phase produces intricate, two-dimensional hexagonal and Kagome structures among the nanoparticle arrangements, with lattice parameters that depend on the type of anchoring of the liquid crystal at the particles surface. These parameters can be tuned via the chirality of the material, thereby offering intriguing possibilities for the creation of hierarchical materials based on the directed assembly of particles in chiral liquid crystals.

**3:06PM P36.00004 Three-Dimensional Topological Solitons in Chiral Liquid Crystals and Ferromagnetic Colloids.**, IVAN SMALYUKH<sup>1</sup>, University of Colorado Boulder — Three-dimensional knotted solitons - often called “hopfions” - have continuous physical fields classified by the Hopf index topological invariant and behave like particles. These hopfions arise in theories in many branches of physics, but their structure and stability are rarely accessible to direct experimental studies. We realize and characterize such static solitons in the molecular alignment fields of chiral liquid crystals and in the magnetization field of colloids with long-range ferromagnetic ordering. Our experiments agree with predictions of numerical modeling based on free energy minimization. By exploiting facile response of the soft matter host media, we demonstrate exquisite control of structure and tunable self-assembly of such solitonic “particles”. This lecture will discuss how liquid crystals and colloids can serve as soft matter model systems in studies of structure, topology and dynamics of three-dimensional topological solitons.

**3:42PM P36.00005 Brownian Dynamics of Colloidal Particles in Lyotropic Chromonic Liquid Crystals<sup>1</sup>**, ANGEL MARTINEZ, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia, PETER J. COLLINGS, Department of Physics and Astronomy, Swarthmore College, Swarthmore, ARJUN G. YODH, Department of Physics and Astronomy, University of Pennsylvania, Philadelphia — We employ video microscopy to study the Brownian dynamics of colloidal particles in the nematic phase of lyotropic chromonic liquid crystals (LCLCs). These LCLCs (in this case, DSCG) are water soluble, and their nematic phases are characterized by an unusually large elastic anisotropy. Our preliminary measurements of particle mean-square displacement for polystyrene colloidal particles (~5 micron-diameter) show diffusive and sub-diffusive behaviors moving parallel and perpendicular to the nematic director, respectively. In order to understand these motions, we are developing models that incorporate the relaxation of elastic distortions of the surrounding nematic field. Further experiments to confirm these preliminary results and to determine the origin of these deviations compared to simple diffusion theory are ongoing; our results will also be compared to previous diffusion experiments in nematic liquid crystals [1-3]. 1. **3:54PM P36.00006 Dielectric Anisotropy of Gold Nanoparticle Colloids in Nematic Liquid Crystals**, ANGELO VISCO, JON FOUST, RIZWAN MAHMOOD, JOSEPH BELOBRADICH, Slippery Rock Univ — We present electrical and optical studies of hexanethiol-treated gold nanoparticle (GNPs) colloids in 4-cyano-4'-pentyl-biphenyl (5CB) liquid crystals. Preliminary data analysis suggests an unusual behavior of sudden drop and then rise in the dielectric anisotropy at a critical concentration of 0.0862% by wt. GNPs and a sudden rise and then drop in the nematic to isotropic transition temperature. Above the critical concentration the data level off to within the uncertainty of the experimental errors. This colloidal system will help us to understand the interaction and the effects of nanoparticles on the self-assembly of LC molecules and the manner in which these particles organize in LC. This study is important for further developments in nanotechnology, sharp and fast display panels, and within the medical field.

**4:06PM P36.00007 Colloidal Transport within Nematics with Arrays of Obstacles**, KUI CHEN, OLIVIA GEBHARDT, Johns Hopkins Univ, GERMAN DRAZER, Rutgers University, DANIEL REICH, ROBERT LEHENY, Johns Hopkins Univ — We have investigated the transport behavior of spherical colloidal particles suspended in the nematic liquid crystal 4-cyano-4'-pentylbiphenyl (5CB) within microfluidic arrays of cylindrical obstacles arranged in a square lattice. Homeotropic anchoring at the surfaces of the obstacles created periodic director-field patterns that strongly influenced the trajectories of the colloids, which had both planar and homeotropic anchoring, as they traversed the arrays under gravity. When the applied force was along a symmetry direction of the lattice, the particles moved parallel to the force but with pronounced modulations in their velocity due to the liquid-crystal-mediated interactions with the posts. With increasing angle between the force and symmetry direction, the particle trajectories underwent a transition in which their average velocity no longer followed the force and instead was parallel to the lattice symmetry direction. The point of this transition was dictated by the particle-post interactions, suggesting a potential new mechanism for particle separations.

**4:18PM P36.00008 Colloidal interactions and self-assembly of plasmonic metal pyramids in nematic liquid crystals.**, SUNGOH PARK, IVAN SMALYUKH, Department of Physics, University of Colorado at Boulder — Combining ordered structure of soft matter systems, such as liquid crystals, with the unique optical properties of metal nano- and micro-particles is a promising approach of designing and realizing mesostructured composites with pre-engineered properties. In this work, we disperse nanofabricated pyramid-shaped plasmonic particles in a nematic host fluid and demonstrate that the particles spontaneously align with respect to the uniform far-field liquid crystal director. This alignment is driven by minimization of the surface anchoring and bulk elastic free energies of the nematic host. Interestingly, multiple stable and metastable orientations of these particles can be controllably observed. Using laser tweezers and video microscopy, we explore inter-particle pair interaction forces as well as the ensuing colloidal self-assembly. We analyze this experimentally observed rich physical behavior of our soft matter composite by invoking electrostatic multipole analogy of elastic distortions induced by the particles in a nematic liquid crystal host and discuss potential practical uses.

**4:30PM P36.00009 Co-dispersion of plasmonic nanorods in thermotropic nematic liquid crystals<sup>1</sup>**, GHADAH SHEETAH, PhD student, QINKUN LIU, PostDoc, IVAN SMALYUKH, Professor — Colloidal dispersions of plasmonic metal nanoparticles in liquid crystals promise the capability of pre-engineering tunable optical properties of mesostructured metal-dielectric composites. Recently, concentrated dispersions of anisotropic gold, silver, and metal alloy nanoparticles in nematic hosts have been achieved and successfully controlled by low-voltage fields [1, 2]. However, to enable versatile designs of material behavior of the composites, simultaneous co-dispersion of anisotropic particles with different shapes, alignment properties, and compositions are often needed. We achieve such co-dispersions and explore their switching characteristics in response to external stimuli like light and electric fields. We demonstrated that spectral characteristics of co-dispersions of multiple types of anisotropic nanoparticles in a common nematic host provides unprecedented variety of electrically- and optically-tunable material behavior, with a host of potential practical applications in electro-optic devices and displays. **4:42PM P36.00010 Tactoids of chiral liquid crystals<sup>1</sup>**, VIVIANA PALACIO-BETANCUR, STIVEN VILLADA-GIL, Departamento de Materiales y Minerales. Universidad Nacional de Colombia, Sede Medellín., YE ZHOU, JULIO C. ARMAS-PREZ, Institute for Molecular Engineering. University of Chicago, JUAN JOS DE PABLO, Institute for Molecular Engineering. University of Chicago. Argonne National Laboratory., JUAN PABLO HERNANDEZ-ORTIZ, Departamento de Materiales y Minerales. Universidad Nacional de Colombia, Sede Medellín. — The phase diagram of chiral liquid crystals confined in ellipsoids is obtained, by following a theoretically informed Monte Carlo relaxation of the tensor alignment field  $\mathbf{Q}$ . The free energy of the system is described by a functional in the framework of the Landau-de Gennes formalism. This study also includes the effect of anchoring strength, curvature, and chirality of the system. In the low chirality region of the phase diagram we found the twist bipolar (BS) phase and some cholesteric phases such as the radial spherical structure (RSS), twist cylinder (TC) and double twist cylinder (DTC) whose axis of rotation is not necessarily aligned with the major axis of the geometry. For high chirality scenarios, the disclination lines are twisted or bent near the surface preventing the formation of symmetric networks of defects, although an hexagonal pattern is formed on the surface which might serve as open sites for collocation of colloids. By analyzing the free energies of isochoric systems, prolate geometries tend to be more favorable for high chirality and low anchoring conditions.

**4:54PM P36.00011 Chiral liquid crystals: the vestigial chiral phases of  $T$ ,  $O$ ,  $I$  matter<sup>1</sup>**, JAAKKO NISSINEN, KE LIU, ROBERT-JAN SLAGER, Lorentz Institute for Theoretical Physics, Leiden University, the Netherlands, KAI WU, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory and Stanford University, USA, JAN ZAAANEN, Lorentz Institute for Theoretical Physics, Leiden University, the Netherlands — We show how chiral order develops in vestigial isotropic phases of  $T$ ,  $O$  and  $I$  liquid crystalline systems in three dimensions. The liquid crystal phases are realized in a lattice model of orientational degrees of freedom with point group symmetries  $G \subset O(3)$ , represented as  $O(3)$ -rotors coupled to  $G$  gauge fields. The model incorporates also disclinations via the gauge fields, features an ordered nematic phase with unbroken  $G$  rotations at low temperatures and a high temperature isotropic liquid phase. We observe an intermediate phase with spontaneous chirality but isotropic  $SO(3)$  symmetry (a liquid) for the gauge groups  $T$ ,  $O$ , and  $I$ , the proper symmetry groups of the tetrahedron, cube and icosahedron, respectively. For the other subgroups of  $SO(3)$ ,  $C_{n \leq \infty}$  and  $D_{n \leq \infty}$ , there is generically only a single phase transition from the nematic phase to the isotropic liquid. We discuss the nature of the phase transitions and conditions under which the chiral phase is stabilized by the nematic order parameter fluctuations. The nature of the vestigial chiral phase is reminiscent of the so-called Ising nematic phase in iron based superconductors.

**5:06PM P36.00012 Structures of cholesteric liquid crystals confined in rectangular microchannels<sup>1</sup>**, QI-HUO WEI, YUBING GUO, JIE XIANG, OLEG LAVRETOVICH, Kent State University — When cholesteric liquid crystals are confined in various geometries, the interplays between the boundary conditions, the bulk structures and different length scales (pitch, penetration depth, and confinement size) may cause frustration and formation of intriguing topological defects and disclination lines. This paper presents our recent studies on the structures of cholesteric liquid crystals confined in rectangular microchannels with homeotropic alignments. The rectangular microchannels with various sizes and aspect ratios are made in glass substrates by using modern nanofabrication techniques. Detailed liquid crystal structures and their optical characterizations will be presented as a function of the channel depth and width.

<sup>1</sup>Work was supported by ACS PRF 53018-ND7

**5:18PM P36.00013 Cooking skyrmions: modeling temperature dependence of defect textures in cholesteric liquid crystals<sup>1</sup>**, SAJEDEH AFGHAH, ANDREW KONYA, JONATHAN SELINGER, ROBIN SELINGER, Liquid Crystal Institute, Kent State University — Using 3-d simulations and analytical calculations, we study temperature dependence of defect structures in liquid crystals in confined geometries. We model a cholesteric liquid crystal confined in a microchannel with homeotropic anchoring, and investigate resulting defect structures—skyrmions, alone or in periodic arrays (bubble domains), and striped textures—as a function of microchannel dimensions, cholesteric pitch, and surface anchoring strength. We model temperature dependence by varying Frank constants and pitch using functions fit to experimental values. Experiments by the Qihuo Wei group show that skyrmion arrays in a microchannel appear to “pop” at a threshold temperature, transforming into elongated defects that span the microchannel’s width. We explore this behavior using simulation and show that skyrmions elongate when their spacing is below a critical distance. Implementation of the simulation code in CUDA for a GPU-equipped computer produces highly efficient performance. We also carry out analytical calculations of free energy to determine optimal/stable structures for skyrmions and other defect textures in thin cells. Both simulation and analytical results are compared to recent experiments by the Qihuo Wei group.

**Session P37 GSOFD DPOLY: Soft Matter Interfaces: Blo-, Dielectrics, Transport and Other Phenomena** 340 - Silvina Matysiak, University of Maryland, College Park

**2:30PM P37.00001 Nonlinear transport of soft droplets in pore networks**, FRANCK VERNEREY, EDUARD BENET CERDA, KANGHYEON KOO, University of Colorado - Boulder — A large number of biological and technological processes depend on the transport of soft colloidal particles through porous media; this includes the transport and separation of cells, viruses or drugs through tissues, membranes and microfluidic devices. In these systems, the interactions between soft particles, background fluid and the surrounding pore space yield complex, nonlinear behaviors such as non-Darcy flows, localization and jamming. We devise a computational strategy to investigate the transport of non-wetting and deformable water droplets in a microfluidic device made of a random distribution of cylindrical obstacles. We first derive scaling laws for the entry of the droplet in a single pore and discuss the role of surface tension, contact angle and size in this process. This information is then used to study the transport of multiple droplets in an obstacle network. We find that when the droplet size is close to the pore size, fluid flow and droplet trafficking strongly interact, leading to local redistributions in pressure fields, intermittent clogging and jamming. Importantly, it is found that the overall droplet and fluid transport display three different scaling regimes depending on the forcing pressure, and that these regimes can be related to droplet properties.

**2:42PM P37.00002 Simulation of non-ionic surfactant micelle formation across a range of temperature and pressure**, GREGORY CUSTER, University of Maryland, PAYEL DAS, IBM Thomas J. Watson Research Center, SILVINA MATYSIAK, University of Maryland — Non-ionic surfactants can, at certain concentrations and thermodynamic conditions, aggregate into micelles due to their amphiphilic nature. Our work looks at the formation and behavior of micelles at extremes of temperature and pressure. Due to the large system size and simulation time required to study micelle formation, we have developed a coarse-grained (CG) model of our system. This CG model represents each heavy atom with a single CG bead. We use the multibody Stillinger-Weber potential, which adds a three-body angular penalty to a two-body potential, to emulate hydrogen bonds in the system. We simulate the linear surfactant  $C_{12}E_5$ , which has a nonpolar domain of 12 carbons and a polar domain of 5 ethers. Our CG model has been parameterized to match structural properties from all-atom simulations of single and dimer surfactant systems. Simulations were performed using a concentration above the experimental critical micelle concentration at 300K and 1atm. We observe an expected region of stable micelle formation at intermediate temperature, with a breakdown at high and low temperature, as well as at high pressure. The driving forces behind the destabilization of micelles and the mechanism of micelle formation at different thermodynamic conditions will be discussed.

**2:54PM P37.00003 On the pH of Aqueous Attoliter-Volume Droplets<sup>1</sup>**, KIERAN P. RAMOS, SAMSON S. VELPULA, TREVOR B. DEMILLE, RYAN PAJELA, LORI S. GOLDNER, Department of Physics, University of Massachusetts Amherst — Droplets of water dispersed in perfluorinated liquids have widespread use including microfluidics, drug delivery and single-molecule measurements. Perfluorinated liquids are distinctly biocompatible due to their stability, low surface tension, lipophobicity, and hydrophobicity. For this reason, the effect of the perfluorinated surface on droplet contents is usually ignored. However, as the droplet diameter is reduced, we expect that any effect of the water/oil interface on droplet contents will become more obvious. We studied the pH of attoliter-volume aqueous droplets in perfluorinated liquids using pH-sensing fluorescent dyes. Droplets were prepared either by sonication or extrusion from buffer and perfluorinated liquids (FC40 or FC77). A non-ionic surfactant was used to stabilize the droplets. Buffer strength, ionic strength, and pH of the aqueous phase were varied and resulting droplet pH compared to the pH of the buffer from which they were formed. Preliminary data are consistent with a pH in droplets that depends on the concentration of non-ionic surfactant. At low surfactant concentrations, the pH in droplets is distinctly lower than the stock buffer. However, as the concentration of non-ionic surfactant is increased the change in pH decreases.

**3:06PM P37.00004 Electrolyte-mediated adsorption to neutral and dielectric interfaces**, JOS ZWANIKKEN, University of Massachusetts, Lowell, YUFEI JING, Northwestern University, VIKRAM JADHAO, Johns Hopkins University, MONICA OLVERA DE LA CRUZ, Northwestern University — Biology relies on electrolytes to regulate molecular interactions and to support functionality in numerous vital processes. Although the role of the electrolyte is generally categorized into two tendencies, namely “salting-out” and “salting-in”, the more versatile aspects can be revealed by a more detailed picture of the microscopic ionic structure. We use molecular dynamics simulations and numerical calculations based on liquid state theory, and obtain high-resolution, quantitative information about the spatial structure of primitive model electrolytes in dielectric confinement, up to high concentrations (0.9 M) and strong electrostatic coupling. The theoretical methods also quantify two relevant underlying thermal forces that are highly tunable by the specific selection of electrolytes. The results refine the understanding of the adsorption behavior of ions and macromolecular solutes, and identify tuning parameters for macromolecular assembly, based on ion size, valency, and ionic composition.

**3:18PM P37.00005 Dipolar fluids near a dielectric surface**, ZIWEI WANG, ERIK LUIJTEN, Northwestern University — The behavior of dipolar fluids near an interface is of fundamental importance in a broad variety of fields, including colloid chemistry, electrochemistry, biochemistry and surface science. The structural properties of such a fluid are affected not only by the presence of surface charge, but also by a dielectric mismatch across the interface. Using large-scale Monte Carlo simulations that explicitly take into account dielectric effects, we investigate a prototypical dipolar fluid. In addition to the organization of the fluid, characterized through the dipolar orientations and spatial correlations, we also calculate the surface tension by employing simulations in the grand-canonical ensemble.

**3:30PM P37.00006 Dielectric effects on the ion distribution near a Janus colloid**, HUANXIN WU, MING HAN, ERIK LUIJTEN, Northwestern University — Spherical Janus colloids, particles with two domains of different materials, are typically heterogeneous in permittivity. This dielectric heterogeneity will influence their behavior in electrolytes, ranging from their aggregation to their electrokinetics in external fields. We investigate the structure of the electric double layer around spherical Janus colloids immersed in solution via molecular dynamics simulations. Polarization of the colloidal surfaces by the surrounding ions is calculated dynamically with a boundary-element method based Poisson solver. One observation is that even neutral Janus colloids may carry a net dipole moment in the presence of asymmetric salts. Moreover, we extend this study to incorporate a *spatially varying permittivity of the solvent* near a charged Janus colloid, and demonstrate the effect of this dielectric variation on the electric double layer.

**3:42PM P37.00007 Preventing Oxide Adhesion of Liquid Metal Alloys to Enable Actuation in Microfluidic Systems**, ISHAN JOSHIPURA, ALEXANDER JOHNSON, HUDSON AYERS, MICHAEL DICKEY, North Carolina State University — This work explores the wetting behavior of an oxide-coated liquid metal, eutectic alloy of gallium and indium ('EGaln'), which remains a liquid at room temperature. Liquid metals uniquely combine fluidity with metallic properties. Combined, these properties enable soft, stretchable, and shape reconfigurable electronics with 'softer than skin' interfaces. Ga forms spontaneously a thin surface oxide that alters its wetting behavior and makes it difficult to move across surfaces without leaving residue behind. We examine the effects of surface roughness (i.e., Cassie-Baxter state) and lubrication to minimize adhesion of Ga oxide to surfaces. Lubricated surfaces create a 'slip-layer' of liquid between the metal and surface that also inhibits wetting. This slip layer allows the metal to move reversibly through microchannels by preventing adhesion of the oxide. The metal may be pumped or moved by using low voltages or pneumatic actuation. Optical microscopy confirms the importance of the slip-layer, which enables non-stick motion of the metal through capillaries. Finally, electrochemical impedance spectroscopy characterizes the electrohydrodynamic motion of EGaln in capillary systems.

**3:54PM P37.00008 Confining capillary waves to control aerosol droplet size from surface acoustic wave nebulisation<sup>1</sup>**, ELIJAH NAZARZADEH, JULIEN REBOUD, RAB WILSON, JONATHAN M. COOPER, University of Glasgow — Aerosols play a significant role in targeted delivery of medication through inhalation of drugs in a droplet form to the lungs. Delivery and targeting efficiencies are mainly linked to the droplet size, leading to a high demand for devices that can produce aerosols with controlled sizes in the range of 1 to 5  $\mu\text{m}$ . Here we focus on enabling the control of the droplet size of a liquid sample nebulised using surface acoustic wave (SAW) generated by interdigitated transducers on a piezoelectric substrate (lithium niobate). The formation of droplets was monitored through a high-speed camera (600,000 fps) and the sizes measured using laser diffraction (Spraytec, Malvern Ltd). Results show a wide droplet size distribution (between 0.8 and 400  $\mu\text{m}$ ), while visual observation (at fast frame rates) revealed that the large droplets (>100  $\mu\text{m}$ ) are ejected due to large capillary waves (80 to 300  $\mu\text{m}$ ) formed at the free surface of liquid due to leakage of acoustic radiation of the SAWs, as discussed in previous literature (Qi et al. Phys Fluids, 2008). To negate this effect, we show that a modulated structure, specifically with feature sizes, typically 200  $\mu\text{m}$ , prevents formation of large capillary waves by reducing the degrees of freedom of the system, enabling us to obtain a mean droplet size within the optimum range for drug delivery (<10  $\mu\text{m}$ ).

**4:06PM P37.00009 Scaling Laws for liquid and ion transport in nanochannels grafted with polyelectrolyte brushes**, GUANG CHEN, SHAYANDEV SINHA, SIDDHARTHA DAS, Univ of Maryland-College Park, SOFT MATTER, INTERFACES, AND ENERGY LABORATORY (SMIEL) TEAM — Grafting nanochannels with polyelectrolyte (PE) brushes renders tremendous functionality to the nanochannels, making them capable of applications such as ion manipulation, ion sensing, current rectification, nanofluidic diode fabrication, and flow control. PE brush is a special case of polymers at interfaces; such brush-like structure is possible only when the grafting density ( $\sigma$ ) is beyond a critical value. In this study, we shall propose scaling laws that identify  $\sigma$ -N (N is the size of the PE molecule) combination that simultaneously ensure that the grafted PE molecules adopt "brush"-like configuration and the height of the PE brushes are smaller than the nanochannel half height. Secondly, we pinpoint the scaling conditions where the electrostatic effects associated with the PE brushes can be decoupled from the corresponding PE excluded volume and elastic effects; such de-coupling has tremendous connotation in context of modeling of electrostatics and transport at PE-brush-covered interfaces. Thirdly, we provide scaling arguments to quantify the dependence of the flow penetration depth into the PE brush as a function of the  $\sigma$ -N combination. Finally, our scaling estimates pinpoint the conditions where the flow or electric field induced deformation of the grafted nanochannel PE brushes can be neglected while modeling the pressure-driven or electroosmotic transport or ionic current in such nanochannels.

**4:18PM P37.00010 Entropic changes in liquid gallium clusters: understanding the anomalous melting temperatures**, NICOLA GASTON, MacDiarmid Institute for Advanced Materials and Nanotechnology, KRISTA STEENBERGEN, Massey University — Melting in finite-sized materials differs in two ways from the solid-liquid phase transition in bulk systems. First, there is an inherent scaling of the melting temperature below that of the bulk, known as melting point depression. Secondly, at small sizes, changes in melting temperature become non-monotonic, and show a size-dependence that is sensitive to the structure of the particle. Melting temperatures that exceed those of the bulk material have been shown to occur in vacuum, but have still never been ascribed a convincing physical explanation. Here we find answers in the structure of the aggregate liquid phase in small gallium clusters, based on molecular dynamics simulations that reproduce the greater-than-bulk melting behavior observed in experiments, and demonstrate the critical role of a lowered entropy in destabilising the liquid state.

**4:30PM P37.00011 Thermocapillary Technique for Shaping and Fabricating Optical Ribbon Waveguides**, KEVIN FIEDLER<sup>1</sup>, SANDRA TROIAN, California Institute of Technology — The demand for ever increasing bandwidth and higher speed communication has ushered the next generation optoelectronic integrated circuits which directly incorporate polymer optical waveguide devices. Polymer melts are very versatile materials which have been successfully cast into planar single- and multimode waveguides using techniques such as embossing, photolithography and direct laser writing. In this talk, we describe a novel thermocapillary patterning method for fabricating waveguides in which the free surface of an ultrathin molten polymer film is exposed to a spatially inhomogeneous temperature field via thermal conduction from a nearby cooled mask pattern held in close proximity. The ensuring surface temperature distribution is purposely designed to pool liquid selectively into ribbon shapes suitable for optical waveguiding, but with rounded and not rectangular cross sectional areas due to capillary forces. The solidified waveguide patterns which result from this non-contact one step procedure exhibit ultrasmooth interfaces suitable for demanding optoelectronic applications. To complement these studies, we have also conducted finite element simulations for quantifying the influence of non-rectangular cross-sectional shapes on mode propagation and losses.

**4:42PM P37.00012 Relaxations of star-shaped polystyrene melts approaching the colloidal limit**, KYLE JOHNSON, University of Michigan, EMMANOUIL GLYNOS, Foundation for Research and Technology-Hellas, GEORGIOS SAKELLARIOU, University of Athens, PETER GREEN, University of Michigan — The dynamics of star-shaped polystyrene melts with functionalities ranging from  $8 < f < 64$  and arm molecular weights ranging from 9 kg/mol  $< M < 80$  kg/mol were investigated using small amplitude oscillatory shear measurements. The frequency dependent storage,  $G'$ , and loss,  $G''$ , moduli were measured in the linear viscoelastic regime in order to characterize the terminal relaxation behavior of the macromolecules. Our studies reveal gradual, low-frequency deviations away from the Milner-McLeish theory for arm retraction indicating more elastic behavior as functionality is increased. The magnitudes of these deviations diminish with increasing arm molecular weight. These elastic deviations are consistent with the emergence of a relaxation representing cooperative structural rearrangements and colloidal behavior. Our results indicate that changes in the size of the core region for low molecular weight arms leads to a transition in the dynamics from an arm retraction mechanism to a cooperative, structural relaxation mechanism.

**4:54PM P37.00013 The origin of star-shaped oscillations of Leidenfrost drops**, XIAOLEI MA, JUSTIN C. BURTON, Department of Physics, Emory University — We experimentally investigate the oscillations of Leidenfrost drops of water, liquid nitrogen, ethanol, methanol, acetone and isopropyl alcohol. The drops levitate on a cushion of evaporated vapor over a hot, curved surface which keeps the drops stationary. We observe star-shaped modes along the periphery of the drop, with mode numbers  $n = 2$  to 13. The number of observed modes is sensitive to the properties of the liquid. The pressure oscillation frequency in the vapor layer under the drop is approximately twice that of the drop frequency, which is consistent with a parametric forcing mechanism [1]. However, the Rayleigh and thermal Marangoni numbers are of order 10,000, indicating that convection should play a dominating role as well. Surprisingly, we find that the wavelength and frequency of the oscillations only depend on the thickness of the liquid, which is twice the capillary length, and do not depend on the mode number, substrate temperature, or the substrate curvature. This robust behavior suggests that the wavelength for the oscillations is set by thermal convection inside the drop, and is less dependent on the flow in the vapor layer under the drop. [1] P. Brunet and J. H. Snoeijer, Eur. Phys. J. Spec. Top. 192, 207 (2011).

**5:06PM P37.00014 The intrinsic structure of liquid interfaces<sup>1</sup>**, MARCELLO SEGA, University of Vienna, Austria, PAL JEDLOVSKY, Department of Chemistry, EKF, Eger, Hungary, BALAZS FABIÁN, Institut UTINAM, Université de Franche-Comté, Besançon, France, GEORGE HORVAI, Budapest University of Technology and Economics, Budapest, Hungary — Thermal capillary waves develop spontaneously at fluid/fluid interfaces, and modulate their shapes on scales much larger than the molecular one, thus smearing any density profile measured or calculated using only a global coordinate system<sup>2</sup>. In this contribution we present a local picture of several thermodynamic quantities (density, energy, free energy, surface tension) at liquid/vapour interfaces, analyzing them both on a molecular layer-by-layer basis<sup>3</sup>, and as a function of the intrinsic distance from the interface<sup>4</sup>, revealing their true, intrinsic structure.

**5:18PM P37.00015 Out of equilibrium GigaPa Young modulus of water nanobridge probed by Force Feedback Microscopy**, SIMON CARPENTIER, CNRS, Inst NEEL, F-38042 Grenoble, France, MARIO S. RODRIGUES, MIGUEL VITORINO, University of Lisboa, Faculty of Sciences, BioISI-Biosystems & Integrative Sciences Institute, Campo Grande, Lisboa, P-1749-016, Portugal, LUCA COSTA, ESRF, The European Synchrotron, 71 Rue des Martyrs, 38000 Grenoble, France, ELISABETH CHARLAIX, CNRS, LIPhy, Grenoble, F-38402, France, JOEL CHEVRIER, CNRS, Inst NEEL, F-38042 Grenoble, France — Because of capillary condensation, water droplets appear in nano/micropores. We report that dynamical properties of such nanobridge dramatically change when probed at different time scales [1]. Using a Force Feedback Microscope [2], the gap between the nano-tip and the surface is continuously varied, and we observe this change in the simultaneous measurements, at different frequencies, of the stiffness  $G'$  (N/m), the dissipative coefficient  $G''$  (kg/sec) together with the static force. This is made possible thanks to feedback force which cancels in real time the force acting on the tip. It avoids the mechanical instabilities due to the nucleation of the nanobridge. As the measuring time approaches the microsecond, the liquid droplet exhibits a large positive stiffness (it is small and negative in the long time limit). Although clearly controlled by surface effects, it compares to the stiffness of a solid nanobridge with a 1 GigaPa Young modulus. [1] Carpentier et al. arXiv preprint arXiv:1503.06756, 2015. **2:30PM P38.00001 In Situ Analysis of the Glass Transition Temperature of Irreversibly Adsorbed Polymer Nanolayers**, MARY BURROUGHS, RODNEY PRIESTLEY, Department of Chemical and Biological Engineering, Princeton University — When a polymer thin film is adsorbed in the melt state, individual chains can strongly adsorb to the supporting substrate in a manner that appears to be irreversible. This irreversible adsorption of polymer chains results from the large number of individual contacts made between monomer units and the substrate that stabilize the polymer from desorption. The formation and development of irreversibly adsorbed layers with increased annealing time has been shown to correlate with changes in their structure and dynamic properties and may impact the properties of thin polymer films. Here we investigate the link between deviations in the glass transition temperature ( $T_g$ ) of polymer thin films from the bulk value and the growth of irreversibly adsorbed nanolayers. Through the use of fluorescence spectroscopy, we are able to directly measure  $T_g$  of polystyrene adsorbed nanolayers in an exposed geometry and in situ. The results allow us to examine the influences of interfaces and molecular weight on the  $T_g$  of adsorbed nanolayers throughout their development. By undertaking these studies, critical information is obtained that assists in the design and processing of technologies in which thin polymer films are placed in contact with solid interfaces.

**2:42PM P38.00002 Tailoring Glassy Dynamics on the Nanoscale: Covalent Bonding versus Physical Adsorption in Polymer-based Nanocomposites**, ADAM HOLT, Univ of Tennessee, Knoxville, VERA BOCHAROVA, SHIWANG CHENG, Chemical Science Division, Oak Ridge National Laboratory, ALEXANDER KISLIUK, ADAM IMEL, THUSITHIA ETAMPAWALA, Univ of Tennessee, Knoxville, TYLER WHITE, TOMONORI SAITO, Chemical Science Division, Oak Ridge National Laboratory, NICOLE SIKES, Columbus State University, MARK DADMUN, ALEXEI SOKOLOV, Univ of Tennessee, Knoxville — Polymer grafted nanoparticles (PGNs) offer improved miscibility, stability, and most importantly dispersibility in a polymer matrix over traditional nanoparticle fillers. However, despite the large interest in the miscibility and dispersibility of PGNs within polymer melts, few attempts have been made to study the material properties of solvent-free PGNs and specifically how they compare to traditional polymer nanocomposites (PNCs). In this experiment, the structure and dynamical properties of PGNs of three different molecular weights with identical grafting densities are directly compared to PNCs with similar polymer volume fraction. We find that the segmental dynamics in the interfacial layer are more strongly influenced by the covalent bonding than in the composite system (chain adsorption) and ascribe this to highly stretched chain conformations near the interface, similar to a polymer brush. These results show that the chain conformations in a polymer melt near an interface, especially on the nanoscale, can strongly influence segmental dynamics and offers an explanation to many of the disputed results in the polymer nanocomposite literature.

**2:54PM P38.00003 Polymer Dynamics Effects on Solute Transport in Hairy Nanoparticle Membranes<sup>1</sup>**, EILEEN BUENNING, CONNOR BILCHAK, CHRISTOPHER DURNING, Columbia University, BRIAN BENICEWICZ, University of South Carolina, ALEXEI SOKOLOV, University of Tennessee/Oak Ridge National Laboratory, SANAT KUMAR, Columbia University — Molecular transport measurements in matrix-free grafted nanoparticle (MFGNP) films have shown remarkable enhancement of permeability and ideal selectivity of small condensable molecules and simple gases over the neat polymer melts and conventional, dispersed nanoparticle composites. Films comprised of covalently-attached poly(methyl acrylate) PMA chains to the surface of 14nm silica particles self-assemble into ordered arrays, and we postulate this structure plays an important role in regulating solute transport. This self-assembly creates interstitial spaces between the nanoparticle cores, which the polymer chains can only fill by stretching. Here we use small-angle neutron scattering (SANS), broadband dielectric spectroscopy (BDS), rheology and temperature-modulated differential scanning calorimetry (TMDSC) to probe polymer chain and segmental dynamics and investigate this hypothesis of chain stretching in MFGNP materials. We found that grafting slows both chain and segmental relaxation, and increases fragility, indicating that the chains are more “frustrated” in the grafted systems. We propose that the effects of the chain/surface interactions on chain dynamics leads to an increase in available free volume and thus enhances transport properties in MFGNP systems.

**3:06PM P38.00004 Effect of Molecular Architecture on Polymer Melt Surface Dynamics**, MARK FOSTER, The University of Akron Dept. of Polymer Science — The dynamics of the thermally stimulated surface height fluctuations in a polymer melt dictate wetting, adhesion, and tribology at that surface. These surface fluctuations can be profoundly altered by tethering of the chains. One type of tethering is the tethering of one part of a molecule to another part of the same molecule. This tethering is found in both long chain branched polymers and in macrocycles. We have studied the surface fluctuations with X-ray Photon Correlation Spectroscopy for melts of well-defined, anionically polymerized polystyrenes of various architectures, including linear, 6 arm star, pom-pom, comb and cyclic architectures. For linear chains, the variation of surface relaxation time with in-plane scattering vector can be fit using a hydrodynamic continuum theory (HCT) of thermally stimulated capillary waves that knows nothing of the chain architecture. Assuming the theory is applicable, apparent viscosities of the films may then be inferred from the XPCS data. For unentangled linear chains, the viscosity inferred from XPCS data in this manner is the same as that measured by conventional bulk rheometry. The HCT does a reasonable job of describing the variation of relaxation time with scattering vector for long branched chains also, but only if a viscosity much larger than that of the bulk is assumed. The discrepancy between the viscosity inferred from surface relaxation times using the HCT and that derived from conventional rheometry grows larger as the bulk  $T_g$  is approached and is different for each long chain branched architecture. However, for densely branched combs and cyclic chains different behaviors are found. **3:42PM P38.00005 Relaxation processes and glass transition in confined 1,4-polybutadiene films: A Molecular Dynamics study**, WOLFGANG PAUL, Martin-Luther-University, 55099 Halle, MATHIEU SOLAR, INSA, Strasbourg, France — We will present results from Molecular Dynamics simulations of a chemically realistic model of 1,4-polybutadiene (PB) chains confined by graphite walls. Relaxation processes in this system are heterogeneous and anisotropic. We will present evidence for a slow additional relaxation process related to chain desorption from the walls. We also study the structural relaxation resolved with respect to the distance from the graphite walls and show the influence of structural changes on the relaxation behavior. The temperature dependence of the dielectric relaxation in layers of different thickness near the walls shows no indication of a shift of  $T_g$  as a function of thickness when analyzed with a Vogel-Fulcher fit. We explain this by the importance of intramolecular dihedral barriers for the glass transition in PB which dominate over the density changes next to a wall except for a 1 nm thick layer directly at the wall.

**3:54PM P38.00006 Unusual Molecular Weight Dependence to the Physical Aging of Thin Polystyrene Films**, MICHAEL THEES, CONNIE ROTH, Emory University — Physical aging and the glass transition are intimately related, with the physical aging rate providing a measure of the stability of the glassy state formed. Previously, we have investigated the physical aging rate in thin supported polystyrene (PS) films finding that the local aging rate is correlated with the local glass transition temperature [Pye et al., *Macromolecules* 43, 8296 (2010)]. These studies were able to provide a measure of the depth to which bulk glassy dynamics are perturbed by the free surface interface, a distance much further than similar measures of liquid-like dynamics. Here, we present physical aging measurements of thin PS films using ellipsometry. Surprisingly, we observe a distinctive molecular weight dependence to the physical aging behavior of thin (30 nm thick) films not present in bulk (1000 nm thick) films for very high molecular weights ( $M_w > 3000$  kg/mol). These results indicate that chain connectivity plays a subtle, but important role in how gradients of glassy dynamics are propagated between the free surface and substrate interfaces

**4:06PM P38.00007 Effects of molecular weight and tacticity on the  $T_g$  of poly(methyl methacrylate) films supported by silica<sup>1</sup>**, KUN GENG, FEI CHEN, OPHELIA TSUI, Boston University Physics Department — The glass transition temperature ( $T_g$ ) of poly(methyl methacrylate) (PMMA) films supported by silica is studied as a function of film thickness at different molecular weights ( $M_w$ ) for different polymer tacticities. The  $T_g$  confinement effect is found to depend on the  $M_w$  and tacticity. For the films with a low  $M_w$  of 2.5 kg/mol,  $T_g$  is depressed for the atactic films, consistent with previous results. In contrast, the films with a higher syndiotactic content exhibit  $T_g$  enlargement as thickness decreases. We tentatively suggest this to be caused by the influence of chain stiffness on the  $T_g$  that dominates at low  $M_w$  and varies with tacticity. For sufficiently high  $M_w$ , the effect of chain stiffness is expected to be small. At  $M_w = 50$  kg/mol, the  $T_g$  confinement effect of the atactic and more syndiotactic films reverses from that observed of the low- $M_w$  counterpart films. We suggest the chain stiffness effect to be negligible at this  $M_w$ , and attribute the opposite  $T_g$  confinement effect to be caused by a competition between the surface  $T_g$  and the substrate  $T_g$  in these films. The  $T_g$  found of bilayers made of the atactic and more syndiotactic PMMAs with this  $M_w$  supports our attribute.

**4:18PM P38.00008 Chain conformation near the substrate interface in nanoparticle stabilized polymer thin films<sup>1</sup>**, DEBORAH BARKLEY, MANI SEN, NAISHENG JIANG, MAYA ENDOH, TADANORI KOGA, Stony Brook University, GUANGCUI YUAN, SUSHIL SATIJA, Center for Neutron Research, NIST, YUGANG ZHANG, OLEG GANG, Brookhaven National Lab, ALAMGIR KARIM, University of Akron — When nanoparticles (NPs) are added to polymer thin films, they often migrate to the film-substrate interface and form a “diffused immobile interfacial layer”, which serves to screen the polymer-substrate interaction and suppress dewetting. The fundamental, but unsolved question is how the conformations of the polymer chains in the layer are affected by the NPs and how that impacts the enhancement of film stability. To address the question, we used dodecane thiol-functionalized gold NPs (2.4 nm diameter) and polystyrene (PS,  $M_w=30$ kDa). We found that the critical concentration of the Au NPs to induce complete dewetting suppression of 20 nm-thick PS/Au thin films on cleaned Si substrates is 5 wt% (wt of particle/wt of polymer). To investigate the interfacial structures at the polymer-solid interface, we rinsed the annealed PS/Au thin films with toluene and characterized the residual interfacial layers by using various x-ray and neutron scattering techniques. The results indicate that the conformation of the polymer chains closer to the substrate becomes less flattened with the addition of gold NPs, allowing chains at the substrate to entangle more effectively with free chains comprising the bulk film. The detailed mechanism will be discussed.

**4:30PM P38.00009 The Effect of Acid-Base Interactions on Conformation of Adsorbed Polymer Chains**, NISHAD DHOPATKAR, HE ZHU, Graduate Student, ALI DHINOJWALA, Professor — Adsorption of polymer chains from solutions is of fundamental interest in polymer science. This adsorption process is governed by the complex interplay between the solvent-polymer, polymer-substrate, and solvent-substrate interaction energies. In early 1970's, Fowkes and his coworkers have introduced the concept of acid base interactions in explaining why PMMA (basic) adsorption was extremely low on acidic substrates from acidic solvents. The acidic solvent molecules compete with the surface for binding with the basic polymer sites and this reduces the adsorption of PMMA. Here, by using interface-selective sum frequency generation spectroscopy (SFG) and attenuated-total-reflectance (ATR)-FTIR spectroscopy we directly measure whether the solvent or polymer molecules interact with the substrate in acidic, basic, and neutral solvents. Surprisingly, we find that the surface acidic site (hydroxyl) groups are still covered with PMMA chains in acidic solvent. The PMMA chains in acidic solvent adsorb with much higher fraction of chains as trains in comparison to loops and tails. Such differences in the static and dynamic conformations have consequences in understanding the exchange kinetics, colloidal stabilization, chromatographic separations, adhesion and friction, and stabilization of nanocomposites.

**4:42PM P38.00010 Surfactants at Single-Walled Carbon Nanotube-Water Interface: Physics of Surfactants, Counter-Ions, and Hydration Shell**<sup>1</sup>, KETAN S. KHARE, MSED, NIST, Gaithersburg, MD 20899 and Physics, Georgetown Univ., DC 20057, FREDERICK R. PHELAN JR., MSED, NIST, Gaithersburg, MD 20899 — Specialized applications of single-walled carbon nanotubes (SWCNTs) require an efficient and reliable method to sort these materials into monodisperse fractions with respect to their defining metrics (chirality, length, etc.) while retaining their physical and chemical integrity. A popular method to achieve this goal is to use surfactants that individually disperse SWCNTs in water and then to separate the resulting colloidal mixture into fractions that are enriched in monodisperse SWCNTs. Recently, experiments at NIST have shown that subtle point mutations of chemical groups in bile salt surfactants have a large impact on the hydrodynamic properties of SWCNT-surfactant complexes during ultracentrifugation. These results provide strong motivation for understanding the rich physics underlying the assembly of surfactants around SWCNTs, the structure and dynamics of counter ions around the resulting complex, and propagation of these effects into the first hydration shell. Here, all-atom molecular dynamics simulations are used to investigate the thermodynamics of SWCNT-bile salt surfactant complexes in water with an emphasis on the buoyant characteristics of the SWCNT-surfactant complexes. Simulation results will be presented along with a comparison with experimental data.

**4:54PM P38.00011 Polyethylene oxide hydration in grafted layers.**<sup>1</sup>, ELENA DORMIDONTOVA, ZILU WANG, Physics Department and Institute of Materials Science, University of Connecticut, Storrs, CT — Hydration of water soluble polymers is one of the key-factors defining their conformation and properties, similar to biopolymers. Polyethylene oxide (PEO) is one of the most important biomedical-applications polymers and is known for its reverse temperature solubility due to hydrogen bonding with water. As in many practical applications PEO chains are grafted to surfaces, e.g. of nanoparticles or planar surfaces, it is important to understand PEO hydration in such grafted layers. Using atomistic molecular dynamic simulations we investigate the details of molecular conformation and hydration of PEO end-grafted to gold surfaces. We analyze polymer and water density distribution as a function of distance from the surface for different grafting densities. Based on a detailed analysis of hydrogen bonding between polymer and water in grafted PEO layers, we will discuss the extent of PEO hydration and its implication for polymer conformation, mobility and layer properties.

**5:06PM P38.00012 The Unusual Conformational Behavior of Polyzwitterionic Brushes in Aqueous Solutions**, JUN MAO, Univ of Chicago, WEI CHEN, Argonne National Laboratory, GUANGCUI YUAN, NIST Center for Neutron Research, National Institute of Standards and Technology, JING YU, Argonne National Laboratory, MATTHEW TIRRELL, Univ of Chicago — Polyzwitterions constitute a peculiar class of polyelectrolytes, which are electrically neutral polymers containing both a positive and a negative charge on each repeating unit. Surfaces coated with polyzwitterionic brushes are resistant to the nonspecific accumulation of proteins and microorganisms, making them excellent candidates for a wide range of antifouling applications, from biocompatible medical devices to marine coatings. The surrounding environment can dramatically influence the conformational behavior of polyzwitterionic brushes. High-density polyzwitterionic brushes poly(2-methacryloyloxyethyl phosphorylcholine) (PMPC) were synthesized using surface initiated atom-transfer radical polymerization, and neutron reflectivity (NR) measurements were performed to investigate the ionic strength dependence of the conformational behaviors of PMPC brushes in monovalent salt solutions. Despite the numerous observations of normal pure polyelectrolyte brushes, NR results showed that both the densely concentrated layer near the substrate surface and the relatively swollen layer into the solution have been observed in different  $q$  range in a single neutron reflectivity profile. These results will definitely help us to better understand the relationship between the solution behaviors of zwitterionic polymer brushes and their antifouling properties.

**5:18PM P38.00013 Homopolymer Adsorption on Hexagonal Surfaces: A Replica-Exchange Monte Carlo Study**, BENJAMIN LIEWEHR, MICHAEL BACHMANN, The University of Georgia — The adsorption behavior and thermodynamic properties of a coarse-grained flexible homopolymer, grafted on a hexagonal patterned surface, are investigated by means of parallel-tempering replica-exchange Monte Carlo simulations. In this study, the strength of the polymer-surface interaction, which is based on a standard Lennard-Jones potential, is changed systematically, mimicking different hexagonally patterned substrate materials. Specific order parameters are introduced to discriminate structural phases, at different surface adsorptions strengths and temperatures, into classes of expanded, globular, droplet, and compact conformations. Finally, we provide a complete structural hyperphase diagram for a polymer with 55 monomers and discuss representative polymer structures.

**Session P39 DBIO GSNP: Information Processing in Cellular Signaling and Gene Regulation**

342 - Andrew J. Mugler, Purdue University

**2:30PM P39.00001 Towards a predictive theory for genetic regulatory networks**, GASPER TKACIK, IST Austria — When cells respond to changes in the environment by regulating the expression levels of their genes, we often draw parallels between these biological processes and engineered information processing systems. One can go beyond this qualitative analogy, however, by analyzing information transmission in biochemical “hardware” using Shannon’s information theory. Here, gene regulation is viewed as a transmission channel operating under restrictive constraints set by the resource costs and intracellular noise. We present a series of results demonstrating that a theory of information transmission in genetic regulatory circuits feasibly yields non-trivial, testable predictions. These predictions concern strategies by which individual gene regulatory elements, e.g., promoters or enhancers, read out their signals; as well as strategies by which small networks of genes, independently or in spatially coupled settings, respond to their inputs. These predictions can be quantitatively compared to the known regulatory networks and their function, and can elucidate how reproducible biological processes, such as embryonic development, can be orchestrated by networks built out of noisy components. Preliminary successes in the gap gene network of the fruit fly *Drosophila* indicate that a full ab initio theoretical prediction of a regulatory network is possible, a feat that has not yet been achieved for any real regulatory network. We end by describing open challenges on the path towards such a prediction.

### 3:06PM P39.00002 Theory of optimal information transmission in E. coli chemotaxis pathway

, GABRIELE MICALI, ROBERT G. ENDRES, Imperial College London — Bacteria live in complex microenvironments where they need to make critical decisions fast and reliably. These decisions are inherently affected by noise at all levels of the signaling pathway, and cells are often modeled as an input-output device that transmits extracellular stimuli (input) to internal proteins (channel), which determine the final behavior (output). Increasing the amount of transmitted information between input and output allows cells to better infer extracellular stimuli and respond accordingly. However, in contrast to electronic devices, the separation into input, channel, and output is not always clear in biological systems. Output might feed back into the input, and the channel, made by proteins, normally interacts with the input. Furthermore, a biological channel is affected by mutations and can change under evolutionary pressure. Here, we present a novel approach to maximize information transmission: given cell-external and internal noise, we analytically identify both input distributions and input-output relations that optimally transmit information. Using E. coli chemotaxis as an example, we conclude that its pathway is compatible with an optimal information transmission device despite the ultrasensitive rotary motors.

### 3:18PM P39.00003 BMP4 density gradient in disk-shaped confinement

, BEHNAZ BOZORGUI, HAMID TEIMOURI, ANATOLY B. KOLOMEISKY, Rice University — We present a quantitative model that explains the scaling of BMP4 gradients during gastrulation and the recent experimental observation that geometric confinement of human embryonic stem cells is sufficient to recapitulate much of germ layer patterning. Based on a assumption that BMP4 diffusion rate is much smaller than the diffusion rate of its inhibitor molecules, our results confirm that the length-scale which defines germ layer territories does not depend on system size.

### 3:30PM P39.00004 Mechanical Feedback and Arrest in Gene Expression

, STUART SEVIER, HERBERT LEVINE, Rice Univ — The ability to watch biochemical events at the single-molecule level has increasingly revealed that stochasticity plays a leading role in many biological phenomena. One important and well known example is the noisy, “bursty” manner of transcription. Recent experiments have revealed relationships between the level and noise in gene expression hinting at deeper stochastic connections. In this talk we will discuss how the mechanical nature of transcription can explain this relationship and examine the limits that the physical aspects of transcription place on gene expression.

### 3:42PM P39.00005 Information processing in multi-step signaling pathways

, AMBHI GANESAN, IBM, ARCHER HAMIDZADEH, Yale University, JIN ZHANG, UCSD, ANDRE LEVCHENKO, Yale University — Information processing in complex signaling networks is limited by a high degree of variability in the abundance and activity of biochemical reactions (biological noise) operating in living cells. In this context, it is particularly surprising that many signaling pathways found in eukaryotic cells are composed of long chains of biochemical reactions, which are expected to be subject to accumulating noise and delayed signal processing. Here, we challenge the notion that signaling pathways are insulated chains, and rather view them as parts of extensively branched networks, which can benefit from a low degree of interference between signaling components. We further establish conditions under which this pathway organization would limit noise accumulation, and provide evidence for this type of signal processing in an experimental model of a calcium-activated MAPK cascade. These results address the long-standing problem of diverse organization and structure of signaling networks in live cells.

### 3:54PM P39.00006 Towards Predictive Modeling of Information Processing in Microbial Ecosystems With Quorum-Sensing Interactions

, TAHIR YUSUFALY, JAMES BOEDICKER, University of Southern California — Bacteria communicate using external chemical signals in a process known as quorum sensing. However, the efficiency of this communication is reduced by both limitations on the rate of diffusion over long distances and potential interference from neighboring strains. Therefore, having a framework to quantitatively predict how spatial structure and biodiversity shape information processing in bacterial colonies is important, both for understanding the evolutionary dynamics of natural microbial ecosystems, and for the rational design of synthetic ecosystems with desired computational properties. As a first step towards these goals, we implement a reaction-diffusion model to study the dynamics of a LuxI/LuxR quorum sensing circuit in a growing bacterial population. The spatiotemporal concentration profile of acyl-homoserine lactone (AHL) signaling molecules is analyzed, and used to define a measure of physical and functional signaling network connectivity. From this, we systematically investigate how different initial distributions of bacterial populations influence the subsequent efficiency of collective long-range signal propagation in the population. We compare our results with known experimental data, and discuss limitations and extensions to our modeling framework.—/abstract—

### 4:06PM P39.00007 Thermodynamics of nuclear transport<sup>1</sup>

, CHING-HAO WANG, PANKAJ MEHTA, Department of Physics, Boston University, Boston, MA 02215, MICHAEL ELBAUM, Department of Materials and Interfaces, Weizmann Institute of Science, Rehovot, Israel — Molecular transport across the nuclear envelope is important for eukaryotes for gene expression and signaling. Experimental studies have revealed that nuclear transport is inherently a nonequilibrium process and actively consumes energy. In this work we present a thermodynamics theory of nuclear transport for a major class of nuclear transporters that are mediated by the small GTPase Ran. We identify the molecular elements responsible for powering nuclear transport, which we term the “Ran battery” and find that the efficiency of transport, measured by the cargo nuclear localization ratio, is limited by competition between cargo molecules and RanGTP to bind transport receptors, as well as the amount of NTF2 (i.e. RanGDP carrier) available to circulate the energy flow. This picture complements our current understanding of nuclear transport by providing a comprehensive thermodynamics framework to decipher the underlying biochemical machinery.

<sup>1</sup>PM and CHW were supported by a Simons Investigator in the Mathematical Modeling in Living Systems grant (to PM).

### 4:18PM P39.00008 Vector Encoding in Biochemical Networks

, GARRETT POTTER, BO SUN, Oregon State University — Encoding of environmental cues via biochemical signaling pathways is of vital importance in the transmission of information for cells in a network. The current literature assumes a single cell state is used to encode information, however, recent research suggests the optimal strategy utilizes a vector of cell states sampled at various time points. To elucidate the optimal sampling strategy for vector encoding, we take an information theoretic approach and determine the mutual information of the calcium signaling dynamics obtained from fibroblast cells perturbed with different concentrations of ATP. Specifically, we analyze the sampling strategies under the cases of fixed and non-fixed vector dimension as well as the efficiency of these strategies. Our results show that sampling with greater frequency is optimal in the case of non-fixed vector dimension but that, in general, a lower sampling frequency is best from both a fixed vector dimension and efficiency standpoint. Further, we find the use of a simple modified Ornstein-Uhlenbeck process as a model qualitatively captures many of our experimental results suggesting that sampling in biochemical networks is based on a few basic components.

### 4:30PM P39.00009 Deciphering the Minimal Algorithm for Development and Information-

genesis. , ZHIYUAN LI, Princeton Center for Theoretical Science, Princeton University, CHAO TANG, Center for Quantitative Biology, Peking University, HAO LI, Dept. of Biochemistry and Biophysics and California Institute for Quantitative Biosciences, University of California, San Francisco — During development, cells with identical genomes acquire different fates in a highly organized manner. In order to decipher the principles underlying development, we used C.elegans as the model organism. Based on a large set of microscopy imaging, we first constructed a “standard worm” in silico: from the single zygotic cell to about 500 cell stage, the lineage, position, cell-cell contact and gene expression dynamics are quantified for each cell in order to investigate principles underlying these intensive data. Next, we reverse-engineered the possible gene-gene/cell-cell interaction rules that are capable of running a dynamic model recapitulating the early fate decisions during C.elegans development. We further formulated the C.elegans embryogenesis in the language of information genesis. Analysis towards data and model uncovered the global landscape of development in the cell fate space, suggested possible gene regulatory architectures and cell signaling processes, revealed diversity and robustness as the essential trade-offs in development, and demonstrated general strategies in building multicellular organisms.

**4:42PM P39.00010 Reliable Signal Transduction** , ROY WOLLMAN, Dept of Chemistry and Biochemistry, University of California, San Diego — Stochasticity inherent to biochemical reactions (intrinsic noise) and variability in cellular states (extrinsic noise) degrade information transmitted through signaling networks. We analyzed the ability of temporal signal modulation - that is dynamics - to reduce noise-induced information loss. In the extracellular signal-regulated kinase (ERK), calcium ( $\text{Ca}^{2+}$ ), and nuclear factor kappa-B ( $\text{NF-}\kappa\text{B}$ ) pathways, response dynamics resulted in significantly greater information transmission capacities compared to nondynamic responses. Theoretical analysis demonstrated that signaling dynamics has a key role in overcoming extrinsic noise. Experimental measurements of information transmission in the ERK network under varying signal-to-noise levels confirmed our predictions and showed that signaling dynamics mitigate, and can potentially eliminate, extrinsic noise-induced information loss. By curbing the information-degrading effects of cell-to-cell variability, dynamic responses substantially increase the accuracy of biochemical signaling networks.

## Wednesday, March 16, 2016 2:30PM - 5:30PM –

**Session P40 GSNP GSOF: More Geometry and Dynamics: Wrinkling, Folding, Snapping, etc.**

343 - Dominic Vella, Oxford University

**2:30PM P40.00001 Rolling Wrinkles on Elastic Substrates** , MICHAEL IMBURGIA, ALFRED CROSBY, Univ of Mass - Amherst — The mechanics of rolling contact between an elastomer layer and a thin film present unique opportunities for taking advantage of elastic instabilities, such as surface wrinkling, to create patterned surfaces. Here we present a plate-to-roll (P2R) geometry to laminate a thin film onto an elastomer layer in order to induce surface wrinkling. First, a poly(dimethylsiloxane) (PDMS) layer is draped around a roller and pressed into contact with a poly(styrene) (PS) film supported on a plate. Once rolling begins, the PS film preferentially laminates onto the PDMS layer. During this process, the deformation of the PDMS layer can induce wrinkling when the contact load exceeds a critical value. Wrinkle feature size consists of amplitudes of  $0.2 - 4\mu\text{m}$  and wavelengths of  $15 - 20\mu\text{m}$ . Wrinkle amplitude can be controlled by contact load and roller curvature, as well as the mechanical properties and thickness of the film and elastomer. We develop semi-empirical equations to describe the effect of contact load and roller curvature on the wrinkle aspect ratio. Finite-element modeling of an elastomer layer in rolling contact with a rigid plate is used to support experimental results. Using these models, wrinkle-based technologies such as optoelectronics and enhanced adhesives can be envisioned.

**2:42PM P40.00002 Slow frictional waves** , Koushik Viswanathan, Purdue University, Narayan Sundaram, Indian Institute of Science, Srinivasan Chandrasekar, Purdue University — Stick-slip, manifest as intermittent tangential motion between two dry solid surfaces, is a friction instability that governs diverse phenomena from automobile brake squeals to earthquakes. We show, using high-speed in situ imaging of an adhesive polymer interface, that low velocity stick-slip is fundamentally of three kinds, corresponding to passage of three different surface waves — separation pulses, slip pulses and the well-known Schallamach waves. These waves, traveling much slower than elastic waves, have clear distinguishing properties. Separation pulses and Schallamach waves involve local interface separation, and propagate in opposite directions while slip pulses are characterized by a sharp stress front and do not display any interface detachment. A change in the stick-slip mode from separation to slip pulse is effected simply by increasing the normal force. Together, these three waves constitute all possible stick-slip modes in adhesive friction and are shown to have direct analogues in muscular locomotory waves in soft bodied invertebrates. A theory for slow wave propagation is also presented which is capable of explaining the attendant interface displacements, velocities and stresses.

**2:54PM P40.00003 Poking around: how indentation reveals wrinkly isometries** , DOMINIC VELLA, University of Oxford, Hamid Ebrahimi, Northeastern University , Joseph Paulsen, Syracuse University, Ashkan Vaziri, Northeastern University, Narayanan Menon, Benny Davidovitch, UMass Amherst — When deforming extremely thin objects, deformation via stretching is relatively expensive. It is therefore natural to seek deformations that preserve lengths, or isometries. Two common examples of such isometries in mechanics are the 'd'-cone (for a plate) and 'mirror buckling' (for a shell). I will show two examples for which the presence of a weak tension means that these isometries are not obtained experimentally. Instead, the systems in question wrinkle and tend to new 'wrinkly isometries': isometries that are only available to a wrinkled object.

**3:06PM P40.00004 Curvature-induced stiffness and the spatial variation of wavelength in wrinkled sheets** , Narayanan Menon, JD Paulsen, Evan Hoffeld, Hunter King, Jiangshui Huang, Thomas Russell, Zhanlong Qiu, Benny Davidovitch, U of Massachusetts, Amherst, Dominic Vella, Mathematical Institute, Oxford University — Natural wrinkle patterns often inhabit surfaces of curved substrates, and typically are spatially nonuniform. However, the unified understanding of wrinkle wavelength [1] in terms of a competition between the bending energy of a sheet and the stiffness provided by the tension or potential energy of the supporting substrate, applies only to nearly-planar, parallel, and spatially uniform wrinkle patterns. We describe theory and experiment that extend this understanding in two major directions. The first is to show that the underlying curvature may be treated as a distinct term in the substrate stiffness. The second is to demonstrate in two very different settings that the local value of the wavelength is determined by the local stiffness of the subphase. Both results are encapsulated in a simple, local law for the wavelength that has greatly expanded applicability. We acknowledge support from the WM Keck Foundation 1. Cerda, E., & Mahadevan, L. (2003). *Physical review letters*, 90, 074302.

**3:18PM P40.00005 Geometry-driven folding transitions in floating thin films** , Joseph D. Paulsen, Syracuse University, Vincent Démery, PCT-ESPCI, France, K. Bugra Toga, Eastman Chemical Company, Zhanlong Qiu, Benny Davidovitch, Thomas P. Russell, Narayanan Menon, Univ of Mass - Amherst — When a thin elastic sheet is compressed, it forms wrinkles to gather excess material, while deforming the fluid or solid substrate by only a small amount. Upon further compression, the sheet may fold, in order to lower the mechanical energy of the system<sup>1</sup>. Here we demonstrate a folding transition that is independent of the mechanical properties of the sheet. We study the deformations of a thin polymer film that has an annular shape, floating on a planar air-water interface. By controlling the concentration of a surfactant outside the film, we vary the tension pulling on the outer boundary of the annulus. The sheet spontaneously folds at a threshold ratio of inner to outer surface tension that depends on the geometry of the sheet, but is independent of its bending rigidity. Our results are consistent with a simple geometric principle: the sheet adopts the unstretched shape that minimizes the interfacial energy of the exposed liquid<sup>2</sup>. Finally, we consider the application of this geometric principle to the folding of a floating indented film.

**3:30PM P40.00006 Ribbon curling** , Anne Juel, University of Manchester, UK, Chris Prior, University of Durham, UK, Julien Moussou, ENS Paris, France, Buddhapriya Chakrabarti, University of Durham, UK, Oliver Jensen, University of Manchester, UK — The procedure of curling a ribbon by running it over a sharp blade is commonly used when wrapping presents. Despite its ubiquity, a quantitative explanation of this everyday phenomenon is still lacking. We address this using experiment and theory, examining the dependence of ribbon curvature on blade curvature, the longitudinal load imposed on the ribbon and the speed of pulling. Experiments in which a ribbon is drawn steadily over a blade under a fixed load show that the ribbon curvature is generated over a restricted range of loads, the curvature/load relationship can be non-monotonic, and faster pulling (under a constant imposed load) results in less tightly curled ribbons. We develop a theoretical model that captures these features, building on the concept that the ribbon under the imposed deformation undergoes differential plastic stretching across its thickness, resulting in a permanently curved shape. The model identifies factors that optimize curling and clarifies the physical mechanisms underlying the ribbon's nonlinear response to an apparently simple deformation.

**3:42PM P40.00007 Periodic Buckling Patterns On Constrained Elastic Shells.** , JOEL MARTHELOT, ANNA LEE, PIERRE-THOMAS BRUN, FRANCISCO LOPEZ JIMENEZ, PEDRO M. REIS, MIT — Thin spherical shells range from nanometer-sized viruses to space vehicles. A pressure differential between the inner and outer part of the shell can result in the buckling and catastrophic failure of the structure. We revisit this classic buckling problem, depressurizing thin elastic shells, which are arrested from within by a concentric spherical mandrel. As a result, buckling is constrained to occur within the gap between the two. Above a critical pressure, dimples appear sequentially on the surface of the shell to form a robust periodic pattern. We perform precision desktop experiments to construct the bifurcation diagram of the process, and explore a range of geometric and material properties. A scaling analysis enables us to rationalize the dependence of the size of the dimples on both the radius of the shell and the radial gap between the shell and the inner rigid mandrel. Moreover, we characterize the process of nucleation and progression of the dimpled pattern front. Particular emphasis is given to the patterns obtained in the strongly nonlinear post-buckling regime where a network of sharp ridges forms.

**3:54PM P40.00008 Defect-controlled buckling of depressurized elastic shells** , ANNA LEE, JOEL MARTHELOT, FRANCISCO LPEZ JIMNEZ, PIERRE-THOMAS BRUN, PEDRO REIS, Massachusetts Institute of Technology — We revisit the classic problem of buckling of spherical elastic shells under pressure loading, with an emphasis on determining the role that engineered imperfections have on the critical buckling pressure. Since the 1960s numerous theoretical and computational studies have addressed this canonical problem in engineering mechanics, but there is a striking lack of precision experiments to corroborate these predictions. We perform an experimental investigation where thin shells of nearly uniform thickness are fabricated by the coating of hemispherical molds with a polymer solution, which upon curing yields the elastic structure. Moreover, our manufacturing technique allows us to introduce a single dimple-like defect with controllable geometric properties. By systematically varying the amplitude of this defect (smaller than the thickness of the shell) we study the effect that these imperfections have on the buckling strength of our spherical shells. Small deviations from the spherical geometry result in large reductions in the buckling pressure and our experimental results agree well with the existing theories. We then perform a broader exploration for other classes of defects, for which theoretical predictions are yet to be developed.

**4:06PM P40.00009 Stress Localization in Elastic Shells** , SARAH SELDEN, ARTHUR EVANS, NAKUL BENDE, RYAN HAYWARD, CHRISTIAN SANTANGELO, Univ of Mass - Amherst — Upon indentation, thin shells react by localizing strain energy in polygonal structures as opposed to a uniform axisymmetric distribution. While the formation of these localized structures are well-characterized for perfect shells, a change in shell thickness or the introduction of a crease fundamentally changes the nature of the shell deformation. We perform finite element simulations, in tandem with experiments to explore the effect of different shell geometries on the energy landscape. We find that the crease induces a new symmetry-breaking localization that does not appear in perfect shells, and we explore the deformation characteristics of the creased shell over a wide range of crease radii, and crease orientations.

**4:18PM P40.00010 Regularizing rigidifying curves to understand the low-energy deformations of thin shells** , SALEM AL MOSLEH, CHRISTIAN SANTANGELO, Univ of Mass - Amherst, GEOMETRY OF MATERIALS TEAM — It is much harder to stretch a piece of paper than bend it. We exploit this fact to simplify the elastic energy of a thin shell. We accomplish this by extending the linear isometric displacements, displacements that do not cause stretching to lowest order, to low energy Nambu-Goldstone modes. This approach fails in an interesting way in the vicinity of “rigidifying curves,” curves with zero normal curvature, because half of the linear isometries are divergent there. We use a renormalization group methods to show that nonlinearities in the strain regularize these divergences. We explore the relationship between these modes and folding along curves of zero normal curvature.

**4:30PM P40.00011 Hunting for ghosts in elastic snap-through** , MICHAEL GOMEZ, DEREK E. MOULTON, DOMINIC VELLA, Mathematical Institute, University of Oxford — Elastic ‘snap-through’ is a striking instability often seen when an elastic system loses bistability, e.g. due to a change in geometry or external loading. The switch from one state to another is generally rapid and hence is used to generate fast motions in biology and engineering. While the onset of instability has been well studied, the dynamics of the transition itself remain much less well understood. For example, the dynamics exhibited by children’s jumping popper toys, or the leaves of the Venus flytrap plant, are much slower than would be expected based on a naive estimate of the elastic timescales. To explain this discrepancy, the natural conclusion has been drawn that some other effect, such as viscoelasticity, must play a role. We demonstrate here that purely elastic systems may show similar ‘slow’ dynamics during snap-through. This behaviour is due to a remnant (or ‘ghost’) of the snap-through bifurcation underlying the instability, analogously to bottleneck phenomena in 1-D dynamical systems. This slowness is a generic consequence of being close to bifurcation — it does not require dissipation. We obtain scaling laws for the length of the delay and compare these to numerical simulations and experiments on real samples.

**4:42PM P40.00012 One Bend, Two Bend: Stepping Towards a Complex Folded Object.** , ANDREW CROLL, DAMITH ROZAIRO, North Dakota State Univ — Crumpled thin films form a very unique jammed state of matter. They are both lightweight and ridged, suggesting broad industrial relevance. While researchers have theorized over the origins of these properties, very little experimental work has been performed directly collecting both structural and material properties in concert. Without testing the strength and interplay of the basic structures making up the larger object (bends, folds, and d-cones) it is difficult if not impossible to completely trust the origin of various material properties and processes (modulus, aging behaviour). Here we show that laser scanning confocal microscopy can be used to image geometry directly in concert with the recording of traditional macroscopic measurements (e.g. force vs displacement). Specifically, we examine the force/displacement behaviour in systems of 1 to N folds created with well understood polymeric materials.

**4:54PM P40.00013 Wrinkling Instability Induced by Imposed Gaussian Curvature in the Zero-tension Limit<sup>1</sup>** , YIWEI SUN, BENNY DAVIDOVITCH, GREGORY GRASON, Univ of Mass - Amherst — The adhesion of thin stiff films onto spherical substrates introduces compressive stresses, which cause the laminated film to buckle out of plane. Previous studies addressed the emerging wrinkle pattern in the limit of zero bending modulus and the presence of surface tension at the boundary, and found the radius of the inner unwrinkled zone scales with the tension. Here we study another fundamental limit: finite bending modulus and zero exerted tension. In this limit, subtlety will arise from the fact that the singular expansion, which previous studies relied on, becomes ill-defined. To reveal the morphology in the zero-tension limit, we employ numerical simulations based on bead-bond model. Surprisingly, we find that the scaling law for the radius of the unwrinkled zone can be generalized from the finite tension to the zero tension limit, by applying a bending modulus dependent term to the tension dominated scale. The simulation results also highlight the residual compressive hoop stress, which is scaled by bending modulus in the absence of tension. The findings suggest the existence of a new, yet unstudied process, by which the deformed shape of the sheet approaches isometry as the bending modulus vanishes, in the absence of boundary loads.

**5:06PM P40.00014 Geometry of Thin Nematic Elastomer Sheets** , HILLEL AHARONI, Univ of Pennsylvania, ERAN SHARON, RAZ KUPFERMAN, Hebrew University of Jerusalem — A thin sheet of nematic elastomer attains 3D configurations depending on the nematic director field upon heating. In this talk we describe the intrinsic geometry of such a sheet, and derive an expression for the metric induced by general smooth nematic director fields. Furthermore, we investigate the reverse problem of constructing a director field that induces a specified 2D geometry. We provide an explicit analytical recipe for constructing any surface of revolution using this method. We demonstrate how the design of an arbitrary 2D geometry is accessible using approximate numerical methods.

**5:18PM P40.00015 Unpredictable Motion and Post-chaotic Self-Organization of Flexible Structures.** , NICHOLAS NECHITAILO, Naval Surface Warfare Center, Dahlgren, Virginia — Two physical phenomena, “reverse buckling” and “post-chaotic self-organization”, were discovered by the author of this paper. The phenomena were analyzed using Newton’s mechanics, Euler bifurcation and buckling theory, and Poincaré’s theory of chaotic motion when “prediction becomes impossible.” However, our experimental and theoretical findings revealed a more complex nonlinear physics with some predictability of final states. Geometric and material nonlinearities in flexible plates, beams and shells lead to transient chaos and unexpected final shapes. In one experiment, an axisymmetric transverse pressure pulse was applied to a circular metal membrane. It buckled, lost axial symmetry and formed a folded six-corner star. In another test, an impulsively stretched rod buckled and obtained a final shape similar to that of a rod under static axial compression. “Reputable” finite element and finite difference codes could not reliably predict deformation of an aluminum beam under a transverse pressure pulse. The anomalous responses were observed in a narrow region of the load amplitude and duration. These were described by simple analytical equations. Similar phenomena were seen in nonlinear equations of motion representing various non-mechanical systems.

**2:30PM P41.00001 Infrared Structural Biology: Detect Functionally Important Structural Motions of Proteins<sup>1</sup>** , AIHUA XIE, Oklahoma State University — Proteins are dynamic. Lack of dynamic structures of proteins hampers our understanding of protein functions. Infrared structural biology (IRSB) is an emerging technology. There are several advantages of IRSB for mechanistic studies of proteins: (1) its excellent dynamic range (detecting structural motions from picoseconds to  $\geq$  seconds); (2) its high structural sensitivity (detect tiny but functionally important structural motions such as proton transfer and changes in hydrogen bonding interaction); (3) its ability to detect different structural motions simultaneously. Successful development of infrared structural biology demands not only new experimental techniques (from infrared technologies to chemical synthesis and cell biology), but also new data processing (how to translate infrared signals into quantitative structural information of proteins). These topics will be discussed as well as examples of how to use IRSB to study structure-function relationship of proteins.

**3:06PM P41.00002 Quantifying the Energy Landscape Statistics in Proteins - a Relaxation Mode Analysis** , ZHIKUN CAI, YANG ZHANG, Univ of Illinois - Urbana — Energy landscape, the hypersurface in the configurational space, has been a useful concept in describing complex processes that occur over a very long time scale, such as the multistep slow relaxations of supercooled liquids and folding of polypeptide chains into structured proteins. Despite extensive simulation studies, its experimental characterization still remains a challenge. To address this challenge, we developed a relaxation mode analysis (RMA) for liquids under a framework analogous to the normal mode analysis for solids. Using RMA, important statistics of the activation barriers of the energy landscape becomes accessible from experimentally measurable two-point correlation functions, e.g. using quasi-elastic and inelastic scattering experiments. We observed a prominent coarsening effect of the energy landscape. The results were further confirmed by direct sampling of the energy landscape using a metadynamics-like adaptive autonomous basin climbing computation. We first demonstrate RMA in a supercooled liquid when dynamical cooperativity emerges in the landscape-influenced regime. Then we show this framework reveals encouraging energy landscape statistics when applied to proteins.

**3:18PM P41.00003 The Onset of Collective Structural Vibrations at the Protein Dynamical Transition** , MENGYANG XU, KATHERINE A. NIESSEN, YANTING DENG, NIGEL S. MICHKI, State Univ of NY - Buffalo, Buffalo, NY, EDWARD H. SNELL, Hauptman-Woodward Medical Research Institute, State Univ of NY - Buffalo, Buffalo, NY, ANDREA G. MARKELZ, State Univ of NY - Buffalo, Buffalo, NY — X-ray, neutron scattering and terahertz measurements [1,2] found a rapid increase in dynamics of critically hydrated proteins above 220 K, termed the protein dynamical transition. Protein function ceases below the DT. It has been suggested that protein dynamics is slaved to the solvent and the DT originates from thermally activated solvent motions. Since previous measurements did not distinguish local diffusive and librational motions from long-range collective vibrations of proteins, it has not been determined how long-range motions are affected by the DT. Using a recently developed technique, crystal anisotropy terahertz microscopy [3] we directly measured the long-range motions for lysozyme and examined the temperature dependence in the 180-290 K range. We find that the distinct intramolecular vibrations do not follow the expected phonon-like behavior of solid state systems where the vibrational bands sharpen and blue shift with decreasing temperature, rather decrease in intensity as the DT is approached and disappear below the DT. This suggests the surrounding solvent below the DT acts as a frozen cage preventing long-range motions. 1.Doster,W.,et al. Phys.Rev.Lett., 2010.104(9):098101. 2.Niessen,K.,et al. Biophys.Rev., 2015.7,201. 3.Acbas,G.,et al. Nat.Comm., 2014.5,3076.

**3:30PM P41.00004 Structural and Dynamic Analysis on IDPs by Modified AWSEM-MD** , HAO WU, GAREGIN PAPOIAN, Univ of Maryland-College Park, PAPOIAN THEORETICAL BIOPHYSICS GROUP TEAM — Unlike globular proteins, intrinsically disordered proteins (IDPs) lack both secondary and tertiary structures and can play key roles in various biological processes, including transcriptional regulation, molecular recognition and cellular signaling. These functions can be potentially elucidated by structural heterogeneity of IDPs. Because of their flexibility and disordered nature, it has been difficult to investigate IDPs both computationally and experimentally. In particular, it is desirable to develop coarse-grained, yet accurate models of IDPs, such that simulations exploring sufficient conformational ensembles could be carried out within feasible times. To achieve this goal, we modified the associative memory, water mediated, structure and energy model (AWSEM-MD), which is typically used for folding of globular proteins or binding studies. We tested modified AWSEM-MD on several well-studied IDPs and found the transient secondary structure propensity is consistent with NMR experimental results. The rugged free energy landscapes obtained also show structural heterogeneity of these IDPs. Our proposed extension of AWSEM-MD may allow simulating a wider range of IDPs with high accuracy and computational efficiency.

**3:42PM P41.00005 Capturing high temperature protein conformations for low-temperature study using ultra-fast cooling** , DAVID MOREAU, HAKAN ATAKISI, ROBERT THORNE, Cornell University — protocols for cooling biomolecular crystals for x-ray cryocrystallography are poorly controlled, leading to crystal-to-crystal and within-crystal non-isomorphism. Furthermore, cooling times below the protein-solvent glass transition of .1 s provide ample time for biological temperature conformations to depopulate and shift. To address these issues, methods and apparatus for cooling biomolecular crystals at rates approaching 100,000 K/s have been developed. These cooling rates are sufficient to eliminate ice formation on cooling without use of cryoprotectants, and to quench additional high-temperature conformations for low-temperature study. Time scales for conformational relaxation can be characterized using variable cooling rates. Possible extension of these methods to maximize conformational quenching will be discussed.

**3:54PM P41.00006 Protein Conformational Entropy is Independent of Solvent** , NATHANIEL NUCCI, Rowan University, VERONICA MOORMAN, JOHN GLEDHILL, KATHLEEN VALENTINE, A. JOSHUA WAND, University of Pennsylvania — Proteins exhibit most of their conformational entropy in individual bond vector motions on the ps-ns timescale. These motions can be examined through determination of the Lipari-Szabo generalized squared order parameter ( $O^2$ ) using NMR spin relaxation measurements. It is often argued that most protein motions are intimately dependent on the nature of the solvating environment. Here the solvent dependence of the fast protein dynamics is directly assessed. Using the model protein ubiquitin, the order parameters of the backbone and methyl groups are shown to be generally unaffected by up to a six-fold increase in bulk viscosity or by encapsulation in the nanoscale interior of a reverse micelle. In addition, the reverse micelle condition permits direct comparison of protein dynamics to the mobility of the hydration layer; no correlation is observed. The dynamics of aromatic side chains are also assessed and provide an estimate of the length- and timescale of protein motions where solvent dependence is seen. These data demonstrate the solvent independence of conformational entropy, clarifying a long-held misconception in the fundamental behavior of biological macromolecules. Supported by the National Science Foundation.

**4:06PM P41.00007 Moving in the Right Direction: Evolution of Protein Structural Vibrations with Functional State and Mutation** , KATHERINE NIESSEN, MENG YANG XU, SUNY University at Buffalo, Physics, EDWARD SNELL, Hauptman-Woodward Medical Research Institute, Buffalo, NY, ANDREA MARKELZ, SUNY University at Buffalo, Physics — Long-range intramolecular vibrations may enable efficient access to functionally important conformations. We examine how these motions change with inhibitor binding and mutation using terahertz anisotropic absorption and molecular modeling [1,2]. The measured anisotropic absorption dramatically changes with 3NAG inhibitor binding for wild type (WT) free chicken egg white lysozyme (CEWL). We examine the evolution of internal motions with binding using normal mode analysis to calculate an ensemble averaged vibrational density of states (VDOS) and isotropic and anisotropic absorptions for both WT and a two residue (R14 and H15) deletion mutant which has a 1.4 higher activity rate [3]. While the VDOS and isotropic response are largely unchanged with inhibitor binding, the anisotropic response changes dramatically with binding. However, for the mutant the calculated unbound anisotropic absorption more closely resembles its bound spectrum, and it has increased calculated mean squared fluctuations in regions overlapping those in its bound state. These results indicate that the mutant's enhanced activity may be due to a shift in the *direction* of vibrations toward those of the bound state, increasing the sampling rate of the bound conformation. [1] DOI: 10.1007/s12551-015-0168-4 [2] DOI: 10.1038/ncomms4076 [3] DOI: 10.1006/jmbi.1999.2572

**4:18PM P41.00008 The Molecular Dynamics Study of the Structural Conversions in the Transformer Protein RfaH** , JEEVAN GC, BERNARD GERSTMAN, PREM CHAPAGAIN, Florida International University — Recently, a class of multi-domain proteins such as RfaH transcription factor are labelled as the transformer proteins as they undergo major conformational transformation for performing multiple functions. In the absence of the inter-domain contacts, the C-terminal domain of RfaH transforms from its alpha-helix conformation to a beta-barrel structure. Each of these states have their own functional role: in its alpha-helix state, RfaH-CTD inhibits the transcription by masking the binding site of RNAP, but in its beta state it facilitates the translation. We used various molecular dynamics simulations to study its transformer-like behavior of full-RfaH and identified key amino acid residues that are important in modulating such behavior. Our results show that the inter domain interactions constitute the major barrier in the alpha-helix to beta-barrel conversion. Once the interfacial interactions are broken, structural conversion is easier. The structural conversion from beta-barrel to alpha-helix proceeds with the rearrangement of the hydrophobic residues followed by the inter domain contacts formation via non-native, transient salt-bridge formation, leading to the formation of the native inter domain salt-bridge and hydrophobic contacts to give the final alpha-helix structure.

**4:30PM P41.00009 Motional displacements in proteins incorporating dynamical diversity<sup>1</sup>** , DERYA VURAL, UT/ORNL Center for Molecular Biophysics, Oak Ridge National Laboratory, P.O. Box 2008, Tennessee 37831 , USA, JEREMY SMITH, UT/ORNL Center for Molecular Biophysics, Oak Ridge National Laboratory, P.O. Box 2008, Tennessee 37831, USA, HENRY GLYDE, Department of Physics and Astronomy, University of Delaware, Newark, Delaware 19716-2570, USA — The average mean square displacement (MSD),  $\langle r^2 \rangle$ , of hydrogen  $H$  in proteins is measured using incoherent neutron scattering methods. The observed MSD shows a marked increase in magnitude at a temperature  $T_D \simeq 240$  K. This is widely interpreted as a dynamical transition to large MSDs which make function possible in proteins. However, when the data is interpreted in terms of a single averaged MSD, the extracted  $\langle r^2 \rangle$  depends on the neutron momentum transfer,  $\hbar Q$ , used in the measurement. We have shown recently that this apparent dependence on  $Q$  arises because the dynamical diversity of the  $H$  in the protein is neglected[2]. We present models of the dynamical diversity of  $H$  in Lysozyme that when used in the analysis of simulated neutron data lead to consistent,  $Q$  independent values for the average MSD and for the diversity model. 2. D. Vural and L. Hong, J. C. Smith and H. R. Glyde. *Phys. Rev. E* **91**, 052705 (2015).

**4:42PM P41.00010 Microsecond dynamics of mismatch repair proteins** , FREDDIE SALSURY, WILLIAM THOMPSON, Wake Forest University — We will present the results of long-time simulations (250ns-1microsecond) of the mismatch repair protein complexes Mutsalpha bound to various substrates, both normal and damaged. We do so to demonstrate the importance of long-range fluctuations and generalized allostery in such systems and how long-scale GPU-enabled simulations can enabled such analysis.

**4:54PM P41.00011 Intermediate State Dependence of Intramolecular Vibrations in Photoactive Yellow Protein** , YANTING DENG, MENG YANG XU, KATHERINE NIESSEN, SUNY Buffalo, Buffalo, NY, MARIUS SCHMIDT, University of Wisconsin, Milwaukee, WI, ANDREA MARKELZ, SUNY Buffalo, Buffalo, NY — Photoactive proteins provide a testbed for the role of long-range collective motions in protein function. Long-range intramolecular vibrations of the protein scaffold may provide efficient energy relaxation[1], enhancement of chromophore vibrations that promote structural transitions[2] and assistance in electron energy transfer[3]. Photoactive yellow protein (PYP) is a cytoplasmic photocycling protein associated with the negative phototactic response to blue light in halohodospira halophile. We measure the intramolecular vibrations of PYP using crystal anisotropy terahertz microscopy (CATM)[4] as a function of photoexcitation. Room temperature CATM measurements are performed in the dark and with continuous illumination at 488 nm, which is found to result in an approximately 20% steady photoexcited state (pB). We find a decrease in anisotropic absorption in frequency range 20-60  $\text{cm}^{-1}$  with photoexcitation. This result may be due to an increase in sample disorder associated with the structural change in pB state. We compare the measured and calculated spectra using molecular dynamics and normal mode/quasi-harmonic analysis to identify the nature of the motions giving rise to the resonant absorption bands. 1. **5:06PM P41.00012 Structure and dynamics of Ebola virus matrix protein VP40 by a coarse-grained Monte Carlo simulation** , RAS PANDEY, University of Southern Mississippi, BARRY FARMER, Air Force Research Laboratory — Ebola virus matrix protein VP40 (consisting of 326 residues) plays a critical role in viral assembly and its functions such as regulation of viral transcription, packaging, and budding of mature virions into the plasma membrane of infected cells. How does the protein VP40 go through structural evolution during the viral life cycle remains an open question? Using a coarse-grained Monte Carlo simulation we investigate the structural evolution of VP40 as a function of temperature with the input of a knowledge-based residue-residue interaction. A number local and global physical quantities (e.g. mobility profile, contact map, radius of gyration, structure factor) are analyzed with our large-scale simulations. Our preliminary data show that the structure of the protein evolves through different state with well-defined morphologies which can be identified and quantified via a detailed analysis of structure factor.

**5:18PM P41.00013 Effects of pressure on the dynamics of a hyperthermophilic protein revealed by quasielastic neutron scattering<sup>1</sup>**, U. R. SHRESTHA, D. BHOWMIK, Wayne State Univ, J. R. D. COPLEY, M. TYAGI, J. B. LEO, NIST Center for Neutron Research, X.-Q. CHU, Wayne State Univ — Inorganic pyrophosphatase (IPPase) from *Thermococcus thioireducens* is a large oligomeric protein derived from hyperthermophilic microorganism that is found near hydrothermal vents deep under the sea, where the pressure is nearly 100 MPa. Here we study the effects of pressure on the conformational flexibility and relaxation dynamics of IPPase over a wide temperature range using quasielastic neutron scattering (QENS) technique. Two spectrometers were used to investigate the  $\beta$ -relaxation dynamics of proteins in time ranges from 2 to 25 ps, and from 100 ps to 2 ns. Our results reveal that, under the pressure of 100 MPa, IPPase displays much faster relaxation dynamics than a mesophilic model protein, hen egg white lysozyme (HEWL) [1], opposite to what we observed previously under the ambient pressure [2]. These contradictory observations imply that high pressure affects the dynamical properties of proteins by distorting their energy landscapes. Accordingly, we derived a general schematic denaturation phase diagram that can be used as a general picture to understand the effects of pressure on protein dynamics and activities. **2:30PM P42.00001 Chemical and Temperature Effects on Diffusion in a Model Polymer/Nanoparticle Composite<sup>1</sup>**, DUSTIN JANES, U.S. Food and Drug Administration, CHRISTOPHER DURNING, Columbia University — Polymers and inks used in medical devices may be strengthened with nanoparticle fillers, so an understanding of how they may affect the release of residuals and additives via diffusion will help modernize biocompatibility testing. Transport of small molecules in polymers with increasing volume fraction of impermeable nanoparticles is often poorly predicted by the simple Maxwell model for heterogeneous media. In this presentation we will examine two diffusing classes, only one of which possesses hydrogen bonding interactions with the nanoparticle surface. Since similar reductions in mutual diffusion coefficients were observed in both cases we attribute the enhancement of the "blocking effect" in nanocomposites to a reduction in polymer mobility in the interfacial volume near the nanoparticle. The temperature and penetrant concentration dependence of the diffusion coefficients were examined in the context of a Vrentas-Duda free volume model that includes a thermally activated prefactor. While data obtained for rubbery poly(methyl acrylate) clearly obeys the expected Arrhenius scaling with  $E_A = 11$  kJ/mol, results for films containing  $d = 14$  nm spherical silica nanoparticles do not, providing more evidence that polymer free volume is perturbed in unexpected ways even for conceptually simple systems.

**2:42PM P42.00002 Controlling Free Volume for Permeability enhancement in Polymer-Grafted Nanocomposites**, CONNOR BILCHAK, EILEEN BUENNING, SANAT KUMAR, CHRISTOPHER DURNING, Columbia University, BRIAN BENICEWICZ, University of South Carolina — Significant advances in polymer membrane technology have been made by exploring glassy materials with intrinsically high 'free volume', allowing for diffusion selectivity. However, the permeability of these materials is restricted by the Robeson Upper Bound and exhibits long-term aging. While nanofiller have been used to avoid the deleterious effect of aging, they further limit transport properties and can result in non-equilibrium structures that phase-separate. We here show that 14nm silica nanoparticles grafted with rubbery Poly(Methyl Acrylate) (PMA) chains form hexatic lattices, solving a common difficulty in this class of membrane constructs of controlled dispersion morphology. In addition, our results show that these materials have permeabilities elevated relative to the neat polymer matrix, offering surprising beneficial gas transport properties. We also show that the 'free volume' available for diffusion can be adequately controlled by tuning polymer chain length and graft density. We propose the morphology of these grafted nanoparticle systems may be manipulated to optimize these composites for a wide variety of vital gas separations.

**2:54PM P42.00003 Gas Transport in Polymer-Grafted Nanoparticles**, KAI ZHANG, SANAT KUMAR, Columbia University — The efficient separation of gases is crucial for clean energy technologies. With their intrinsic multiscale features and excellent self-assembly properties, polymer-grafted nanoparticles (PGNP) material makes a good candidate for effective gas separation, but the basic understanding of gas transport in PGNPs is still missing. While the nanoparticles cores are spherical, the corona of the PGNPs can be deformed into anisotropic space-filling polygons at high density that are commensurate with the crystal structures (Wigner-Seitz cells). Such deformation indicates that the polymer chains are extended or compressed along different directions and create cavities within the crystals that can help to improve the gas selectivity. We use coarse-grained computer simulations to study the solubility and diffusion of gas molecules inside the crystalline packing of the NP cores. By tuning the degree of polymerization, the surface density of grafting chains and the size of gas molecules, we systematically investigate the dependence of gas transport on these parameters. We find that the void formed by three contacting monomers imposes a critical lengthscale beyond which the transport becomes highly size selective.

**3:06PM P42.00004 Understanding transport in model water desalination membranes**, EDWIN CHAN, National Institute of Standards and Technology — Polyamide based thin film composites represent the the state-of-the-art nanofiltration and reverse osmosis membranes used in water desalination. The performance of these membranes is enabled by the ultrathin (~100 nm) crosslinked polyamide film in facilitating the selective transport of water over salt ions. While these materials have been refined over the last several decades, understanding the relationships between polyamide structure and membrane performance remains a challenge because of the complex and heterogeneous nature of the polyamide film. In this contribution, we present our approach to addressing this challenge by studying the transport properties of model polyamide membranes synthesized via molecular layer-by-layer (mLbL) assembly. First, we demonstrate that mLbL can successfully construct polyamide membranes with well-defined nanoscale thickness and roughness using a variety of monomer formulations. Next, we present measurement tools for characterizing the network structure and transport of these model polyamide membranes. Specifically, we used X-ray and neutron scattering techniques to characterize their structure as well as a recently-developed indentation based poromechanics approach to extrapolate their water diffusion coefficient. Finally, we illustrate how these measurements can provide insight into the original problem by linking the key polyamide network properties, i.e. water-polyamide interaction parameter and characteristic network mesh size, to the membrane performance.

**3:42PM P42.00005 Salt transport properties of model reverse osmosis membranes using electrochemical impedance spectroscopy**, KATHLEEN FELDMAN, EDWIN CHAN, GERY STAFFORD, CHRISTOPHER STAFFORD, NIST — With the increasing shortage of clean water, efficient purification technologies including membrane separations are becoming critical. The main requirement of reverse osmosis in particular is to maximize water permeability while minimizing salt permeability. Such performance optimization has typically taken place through trial and error approaches. In this work, key salt transport metrics are instead measured in model reverse osmosis membranes using electrochemical impedance spectroscopy (EIS). As shown previously, EIS can provide both the membrane resistance  $R_m$  and membrane capacitance  $C_m$ , with  $R_m$  directly related to salt permeability. The membranes are fabricated in a molecular layer by layer approach, which allows for control over such parameters as thickness, surface and bulk chemistry, and network geometry/connectivity.  $R_m$ , and therefore salt permeability, follows the expected trends with thickness and membrane area but shows unusual behavior when the network geometry is systematically varied. By connecting intrinsic material properties such as the salt permeability with macroscopic performance measures we can begin to establish design rules for improving membrane efficiency and facilitate the creation of next-generation separation membranes.

**3:54PM P42.00006 Using Indentation to Characterize Water Transport and Structure in Nafion Thin Films**<sup>1</sup>, ERIC DAVIS, Department of Chemical and Biomolecular Engineering, Clemson University, Clemson, SC 29634, NICHOLE NADERMANN, KIRT PAGE, CHRISTOPHER STAFFORD, EDWIN CHAN, Materials Science and Engineering Division, National Institute of Standards and Technology, Gaithersburg, MD 20899 — Perfluorinated ionomers, specifically Nafion, are the state-of-the-art polymer used in fuel cells. For this application, Nafion is utilized in both a bulk (hundreds of microns) and confined (tens of nanometers) state. For Nafion thin films in a confined state, i.e., Nafion as thin film coatings on catalyst particles, in-plane transport may play a critical role in the movement of water and protons through this catalysis layer. In this study, water transport was measured for a series of Nafion thin film thicknesses using poroelastic relaxation indentation (PRI). Unlike traditional through-thickness diffusion measurement techniques for thin polymer films (e.g., quartz crystal microbalance), PRI can be used to probe the in-plane water transport behavior. Relative to bulk Nafion, reduced in-plane water diffusion was observed in thin film Nafion, and below approximately 1 micron, water diffusivity and Nafion film thickness exhibited a logarithmic relationship. Equilibrium swelling measurements of water saturated Nafion thin films were used in conjunction with pore network theory to develop a picture of how the molecular-scale structure of Nafion changes with confinement to nanoscale film thicknesses.

<sup>1</sup>Using Indentation to Characterize Water Transport and Structure in Nafion Thin Films

**4:06PM P42.00007 Water and polymer dynamics in highly crosslinked polyamide membranes**, BRADLEY FRIEBERG, EDWIN CHAN, MADHU TYAGI, CHRISTOPHER STAFFORD, CHRISTOPHER SOLES, National Institute of Standards and Technology — Highly crosslinked polyamides for reverse osmosis are the state-of-the-art active material in membranes for desalination. The thin film composite membrane structure that is used commercially has been empirically designed to selectively allow the passage of water molecules and minimize the passage of solutes such as salt. However, due to the large roughness and variability of the polyamide layer, there is a limited understanding of the structure-property relationship for these materials as well as the transport mechanism. To better understand the water transport mechanism we measure the water and polymer dynamics of polyamide membranes using quasi-elastic neutron scattering (QENS). By hydrating the membrane with deuterated water, we are able to isolate the dynamics of the hydrogenated membrane on the pico- and nanosecond time scales. By subsequently hydrating the membranes with hydrogenated water, the QENS measurements on the same times scales reveal information about both the translational and rotational dynamics of water confined within the polyamide membrane. Further understanding of the water diffusion mechanism will establish design rules in which the performance of future membrane materials can be improved.

**4:18PM P42.00008 CO<sub>2</sub> adsorption in a hierarchically structured carbon by SANS**, LILIN HE, JITENDRA BAHADUR, YURI MELNICHENKO, CRISTIAN CONTESCU, NIDIA GALLEGO, Oak Ridge National Laboratory — This contribution investigated the high pressure adsorption behavior of CO<sub>2</sub> at T = 296 K in hierarchically structured carbon using small-angle neutron scattering (SANS) technique. We observed a strong densification of CO<sub>2</sub> in micropores accompanied by non-monotonic adsorption-induced pore deformation. Liquid-like density of CO<sub>2</sub> confined in the micropores was reached with increasing pressure to 20 bar, which corresponds to the relative pressure of  $P/P_{sat} \sim 0.3$ . At  $P > 20$  bar, density of confined CO<sub>2</sub> approached a plateau. The size of micropores first increases with pressure, reached a maximum at 20 bar, and then decreased with further increasing pressure. A complementary SANS experiment carried out on the same microporous carbon saturated with argon that is neutron-transparent and non-adsorbing inert shows no deformation of micropores at pressures up to  $\sim 200$  bars. This result proved that the observed deformation of micropores in CO<sub>2</sub> was an adsorption-induced phenomenon, caused by the solvation pressure - induced strain and strong densification of confined CO<sub>2</sub> in the micropores.

**4:30PM P42.00009 Characterization of nanoscale spatial distribution of small molecules in amorphous polymer matrices**, RALM RICARTE, MARC HILLMYER, TIMOTHY LODGE, University of Minnesota — Hydroxypropyl methylcellulose acetate succinate (HPMCAS) can significantly enhance the efficacy of active pharmaceutical ingredients (APIs). Yet, the interactions between species in HPMCAS-API blends are not understood. Elucidating these interactions is difficult because the spatial distributions of HPMCAS and API in the blends are ambiguous; the polymer and drug may be molecularly mixed or the species may form phase separated domains. As these phase separated domains may be less than 100 nm in size, traditional characterization techniques may not accurately evaluate the spatial distribution. To address this challenge, we explore the use of electron energy-loss spectroscopy (EELS) for detecting the model API phenytoin in an HPMCAS-phenytoin blend. Using EELS, we directly measured with high accuracy and precision the phenytoin concentrations in several blends. We present evidence that suggests phase separation occurs in blends that have a phenytoin loading of approximately 50 wt percent. Finally, we demonstrate that this technique achieves a sub-100 nm spatial resolution and can detect several other APIs.

**4:42PM P42.00010 Quantitative monitoring of membrane permeation via in-situ ATR FT-IR spectroscopy**<sup>1</sup>, BRYAN BECKINGHAM, Lawrence Berkeley National Laboratory; Auburn University, DANIEL MILLER, Lawrence Berkeley National Laboratory — Ion conducting membranes are of interest for various energy applications including fuel cells and artificial photosynthesis systems. Within the context of artificial photosynthesis, membranes are desired that facilitate the ion transport necessary to feed the electrochemical reactions while meeting various additional selectivity and permeability demands depending on the CO<sub>2</sub> reduction products. Herein, we demonstrate the use of in-situ ATR FT-IR spectroscopy to quantitatively resolve the concentration of single and multicomponent mixtures of various CO<sub>2</sub> reduction products including methanol, formate and acetate. We then apply this methodology to the in-situ monitoring of the permeation of single and multicomponent mixtures across commercially available membranes. Membrane permeabilities and selectivities calculated from the single component time-resolved concentration curves are compared to the multicomponent permeation experiments.

<sup>1</sup>This material is based upon work performed at the Joint Center for Artificial Photosynthesis, a DOE Energy Innovation Hub, supported through the Office of Science of the U.S. Department of Energy under Award Number DE-SC000493.

**4:54PM P42.00011 Transport of Water in Semicrystalline Block Copolymer Membranes**, DANIEL HALLINAN, ONYEKACHI OPARAJI, Florida State Univ — Poly(styrene)-block-poly(ethylene oxide) (PS-*b*-PEO) is a semicrystalline block copolymer (BCP) with interesting properties. It is mechanically tough, amphiphilic, and has a polar phase. The mechanical toughness is due to the crystallinity of PEO and the high glass transition temperature of PS, as well as the morphological structure of the BCP. The polymer has high CO<sub>2</sub>, water, and salt solubility that derive from the polar PEO component. Potential applications include CO<sub>2</sub> separation, water purification, and lithium air batteries. In all of the aforementioned applications, water transport is an important parameter. The presence of water can also affect thermal and mechanical properties. Water transport and thermal and mechanical properties of a lamellar PS-*b*-PEO copolymer have been measured as a function of water activity. Water transport can be affected by the heterogeneous nature of a semicrystalline BCP. Therefore, Fourier transform infrared - attenuated total reflectance (FTIR-ATR) spectroscopy has been employed, because water transport and polymer swelling can be measured simultaneously. The effect of BCP structure on transport has been investigated by comparing water transport in PS-*b*-PEO to a PEO homopolymer. The crystalline content of the PEO and the presence of glassy PS lamellae will be used to explain the transport results.

**5:06PM P42.00012 Elasticity dominated surface segregation of small molecules in polymer mixtures**, SALVATORE CROCE, Durham University, JAROSLAW KRAWCZYK, Durham University, Lodz University of Technology, TOM MCLEISH, BUDDHAPRIYA CHAKRABARTI, Durham University — When a binary polymer mixture with mobile components is left to equilibrate, the low molecular weight component migrates to the free surface. A balance between loss of translational entropy and gain in surface energy dictates the equilibrium partitioning ratio and the migrant fraction. Despite its ubiquity and several theoretical and experimental investigations, the phenomenon is not fully understood. Further, methods by which migration can be controlled are in its nascent stage of development. We propose a new phenomenological free energy functional that incorporates the elasticity of bulk polymer mixtures (reticulated networks and gels) and show (using mean field and self-consistent field theories) that the migrant fraction decreases with increasing the bulk modulus of the system. Further, a wetting transition observed otherwise for large values of miscibility parameter and polymerization index can be avoided by increasing the elastic modulus of the system. Estimated values of moduli (for the effect to be observable) are akin to those of rubbery polymers. Our work paves the way for controlling surface migration in complex industrial formulations with polymeric ingredients where this effect leads to decreased product stability and performance.

**5:18PM P42.00013 Anomalous Diffusion of Water in Lamellar Membranes Formed by Pluronic Polymers**<sup>1</sup>, ZHE ZHANG, Biology and Soft-Matter Division, Oak Ridge National Laboratory; Julich Center for Neutron Science., MICHAEL OHL, Oak Ridge National Laboratory; Julich Center for Neutron Science., YOUNGKYU HAN, GREGORY SMITH, CHANGWOO DO, Biology and Soft-Matter Division, Oak Ridge National Laboratory, BIOLOGY AND SOFT-MATTER DIVISION, OAK RIDGE NATIONAL LABORATORY TEAM, JULICH CENTER FOR NEUTRON SCIENCE TEAM — Water diffusion is playing an important role in polymer systems. We calculated the water diffusion coefficient at different layers along z-direction which is perpendicular to the lamellar membrane formed by Pluronic block copolymers (L62: (EO<sub>6</sub>-PO<sub>34</sub>-EO<sub>6</sub>)) with the molecular dynamics simulation trajectories. Water molecules at bulk layers are following the normal diffusion, while that at hydration layers formed by polyethylene oxide (PEO) and hydrophobic layers formed by polypropylene oxide (PPO) are following anomalous diffusion. We find that although the subdiffusive regimes at PEO layers and PPO layers are the same, which is the fractional Brownian motion, however, the dynamics are different, i.e. diffusion at the PEO layers is much faster than that at the PPO layers, and meanwhile it exhibits a normal diffusive approximation within a short time period which is governed by the localized free self-diffusion, but becomes subdiffusive after  $t > 8$  ps, which is governed by the viscoelastic medium.

Session P43 GSNP GSOF: Granular Materials 346 - Eric DeGiuli, cole Polytechnique Fdrale de Lausanne

**2:30PM P43.00001 A Phase Diagram Unifies Energy Dissipation, Kinetics, and Rheology in Inertial Granular Flows**, ERIC DEGIULI, Ecole Polytech Fed de Lausanne, JIM MCELWAINE, Durham University, MATTHIEU WYART, Ecole Polytech Fed de Lausanne — Flows of hard granular materials depend strongly on the interparticle friction coefficient  $\mu_p$  and on the inertial number  $I$ , which characterizes proximity to the jamming transition where flow stops. Guided by numerical simulations, we derive the phase diagram of dense inertial flow of spherical particles, finding three regimes for  $10^{-4} < I < 0.1$ : frictionless, frictional sliding, and rolling. These are distinguished by the dominant means of energy dissipation, changing from collisional to sliding friction, and back to collisional, as  $\mu_p$  increases from zero at constant  $I$ . The three regimes differ in their kinetics and rheology; in particular, the velocity fluctuations and the stress anisotropy both display non-monotonic behavior with  $\mu_p$ , corresponding to transitions between the three regimes of flow. We characterize the scaling properties of these regimes, show that energy balance yields scaling relations for each of them, and explain why friction qualitatively affects flow.

**2:42PM P43.00002 Enhanced Flow of Granular Material**, GEORGE MCMURDY, SCOTT FRANKLIN, CHARLES BACHMANN, Rochester Institute of Technology — We study a peculiar, anomalous weakening in wet sand brought about by the addition of small amounts of fine silt. The effect has been observed in uncontrolled field experiments, which we reproduce in the lab. Samples consist of sand from a local state park with a broad grain-size distribution between 300-600 microns, to which we add controlled amounts of silt, with a size distribution between 25-75 microns. Moisture contents range from 0-15% (by mass); we find our samples unable to hold much more than 15%. Samples are formed into free-standing cylinders and loaded from above until collapse. Mass fraction of silt varies from 0-20%, spanning the range observed in coastal sands. Results are compared with dynamic deflection moduli found in the field, and possible mechanisms are discussed.

**2:54PM P43.00003 Solid-liquid like phase transition in a confined granular suspension**, NARIAKI SAKAI, FREDERIC LECHENAULT, MOKHTAR ADDA BEDIA, Laboratoire de Physique Statistique - Ecole Normale Supérieure, Paris — We present an experimental study of a liquid-solid like phase transition in a two-dimensional granular media. Particles are placed in a vertical Hele-Shaw cell filled with a denser solution of cesium-chloride. Thus, when the cell is rotated around its axis, hydrostatic pressure exerts a centripetal force on the particles which confines them towards the center. This force is in competition with gravity, thus by modifying the rotation rate, it is possible to transform continuously and reversibly the sample from a disordered loose state to an ordered packed state. The system presents many similarities with thermal systems at equilibrium like density and interface fluctuations, and the transition between the two phases goes through a coexistence state, where there is nucleation and growth of locally ordered domains which are captured by the correlation function of the hexatic order parameter. We discuss the possibility to extend the grand-canonical formalism to out-of-equilibrium systems, in order to uncover a state equation between the density and the pressure in the medium.

**3:06PM P43.00004 Forces and Flows in Non-Newtonian Suspensions<sup>1</sup>**, MELODY LIM, JONATHAN BARES, ROBERT BEHRINGER, Duke University — Above a certain solid mass fraction, suspensions of dense granular particles in water exhibit non-Newtonian behavior, including impact-activated solidification. Although it has been suggested that solidification depends on interactions with the suspension boundary, quantitative experiments on the boundary forces have not been reported. In the present experiments, we determine the magnitude and timings of impactor-driven events in both the boundaries and body of the suspension using high-speed video, tracer particles, and photoelastic container boundaries. We observe a shock-like propagation in the cornstarch suspension during impact. The dynamics of the shockfront are strongly correlated to those of the intruder. We also observe a second extremely fast shockfront, associated with the propagation of forces to the boundaries of the suspension. The dynamics of this shockfront do not depend on the intruder dynamics, but are correlated to the volume fraction of cornstarch particles in the suspension. The observed shockfront propagates at a speed which is faster than the sound speed in the experiment container.

**3:18PM P43.00005 Cooling of 3D Granular Gases: Experiments in Microgravity<sup>1</sup>**, KIRSTEN HARTH, SANDRA WEGNER, TORSTEN TRITTEL, RALF STANNARIUS, Institute of Experimental Physics and MARS, Otto von Guericke University Magdeburg — Granular gases are ensembles of macroscopic grains, which move randomly and interact through inelastic collisions. This non-equilibrium statistical system is easy to picture, but still insufficiently understood. Numerous theoretical treatments have been performed, favorably with spherical grains and periodic boundaries, starting from a homogeneous state. Experimentally, such a gas in 3D can only be realized with strong external forcing or in microgravity. We have recently demonstrated that the use of elongated grains facilitates the realization of 3D experiments beyond the Knudsen regime (1). Main findings in a sounding rocket experiment were non-Gaussian velocity distributions and a violation of the equipartition of kinetic energy in the steady state. Rotational degrees of freedom are under-excited. When the excitation is stopped, energy is dissipated, the granular gas is "cooling". We present the first quantitative study of the cooling of a granular gas, based on a 3D data evaluation, from drop tower experiments. The evolution of the kinetic energy in translational and rotational degrees of freedom is compared to Haff's law and recent numerical studies. Additionally, we analyze velocity and density distributions. (1) K. Harth et al., Phys. Rev. Lett. 110 144102 (2013)

**3:30PM P43.00006 ABSTRACT WITHDRAWN —**

**3:42PM P43.00007 Flying in a sandstorm: granular flow dynamics around an intruder**, YASIN KARIM, ERIC CORWIN, University of Oregon — Using high-speed imaging and direct force measurements, we study the flow dynamics around an intruder in a quasi-two dimensional granular gas. We also vary the geometry of the intruder and explore how changing the curvature, for instance, affects the lift force. For a given angle of attack, an intruder with a straighter side facing the flow experiences higher lift than one with a more convex side. We use particle image velocimetry to measure flow fields and correlate them with our direct force measurements to elaborate on how granular gas flows respond to changes in intruder geometry.

**3:54PM P43.00008 Collisional Model of the Stopping Force of 3D Granular Impact<sup>1</sup>**, CACEY STEVENS, JONATHAN BARES, ROBERT BEHRINGER, Department of Physics, Duke University — A dense granular packing can cause a free-falling intruding object to come to an abrupt stop as its momentum is dissipated to the grains. An empirical force law has been widely accepted to describe this process; it characterizes the stopping force as the sum of depth-dependent friction and velocity-dependent inertial drag.<sup>2</sup> However, a complete interpretation of this force, incorporating grain-scale interactions during impact, remains unresolved. Here, the momentum transfer is proposed to occur through sporadic collisions with clusters of high force-carrying grains at the intruder's surface.<sup>3</sup> To test this model in 3D impact experiments, we determine the forces acting on an intruder decelerating through a dense granular medium using high-speed video of its trajectory. By attaching a rod to the intruder and observing its motion from perpendicular angles, we obtain all translational and rotational dynamics. We vary the shape of the impeding object to infer intruder-grain interactions from its consequent path. As a result, we connect the inertial drag to the effect of intruder shape and rotation based on the collisional model.

**4:06PM P43.00009 Real-time magnetic resonance imaging of highly dynamic granular phenomena**, ALEXANDER PENN, Laboratory for Energy Science and Engineering, ETH Zurich and Institute for Biomedical Engineering, University and ETH Zurich, KLAAS P. PRUESSMANN, Institute for Biomedical Engineering, University and ETH Zurich, CHRISTOPH MLLER, Laboratory for Energy Science and Engineering, ETH Zurich — Probing non-intrusively the interior of three-dimensional granular systems is a challenging task for which a number of imaging techniques have been applied including positron emission particle tracking, X-ray tomography and magnetic resonance imaging (MRI). A particular advantage of MRI is its versatility allowing quantitative velocimetry through phase contrast encoding and tagging, arbitrary slice orientations and the flexibility to trade spatial for temporal resolution and vice versa during image reconstruction. However, previous attempts to image granular systems using MRI were often limited to (pseudo-) steady state systems due to the poor temporal resolution of conventional imaging methodology. Here we present an experimental approach that overcomes previous limitations in temporal resolution by implementing a variety of methodological advances, viz. parallel data acquisition through tailored multiple receiver coils, fast gradient readouts for time-efficient data sampling and engineered granular materials that contain signal sources of high proton density. Achieving a spatial and temporal resolution of, respectively, 2 mm x 2 mm and 50 ms, we were able to image highly dynamic phenomena in granular media such as bubble coalescence and granular compaction waves.

**4:18PM P43.00010 Investigation of the effect of wall friction on the flow rate in 2D and 3D Granular Flow<sup>1</sup>**, BRENDA CARBALLO-RAMIREZ, MOLLIE PLEAU, NALINI EASWAR, Smith College, SUMIT BIRWA, TCIS Hyderabad, NEIL SHAH, SHUBHA TEWARI, University of Massachusetts — We have measured the mass flow rate of spherical steel spheres under gravity in vertical, straight-walled 2 and 3-dimensional hoppers, where the flow velocity is controlled by the opening size. Our measurements focus on the role of friction and its placement along the walls of the hopper. In the 2D case, an increase in the coefficient of static friction from  $\mu = 0.2$  to 0.6 is seen to decrease the flow rate significantly. We have changed the placement of frictional boundaries/regions from the front and back walls of the 2D hopper to the side walls and floor to investigate the relative importance of the different regions in determining the flow rate. Fits to the Beverloo equation show significant departure from the expected exponent of 1.5 in the case of 2D flow. In contrast, 3D flow rates do not show much dependence on wall friction and its placement. We compare the experimental data to numerical simulations of gravity driven hopper granular flow with varying frictional walls constructed using LAMMPS\*. \*<http://lammps.sandia.gov>

**4:30PM P43.00011 Normal coefficient of restitution of wet particles<sup>1</sup>** , KAI HUANG, THOMAS MUELLER, INGO REHBERG, Experimentalphysik V, University of Bayreuth — The normal coefficient of restitution (COR) for a spherical particle bouncing on a wet surface is investigated experimentally. The dependence of the COR on the impact velocity and various particle and liquid properties will be presented and discussed in terms of dimensionless numbers that characterize the interplay between inertial, viscous, and surface forces. At a fixed ratio of the liquid film thickness  $\delta$  to the particle diameter  $D$ , the wet COR is found to be inverse proportional to the Stokes number  $St$ , which measures the inertia of the particle to the viscous force from the liquid. This relation provides a convenient way of predicting wet COR with two fit parameters. For two different types of particles, we vary systematically the dimensionless film thickness  $\delta/D$  and discuss its influence on the fit parameters. Finally, we rationalize the observations with a model that considers possible sources of energy dissipation associated with a wet impact.

**4:42PM P43.00012 Long-term behavior of granular chains held between walls is really equilibrium.<sup>1</sup>** , MICHELLE PRZEDBORSKI, Brock University, SURAJIT SEN, State University of New York at Buffalo, THAD HARROUN, Brock University — Granular chains have been the focus of a number of studies, in part due to their numerous applications, ranging from shock absorption and vibration reduction to energy localization. Force impulses to an unloaded granular chain result in a propagating solitary wave (SW), analogous to a soliton of the Korteweg-de Vries equation. When SWs collide with a boundary or another SW, secondary solitary waves (SSWs) are produced as grains break contact. A consequence of this process is the transition from a non-ergodic, SW dominant, phase to the stable “quasi-equilibrium” (QE) phase, thought to be distinct from true thermodynamic equilibrium due to the absence of equipartitioning of energy. We show that, in the absence of energy dissipation, when granular systems are allowed to evolve to extremely long times, the number of SSWs becomes sufficiently large that the system actually approaches a true equilibrium phase. In this extreme-time limit, energy in fact becomes equipartitioned among all grains, and we illustrate how the specific heat and kinetic energy fluctuations can be predicted by the generalized equipartition theorem, regardless of the degree of the interaction potential. This opens up the possibility that granular systems should be treated by equilibrium statistical mechanics.

**4:54PM P43.00013 Experimental observations of root growth in a controlled photoelastic granular material** , SERGE MORA, JONATHAN BARES, LMGC Montpellier, JEAN-YVES DELENNE, INRA-UMR-IATE Montpellier, THIERRY FOURCAUD, CIRAD-UMR-AMAP Montpellier — The mechanism of root growth in soil is a key issue to understand both how to improve plant development and how to stabilize grounds. However, no experimental studies have been carried out to directly observe root development and surrounding stress while imposing specific grain configurations or mechanical loading. We present a novel set-up which permits to observe the development of chickpea root networks in a 2D granular material made of bidisperse photoelastic discs while imposing the position of the grains, the intergranular spacing and the nature of the system confinement: (i) open cell, (ii) confined cell (iii) sheared cell. In the experimental apparatus several root development cells are treated in parallel to increase the statistical meaning of the observations. Evolution of the root network is followed as well as position and pressure inside each disc by mean of a camera and classical photoelastic techniques. Preliminary results will be presented.

**5:06PM P43.00014 Topological interlocking provides stiffness to stochastically micro-cracked materials beyond the transport percolation limit.** , ANIRBAN PAL, CATALIN PICU, Department of Mechanical, Aerospace and Nuclear Engineering, Rensselaer Polytech Institute, MARIAN V. LUPULESCU, New York State Museum, Research and Collections — We study the mechanical behavior of two-dimensional, stochastically microcracked continua in the range of crack densities close to, and above the transport percolation threshold. We show that these materials retain stiffness up to crack densities much larger than the transport percolation threshold, due to topological interlocking of sample sub-domains. Even with a linear constitutive law for the continuum, the mechanical behavior becomes non-linear in the range of crack densities bounded by the transport and stiffness percolation thresholds. The effect is due to the fractal nature of the fragmentation process and is not linked to the roughness of individual cracks. We associate this behavior to that of itacolumite, a sandstone that exhibits unusual flexibility.

Session P44 GQI: Quantum Error Correction 347 - Jacob Taylor, University of Maryland / NIST

**2:30PM P44.00001 A universal fault-tolerant gate set for the 5-qubit quantum code** , THEODORE YODER, RYUJI TAKAGI, ISAAC CHUANG, Massachusetts Institute of Technology — While the smallest single-error correcting classical code encodes one bit in just three, the smallest such quantum code requires five qubits to protect one qubit. Yet, the 5-qubit quantum code is widely regarded as useless when it comes to encoded quantum computation, as it supports just one non-Pauli transversal gate, the  $K = SH$  gate where  $H$  is Hadamard and  $S$  is the phase gate. However, transversal gates, though convenient, are not all there is to fault-tolerant computation. Here we develop non-transversal, fault-tolerant logical gates for the 5-qubit quantum code, including logical controlled-Z (CZ) and logical controlled-controlled-Z (CCZ). With  $K$ , we can then create fault-tolerant CNOT and Toffoli gates. Together, logical Toffoli and  $K$  imply that the 5-qubit code is capable of universal, fault-tolerant quantum computation. Moreover, we achieve our results without magic states. Indeed, no ancillary qubits beyond those needed for error-correction are necessary in any of our fault-tolerant constructions. We also report fault-tolerance thresholds for our new gates, calculated by exact computer simulation. In some cases, our logical gates on the 5-qubit code have better thresholds than the analogous constructions on the next smallest quantum code, the 7-qubit code.

**2:42PM P44.00002 Quantum fault-tolerant thresholds for universal concatenated schemes** , CHRISTOPHER CHAMBERLAND, TOMAS JOCHYM-O'CONNOR, Institute for Quantum Computing, University of Waterloo, RAYMOND LAFLAMME, Institute for Quantum Computing, University of Waterloo, Perimeter Institute — Fault-tolerant quantum computation uses ancillary qubits in order to protect logical data qubits while allowing for the manipulation of the quantum information without severe losses in coherence. While different models for fault-tolerant quantum computation exist, determining the ancillary qubit overhead for competing schemes remains a challenging theoretical problem. In this work, we study the fault-tolerance threshold rates of different models for universal fault-tolerant quantum computation. Namely, we provide different threshold rates for the 105-qubit concatenated coding scheme for universal computation without the need for state distillation. We study two error models: adversarial noise and depolarizing noise and provide lower bounds for the threshold in each of these error regimes. Establishing the threshold rates for the concatenated coding scheme will allow for a physical quantum resource comparison between our fault-tolerant universal quantum computation model and the traditional model using magic state distillation.

**2:54PM P44.00003 Critical parameters of a noise model that affect fault tolerant quantum computation on a single qubit** , PAVITHRAN IYER, Univ of Sherbrooke, MARCUS P DA SILVA, Raytheon BBN Technologies, DAVID POULIN, Univ of Sherbrooke — In this work, we aim to determine the parameters of a single qubit channel that can tightly bound the logical error rate of the Steane code. We do not assume any a priori structure for the quantum channel, except that it is a CPTP map and we use a concatenated Steane code to encode a single qubit. Unlike the standard Monte Carlo technique that requires many iterations to estimate the logical error rate with sufficient accuracy, we use techniques to compute the complete effect of a physical CPTP map, at the logical level. Using this, we have studied the predictive power of several physical noise metrics on the logical error rate, and show, through numerical simulations with random quantum channels, that, on their own, none of the natural physical metrics lead to accurate predictions about the logical error rate. We then show how machine learning techniques help us to explore which features of a random quantum channel are important in predicting its logical error rate.

**3:06PM P44.00004 Doubled Color Codes** , SERGEY BRAVYI, IBM Watson Research Center — Combining protection from noise and computational universality is one of the biggest challenges in the fault-tolerant quantum computing. Topological stabilizer codes such as the 2D surface code can tolerate a high level of noise but implementing logical gates, especially non-Clifford ones, requires a prohibitively large overhead due to the need of state distillation. In this talk I will describe a new family of 2D quantum error correcting codes that enable a transversal implementation of all logical gates required for the universal quantum computing. Transversal logical gates (TLG) are encoded operations that can be realized by applying some single-qubit rotation to each physical qubit. TLG are highly desirable since they introduce no overhead and do not spread errors. It has been known before that a quantum code can have only a finite number of TLGs which rules out computational universality. Our scheme circumvents this no-go result by combining TLGs of two different quantum codes using the gauge-fixing method pioneered by Paetznick and Reichardt. The first code, closely related to the 2D color code, enables a transversal implementation of all single-qubit Clifford gates such as the Hadamard gate and the  $\pi/2$  phase shift. The second code that we call a doubled color code provides a transversal T-gate, where T is the  $\pi/4$  phase shift. The Clifford+T gate set is known to be computationally universal. The two codes can be laid out on the honeycomb lattice with two qubits per site such that the code conversion requires parity measurements for six-qubit Pauli operators supported on faces of the lattice. I will also describe numerical simulations of logical Clifford+T circuits encoded by the distance-3 doubled color code. Based on a joint work with Andrew Cross.

**3:42PM P44.00005 Efficiently simulable approximations to realistic incoherent and coherent errors and their application to threshold estimation** , MAURICIO GUTIERREZ, KENNETH BROWN, Georgia Institute of Technology — Classical simulations of noisy stabilizer circuits are often used to estimate the threshold of a quantum error-correcting code (QECC). It is not completely clear how sensitive a code's threshold is to the error model, and whether or not a Pauli channel (PC) is a good approximation for realistic non-stabilizer errors. Within the stabilizer formalism, it has been shown that for a single qubit more accurate approximations can be obtained by expanding the PC. We now examine the feasibility of employing these error approximations at the single-qubit level to obtain better estimates of a QECC's threshold. We calculate the level-1 pseudo-threshold for the Steane  $[[7,1,3]]$  code for several error models. At the logical level, the Pauli twirled channel (PTC) provides an extremely accurate approximation for incoherent channels. However, for coherent channels, the PTC severely underestimates the magnitude of the error. By computing the effective 1-qubit process matrix for the whole circuit at low error rates, it becomes clear that this behavior is due to the stronger persistence of off-diagonal entries in the coherent channels. Therefore, if the main source of error in the quantum system is coherent, reliable stabilizer simulations should employ expanded Clifford channels.

**3:54PM P44.00006 Decoder for 3-D color codes** , KUNG-CHUAN HSU, TODD BRUN, University of Southern California — Transversal circuits are important components of fault-tolerant quantum computation. Several classes of quantum error-correcting codes are known to have transversal implementations of any logical Clifford operation. However, to achieve universal quantum computation, it would be helpful to have high-performance error-correcting codes that have a transversal implementation of some logical non-Clifford operation. The 3-D color codes<sup>1</sup> are a class of topological codes that permit transversal implementation of the logical  $\pi/8$ -gate. The decoding problem of a 3-D color code can be understood as a graph-matching problem on a three-dimensional lattice. Whether this class of codes will be useful in terms of performance is still an open question. We investigate the decoding problem of 3-D color codes and analyze the performance of some possible decoders.

<sup>1</sup>H. Bombín, New J. Phys. **17**, 083002 (2015).

**4:06PM P44.00007 High-threshold decoding algorithms for the gauge color code** , WILLIAM ZENG, Rigetti Computing, BENJAMIN BROWN, Niels Bohr Institute, University of Copenhagen — Gauge color codes are topological quantum error correcting codes on three dimensional lattices. They have garnered recent interest due to two important properties: (1) they admit a universal transversal gate set, and (2) their structure allows reliable error correction using syndrome data obtained from a measurement circuit of constant depth. Both of these properties make gauge color codes intriguing candidates for low overhead fault-tolerant quantum computation. Recent work by Brown et al. calculated a threshold of 0.31% for a particular gauge color code lattice using a simple clustering decoder and phenomenological noise. We show that we can achieve improved threshold error rates using the efficient Wootton and Loss Markov-chain Monte Carlo (MCMC) decoding. In the case of the surface code, the MCMC decoder produced a threshold close to that code's upper bound. While no upper bound is known for gauge color codes, the thresholds we present here may give a better estimate.

**4:18PM P44.00008 ABSTRACT WITHDRAWN —**

**4:30PM P44.00009 Potts glass reflection of the decoding threshold for qudit quantum error correcting codes<sup>1</sup>** , YI JIANG, University of California, Riverside, ALEXEY A. KOVALEV, University of Nebraska—Lincoln, LEONID P. PRYADKO, University of California, Riverside — We map the maximum likelihood decoding threshold for qudit quantum error correcting codes to the multicritical point in generalized Potts gauge glass models, extending the map constructed previously for qubit codes [1]. An  $n$ -qudit quantum LDPC code, where a qudit can be involved in up to  $m$  stabilizer generators, corresponds to a  $\mathbb{Z}_d$  Potts model with  $n$  interaction terms which can couple up to  $m$  spins each. We analyze general properties of the phase diagram of the constructed model, give several bounds on the location of the transitions, bounds on the energy density of extended defects (non-local analogs of domain walls), and discuss the correlation functions which can be used to distinguish different phases in the original and the dual models.

**4:42PM P44.00010 Fault-tolerant quantum computation in multiqubit block codes: performance and overhead**<sup>1</sup>, TODD BRUN, Univ of Southern California — Fault-tolerant quantum computation requires that quantum information remain encoded in a quantum error-correcting code at all times; that a universal set of logical unitary gates and measurements is available; and that the probability of an uncorrectable error is low for the duration of the computation. Quantum computation can in principle be scaled up to unlimited size if the rate of decoherence is below a threshold. The main constructions that have been studied involve encoding each logical qubit in a separate block (either a concatenated code or a block of the surface code), which typically requires thousands of physical qubits per logical qubit, if not more. To reduce this overhead, we consider using multiqubit codes to achieve much higher storage rates. We estimate performance and overhead for certain families of codes, and ask: how large a quantum computation can be done as a function of the decoherence rate for a fixed size code block? Finally, we consider remaining open questions and limitations to this approach.

<sup>1</sup>This work is supported by NSF Grant No. CCF-1421078.

**4:54PM P44.00011 Numerical Simulation of Coherent Error Correction**, DANIEL CROW, ROBERT JOYNT, MARK SAFFMAN, Univ of Wisconsin, Madison — A major goal in quantum computation is the implementation of error correction to produce a logical qubit with an error rate lower than that of the underlying physical qubits. Recent experimental progress demonstrates physical qubits can achieve error rates sufficiently low for error correction, particularly for codes with relatively high thresholds such as the surface code and color code. Motivated by experimental capabilities of neutral atom systems, we use numerical simulation to investigate whether coherent error correction can be effectively used with the 7-qubit color code. The results indicate that coherent error correction does not work at the 10-qubit level in neutral atom array quantum computers. By adding more qubits there is a possibility of making the encoding circuits fault-tolerant which could improve performance.

**5:06PM P44.00012 Noise Estimation and Adaptive Encoding for Asymmetric Quantum Error Correcting Codes**<sup>1</sup>, JAN FLORJANCZYK, TODD BRUN, Univ of Southern California, CENTER FOR QUANTUM INFORMATION SCIENCE AND TECHNOLOGY TEAM — We present a technique that improves the performance of asymmetric quantum error correcting codes in the presence of biased qubit noise channels. Our study is motivated by considering what useful information can be learned from the statistics of syndrome measurements in stabilizer quantum error correcting codes (QECC). We consider the case of a qubit dephasing channel where the dephasing axis is unknown and time-varying. We are able to estimate the dephasing angle from the statistics of the standard syndrome measurements used in stabilizer QECC's. We use this estimate to rotate the computational basis of the code in such a way that the most likely type of error is covered by the highest distance of the asymmetric code. In particular, we use the  $[[15, 1, 3]]$  shortened Reed-Muller code which can correct one phase-flip error but up to three bit-flip errors. In our simulations, we tune the computational basis to match the estimated dephasing axis which in turn leads to a decrease in the probability of a phase-flip error. With a sufficiently accurate estimate of the dephasing axis, our memory's effective error is dominated by the much lower probability of four bit-flips.

**5:18PM P44.00013 Details of  $[[7,1,3]]$  Syndrome Measurements**, YAAKOV WEINSTEIN, MITRE — We explore different aspects of syndrome measurements (SM) for the  $[[7,1,3]]$  quantum error correction code. This includes determining how often to apply SM, comparing the performance of different SM, rearranging the order in which SM are applied, and exploring the effects of improving SM ancilla state construction. Finally, we attempt to formulate gates and their attached SM as superoperators.

## Wednesday, March 16, 2016 2:30PM - 5:30PM –

Session P45 GQI: Semiconductor Qubits: Quantum Dot / Donor Devices and Readout 348 - John Gamble, Sandia National Laboratory

**2:30PM P45.00001 Nuclear-driven electron spin rotations in a coupled silicon quantum dot and single donor system**, PATRICK HARVEY-COLLARD, Univ of Sherbrooke, NOAH TOBIAS JACOBSON, MARTIN RUDOLPH, GREGORY A. TEN EYCK, JOEL R. WENDT, TAMMY PLUYM, MICHAEL P. LILLY, Sandia National Laboratories, MICHEL PIORO-LADRIRE, Univ of Sherbrooke, MALCOLM S. CARROLL, Sandia National Laboratories — Single donors in silicon are very good qubits. However, a central challenge is to couple them to one another. To achieve this, many proposals rely on using a nearby quantum dot (QD) to mediate an interaction. In this work, we demonstrate the coherent coupling of electron spins between a single  $^{31}\text{P}$  donor and an enriched  $^{28}\text{Si}$  metal-oxide-semiconductor few-electron QD. We show that the electron-nuclear spin interaction can drive coherent rotations between singlet and triplet electron spin states. Moreover, we are able to tune electrically the exchange interaction between the QD and donor electrons. The combination of single-nucleus-driven rotations and voltage-tunable exchange provides all elements for future all-electrical control of a spin qubit, and requires only a single dot and no additional magnetic field gradients. This work was performed, in part, at the Center for Integrated Nanotechnologies, an Office of Science User Facility operated for the U.S. Department of Energy (DOE) Office of Science. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. DOE's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**2:42PM P45.00002 All-electrical control of a singlet-triplet qubit coupled to a single nuclear spin**<sup>1</sup>, N. TOBIAS JACOBSON, Sandia National Laboratories, PATRICK HARVEY-COLLARD, Sandia National Laboratories and Universite de Sherbrooke, ANDREW BACZEWSKI, JOHN GAMBLE, MARTIN RUDOLPH, ERIK NIELSEN, RICHARD MULLER, MALCOLM CARROLL, Sandia National Laboratories — Donor nuclear spins in isotopically purified silicon have very long coherence times, suggesting that they may form high-quality quantum memories. We propose that coupling these nuclear spins to few-electron quantum dots could enable nuclear spin readout and two-qubit operations of the joint quantum dot and nuclear spin system without the need for electron spin resonance. As a step towards this goal, our group recently demonstrated coherent singlet/triplet electron spin rotations induced by the hyperfine interaction between electronic spin degrees of freedom and a single nuclear spin in isotopically purified silicon. In this talk, I will discuss the feasibility of universal all-electrical control of such a singlet/triplet electron spin qubit and explore the decoherence mechanisms that we expect to dominate. Finally, I will examine the relative merits of AC and pulsed DC gating schemes.

<sup>1</sup>Sandia is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the US Department of Energy National Nuclear Security Administration under Contract No. DE-AC04- 94AL85000.

**2:54PM P45.00003 Full Controllability of a Singlet-Triplet Qubit Coupled to a Nuclear Spin Qubit**, ANDREW D. BACZEWSKI, JOHN KING GAMBLE, N. TOBIAS JACOBSON, RICHARD P. MULLER, ERIK NIELSEN, STEPHEN M. CARR, MALCOLM S. CARROLL, Sandia National Laboratories, MATTHEW CURRY, Sandia National Laboratories and University of New Mexico, PATRICK HARVEY-COLLARD, Sandia National Laboratories and Universit  de Sherbrooke, RYAN M. JOCK, MARTIN RUDOLPH, Sandia National Laboratories — Recent experimental developments indicate that it is possible to drive coherent singlet-triplet rotations in a MOS quantum dot coupled to a single nearby phosphorus donor through the electron-nucleus hyperfine interaction. With the addition of NMR, we propose that it is possible to achieve universal 2-qubit control spanning i.) an electronic singlet-triplet subspace of the dot, ii.) the spin-1/2 donor nucleus, and iii.) entangling operations between them. We will assess the practicality of such an approach given realistic experimental conditions and constraints, including a comparison of pulsed and RF control of the detuning between the donor and dot. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Security Administration under contract DE-AC04-94AL85000.

**3:06PM P45.00004 Transport through an impurity tunnel coupled to a Si/SiGe quantum dot**, RYAN H. FOOTE, DANIEL R. WARD, University of Wisconsin-Madison, J.R. PRANCE, Lancaster University, JOHN KING GAMBLE, ERIK NIELSEN, Sandia National Laboratories, BRANDUR THORGRIMSSON, D.E. SAVAGE, University of Wisconsin-Madison, A.L. SARAIVA, Universidade Federal do Rio de Janeiro, MARK FRIESEN, S.N. COPPERSMITH, M.A. ERIKSSON, University of Wisconsin-Madison — Here we present measurements of transport through a gate-defined quantum dot formed in a Si/SiGe heterostructure, demonstrating controllable tunnel coupling between the quantum dot and a localized electronic state.<sup>1</sup> Combining experimental stability diagram measurements with 3D capacitive modeling based on the expected electron density profiles, we determine the most likely location of the localized state in the quantum well. <sup>1</sup>Ryan H. Foote *et al.*, *Appl. Phys. Lett.* **107**, 103112 (2015)

**3:18PM P45.00005 Silicon quantum dots with counted antimony donor implants**, MEENAKSHI SINGH, JOSE PACHECO, DANIEL PERRY, JOEL WENDT, RONALD MANGINELL, JASON DOMINGUEZ, TAMMY PLUYM, DWIGHT LUHMAN, EDWARD BIELEJEC, MICHAEL LILLY, MALCOLM CARROLL, Sandia National Laboratory — Antimony donor implants next to silicon quantum dots have been detected with integrated solid-state diode detectors with single ion precision. Devices with counted number of donors have been fabricated and low temperature transport measurements have been performed. Charge offsets, indicative of donor ionization and coupling to the quantum dot, have been detected in these devices. The number of offsets corresponds to 10-50% of the number of donors counted. We will report on tunneling time measurements and spin readout measurements on the donor offsets. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE Office of Basic Energy Sciences user facility. The work was supported by Sandia National Laboratories Directed Research and Development Program. Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a Lockheed-Martin Company, for the U. S. Department of Energy under Contract No. DE-AC04-94AL85000.

**3:30PM P45.00006 Detection of ion implanted patterns in silicon using STM**, HYUN-SOO KIM, Univ of Maryland-College Park, A.N. RAMANAYAKA, Joint Quantum Institute, Univ of Maryland-College Park, K.J. DWYER, Univ of Maryland-College Park, M.D. STEWART JR., J.M. POMEROY, National Institute of Standards and Technology — Ion implanted regions in silicon are scanned using STM to detect features which will facilitate in-situ overlay and alignment of STM hydrogen patterned nano-devices. STM hydrogen lithography is used to make atomically precise devices such as single electron transistors and single atom qubits. However, with currently available imaging techniques, we are limited to make devices on a single plane using STM lithography. In-situ detection of high local doping concentrations using STM will allow precise alignment between the multiple layers of buried nano-devices and metal electrodes.

**3:42PM P45.00007 Atomistic simulations of negatively charged donor states probed in STM experiments**, ARCHANA TANKASALA, Purdue University, USA, JOE SALFI, SVEN ROGGE, CQCCT, University of New South Wales, Australia, GERHARD KLIMECK, RAJIB RAHMAN, Purdue University, USA — A single donor in silicon binding two electrons ( $D^-$ ) is important for electron spin readout and two-qubit operations in a donor based silicon (Si) quantum computer, and has recently been probed in Scanning Tunneling Microscope (STM) experiments for sub-surface dopants. In this work, atomistic configuration interaction technique is used to compute the two-electron states of the donor taking into account the geometry of the STM-vacuum-silicon-reservoir device. While 45 meV charging energy is obtained for  $D^-$  in bulk Si, the electrostatics of the device reduces the charging energy to ~30 meVs. It is also shown that the reduced charging energy enables spin triplet states to be bound to the donor. The exchange splitting between the singlet and triplet states can be tuned by an external electric field. The computed wavefunctions of the  $D^-$  state helps to understand how the contribution of the momentum space valley states change with donor depth and electric field.

**3:54PM P45.00008 Atomic Precision Donor Devices Fabricated on Strained Silicon on Insulator (sSOI) with SiGe**, E. YITAMBEN, E. BUSSMANN, D.A. SCRYMGEOUR, M. RUDOLPH, S.M. CARR, D.R. WARD, M.S. CARROLL, Sandia National Laboratories — Recently, Si:P donor spin qubits have achieved coherence times (nuclear & e-) that underscore their quantum computing potential. One next major challenge is to integrate donors into a gated structure where electrons can be moved between P, or drawn off of the P to interact, e.g. to an interface as in Kane's proposal. A key constraint is limited thermal budget, to limit P thermal segregation, which precludes typical gate oxidation of Si. We are developing an alternative materials stack utilizing an interfacial barrier layer of relaxed epitaxial SiGe, with donors placed in a strained Si-on-insulator (sSOI) substrate. We fabricate atomic precision donor structures in sSOI via STM hydrogen lithography. Utilizing Si microfabrication and STM in tandem with our Si and Ge molecular beam epitaxy (MBE), we fabricated devices to test our SiGe/sSOI stack concept and atomic-precision fab techniques. To establish our donor-doping capability, we made Hall and Van der Pauw devices in P:sSOI delta-doped layers exhibiting  $n_e > 10^{14}/\text{cm}^2$  and mobilities of  $\sim 100 \text{ cm}^2/\text{Vs}$  ( $T=4\text{K}$ ) similar to results reported relaxed Si reported elsewhere. Second, we have grown our concept epitaxial SiGe/sSOI stack, evaluated the morphology using STM, and fabricated Hall devices to evaluate low-T transport in our first SiGe/sSOI. Here, we report on these advances in atomic precision donor fab, along with STM analysis our MBE SiGe/sSOI. This work extends STM-based atom precision fab on strained Si toward a vertically gated architecture.

#### 4:06PM P45.00009 Low-frequency conductance fluctuations in Si:P and Ge:P $\delta$ -layers , SAQUIB

SHAMIM, Department of Physics, Indian Institute of Science, Bangalore 560 012, India, SUDDHASATTA MAHAPATRA, GIORDANO SCAPPUCCI<sup>1</sup>, W. M. KLESSE, MICHELLE Y. SIMMONS, Centre for Quantum Computation and Communication Technology, University of New South Wales, Sydney NSW 2052, Australia, ARINDAM GHOSH, Department of Physics, Indian Institute of Science, Bangalore 560 012, India — Delta doped Si:P and Ge:P devices offer a formidable platform for application towards quantum computation. The fabrication of single donor devices by STM-lithography takes us forward to address the solid state quantum bits. The atomic scale control however makes the devices extremely sensitive to fluctuations and disorder which affect their long term stability. Hence, a study of low frequency  $1/f$  noise for these devices is desirable. We measure  $1/f$  noise in Si:P and Ge:P  $\delta$ -layers of varying doping density. Fluctuations in conductivity arise due to fluctuations in mobility and the Hooge parameter scales inversely with mobility as  $1/\mu^3$  for all devices. For highly doped Ge:P  $\delta$ -layer, the noise magnitude in a perpendicular magnetic field ( $B_{\perp}$ ) reduces by factors of two at the phase breaking field and the Zeeman field indicating universal conductance fluctuations (UCF). The phase breaking length  $l_{\phi}^{UCF}$  extracted by fitting the  $B_{\perp}$  dependence of noise to the crossover function matches well with  $l_{\phi}^{WL}$  extracted from weak localization (WL) fits to magnetoconductivity indicating that both UCF and WL are governed by same scattering rates.

#### 4:18PM P45.00010 Weak measurement and quantum steering of spin qubits in silicon , ANDREA

MORELLO, JUHA MUHONEN<sup>1</sup>, STEPHANIE SIMMONS<sup>2</sup>, SOLOMON FREER, JUAN DEHOLLAIN, UNSW Australia, JEFFREY MCCALLUM, DAVID JAMIESON, Univ Melbourne, KOHEI ITOH, Keio University, ANDREW DZURAK, UNSW Australia — Single-shot, projective measurements have been demonstrated with very high fidelities on both the electron [1] and the nuclear [2] spin of single implanted phosphorus (<sup>31</sup>P) donors in silicon. Here we present a series of experiments where the measurement strength is continuously reduced, giving access to the regime of weak measurement of single spins. For the electron qubit, the measurement strength is set by the measurement time compared to the spin-dependent tunneling time between the <sup>31</sup>P donor and a charge reservoir. For the nuclear qubit, the measurement strength is set by the rotation angle of an ESR pulse.

We have demonstrated quantum steering of the spin states, with curious and useful applications. We can improve the fidelity of electron qubit initialization by steering it towards the ground state, thus bypassing thermal effects on the initialization process. We can also accurately measure the electron-reservoir tunnel coupling, without the electron ever tunneling away from the <sup>31</sup>P atom. Finally, these techniques allow the study of weak values and Leggett-Garg inequalities.

#### 4:30PM P45.00011 Single-Shot Charge Readout Using a Cryogenic Heterojunction Bipolar Transistor Preamplifier Inline with a Silicon Single Electron Transistor at Millikelvin Temperatures<sup>1</sup> , MATTHEW CURRY, University of New Mexico, TROY ENGLAND, JOEL WENDT, TAMMY PLUYM, MICHAEL LILLY, STEPHEN

CARR, MALCOLM CARROLL, Sandia National Laboratories — Single-shot readout is a requirement for many implementations of quantum information processing. The single-shot readout fidelity is dependent on the signal-to-noise-ratio (SNR) and bandwidth of the readout detection technique. Several different approaches are being pursued to enhance read-out including RF-reflectometry, RF-transmission, parametric amplification, and transistor-based cryogenic preamplification. The transistor-based cryogenic preamplifier is attractive in part because of the reduced experimental complexity compared with the RF techniques. Here we present single-shot charge readout using a cryogenic Heterojunction-Bipolar-Transistor (HBT) inline with a silicon SET charge-sensor at millikelvin temperatures. For the relevant range of HBT DC-biasing, the current gain is 100 to 2000 and the power dissipation is 50 nW to 5  $\mu$ W, with the microfabricated SET and discrete HBT in an integrated package mounted to the mixing chamber stage of a dilution refrigerator. We experimentally demonstrate a SNR of up to 10 with a bandwidth of 1 MHz, corresponding to a single-shot time-domain charge-sensitivity of approximately  $10^{-4}$   $e/\sqrt{\text{Hz}}$ . This measured charge-sensitivity is comparable to the values reported using the RF techniques.

<sup>1</sup>Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a Lockheed-Martin Company, for the U. S. Department of Energy under Contract No. DE-AC04-94AL85000.

#### 4:42PM P45.00012 Flexible Low-power SiGe HBT Amplifier Circuits for Fast Single-shot Spin Readout<sup>1</sup> , TROY ENGLAND, MICHAEL LILLY, Sandia National Labs, MATTHEW CURRY, CQuIC and the Dept. of Physics and Astronomy, University

of New Mexico, STEPHEN CARR, MALCOLM CARROLL, Sandia National Labs — Fast, low-power quantum state readout is one of many challenges facing quantum information processing. Single electron transistors (SETs) are potentially fast, sensitive detectors for performing spin readout of electrons bound to Si:P donors. From a circuit perspective, however, their output impedance and nonlinear conductance are ill suited to drive the parasitic capacitance of coaxial conductors used in cryogenic environments, necessitating a cryogenic amplification stage. We will introduce two new amplifier topologies that provide excellent gain versus power tradeoffs using silicon-germanium (SiGe) heterojunction bipolar transistors (HBTs). The AC HBT allows in-situ adjustment of power dissipation during an experiment and can provide gain in the millikelvin temperature regime while dissipating less than 500 nW. The AC Current Amplifier maximizes gain at nearly 800 A/A. We will also show results of using these amplifiers with SETs at 4 K. This work was performed, in part, at the Center for Integrated Nanotechnologies, a U.S. DOE Office of Basic Energy Sciences user facility. Sandia National Laboratories is a multi-program laboratory operated by Sandia Corporation, a Lockheed-Martin Company, for the U. S. Department of Energy under Contract No. DE-AC04-94AL85000.

<sup>1</sup>Flexible Low-power SiGe HBT Amplifier Circuits for Fast Single-shot Spin Readout

#### 4:54PM P45.00013 Dispersively Detected Pauli Spin-Blockade in a Silicon Nanowire Field-Effect Transistor , ANDREAS BETZ, Hitachi Cambridge Laboratory, Cambridge, UK, R WACQUEZ, M. VINET, X. JEHL, CEA-LETI, Grenoble,

France, A.L. SARAIVA, Universidade Federal do Rio de Janeiro, Brasil, M. SANQUER, CEA-LETI, Grenoble, France, A.J. FERGUSON, Cavendish Laboratory, Cambridge, UK, M.F. GONZALEZ-ZALBA, Hitachi Cambridge Laboratory, Cambridge, UK — We report the dispersive readout of the spin state of a double quantum dot (DQD) formed at the corner states of a silicon nanowire FET. Two face-to-face topgate electrodes allow us to independently tune the charge occupation of the quantum dot system down to the few-electron limit. We measure the charge stability of the DQD in DC transport as well as dispersively via in situ gate-based radio frequency (rf) reflectometry, where one top-gate electrode is connected to a resonator. The latter removes the need for external charge sensors in quantum computing architectures and provides a compact way to readout the dispersive shift caused by changes in the quantum capacitance during inter-dot charge transitions. Here, we observe Pauli spin-blockade in the rf response of the circuit at finite magnetic fields between singlet and triplet states. The blockade is lifted at higher magnetic fields when intra-dot triplet states become the ground state configuration. A line shape analysis of the dispersive signal reveals furthermore an intra-dot valley-orbit splitting  $\Delta_{vo} \simeq 145 \mu\text{eV}$ . Our results open up the possibility to operate compact CMOS technology as a singlet-triplet qubit and make split-gate silicon nanowire architectures an ideal candidate for the study of spin dynamics.

**5:06PM P45.00014 Characterization and Monte Carlo simulation of single ion Geiger mode avalanche diodes integrated with a quantum dot nanostructure** , PETER SHARMA, J. B. S. ABRAHAM, G. TEN EYCK, K. D. CHILDS, E. BIELEJEC, M. S. CARROLL, Sandia National Laboratories — Detection of single ion implantation within a nanostructure is necessary for the high yield fabrication of implanted donor-based quantum computing architectures. Single ion Geiger mode avalanche (SIGMA) diodes with a laterally integrated nanostructure capable of forming a quantum dot were fabricated and characterized using photon pulses. The detection efficiency of this design was measured as a function of wavelength, lateral position, and for varying delay times between the photon pulse and the overbias detection window. Monte Carlo simulations based only on the random diffusion of photo-generated carriers and the geometrical placement of the avalanche region agrees qualitatively with device characterization. Based on these results, SIGMA detection efficiency appears to be determined solely by the diffusion of photo-generated electron-hole pairs into a buried avalanche region. Device performance is then highly dependent on the uniformity of the underlying silicon substrate and the proximity of photo-generated carriers to the silicon-silicon dioxide interface, which are the most important limiting factors for reaching the single ion detection limit with SIGMA detectors. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**5:18PM P45.00015 Joint measurement of electron spin qubits via proximal conductance<sup>1</sup>** , JASON KESTNER, Department of Physics, UMBC — We propose a method to carry out joint measurements on spin qubits that are separated by several microns. Joint measurements, which reveal multi-qubit properties without determining anything about the individual qubits, are a key ingredient to performing quantum error correction and to producing measurement-based entanglement of non-interacting qubits. We presume that the qubits are capacitively coupled to a common conductance channel and are separated by a distance less than the phase coherence length of the semiconductor, and we calculate the tolerance of the procedure to various experimental imperfections. Conditions for carrying out  $N$ -qubit syndrome measurements are discussed.

<sup>1</sup>Support provided by UMBC Office of Research through an SRAIS award.

**2:42PM P46.00002 Orbital-free *ab initio* molecular dynamics study of the free liquid surface of Cd.** , BEATRIZ GONZALEZ DEL RIO, LUIS ENRIQUE GONZALEZ TESEDO, Fisica Teorica, Atomica y Optica, Universidad de Valladolid — We report results of an orbital-free *ab initio* molecular dynamics (OF-AIMD) study of the free liquid surface of Cd at 800 K. A key ingredient in the OF-AIMD method is the local ionic pseudopotential describing the ions-valence electrons interaction. We have developed a force-matching method [1] to derive a local ionic pseudopotential suitable to account for a rapidly varying density system, such as a free liquid surface. Results are reported for several structural properties. The calculated reflectivity shows a marked maximum whose origin is related to the surface layering, along with a shoulder located at a much smaller wavevector transfer. [1] B. G. del Rio and L. E. Gonzalez, J. Phys.: Condens. Matter **26**, 465102 (2014)

**2:54PM P46.00003 A parametric study of surface roughness and bonding mechanisms of aluminum alloys with epoxies: a molecular dynamics simulation.<sup>1</sup>** , RAJENDRA TIMILSINA, STEPHANIE TERMAATH, Univ of Tennessee, Knoxville — The marine environment is highly aggressive towards most materials. However, aluminium-magnesium alloys (Al-Mg, specifically, 5xxx series) have exceptionally long service life in such aggressive marine environments. For instance, an Al-Mg alloy, AA5083, is extensively used in naval structures because of its good mechanical strength, formability, seawater corrosion resistance and weldability. However, bonding mechanisms of these alloys with epoxies in a rough surface environment are not fully understood yet. It requires a rigorous investigation at molecular or atomic levels. We performed a molecular dynamics simulation to study an adherend surface preparation and surface bonding mechanisms of Al-Mg alloy (AA5083) with different epoxies by developing several computer models. Various distributions of surface roughness are introduced in the models and performed molecular dynamics simulations. Formation of a beta phase (Al<sub>3</sub>Mg<sub>2</sub>), microstructures, bonding energies at the interface, bonding strengths and durability are investigated.

**3:06PM P46.00004 ABSTRACT WITHDRAWN —**

**3:18PM P46.00005 Viscoelastic damping in crystalline composites and alloys** , RAGHAVAN RANGANATHAN, RAHMI OZISIK, PAWEL KEBLINSKI, Rensselaer Polytech Inst — We use molecular dynamics simulations to study viscoelastic behavior of model Lennard-Jones (LJ) crystalline composites subject to an oscillatory shear deformation. The two crystals, namely a soft and a stiff phase, individually show highly elastic behavior and a very small loss modulus. On the other hand, when the stiff phase is included within the soft matrix as a sphere, the composite exhibits significant viscoelastic damping and a large phase shift between stress and strain. In fact, the maximum loss modulus in these model composites was found to be about 20 times greater than that given by the theoretical Hashin-Shtrikman upper bound. We attribute this behavior to the fact that in composites shear strain is highly inhomogeneous and mostly accommodated by the soft phase, corroborated by frequency-dependent Grüneisen parameter analysis. Interestingly, the frequency at which the damping is greatest scales with the microstructural length scale of the composite. Finally, a critical comparison between damping properties of these composites with ordered and disordered alloys and superlattice structures is made.

**3:30PM P46.00006 A general and predictive model of anisotropic grain boundary energy and morphology for polycrystal-level simulations** , BRANDON RUNNELS, University of Colorado Colorado Springs, IRENE BEYERLEIN, Los Alamos National Laboratory, SERGIO CONTI, University of Bonn, MICHAEL ORTIZ, California Institute of Technology — In this work, a new model for anisotropic GB energy and morphology is formulated that is fast, general, dependent on only three material parameters, and is verified by comparison with more than 40 MD and experimental datasets for (a)symmetric, tilt/twist, FCC/BCC materials, as well as experimental measurements. A relaxation algorithm is presented that is able to efficiently compute the optimal facet pattern and corresponding relaxed energy. Finally, the GB model is implemented as an interface model in a polycrystal simulation to observe the effects of GB in conjunction with elastic and plastic deformation. The simulations are compared with those using an isotropic GB model, and the effect of the GB isotropy on the bulk properties and microstructure is determined. The results have applications towards, e.g., improved polycrystal simulations, understanding void nucleation, and GB engineering.

**3:42PM P46.00007 Atomic-Scale Imprinting into Amorphous Metals**, UDO SCHWARZ, RUI LI, GEORG SIMON, EMELY KINSER, ZE LIU, ZHENG CHEN, CHAO ZHOU, JONATHAN SINGER, CHINEDUM OSUJI, JAN SCHROERS, Yale University — Nanoimprinting by thermoplastic forming (TPF) has attracted significant attention in recent years due to its promise of low-cost fabrication of nanostructured devices. Usually performed using polymers, amorphous metals have been identified as a material class that might be even better suited for nanoimprinting due to a combination of mechanical properties and processing ability. Commonly referred to as metallic glasses, their featureless atomic structure suggests that there may not be an intrinsic size limit to the material's ability to replicate a mold. To study this hypothesis, we demonstrate atomic-scale imprinting into amorphous metals by TPF under ambient conditions. Atomic step edges of a SrTiO<sub>3</sub> (STO) single crystal used as mold were successfully imprinted into Pt-based bulk metallic glasses (BMGs) with high fidelity. Terraces on the BMG replicas possess atomic smoothness with sub-Angstrom roughness that is identical to the one measured on the STO mold. Systematic studies revealed that the quality of the replica depends on the loading rate during imprinting, that the same mold can be used multiple times without degradation of mold or replicas, and that the atomic-scale features on as-imprinted BMG surfaces has impressive long-term stability (months).

**3:54PM P46.00008 First principles study of lattice disordering and magnetic behavior in Cu-NiMnAl and CuNiMnSn Heusler alloys**, SHIFRAH ARON-DINE, Harvey Mudd College, GREGORY POMREHN, The Boeing Company, AURORA PRIBRAM-JONES, Lawrence Livermore National Lab, LORI BASSMAN, Harvey Mudd College — In this work we present density functional theory calculations on two new Heusler alloys, CuNiMnAl and CuNiMnSn, and explore how the electronic properties of these structures are affected by atomic disordering. Elements are disordered 1%-25% on constant and varying sublattices to explore changes in electronic structure and magnetization. We then use a Monte Carlo method to predict expected magnetic behavior and compare with experimental results.

**4:06PM P46.00009 First principles statistical mechanics of alloys and magnetism<sup>1</sup>**, MARKUS EISENBACH, SUFFIAN N. KHAN, YING WAI LI, Oak Ridge National Lab — Modern high performance computing resources are enabling the exploration of the statistical physics of phase spaces with increasing size and higher fidelity of the Hamiltonian of the systems. For selected systems, this now allows the combination of Density Functional based first principles calculations with classical Monte Carlo methods for parameter free, predictive thermodynamics of materials. We combine our locally selfconsistent real space multiple scattering method for solving the Kohn-Sham equation with Wang-Landau Monte-Carlo calculations (WL-LSMS). In the past we have applied this method to the calculation of Curie temperatures in magnetic materials. Here we will present direct calculations of the chemical order disorder transitions in alloys. We present our calculated transition temperature for the chemical ordering in CuZn and the temperature dependence of the short-range order parameter and specific heat. Finally we will present the extension of the WL-LSMS method to magnetic alloys, thus allowing the investigation of the interplay of magnetism, structure and chemical order in ferrous alloys.

**4:18PM P46.00010 First-principles Co database: Energetics of binary Co alloys and compounds<sup>1</sup>**, SHAHAB NAGHAVI, VINAY HEGDE, CHRIS WOLVERTON, Department of Materials Science and Engineering, Northwestern University, Evanston, Illinois 60208, USA — The field of superalloys has received a recent spike in interest with the discovery of metastable  $\gamma'$ -Co<sub>3</sub>(Al,W) precipitates with the L1<sub>2</sub> structures. We present density functional calculations for the first and second nearest-neighbor solute-vacancy binding energies of 27 substitutional solutes in fcc-cobalt. As by-products, we also calculate the dilute mixing energy, dilute volume of mixing, and solubility enthalpy. A modest correlation between the solute size and its binding to an accompanying vacancy has been found. Our calculations reveal that a vacancy not only relieves the strain associated with large solutes, but also mediates a weak bonding between the large solute and its next nearest-neighbor atoms, resulting in high solute-vacancy binding energies. We also find that the solute-vacancy binding energy is minimized for a half-filled *d*-band, in the middle of a transition metal series, and varies parabolically with the *d*-band filling. In general, 4*d* and their counterpart 5*d* transition metals have nearly similar solute-vacancy binding energies, but much larger than those of 3*d* transition metals, and the deviation increase by moving away from a half-filled band.

**4:30PM P46.00011 X-ray measurements of the self-organization of martensitic variants during thermal cycling**, DANIEL PEREZ, University of Ottawa, MARK SUTTON, McGill University, MICHAEL ROGERS, University of Ottawa — The deformation of most types of metals involves an irreversible flow of crystallographic dislocations. This allows for their ductility. The deformation of a metallic shape memory alloy (SMA), on the other hand, is accommodated by a solid-solid phase transition. If deformed in the low-temperature martensitic phase, an SMA can be returned to its original shape by raising its temperature to the point where it changes back to its high-temperature parent phase. When the reverse occurs and the transformation is from parent to martensitic phase, an SMA goes from a high-symmetry to a low-symmetry state in which a number of martensitic variants are produced. We monitored the self-organization of these variants during cycles of periodic thermal driving. This was done using in situ X-ray Photon Correlation Spectroscopy (XPCS), which uses correlation from X-ray speckle to quantify the degree of microstructural change in a material. Our measurements revealed enhanced reversibility in the organization of the martensitic variants as the system evolved during repeated thermal cycling.

**4:42PM P46.00012 Long-time atomistic evolution of grain boundary in nickel using the kinetic activation-relaxation technique**, SAMI MAHMOUD, MICKAL TROCHET, OSCAR RESTREPO, NORMAND MOUSSEAU, University of Montreal — The microscopic mechanisms associated with the evolution of metallic materials are still a matter of debate as both experimental and numerical approaches fail to provide a detailed atomic picture of their time evolution. Here, we use the kinetic activation-relaxation technique (k-ART) [1], an unbiased off-lattice kinetic Monte Carlo method with on-the-fly catalog building to overcome these limitations and follow the atomistic evolution of a 10,000-atom grain boundary Ni system over macroscopic time scales. We first characterize the kinetic properties of four different empirical potentials, the embedded atom method (EAM), the first and second modified embedded atom method (MEAM1NN and MEAM2NN respectively) and the Reax force field (ReaxFF) potentials. Comparing the energetics, the elastic effects and the diffusion mechanisms for systems with one to three vacancies and one to three self-interstitials in nickel simulated over second time scale, we conclude that ReaxFF and EAM potentials are closest to experimental values. We then proceed to study the long-time evolution of a grain boundary with the Reax forcefield and to offer a detailed description of its energy landscape, including the exact description of short and long-range effects on self-diffusion along the interface. [1] N. Mousseau *et al*, *Comput. Mater. Sci.*, vol. 100, pp. 111–123, 2015.

**4:54PM P46.00013 Fluid-like flows in large-strain deformation of metals** , HO YEUNG, National Institute of Standards and Technology, DINAKAR SAGAPURAM<sup>1</sup>, Koushik Viswanathan, Purdue University, NARAYAN SUNDARAM, Indian Institute of Science, ANIRBAN MAHATO, KEVIN TRUMBLE, SRINIVASAN CHANDRASEKAR, Purdue University — Laminar or smooth plastic flow, commonly observed in large deformation of metals, becomes unstable under certain conditions, resulting in inhomogeneous plastic flow. Using *in situ* imaging, we demonstrate the unique features of two inhomogeneous flow modes in metal plasticity — the well-known shear band flow and the recently discovered sinuous flow — and methods for suppressing them. Both modes occur via a two stage process — nucleation and flow development. The nucleation stage results in a weak material zone and the development stage involves imposition of significant strains. In the case of shear bands, using additional micro-marker techniques, we show that the second stage is well described by a viscous slider model. As a result, controlling the second stage causes band formation to cease. We demonstrate the use of this method — Passive Geometric Flow control — to form long strips from metallic alloys that are difficult to form conventionally. For sinuous flow, nucleation and flow formation kinematics show remarkable resemblance with flows in complex fluids. The nucleation stage can be altered using suitable ink coatings on the free surface or by surface pre-straining, and we use this idea to demonstrate complete sinuous flow suppression.

<sup>1</sup>Membership pending

**5:06PM P46.00014 Grain Growth in Cerium Metal** , JASON COOLEY, Los Alamos National Laboratory, MARTHA KATZ, None, CHARLES MIELKE, JOEL MONTALVO, Los Alamos National Laboratory — We report on grain growth in forged and rolled cerium plate for temperatures from 350 to 700 degrees C and times from 30 to 120 minutes. The cerium was made by arc-melting into a 25 mm deep by 80 mm diameter copper mold. The resulting disk was forged at room temperature to a 25% reduction of thickness four times with a 350 degree C strain relief heat treatment for 60 minutes between forging steps. The resulting 8 mm thick plate was cold rolled at room temperature to a 25% reduction of thickness three times with a 350 C strain relief heat treatment between steps resulting in a plate approximately 3 mm thick. 5 x 10 mm coupons were cut from the plate for the grain growth study.

**5:18PM P46.00015 Ab initio calculation of oxygen self-diffusion coefficient in uranium dioxide**  $\text{UO}_2$  , BORIS DORADO, CEA, DAM, DIF - Bruyeres-le-Chatel, France, PHILIPPE GARCIA, CEA, DEN, DEC - Cadarache, France, MARC TORRENT, CEA, DAM, DIF - Bruyeres-le-Chatel, France — Uranium dioxide  $\text{UO}_2$  is the most widely used nuclear fuel worldwide and its atomic transport properties are relevant to practically all engineering aspects of the material. Although transport properties have already been studied in  $\text{UO}_2$  by means of first-principles calculations, the ab initio determination of self-diffusion coefficients has up to now remained unreachable because the relevant computational tools were neither available or adapted. The present work reports our results related to the ab initio calculation of the oxygen self-diffusion coefficient in  $\text{UO}_2$ . We first determine the Gibbs free energies of formation of oxygen charged defects by calculating both the electronic and vibrational (hence entropic) contributions. Then, we use the transition state theory in order to compute the effective jump frequency of the defects, which in turn provides us with the value of the pre-exponential factor. The results are compared to self-diffusion data obtained experimentally with a careful monitoring of the relevant thermodynamic conditions (oxygen partial pressure, temperature, impurity content).

## Wednesday, March 16, 2016 2:30PM - 5:06PM – Session P47 FOEP: Beyond the Lab: Bringing History and Physics to the Public 312 -

**2:30PM P47.00001 Creating a Community to Strengthen the Broader Impacts of Condensed Matter Physics Research**<sup>1</sup> , SHIREEN ADENWALLA, JOCELYN BOSLEY, Dept of Physics, University of Nebraska, GREGORY VOTH, Dept of Physics, Wesleyan University, LEIGH SMITH, Dept of Physics, University of Cincinnati — The Broader Impacts (BI) merit criteria set out by the National Science Foundation are essential for building the public support necessary for science to flourish. Condensed matter physicists (CMP) have made transformative impacts on our society, but these are often invisible to the public. Communicating the societal benefits of our research can be challenging, because CMP consists of many independent research groups for whom effective engagement in the public arena is not necessarily a forte. Other BI activities, such as engaging K-12 students and teachers to increase scientific literacy and strengthen the STEM workforce, may be very effective, but these are often isolated and short in duration. To increase the visibility of CMP and to make the implementation of BI activities more efficient, we have created a website with two sides: a public side to communicate to a broad audience exciting scientific discoveries in CMP and the technologies they enable, and a private side for condensed matter researchers to communicate with one another about effective broader impact activities. Here we discuss the content of the new website, and the best practices we have identified for communicating the excitement of CMP research to the broadest possible audience.

**2:42PM P47.00002 Schrödinger's Magnetic Ambitions: His Attempts in the 1940s to Understand Terrestrial Magnetism through a Unitary Field Theory.** , PAUL HALPERN, University of the Sciences in Philadelphia — In 1943, Schrödinger presented several papers to the Royal Irish Academy outlining his efforts to unify electromagnetism, gravitation, and what is now known as the strong force in a Unitary Field Theory. To furnish experimental proof for his ideas, he suggested that variations in Earth's magnetic field might be understood through his theoretical notion that electromagnetism is attenuated by a kind of cosmological constant. We'll explore the nature and context of his proposal and examine reactions to his assertions.

**2:54PM P47.00003 The Schrödinger Sessions: Science for Science Fiction**<sup>1</sup> , CHAD ORZEL, Union College Dept. of Physics and Astronomy, EMILY EDWARDS, STEVEN ROLSTON, Joint Quantum Institute — In July 2015, we held a workshop for 17 science fiction writers working in a variety of media at the Joint Quantum Institute at the University of Maryland, College Park. "The Schrödinger Sessions," funded by an outreach grant from APS, provided a three-day "crash course" on quantum physics and technology, including lectures from JQI scientists and tours of JQI labs. The goal was to better inform and inspire stories making use of quantum physics, as a means of outreach to inspire a broad audience of future scientists. We will report on the contents of the workshop, reactions from the attendees and presenters, and future plans.

<sup>1</sup>Funded by an Outreach Mini-Grant from the APS

**3:06PM P47.00004 Layman friendly spectroscopy<sup>1</sup>**, STIPO SENTIC, SHARON SESSIONS, New Mexico Tech — Affordable consumer grade spectrometers (e.g. SCiO, Qualcomm Tricorder XPRIZE) are becoming more available to the general public. We introduce the concepts of spectroscopy to the public and K12 students and motivate them to delve deeper into spectroscopy in a dramatic participatory presentation and play. We use diffraction gratings, lasers, and light sources of different spectral properties to provide a direct experience of spectroscopy techniques. Finally, we invite the audience to build their own spectrometer—utilizing the APS SpectraSnapp cell phone application—and study light sources surrounding them in everyday life. We recontextualize the stigma that science is hard (e.g. Math, Science Popular Until Students Realize They're Hard, The Wall Street Journal) by presenting the material in such a way that it demonstrates the scientific method, and aiming to make failure an impersonal scientific tool—rather than a measure of one's ability, which is often a reason for shying away from science. We will present lessons we have learned in doing our outreach to audiences of different ages.

<sup>1</sup>This work is funded by the APS Outreach Grant "Captain, we have matter matters!" We thank New Mexico Tech Physics Department and Physics Club for help and technical equipment.

**3:18PM P47.00005 Value of Fundamental Science**, ALEXEY BUROV, Fermilab — Fundamental science is a hard, long-term human adventure that has required high devotion and social support, especially significant in our epoch of Mega-science. The measure of this devotion and this support expresses the real value of the fundamental science in public opinion. Why does fundamental science have value? What determines its strength and what endangers it? The dominant answer is that the value of science arises out of curiosity and is supported by the technological progress. Is this really a good, astute answer? When trying to attract public support, we talk about the mystery of the universe<sup>1</sup>. Why do these words sound so attractive? What is implied by and what is incompatible with them? More than two centuries ago, Immanuel Kant asserted an inseparable entanglement between ethics and metaphysics. Thus, we may ask: which metaphysics supports the value of scientific cognition, and which does not? Should we continue to neglect the dependence of value of pure science on metaphysics? If not, how can this issue be addressed in the public outreach? Is the public alienated by one or another message coming from the face of science? What does it mean to be politically correct in this sort of discussion?

**3:30PM P47.00006 Putting Research in the Classroom: A Partnership for Curriculum Building**, NATHAN TOMPKINS, ANIQUE OLIVIER-MASON, Brandeis University — Many science classes today are taught in a historical context as if scientific discovery was something that only happened in the past with textbooks focused on presenting facts and equations without conveying that the process of science is to ask and answer questions. To address these deficiencies we have developed a science outreach course to unite high school science educators with young researchers for a series of workshops to develop teaching modules. The modules connect specific textbook concepts and state standards to current materials science research in hands-on learning experiences for high school students. The idea is to make math, science, technology, and engineering concepts more exciting, accessible, and relevant to high school students through interactions with diverse researchers and instruction from curriculum based on cutting-edge materials science research. The goal is to demonstrate that science is a living, active process of inquiry and questioning; not simply a litany of facts, figures, and historical anecdotes. The ultimate aim is for the teaching modules prepared in this course to be packaged and prepared for dissemination to schools outside the immediate vicinity in order to expand the reach to communities underrepresented in the sciences.

**3:42PM P47.00007 Discover Science Initiative, outreach and professional development at the University of California, Irvine<sup>1</sup>**, JILL PESTANA, JAMES EARTHMAN, Univ of California - Irvine — Discover Science Initiative (DSI) is an unprecedented success in the Southern Californian community by reaching out to over 5,000 participants through eight hands-on workshops on topics from fungi to the physics of light, and two large events in the past year. The DSI vision is to provide an avenue for University of California, Irvine (UCI) students and faculty from all departments to engage with the local community through workshops and presentations on interdisciplinary, state-of-the-art STEM research unique to UCI. DSI provides professional development opportunities for diverse students at UCI, while providing outreach at one of the most popular educational centers in Southern California, the Discovery Cube, which hosts over 400,000 guests each year. In DSI, students engage in peer-to-peer mentoring with guidance from the UCI School of Education in designing workshops, leading meetings, and managing teams. Also, students practice science communication, coached by certified communications trainers. Students involved in DSI learn important skills to complement their academic degrees, and stay motivated to pursue their career goals.

<sup>1</sup>Support for DSI is from Diverse Educational and Doctoral Experience (DECADE) at UCI.

**3:54PM P47.00008 Texas A&M Physics Festival: bringing together the community, faculty, and students**, TATIANA ERUKHIMOVA, Texas A&M University — Texas A&M Physics Festival started in 2003 with a dozen of hands-on exhibits and an inaugural lecture by Stephen Hawking. Over the years it evolved into one of the largest STEM outreach events in the area. The Festival attracts over 4000 visitors annually from all over Texas and other states. It features over 100 interactive exhibits displayed by faculty and students, public lectures by world-renowned scientists and astronauts, professional bubble shows, and many other activities. I will report on the structure of the Festival as well as strategies for involving undergraduate and graduate students and faculty in public outreach. I will further discuss the results of an independent evaluation of the 2015 Festival by the NSF-funded EvalFest program.

**4:06PM P47.00009 Movie Physics: pirates, spies and other worlds.<sup>1</sup>**, BEATRIZ GONZALEZ DEL RIO, V. GONZALEZ-FERNANDEZ, Universidad de Valladolid and Physics League Association, J.L. MARTIN, Physics League Association, L. SANCHEZ-TEJERINA, Universidad de Valladolid and Physics League Association, G. PEREZ, L. ARES, E. VASALLO, P. MARTIN, V. VILLA, S. GARCIA, M. VARA, S. MARTIN, P. ALVAREZ, C. GONZALEZ, P. LOPEZ, Physics League Association, M.A. BURGOS, Universidad de Valladolid and Physics League Association, V.M. GONZALEZ, J. CARBAJO, Physics League Association, C. MATEOS, Universidad de Valladolid and Physics League Association — Taking advantage of many popular films, the basics of many physical principles can be shown in a really attractive and stunning way. Five shows/workshops form this project attending the necessities of the target public: kids become pirates, high-school students are pushed to the limit and visit other fantasy worlds, and the general public discover the powers of physics and some terrifying secrets. By November 2015 we have obtained more than 2900 viewers. The activities have been presented in different national and international conferences, on an international science fair and have been published by several Spanish media. During 2015 the Physics League Association has received three international awards due to some activities from this project. Additional Authors: B. G. del Rio [1,2], V. Gonzalez-Fernandez [1,2], J. L. Martin [1], L. Sanchez-Tejerina [1,2], G. Prez [1], L. Ares [1], E. Vasallo [1], P. Martin [1], V. Villa [1], S. Garca [1], M. Vara [1], S. Martin [1], P. Alvarez [1], C. Gonzalez [1], P. **4:18PM P47.00010 Title: SCOAP<sup>3</sup>: Explanation and Current Status** , MATTHEW MARSTELLER, Carnegie Mellon University — The Sponsoring Consortium for Open Access Publishing in Particle Physics (SCOAP<sup>3</sup>) is a successful global partnership of libraries, funding agencies and research centers. SCOAP<sup>3</sup> has negotiated with journal publishers on behalf of libraries and institutions from around the world to produce open access literature in particle physics journals that were previously published in a traditional subscription-based model. This presentation will provide an overview of the process, an update of its status and some intriguing research metrics that have emerged.

**4:30PM P47.00011 First Megascience Experiment at Fermilab: Through Hardship to Protons** , VITALY PRONSKIKH, VALERIE HIGGINS, Fermi National Accelerator Laboratory — The E-36 experiment on the small angle proton-proton scattering that officially started in 1970, making use of the Main Ring beams and giving rise to a chain of similar experiments that continued after 1972, was the first experiment at the newly built NAL. It was also the first US/USSR collaboration in particle physics as well as the first experiment that can be confidently characterized as megascience. The experimental data were interpreted as an indication of the pomeron, a quasiparticle that had been named after the Soviet theorist I. Pomeranchuk. The idea of the experiment can be traced back to the Rochester conference held in 1970 in Kiev where two American and Soviet physicists met to develop it and later acquainted NAL director Robert Wilson with it. Wilson enthusiastically set the stage for the experiment at NAL. Involving a gas-jet target built at the Dubna machine shop of Joint Institute for Nuclear Research and brought to Batavia, Illinois, the experiment established cooperation between the US and the Soviets in the spirit of their contemporary Apollo-Soyuz space program, thus breaking the ice of the Cold War from within high-energy physics. In this talk based on the Fermilab Archives and interviews, we discuss the financial and administrative obstacles raised by Soviet officials that the Russian collaborators had to overcome, interinstitutional tensions among the Soviets that accompanied the collaboration, NAL culture as well as the roles of scientists in megascience as ambassadors of peace.

**4:42PM P47.00012 ABSTRACT WITHDRAWN —**

**4:54PM P47.00013 The Japanese aerial attack on Hanford Engineer Works** , CHARLES W. CLARK, Joint Quantum Institute — The day before the Pearl Harbor attack, December 6, 1941, the University of Chicago Metallurgical Laboratory was given four goals: design a plutonium (Pu) bomb; produce Pu by irradiation of uranium (U); extract Pu from the irradiated U; complete this in time to be militarily significant.<sup>1</sup> A year later the first controlled nuclear chain reaction was attained in Chicago Pile 1 (CP-1). In January 1943, Hanford, WA was chosen as the site of the Pu factory.<sup>2</sup> Neutron irradiation of <sup>238</sup>U was to be used to make <sup>239</sup>Pu. This was done by a larger version of CP-1, Hanford Reactor B, which went critical in September 1944. By July 1945 it had made enough Pu for two bombs: one used at the Trinity test in July; the other at Nagasaki, Japan in August. I focus on an ironic sidelight to this story: disruption of hydroelectric power to Reactor B by a Japanese fire balloon attack on March 10, 1945. This activated the costly coal-fired emergency backup plant to keep the reactor coolant water flowing, thwarting disaster and vindicating the conservative design of Hanford Engineer Works.

**Session P48 GQI: Quantum Control in Superconducting Circuits** 349 - Alexander Korotkov, University of California, Riverside

**2:30PM P48.00001 Quantum Control of Cavity Resonators, Part I: Control Algorithms** , PHILIP REINHOLD, REINIER HEERES, NISSIM OFEK, KATRINA SLIWA, Yale University, MICHAEL HATRIDGE, University of Pittsburgh, STEFAN KRASTANOV, LIANG JIANG, LUIGI FRUNZIO, MICHEL DEVORET, ROBERT SCHOELKOPF, Yale University — Harmonic oscillators are linear systems with equally spaced energy levels, which makes them hard to control. We have previously explored a constructive control approach mediated by a far off-resonantly coupled two-level ancilla. Here we present an extension to that method which relies on optimal control algorithms to allow much more efficient quantum control of a combined resonator ancilla system. We show that full control of the resonator is possible on a time-scale of order  $1/\chi$ , the dispersive shift. In practice this means that a unitary operation on the Hilbert space of our superconducting resonator truncated to 8 levels can be performed using a pulse of around a microsecond.

**2:42PM P48.00002 Quantum Control of Cavity Resonators, Part II: Experiment** , REINIER HEERES, PHILIP REINHOLD, NISSIM OFEK, KATRINA SLIWA, Yale University, MICHAEL HATRIDGE, University of Pittsburgh, STEFAN KRASTANOV, LIANG JIANG, LUIGI FRUNZIO, MICHEL DEVORET, ROBERT SCHOELKOPF, Yale University — Harmonic oscillators offer a large Hilbert space that can potentially be used to encode multiple bits of quantum information. The long lifetime of superconducting cavity resonators make them a suitable candidate to explore this direction. Due to the linearity of harmonic oscillators it is not directly obvious how to manipulate them. Here we show that pulses designed using optimal control methods allow us to manipulate the combined cavity – transmon system on a time-scale of order  $1/\chi$ , the dispersive shift; in practice pulses of about a microsecond long. Several example unitary operations addressing the first 8 levels of the resonator are described and characterized.

**2:54PM P48.00003 Optimal control of single flux quantum (SFQ) pulse sequences** , PER LIEBERMANN, FRANK WILHELM, Saarland University — Single flux quantum (SFQ) pulses are a natural candidate for on-chip control of superconducting qubits [1]. High accuracy quantum gates are accessible with quantum optimal control methods. We apply trains of SFQ pulses to operate single qubit gates, under the constraint of fixed amplitude and duration of each pulse. Timing of the control pulses is optimized using genetic algorithms and simulated annealing, decreasing the average fidelity error by several orders of magnitude. Furthermore we are able to reduce the gate time to the quantum speed limit. Leakage out of the qubit subspace as well as timing errors of the pulses are considered, exploring the robustness of our optimized sequence. This takes us one step further to a scalable quantum processor. [1] R. McDermott and M.G. Vavilov, Phys. Rev. Appl. 2, 014007 (2014)

**3:06PM P48.00004 Robust Control of a Two-Qubit Operation in 3D Circuit Quantum Electrodynamics** , JOSEPH ALLEN, ATI, University of Surrey, ROBERT KOSUT, SC Solutions, Inc., JAEWOO JOO, ERAN GINOSSAR, ATI, University of Surrey — Superconducting qubits have shown great improvement in coherence times with the introduction of 3D cavities. In order to control the qubits in 3D a microwave drive is usually coupled to the common mode of the cavity, which makes individual addressability a challenge and causes additional unwanted single and two-qubit dynamics when performing two qubit operations. Quantum information processing requires precise control of the system dynamics in the presence of potential uncertainties in the estimated system parameters. We use optimal control theory to develop pulse shapes that are able to implement an all-microwave two-qubit gate, while mitigating extra unwanted interaction terms, with  $\mathcal{F} = 0.9964$ . In addition we develop pulses which are robust to errors in the two qubit transition frequencies. This is demonstrated with experimentally relevant parameters and includes realistic constraints in the possible pulse shapes, presenting pulses that can be implemented in experiment.

**3:18PM P48.00005 Gradient Optimization for Analytic conTrols - GOAT** , ELIE ASSÉMAT, Saarland University, SHAI MACHNES, DAVID TANNOR, Weizmann Institute of Science, FRANK WILHELM-MAUCH, Saarland University — Quantum optimal control becomes a necessary step in a number of studies in the quantum realm. Recent experimental advances showed that superconducting qubits can be controlled with an impressive accuracy. However, most of the standard optimal control algorithms are not designed to manage such high accuracy. To tackle this issue, a novel quantum optimal control algorithm have been introduced: the Gradient Optimization for Analytic conTrols (GOAT). It avoids the piecewise constant approximation of the control pulse used by standard algorithms. This allows an efficient implementation of very high accuracy optimization. It also includes a novel method to compute the gradient that provides many advantages, e.g. the absence of backpropagation or the natural route to optimize the robustness of the control pulses. This talk will present the GOAT algorithm and a few applications to transmons systems.

**3:30PM P48.00006 Fast resonator reset in circuit QED using open quantum system optimal control** , SAMUEL BOUTIN, Département de Physique, Université de Sherbrooke, CHRISTIAN KRAGLUND ANDERSEN, Department of Physics and Astronomy, Aarhus University, JAYAMEENAKSHI VENKATRAMAN, Department of Physics, Indian Institute of Technology Kanpur, ALEXANDRE BLAIS, Département de Physique, Université de Sherbrooke and Canadian Institute for Advanced Research — Practical implementations of quantum information processing requires repetitive qubit readout. In circuit QED, where readout is performed using a resonator dispersively coupled to the qubits, the measurement repetition rate is limited by the resonator reset time. This reset is usually performed passively by waiting several resonator decay times. Alternatively, it was recently shown that a simple pulse sequence allows to decrease the reset time to twice the resonator decay time [1]. In this work, we show how to further optimize the ring-down pulse sequence by using optimal control theory for open quantum systems. Using a new implementation of the open GRAPE algorithm that is well suited to large Hilbert spaces, we find active resonator reset procedures that are faster than a single resonator decay time. Simple quantum speed limits for this kind of active reset processes will be discussed. [1] McClure et al., arXiv 1503.01456

**3:42PM P48.00007 ABSTRACT WITHDRAWN —**

**3:54PM P48.00008 Analysis of non-adiabatic effects in circuit QED measurement of a transmon** , ERIC MLINAR, MOSTAFA KHEZRI, University of California, Riverside, JUSTIN DRESSEL, Chapman University, ALEXANDER N. KOROTKOV, University of California, Riverside — In a circuit QED setup with a transmon qubit dispersively coupled to a driven resonator, we investigate whether rapid resonator ringup will cause nonadiabatic effects that disturb the qubit state. We show that only unrealistically fast high-power pulses will produce significant deviations from adiabatic behavior, while typically the qubit-resonator dynamics is well described by coherent evolution in the joint eigenbasis. Nevertheless, even in typical parameter regimes we show that the qubit nonlinearity still produces a dynamical shearing effect that squeezes the state of the resonator field.

**4:06PM P48.00009 A method of extracting operating parameters of a quantum circuit** , EYOB A. SETE, MAXWELL BLOCK, MICHAEL SCHEER, CRIS ZANOCI, MEHRNOOSH VAHIDPOUR, DANE THOMPSON, CHAD RIGETTI, Rigetti Quantum Computing, Berkeley, CA — Rigorous simulation-driven design methods are an essential component of traditional integrated circuit design. We adapt these techniques to the design and development of superconducting quantum integrated circuits by combining classical finite element analysis in the microwave domain with Brune circuit synthesis by Solgun [PhD thesis 2014] and BKD Hamiltonian analysis by Burkard et al. [Phys. Rev. B **69**, 064503 (2004)]. Using the Hamiltonian of the quantum circuit, constructed using the synthesized equivalent linear circuit and the nonlinear Josephson junctions' contributions, we extract operating parameters of the quantum circuit such as resonance coupling strength, dispersive shift, qubit anharmonicity, and decoherence rates for single- and multi-port quantum circuits. This approach has been experimentally validated and allows the closed-loop iterative simulation-driven development of quantum information processing devices.

**4:18PM P48.00010 Critical fluctuations near excitation threshold of a quantum parametric oscillator** , M. I. DYKMAN, Michigan State University, Y. NAKAMURA, The University of Tokyo and CEMS RIKEN, Z. R. LIN, CEMS RIKEN — A weakly damped parametrically driven oscillator has several vibrational states already for weak driving. These are stable and unstable states with twice the modulation period and also the steady state. At the critical point all states merge. We show that this leads to anomalously strong quantum fluctuations. These fluctuations are similar whether the friction, in the classical picture, is linear or nonlinear. The critical region is  $\propto [\hbar(2\bar{n} + 1)]^{1/3}$  along the field frequency axis and  $\propto [\hbar(2\bar{n} + 1)]^{2/3}$  along the field amplitude axis, where  $\bar{n}$  is the Planck number. The correlation time scales as  $[\hbar(2\bar{n} + 1)]^{-2/3}$ . The number of photons for  $\bar{n} = 0$  scales as  $\hbar^{-2/3}$ . It is determined by the oscillator nonlinearity and decay rate. Above the threshold, quantum fluctuations induce transitions between the period-two states over the quasienergy barrier. We find the effective quantum activation energies for such transitions and their scaling with the difference of the driving amplitude from its critical value. We also present the results of relevant experimental observations obtained with a circuit QED system.

**4:30PM P48.00011 Fluctuations of a parametric oscillator: from the semiclassical to a strongly quantum regime** , YAXING ZHANG, MARK DYKMAN, Michigan State University — A semiclassical parametric oscillator has two dynamically stable vibrational states with equal amplitudes and with phases differing by  $\pi$ . The rate of switching between these states is exponentially small, and the oscillator displays fluctuations with the reciprocal correlation time given by this rate. It also displays critical slowing down near the excitation threshold. The parameter of the “quantumness” is the ratio of the nonequidistance  $\hbar V$  of the oscillator energy levels due to the nonlinearity and the level width  $\hbar\Gamma$  due to decay. In the strongly-quantum regime where  $V/\Gamma \gg 1$  and driving is not too strong, the picture of coexisting vibrational states with opposite phases does not apply. An insight into the transition from the semiclassical to strongly-quantum regime can be gained by studying the quasienergy spectrum and the decay of quantum fluctuations. An analogue of the critical slowing down in the strongly-quantum regime is a sharp increase of the fluctuation correlation time that occurs at a hypersurface in the oscillator parameter space. We find that the quasienergy spectrum and the ratio of the level spacing to their width also sensitively depend on the parameters, in particular on  $V/\Gamma$ .

**4:42PM P48.00012 Robust tomography of microwave resonator arrays for quantum simulation with light** , AMAN LACHAPPELLE, JOHN C OWENS, RUICHAO MA, JONATHAN SIMON, DAVID SCHUSTER, Univ of Chicago — We are interested in using a bottom-up approach to create topologically non-trivial states of light via Hamiltonian engineering in coupled microwave cavities. Characterization and reduction of disorder is paramount to realizing and studying idealized many-body Hamiltonians. Our tight-binding lattices are made of arrays of evanescently coupled three-dimensional microwave resonators. From the spectroscopic response measured at specific lattice sites, we develop methods to fully map out the underlying tight-binding Hamiltonian, including onsite energies, nearest-neighbor couplings and the local dissipation on all sites. We show that for a 1D system, one reflection measurement off of the site at the end of the chain is sufficient, while for 2D only measurements along one edge of the system is sufficient for complete tomography of the lattice Hamiltonian. The transmission between neighboring sites also reveals the phase of the tunnel coupling, thereby allow direct measurement of the flux in lattices with time-reversal breaking synthetic gauge fields. These methods can be readily applied to many other physical systems for the characterization of quantum processes or the validation of quantum simulators.

**4:54PM P48.00013 Analysis of qubit dynamics under strong resonant pulses using Floquet theory**, CHUNQING DENG, FEIRUO SHEN, JEAN-LUC ORGIAZZI, University of Waterloo, SAHEL ASHHAB, Qatar Foundation, ADRIAN LUPASCU, University of Waterloo — Resonant driving is the most common way of implementing single-qubit gates in various quantum systems. Most of the experiments and optimization of such gates are performed in the weak-driving regime, where the qubit dynamics is relatively slow and well described using the rotating wave approximation. However, the implementation of qubit gates with strong driving, which in principle promises a higher speed, has not been studied extensively. In this work, we consider the dynamics of a qubit driven by strong resonant pulses in the framework of Floquet theory. We analyze the role of pulse shaping in the dynamics, as determined by nonadiabatic transitions between the Floquet states. By suppressing the nonadiabatic transitions, we show that high-fidelity single-qubit operations can be achieved in very short times. This work provides the theoretical basis for optimizing strong pulses for single-qubit gates. These results are particularly relevant for the implementation of single-qubit gates in superconducting qubits, where strong driving with shaped pulses has been demonstrated experimentally.

**5:06PM P48.00014 Flexible, low-latency architecture for qubit control and measurement in circuit QED.**, WOUTER VLOTHUIZEN, D. DEURLOO, QuTech, Delft University of Technology and Netherlands Organisation for Applied Scientific Research (TNO), Delft, The Netherlands, J. DE STERKE, Topic Embedded Systems, Delft, The Netherlands, R. VERMEULEN, R.N. SCHOUTEN, LEO DICARLO, QuTech and Kavli Institute of Nanoscience, Delft University of Technology, Delft, The Netherlands — Increasing qubit numbers in circuit QED requires an extensible architecture for digital waveform generation of qubit control and measurement signals. For quantum error correction, the ability to select from a number of predetermined waveforms based on measurement results will become paramount. We present a room-temperature architecture with very low latency from measurement to waveform output. This modular FPGA-based system can generate both baseband and RF modulated signals using DACs clocked at 1 GHz. A backplane that interconnects several modules allows exchange of (measurement) information between modules and maintains deterministic timing across those modules. We replace the typical line based sequencer used in arbitrary waveform generators by a user programmable processor that treats waveforms and measurements as instructions added to a conventional CPU architecture. This allows for flexible coding of triggering, repetitions, delays and interactions between measurement and signal generation. We acknowledge funding from the Dutch Research Organization (NWO), an ERC Synergy Grant, and European project SCALEQIT.

**5:18PM P48.00015 Fock State Generator**, SHAVINDRA PREMARATNE, Department of Physics, University of Maryland; Laboratory for Physical Sciences, F.C. WELLSTOOD, JQI, CNAM, Department of Physics, University of Maryland, B.S. PALMER, Department of Physics, University of Maryland; Laboratory for Physical Sciences — Using a single junction Al/AIO<sub>x</sub>/Al transmon qubit coupled to a superconducting Al cavity (at a temperature 15 mK), we have used a Raman technique to produce a single Fock state in the cavity. The technique requires 3 microwave tones to drive the system from the ground state of the cavity/qubit system. We achieve an experimental fidelity of the final Fock state of around 90%, limited by thermal photons in the cavity and by decay during the operation time. Using this technique, we have also generated an arbitrary superposition of Fock states and a superposition of qubit and cavity states. Results, simulations and applications of this technique will be discussed.

## Wednesday, March 16, 2016 2:30PM - 5:18PM –

**Session P50 DAMOP: Quenched Atomic Systems and Thermalization** Hilton Baltimore Holiday Ballroom  
1 - Mohammad Maghrebi, Joint Quantum Institute, University of Maryland

**2:30PM P50.00001 Prethermalization and exponentially slow energy absorption in periodically driven many-body systems**, DMITRY ABANIN, WEN WEI HO, University of Geneva, Switzerland, WOJCIECH DE ROECK, KU Leuven, Belgium, FRANCOIS HUVENEERS, Universit Paris-Dauphine, France — We establish some general dynamical properties of lattice many-body systems that are subject to a high-frequency periodic driving. We prove that such systems have a quasi-conserved extensive quantity  $H_*$ , which plays the role of an effective static Hamiltonian. The dynamics of the system (e.g., evolution of any local observable) is well-approximated by the evolution with the Hamiltonian  $H_*$  up to time  $\tau_*$ , which is exponentially long in the driving frequency. We further show that the energy absorption rate is exponentially small in the driving frequency. In cases where  $H_*$  is ergodic, the driven system prethermalizes to a thermal state described by  $H_*$  at intermediate times  $t < \tau_*$ , eventually heating up to an infinite-temperature state at times  $t \sim \tau_*$ . Our results indicate that rapidly driven many-body systems generically exhibit prethermalization and very slow heating. We briefly discuss implications for cold atoms experiments which realize topological states by periodic driving.

**2:42PM P50.00002 Universal aspects of thermalization after a quantum quench**, JAMES R. GARRISON, University of California, Santa Barbara, TARUN GROVER, Kavli Institute for Theoretical Physics — A very fundamental problem in quantum statistical mechanics involves whether—and how—an isolated quantum system will thermalize at long times. The Eigenstate Thermalization Hypothesis (ETH) posits that when thermalization occurs, it occurs at the level of each individual energy eigenstate. In recent work [1], we examined an isolated quantum system that obeys ETH and identified the precise class of operators for which ETH is satisfied. Here, we use similar techniques to study the more general case of a time-evolved system after a quantum quench. Given a “typical” initial state, we investigate the class of operators that thermalize and the associated time scales, and remark on the similarities and differences compared with a single eigenstate at finite energy density. Possible experimental implications will be discussed. [1] J. R. Garrison and T. Grover, arXiv:1503.00729.

**2:54PM P50.00003 Short- and long-time dynamics of isolated many-body quantum systems<sup>1</sup>**, MARCO TAVORA, Yeshiva University, JONATHAN TORRES-HERRERA, Universidad Autonoma de Puebla, Mexico, LEA FERREIRA DOS SANTOS, Yeshiva University — We show our results for the relaxation process of isolated interacting quantum spin chains in the integrable and chaotic regimes. The dynamics of the survival probability (the probability for finding the system still in its initial state at later times) and of few-body observables are analyzed. Different time scales are considered. While the short-time evolution is determined by the shape of the weighted energy distribution of the initial state, the long-time behavior depends on the bounds of the spectrum. Both numerical and analytical results are presented as well as comparisons with existing rigorous mathematical derivations. We consider initial states that can be prepared in experiments with cold atoms in optical lattices.

<sup>1</sup>NSF Grant No. DMR-1147430.

**3:06PM P50.00004 Temperature of a small quantum system as an internal property**, JIAOZI WANG, WENGE WANG, Univ of Sci & Tech of China — Equilibration of small quantum systems is a topic of current interest both theoretically and experimentally. In this work, we study the extent to which a temperature can be assigned to a small quantum (chaotic) system as an internal property, but not as a property of any large environment. Specifically, we study a total system, which is composed of an Ising chain in a nonhomogeneous transverse field and an additional spin coupled to one of the spins in the chain. The additional spin can be used as a probe to detect local temperature of the chain. The total system lies in a pure state under unitary evolution and initial state of the chain is prepared in a typical state within an energy shell. Our numerical simulations show that the reduced density matrix of the probe spin approaches canonical states with similar temperatures at different locations of the chain beyond a relaxation time, and the results are close to the theoretical prediction given by the statistical mechanics in the thermodynamic limit, namely  $\beta = \frac{\partial \ln \rho(E)}{\partial E}$  with  $\rho(E)$  being the density of states. We also study effects due to finite size of the chain, including the dependence on initial state of the probe and difference of numerically-obtain temperature from theoretical results.

**3:18PM P50.00005 Temporal fluctuations after a quantum quench: Many-particle dephasing**, FLORIAN MARQUARDT, University of Erlangen-Nuremberg, THOMAS KIENDL, Free University Berlin — After a quantum quench, the expectation values of observables continue to fluctuate in time. In the thermodynamic limit, one expects such fluctuations to decrease to zero, in order for standard statistical physics to hold. However, it is a challenge to determine analytically how the fluctuations decay as a function of system size. So far, there have been analytical predictions for integrable models (which are, naturally, somewhat special), analytical bounds for arbitrary systems, and numerical results for moderate-size systems. We have discovered a dynamical regime where the decrease of fluctuations is driven by many-particle dephasing, instead of a redistribution of occupation numbers. On the basis of this insight, we are able to provide exact analytical expressions for a model with weak integrability breaking (transverse Ising chain with additional terms). These predictions explicitly show how fluctuations are exponentially suppressed with system size.

**3:30PM P50.00006 Persistent Hall response after a quantum quench in Dirac systems**, JUSTIN WILSON, JUSTIN SONG, GIL REFAEL, Caltech — The geometry and topology of quantum states play a central role in producing novel types of responses, such as the quantum anomalous Hall effect. These have featured prominently in topological materials in equilibrium as well as driven systems in the steady state. Here we unveil how quantum geometry yields radically new types of responses in systems far from equilibrium such as that realized in a quantum quench. To illustrate this, we consider quenches of two-band systems with spin-orbit coupling (e.g. Dirac systems). We find that quenching a time-reversal broken gap gives a Hall-type response that persists even at long times. Intimately tied to the quantum geometry of the underlying Hilbert space, the unconventional persistent Hall response yield clear signatures in quench protocols that can be implemented in cold atoms set-ups.

**3:42PM P50.00007 Quantum Quenches in Arrays of Coupled Luttinger Liquids<sup>1</sup>**, ANDREW JAMES, ANDREW HALLAM, University College London, ROBERT KONIK, Brookhaven National Laboratory, ANDREW GREEN, University College London — Cold atom realisations of one dimensional interacting bosonic models are typically formed as large arrays of decoupled tubes. A low energy description of the individual tubes (including the Lieb-Liniger case) is provided by Luttinger liquid theory. Using matrix product state methods combined with integrability, we study the time evolution of an infinite array of coupled Luttinger Liquids, after a quantum quench in which *interchain* tunnelling is switched on to form a 2D system. We extract the time dependence of the density, bosonic modes, the Loschmidt echo and the entanglement entropy and consider possible implications for phase transitions in the coupled chain system. Our results are compared to perturbation theory and contrasted with simulations for coupled arrays of massive chains.

**3:54PM P50.00008 Melting of a spin domain wall in the context of recent experiments with ultracold atoms**, LEV VIDMAR, Penn State University, DEEPAK IYER, Bucknell University, MARCOS RIGOL, Penn State University — When a one-dimensional spin domain wall of the form  $|\uparrow \dots \uparrow \uparrow \downarrow \downarrow \dots \downarrow \rangle$  is melting, transverse spin correlations in the XX model exhibit a power-law decay in the melted region. This model can be mapped to hard-core bosons via Jordan-Wigner transformation. For hard-core bosons, these emerging power-law correlations correspond to singularities in the quasimomentum distribution at finite quasimomenta  $\pm \pi/2$ , resulting in a dynamical quasicondensation with the emerging phase order different from the ground-state order. This phenomenon has been recently observed experimentally with ultracold bosons in optical lattices [1]. Here we study the emergence of correlations in melting domain walls for hard-core bosons, spinless fermions and the Fermi-Hubbard model at infinite onsite repulsion. In all cases, the density dynamics exhibit identical ballistic expansion, while the correlations show strikingly different features. References: [1] Vidmar et al, PRL 115, 175301 (2015)

**4:06PM P50.00009 Spatio-temporal correlations after a quantum quench in the Bose-Hubbard model<sup>1</sup>**, MATTHEW FITZPATRICK, MALCOLM KENNETT, Simon Fraser University — The quench dynamics of the Bose-Hubbard model (BHM) has received considerable attention in recent years. Theoretically, it has proven challenging to study spatio-temporal correlations in the BHM in dimensions higher than one. We use the Schwinger-Keldysh technique and a strong-coupling expansion to develop a two-particle irreducible formalism that allows the study of spatio-temporal correlations in both the superfluid (SF) and Mott-insulating (MI) regimes during a quantum quench for dimensions higher than one. In this talk, we focus on quenches from the SF to the MI regime and present our numerical results for the evolution of two-time correlation functions. We relate our results to recent cold-atom experiments.

**4:18PM P50.00010 Entanglement dynamics after a quantum quench in the O(N) model<sup>1</sup>**, YONAH LEMONIK, ADITI MITRA, New York University — The entanglement properties of quenched quantum systems is an active area of study, however results in dimensions other than  $d = 1$  are generally lacking. We remedy this by investigating the entanglement properties after a critical quench in the bosonic O(N) model in  $d = 3$ , comparing our results to the free massless theory. We find that the evolution of the entanglement entropy for the free and interacting systems is nearly identical, as expected from a "quasi-particle" picture. However, the low-lying entanglement spectrum is controlled by the different non-equilibrium critical exponents of these two systems. Therefore we demonstrate that these critical exponents can be extracted by studying purely the entanglement in the system.

**4:30PM P50.00011 Quench dynamics of 1D spin-imbalanced Fermi-Hubbard model<sup>1</sup>**, XIAO YIN, LEO RADZIHOVSKY, University of Colorado at Boulder — We study a non-equilibrium dynamics of a 1D spin-imbalanced Fermi-Hubbard model following a quantum quench of on-site interaction, using bosonization and exact analysis. By focusing on the evolution of singlet-, triplet-, density and magnetization correlation functions, we find that the evolution and the final state display a strong dependence on the initial state. Thus, we demonstrate that such quantum quench may be used as a new approach to identify and probe the 1D gapless analogue of the elusive FFLO state.

**4:42PM P50.00012 Quenched dynamics of superconducting Dirac fermions on honeycomb lattice**, MING LU, X. C. XIE<sup>1</sup>, International Center for Quantum Materials, School of Physics, Peking University, X.C. XIE'S GROUP TEAM — We study the BCS pairing dynamics for the superconducting Dirac fermions on honeycomb lattice after a sudden quench of pairing strength. We observe two distinct phases, one is the synchronized phase with undamped oscillations of pairing amplitude; the other phase has the pairing amplitude oscillates from positive to negative. The exact phase transition point is given by investigating the integrability of the system. Different from the previous work on normal superconducting fermions, which has three distinct phases, our results show the absence of the Landau damped phase and over damped phase. Moreover, we present a linear analysis in the weakly quenched regime, showing that in a rather long time scale, the dynamics can be approximated as the periodic oscillation with  $2\Delta_\infty$  angular frequency along with the logarithmic decay of the pairing amplitude, in contrast of the  $t^{-1/2}$  decay for the normal fermions, namely the Landau damped phase.

**4:54PM P50.00013 Preparation of Bose Einstein condensates in realistic trapping potentials for precision atom interferometry**, KATERINE POSSO TRUJILLO, ERNST M. RASEL, NACEUR GAALOUL, Univ Hannover, QUANTUS TEAM — Preparation of Bose Einstein condensates in realistic trapping potentials for precision atom interferometry. Theoretical studies of the ground state and the dynamical properties of Bose Einstein condensates (BECs) are typically realized by considering the ensemble as being initially trapped by a harmonic potential. Dramatic discrepancies were found by comparing numerical results of the long-time expansion of BECs after being released from the harmonic trap, and measurements of the free evolution and delta-kick cooling (DKC) of a <sup>87</sup>Rb BEC on large timescales of up to 2 s in micro-gravity (micro-g) environment such as those performed in the QUANTUS project from our group [1]. The modification in the dynamics of a <sup>87</sup>Rb BEC with the application of DKC by using experimentally implemented trapping geometries and the effect of gravity have been studied. Three different configurations have been considered: atom chip-based potential, dipole trap and the time-averaged orbiting potential. Such discrepancies may be crucial in high precision atom interferometry experiments in micro-g and zero-g platforms in which the implementation of DKC is mandatory to achieve the long-expansion times required. [1] H. Mntinga et al., Phys. Rev. Lett. vol. 110 093602 (2013).

**5:06PM P50.00014 Memory effects in noninteracting isolated systems from dynamical geometry transformations in ultracold quantum gases**, CHEN-YEN LAI, CHIN-CHUN CHIEN, Univ of California - Merced — Memory effects have been of broad interest and particularly relevant in condensate matter systems where dynamical properties depend on history. Here we explore possibilities of observing memory effects in simple isolated quantum systems undergoing geometry transformations. By transforming into lattices supporting flat-bands consisting of localized states, memory effects could be observed in ultracold atoms in optical lattices due to different time scales of localized and mobile atoms. As an optical lattice is continuously transformed from a triangular lattice into a kagome or square lattice, the system reaches a non-thermal quasi-steady state. In the absence of interactions and dissipations, the emergence of steady states are highly nontrivial and crucial in identifying memory effects unambiguously. Moreover, when the lattices transform from a triangular lattice into a kagome lattice with a flat band, history-dependent density distributions even in noninteracting systems can be observed in fermionic as well as bosonic systems. Rapid growth of cold atom technology and possibilities of various mechanisms for inducing memory effect promise interesting applications of novel quantum devices utilizing memory effect, especially in the thriving field of atomtronics. (arXiv:1510.08978)

**2:30PM P51.00001 Heterostructure Symmetry and the Orientation of the Quantum Hall Nematic Phases<sup>1</sup>**, J.P. EISENSTEIN, J. POLLANEN, K.B. COOPER<sup>2</sup>, S. BRANDSEN, Institute for Quantum Information and Matter and Dept. of Physics, Caltech, Pasadena, CA, L.N. PFEIFFER, K.W. WEST, Dept. of Electrical Engineering, Princeton University, Princeton, NJ — The native symmetry-breaking potential which consistently orients the quantum Hall nematic phases in high mobility 2D electron systems relative to the host semiconductor crystal axes remains unknown. Here we report an extensive set of measurements examining the role of the structural symmetries of the potential confining the 2D system in determining the orientation of the nematics [1]. In single quantum well samples we find that neither the local symmetry of the confinement potential nor the depth of the 2D electron system beneath the sample surface dictates the orientation of the nematic. In contrast, for 2D electrons confined at a single heterointerface between GaAs and AlGaAs, the nematic orientation does depend on the depth of the 2D electron system beneath the sample surface. We relate these results to various theoretical models of the symmetry-breaking potential. [1] J. Pollanen et al., Phys. Rev B 92, 115410 (2015).

**2:42PM P51.00002 Nematic quantum phase transition of composite Fermi liquids in half-filled Landau levels and their geometric response**, YIZHI YOU, University of Illinois at Urbana-Champaign, GIL YOUNG CHO, Korea Advanced Institute of Science and Technology, EDUARDO FRADKIN, University of Illinois at Urbana-Champaign — We present a theory of isotropic-nematic quantum phase transition in the composite Fermi liquid arising in the half-filled Landau levels. We show that the quantum phase transition is triggered by the attractive quadrupolar interaction. By performing flux attachment, system turns into a composite Fermi liquid. The nematic order parameters act as the dynamical metric interplaying with the underlying topology, the Chern-Simons theory. Here both the fluctuations of the gauge field and the nematic order parameter can soften the Fermi surface and thus the fermions form a non-Fermi liquid. The effective field theory for the isotropic-nematic phase transition has  $z = 3$  dynamical exponent due to the Landau damping due to the finite density of the fermions. We show that there is a Berry phase term of the nematic order parameter, which can be interpreted as the Hall viscosity of the dynamical metric. We also find the Wen-Zee-like term, which effectively dresses the nematic vortex with the electric charge. Both of the terms are originated from the time reversal breaking fluctuation of the Chern-Simons gauge fields. This indicates the fluctuations of the gauge fields modify the Hall viscosity and orbital spin of the compressible half-filled Landau level.

**2:54PM P51.00003 Phase Transition between Fermionic IQHE and Bosonic FQHE Via Feshbach Resonance**, SHUAN-FAN LIOU, KUN YANG, National High Magnetic Field Laboratory and Florida State Univ, ZI-XIANG HU, Chongqing University, China — We study an integer quantum Hall system with two species of fermions with total Landau filling factor two (or one per kind of fermions) on disk geometry. Via Feshbach resonance fermions interact with each other such that two different species of fermions become a boson as coupling strength increases. Through exact diagonalization method, we see that fermions undergo a phase transition from fermionic integer quantum Hall phase to bosonic fractional quantum Hall phase with  $\nu = \frac{1}{2}$ . Besides, it seems to be a second order phase transition by investigating the expectation value of particle number of bosons.

**3:06PM P51.00004 The effect of Landau level mixing on spin polarization of composite fermions: a non-perturbative study**, YUHE ZHANG, JAINENDRA K. JAIN, Department of Physics, 104 Davey Lab, Pennsylvania State University, University Park, PA 16802, USA — The spin polarization transitions enable precise tests of the fractional quantum Hall (FQH) theory. Possible factors responsible for the deviations between theories and experiments include Landau level (LL) mixing and finite quantum well width. Previous works generally treat LL mixing perturbatively. Following [1], we perform a fixed-phase diffusion Monte Carlo study to solve the many-body Schrodinger equation within the approximation of fixing the phase of the wave function. We calculate the critical Zeeman energy ( $E_z$ ) needed to fully spin polarize several FQH states, and find that  $E_z$  depends less sensitively on LL mixing than previously thought. We also take into account the effect of finite quantum well width by using an effective two-dimensional interaction based on the realistic charge distribution. We compare our results with experiments and make further predictions. [1] G. Ortiz, D. M. Ceperley, and R.M. Martin, Phys. Rev. Lett. 71, 2777 (1993).

**3:18PM P51.00005 Competing states for the fractional quantum Hall effect in the 1/3-filled second Landau level**, JAE-SEUNG JEONG, Institute for Basic Science:Center for Correlated Electron Systems, Department of Physics & Astronomy, Seoul National University, Seoul 08826, Korea, HANTAO LU, Center for Interdisciplinary Studies & Key Laboratory for Magnetism and Magnetic Materials of the MoE, Lanzhou University, Lanzhou 730000, China, KENJI HASHIMOTO, Max Planck Institute for Mathematics Vivatsgasse 7, 53111 Bonn, Germany, SUK BUM CHUNG, Institute for Basic Science : Center for Correlated Electron Systems, Department of Physics & Astronomy, Seoul National University, Seoul 08826, Korea, KWON PARK, School of Physics, Korea Institute for Advanced Study, Seoul 130-722, Korea — We study the nature of the fractional quantum Hall state in the 1/3-filled second Landau level at filling factor 7/3 via exact diagonalization. We show a series of transitions in the energy spectrum from a Laughlin-type spectrum, to an intermediate compressible spectrum, to a reentrant incompressible spectrum, and to a compressible spectrum with decrease of the Haldane pseudopotential. To search for a trial state describing the 7/3 state, we compute the overlap of the exact 7/3 ground state with various competing states including the Laughlin state, the particle-hole conjugate of the  $Z_4$  parafermion state, the fermionic Haffnian state, the antisymmetrized product state of two composite fermion seas (CFSs) at 1/6 filling, and the antisymmetrized correlated state of two CFSs at 1/4 filling, which are obtained as an antisymmetrized projection of the bilayer quantum Hall states. Specifically, we prove that the fermionic Haffnian state is equivalent to the antisymmetrized projection of the Halperin (551) state.

**3:30PM P51.00006 SU(3) and SU(4) singlet quantum Hall states at  $\nu = 2/3^1$** , FENGCHENG WU, Department of Physics, University of Texas at Austin, INTI SODEMANN, Department of Physics, Massachusetts Institute of Technology, ALLAN H. MACDONALD, Department of Physics, University of Texas at Austin, THIERRY JOLICOEUR, Laboratoire de Physique Théorique et Modèles statistiques, CNRS and Université Paris-Sud — We report on an exact diagonalization study of fractional quantum Hall states at a filling factor  $\nu = 2/3$  in a system with a four-fold degenerate  $n=0$  Landau level and SU(4) symmetric Coulomb interactions. Our investigation reveals previously unidentified SU(3) and SU(4) singlet ground states which appear at flux quantum shift 2 when a spherical geometry is employed, and lie outside the established composite-fermion or multicomponent Halperin state patterns. We will present the pair correlation functions of these states, and describe similar singlets at another filling factor 2/5. Strategies to construct trial wave functions will be discussed.

**3:42PM P51.00007 Adiabatic Transport of Geometric Singularities in the Quantum Hall Effect**, MICHAEL LASKIN, YU HUNG CHU, University of Chicago, TANKUT CAN, SUNY Stonybrook, PAUL WIEGMANN, University of Chicago — We present a framework for studying the fractional Quantum Hall Effect (FQHE) on singular surfaces - in particular surfaces with multiple geometric singularities. It is now known that, aside from the Hall conductance and viscosity, there exists a third universal transport coefficient of the FQHE - the gravitational anomaly. This coefficient is difficult to measure since it usually appears as a higher order correction to observable quantities, such as the particle density. Singular surfaces are the first setting where the gravitational anomaly appears as a leading order effect. These surfaces are therefore ideal for studying geometric response and the gravitational anomaly within the FQHE. We expand the generating functional in the large  $N$  limit on such surfaces. From there, we braid the conical singularities of the surface and find a remarkable result - the gravitational anomaly determines the braiding statistics of the transported conical singularities.

**3:54PM P51.00008 Quantum Hall State on Singular Surfaces**, YU HUNG CHIU, Univ of Chicago, TANKUT CAN, Simons center for Geometry and Physics, Stony Brook University, MICHAEL LASKIN, PAUL B. WIEGMANN, Univ of Chicago — We propose a framework to study the response towards geometry with FQHE state on singular surfaces. Such study on singular surface provides a path to measure the gravitational anomaly, the third universal transport coefficient of FQHE, in leading order. The large  $N$  expansion of generating functional is computed via two independent methods: a Ward Identity and a field theory approach. Meanwhile the second moment of the density is also obtained via Ward Identity. We observe that the generating functional on singular surfaces can be viewed as vertex operators at the cone tips. Divergence in the Liouville functional due to singularities is, as expected, a source for the modification, but not the sole source. From both methods, we are able to obtain the charge and conformal dimension  $h_\alpha$  of such a vertex operator. The talk will concentrate on the one cone result obtained via both approaches.

**4:06PM P51.00009 12/5 and 13/5 fractional quantum Hall states and Landau level mixing**, KIRYL PAKROUSKI, Theoretische Physik, ETH Zurich, Zurich 8093, Switzerland, MICHAEL PETERSON, Physics & Astronomy, California State University, Long Beach, CA, US, YANG-LE WU, Joint Quantum Institute and Condensed Matter Theory Center, Department of Physics, University of Maryland, College Park, Maryland 20742, US, MATTHIAS TROYER, Theoretische Physik, ETH Zurich, Zurich 8093, Switzerland — We use exact diagonalization to study the way Landau level mixing breaks the particle-hole symmetry between the 12/5 and 13/5 fractional quantum Hall states in GaAs. We discuss the possible relationship between our observations and the absence of the 13/5 state in experiment.

**4:18PM P51.00010 Exactly Solvable Model for Impurity Scattering at the Edge of the  $\nu = 2/3$  FQH State**, CHRIS HEINRICH, MICHAEL LEVIN, University of Chicago — We present an exactly solvable model for impurity scattering on the edge of a  $\nu = 2/3$  FQH state that is valid in the strong scattering limit. For this model we obtain exact mode expansions for the charge density and current operators, as well as the exact low energy spectrum. Importantly, we find that the low energy theory of the model consists of decoupled and counterpropagating charge and neutral modes, agreeing with the earlier work of Kane, Fisher, and Polchinski. Unlike the previous derivation, which relied on perturbative renormalization group arguments, our approach allows us to derive the emergence of decoupled charge and neutral modes from a microscopic model which is initially far from the decoupled fixed point.

**4:30PM P51.00011 Fragile Fractional Quantum Hall States in the Lowest and the Second Landau Level**, GABOR CSATHY, ETHAN KLEINBAUM, Purdue University, ASHWANI KUMAR, Monmouth College, NODAR SAMKHARADZE, Purdue University, LOREN PFEIFFER, KEN WEST, Princeton University — Ultra-low temperature measurements of the two-dimensional electron gas have revealed some of the most fragile fractional quantum Hall states. In these experiments electron thermalization was achieved using a He-3 immersion cell and the temperature of the bath is monitored using a quartz tuning fork viscometer. We will review the recently discovered fractional quantum Hall state at filling factor  $\nu = 3 + 1/3$  observed in the second Landau level and those at the filling factor  $\nu = 4/11$  and  $5/13$  in the lowest Landau level. The work at Purdue was supported by NSF DMR 1207375 and 1505866 grants. The work at Princeton University was funded by the Gordon and Betty Moore Foundation through the EPiQS initiative Grant GBMF4420, and by the National Science Foundation MRSEC Grant DMR-1420541.

**4:42PM P51.00012 Band geometry of higher Landau levels<sup>1</sup>**, RAHUL ROY, FENNER HARPER, THOMAS JACKSON, University of California, Los Angeles — A set of recent results have shown that the quantum geometry of bands as encoded in quantities such as the mean fluctuations of the Berry curvature and the quantum metric provide a useful way of analyzing the stability of FQHE phases in Chern bands. These quantum geometric quantities measure the closeness of Chern bands to the lowest Landau level. Here, we find a more complete set of criteria for the stability of FQHE phases which incorporate a distance measure to an arbitrary Landau level.

<sup>1</sup>Supported by the NSF under CAREER DMR-1455368 and the Alfred P. Sloan foundation

**4:54PM P51.00013 Fractional Chiral metal from the wire construction**, ADOLFO GRUSHIN, Univ of California - Berkeley, TOBIAS MENG, Technical University Dresden, KIRILL SHTENGEL, Univ of California - Riverside, JENS BARDARSON, Max Planck Institute for the Physics of Complex Systems — In this work we use the wire construction to build integer and fractional phases of the 4+1 dimensional quantum Hall effect by coupling 3+1 dimensional Weyl semimetals in an extra dimension. In the presence of an external magnetic field, each Weyl species reduces to a (degenerate) chiral wire, the zeroth Landau level, which, upon coupling, delivers a consistent response to an external electromagnetic field in terms of a 4+1 dimensional Chern Simons field theory. Going one step beyond, we show that the theory at the boundary is gapless and explicitly write the quantum field theory that represents and defines this novel state of matter, the fractional chiral metal. We end by discussing the construction in the absence of external magnetic fields.

**5:06PM P51.00014 Mapping a fractional quantum Hall state to a fractional Chern insulator**, YINHAN ZHANG, JUNREN SHI, Peking University — We establish a variational principle for properly mapping a fractional quantum Hall (FQH) state to a fractional Chern insulator (FCI). We find that the mapping has a gauge freedom which could generate a class of FCI ground state wave functions appropriate for different forms of interactions. Therefore, the gauge should be fixed by a variational principle that minimizes the interaction energy of the FCI model. For a soft and isotropic electron-electron interaction, the principle leads to a gauge coinciding with that for maximally localized two-dimensional projected Wannier functions of a Landau level.

**5:18PM P51.00015 Suppression of interference in quantum Hall Mach-Zehnder geometry by upstream neutral modes**, YUVAL GEFEN, The Weizmann Institute of Science, Israel, MOSHE GOLDSTEIN, Tel Aviv University, Israel — Mach-Zehnder interferometry has been suggested as a probe for anyonic quasiparticles in fractional quantum Hall states. However, all experimental attempts to measure such an interference signal have failed to date, despite the high visibility of interference fringes in the integer quantum Hall case. In our work we have studied the relation between this null result and another recent surprising experimental finding, namely the detection of upstream neutral modes in virtually all fractional quantum Hall states (including, e.g., filling  $1/3$ ), not only in hole-like filling factors (such as  $2/3$ ). We have found that the excitation of upstream modes makes the interference visibility in the Mach-Zehnder geometry decay exponentially with the total length of the interferometer arms, even when the lengths are exactly equal. We also suggest ways to overcome this suppression.

**2:30PM P52.00001 A general framework for analyzing pulsed optomechanical systems**, BASSAM HELOU, BELINDA PANG, HAIXING MIAO, YANBEI CHEN, Caltech — One difficulty in understanding driven optomechanical systems comes from keeping track of the continuum of input and output optical modes. Can we formulate a simpler description? In the case of optical pulses of finite duration, the answer is yes. The dynamics of the joint optical and mechanical system can be summarized by a finite number of generalized modes! On the other hand, the analysis of the entanglement structure between the mechanics and optics is more involved, but could be approximated by a simple and bounded structure. Our work has immediate applications to the quantum engineering of optomechanical setups. We rigorously justify the formalism used in proposals for arbitrary Fock state preparation, extend the proposals to more realistic setups, and propose additional state preparation and state transfer protocols.

**2:42PM P52.00002 Quench dynamics in optomechanical arrays**, SADEGH RAEISI, VITTORIO PEANO, FLORIAN MARQUARDT, University of erlangen-nuremberg — Optomechanical arrays are a novel quantum system that provide a promising tool for exploring many-body physics. The tunability of optomechanical arrays can be exploited for studying the non-equilibrium dynamics. Despite the technological challenges, experimental implementation of simple one-dimensional systems seems feasible in the next few years. Here we focus on the non-equilibrium dynamics of one-dimensional optomechanical arrays and investigate the quench dynamics in these systems. In particular, we study the topological properties and phases of these one-dimensional optomechanical arrays.

**2:54PM P52.00003 Correlated anomalous phase diffusion of sideband-excited phonons in an electromechanical resonator**, XIAOSHI DONG, FENGPEI SUN, JIE ZOU, Hong Kong University of Science and Technology, MARK DYKMAN, Michigan State University, HOBUN CHAN, Hong Kong University of Science and Technology — We study the phase fluctuations of self-sustained oscillations induced by dynamical backaction in a micromechanical resonator. The resonator has two vibrational modes with strongly differing frequencies and decay rates. The high-frequency mode acts as a phonon cavity mode, playing a similar role as photon modes in optomechanical systems. When sufficiently strong pumping is applied at the blue-detuned sideband of the cavity, the dynamical backaction leads to a parametric instability accompanied by self-sustained oscillations. We find that self-sustained oscillations are induced not only in the low frequency mechanical mode, but also in the high frequency cavity mode. The nonlinear nature of the backaction leads to hysteresis of this self-sustained oscillations. In each mode, the phase undergoes anomalous diffusion, where the mean square phase change in time follows a superlinear power law. The exponent of this power law is determined by the  $1/f$ -type intrinsic frequency noise of the resonator. Remarkably, the phase fluctuation of the two modes show near perfect anti-correlation, our findings show that self-sustained oscillations induced by dynamical backaction offer new opportunities of phase manipulation and investigation of fundamental properties of resonating.

**3:06PM P52.00004 Topological energy transfer in an optomechanical system with an exceptional point<sup>1</sup>** , HAITAN XU, DAVID MASON, LUYAO JIANG, JACK HARRIS, Yale University — We have measured an exceptional point in a cryogenic cavity optomechanical system, and have studied its topological properties. An exceptional point is a topological defect in the spectrum of a pair of coupled oscillators at which the system's two complex eigenvalues coalesce. We monitored the evolution of two mechanical oscillators while using a laser to encircle the exceptional point, thereby realizing topological energy transfer between mechanical modes. Moreover, by reversing the encircling direction, we observe the breakdown of the adiabatic theorem and show that the energy transfer possesses a diode-like asymmetry.

<sup>1</sup>This work is supported by AFOSR Grant FA9550-15-1-0270.

**3:18PM P52.00005 Optomechanical synchronization phenomena in the presence of (quantum) noise** , TALITHA WEISS, ANDREAS KRONWALD, STEFAN WALTER, FLORIAN MARQUARDT, Institute for Theoretical Physics, FAU Erlangen-Nuremberg — Synchronization is a phenomenon that appears in various natural and man-made systems. Optomechanical limit-cycle oscillators can synchronize when they are coupled to each other or to an external periodic force. Classically, in the absence of noise, different synchronization regimes can be identified. Notably, optomechanical systems tend to synchronize either in-phase or anti-phase. We investigate how the synchronization behaviour is affected in the presence of the fundamental quantum noise (arXiv:1507.06190). We find a regime where fluctuations drive transitions between the classical synchronization states and explore the quantum-to-classical crossover. Finally, we compare the effects of quantum noise to the effects of thermal noise.

**3:30PM P52.00006 Stochastic dynamics and phase-field roughening in optomechanical oscillator arrays** , ROLAND LAUTER, University of Erlangen-Nuremberg, ADITI MITRA, New York University, FLORIAN MARQUARDT, University of Erlangen-Nuremberg — We consider arrays of coupled optomechanical systems, each of which consists of a laser-driven optical mode interacting with a mechanical (vibrational) mode. For sufficiently strong laser driving, the mechanical modes can settle into stable finite-amplitude oscillations on a limit cycle. We study the collective classical nonlinear dynamics of the phases of these oscillators, which is effectively described by an extension of the well-known Kuramoto model. In this extended model, we study the effect of noise on the dynamics in the case of homogeneous-phase initial conditions. We analytically establish a connection to the physics of surface growth as described by the Kardar-Parisi-Zhang model. Simulations of one-dimensional arrays of our model indeed show roughening of the phase field and universal scaling of the phase-field width. In contrast to the continuum Kardar-Parisi-Zhang model, our model is a genuine lattice model. We discuss interesting effects due to this difference, including crossover timescales and the role of instabilities of the roughening process.

**3:42PM P52.00007 Topological Transport of Light and Sound** , CHRISTIAN BRENDL, VITTORIO PEANO, MICHAEL SCHMIDT, FLORIAN MARQUARDT, FAU Erlangen-Nuremberg — Since they exploit global features of a materials band structure, topological states of matter are particularly robust. Having already been observed for electrons, atoms, and photons, it is an outstanding challenge to create a Chern insulator of sound waves in the solid state. In this work, we propose an implementation based on cavity optomechanics in a photonic crystal. We demonstrate the feasibility of our proposal by means of an effective lattice model as well as first principle simulations. The topological properties of the sound waves can be wholly tuned in situ by adjusting the amplitude and frequency of a driving laser that controls the optomechanical interaction between light and sound. The resulting chiral, topologically protected phonon transport can be probed completely optically.

**3:54PM P52.00008 ORIGIN AND IMPLICATIONS OF  $A^2$  -LIKE CONTRIBUTION IN THE QUANTIZATION OF CIRCUIT-QED SYSTEMS** , MOHAMMAD MOEIN MALEKAKHLAGH, HAKAN TURECI, Princeton Univ — It is known that the electromagnetic modal structure of a cavity is modified by placing an atom into it. In cavity QED, this phenomenon manifests itself through the appearance of the  $A^2$ -contribution, a gauge-dependent diamagnetic term. Despite the negligible effect in the case of atomic cavity QED systems, in recent superconducting circuit realizations [1] these corrections may be observable and have qualitative implications. In this talk [2], we revisit the canonical quantization of a circuit QED system consisting of a single superconducting transmon qubit coupled to a multimode superconducting microwave resonator. We introduce a new set of modes that properly satisfies current conservation in the entire circuit and discuss how in terms of this set of modes, light-matter coupling can deviate drastically from the previous theories in the literature. Finally, we present a sum rule for the dipole transition matrix elements of a multi-level transmon qubit which provides an upper bound for the possible light-matter coupling strengths. [1] Neereja M. Sundaresan, Yanbing Liu, Darius Sadri, Laszlo J. Szocs, Devin L. Underwood, Moein Malekakhlagh, Hakan E. Tureci, Andrew A. Houck, Phys. Rev. X 5, 021035 [2] Moein Malekakhlagh and Hakan E. Tureci, arXiv:1506.02773 (2015)

**4:06PM P52.00009 Dynamical Gauge Fields in Optomechanics** , STEFAN WALTER, FLORIAN MARQUARDT, University of Erlangen-Nürnberg — Artificial gauge fields for neutral particles such as photons, recently attracted a lot of attention in various fields ranging from photonic crystals to ultracold atoms in optical lattices to optomechanical arrays. Here we point out that, among all implementations of gauge fields, the optomechanical setting allows for the most natural extension where the gauge field becomes dynamical. The mechanical oscillation phases determine the effective artificial magnetic field for the photons, and once these phases are allowed to evolve, they respond to the flow of photons in the structure. We discuss a simple three-site model where we identify four different regimes of the gauge-field dynamics. Furthermore, we extend the discussion to a two-dimensional lattice. Our proposed scheme could for instance be implemented using optomechanical crystals.

**4:18PM P52.00010 Topologically Reconfigurable Atomic Lattice Quantum Metamaterial.** , PANKAJ JHA, MICHAEL MREJEN, JEONGMIN KIM, CHIHUI WU, YUAN WANG, Univ of California - Berkeley, YURI ROSTOVTSSEV, Univ of North Texas, Denton, XIANG ZHANG, Univ of California - Berkeley — Metamaterials have attracted unprecedented attention owing to their exceptional light-matter interaction properties. However, harnessing metamaterial at single photon or few photon excitations is still a long way to go due to several critical challenges such as optical loss, defects to name a few. Here we introduce and theoretically demonstrate a novel platform toward quantum metamaterial, immune to aforementioned challenges, with ultra-cold neutral atoms trapped in an artificial crystal of light. Such periodic atomic density grating – an atomic lattice – exhibits extreme anisotropic optical response where it behaves like a metal in one direction but dielectric along orthogonal directions. We harness the interacting dark resonance physics to eliminate the absorption loss and demonstrate an all-optical and ultra-fast control over the photonic topological transition from a close to an open topology at the same frequency. Such atomic lattice quantum metamaterial enables dynamic manipulation of the decay rate of a quantum emitter by more than an order of magnitude. Our proposal brings together two important contemporary realm of science – cold atom physics and metamaterial for applications in both fundamental and applied science. Atomic lattice quantum metamaterial may provide new opportunities, at single or few photon level, for quantum sensing, quantum information processing with metamaterials.

**4:30PM P52.00011 Optomechanical Quantum Correlation Thermometry** , T. P. PURDY, Joint Quantum Institute/NIST, K. E. GRUTTER, M. I. DAVANCO, K. SRINIVASAN, Center for Nanoscale Science and Technology/NIST, J. M. TAYLOR, Joint Quantum Institute/NIST; Joint Center for Quantum Information and Computer Science/UMD — We present an optomechanical approach for producing accurate thermometry over a wide temperature range using quantum Brownian motion. Optical measurements induce quantum correlations in an optomechanical system when quantum-limited intensity fluctuations of a probe laser drive mechanical motion. The size of the correlations in the weak probe limit are dictated by the scale of individual phonons. We have recently measured optomechanical quantum correlations in the cross correlation spectrum between the amplitude and phase fluctuations of a single probe laser interacting with a silicon nitride optomechanical crystal. These correlations are independent of thermally-induced Brownian motion. However, Brownian motion does simultaneously produce much larger correlation signals between other optical quadratures. A comparison of the size of thermally-induced correlations to quantum correlations allows us to absolutely calibrate Brownian motion thermometry to the mechanical energy quantization scale.

**4:42PM P52.00012 Energy decay measurements in graphene-based mechanical resonators** , PETER WEBER, JOHANNES GÜTTINGER, ADRIEN NOURY, JOEL MOSER, ADRIAN BACHTOLD, ICFO - Institut de Ciències Fotoniques, The Barcelona Institute of Science and Technology, 08860 Castelldefels (Barcelona), Spain — Shrinking nanomechanical resonators has led to new record sensitivities in mass and force detection and has provided novel insights into the rich physics of mechanical nonlinearities. However, the high sensitivity and enhanced nonlinearities in ultra small resonators pose new challenges for the detection of motion. This has so far prevented a more detailed investigation of the energy decay, which is the key figure of merit for most technological and scientific applications. Here we present a method to carry out time-resolved energy decay measurements of few-layer graphene resonators. In the high vibration amplitude regime, we observe a strong deviation from previous energy decay measurements. Contrary to expectations, the exponential decay rate decreases abruptly at a few threshold amplitudes. At the lowest measured vibrational amplitude, the energy decay rate is weakest, corresponding to quality factors that can surpass 1 million.

**4:54PM P52.00013 Demonstration of the reversed dissipation regime in cavity electro-mechanics** , A.K. FEOFANOV, L.D. TOTH, N.R. BERNIER, T.J. KIPPENBERG, Ecole polytechnique federale de Lausanne — Cavity optomechanical phenomena, such as cooling, amplification or optomechanically induced transparency, emerge due to a strong imbalance in the dissipation rates of the parametrically coupled electromagnetic and mechanical resonators. Here we explore experimentally for the first time the reversed dissipation regime where the mechanical energy relaxation rate exceeds the energy decay rate of the electromagnetic cavity. We demonstrate optomechanically induced modifications of the microwave cavity resonance frequency and decay rate as well as mechanically-induced amplification of the electromagnetic mode and self-sustained oscillations (maser action) with high spectral purity of emitted microwave tone.

**5:06PM P52.00014 Ground state cooling of a nanomechanical resonator using electron transport in hybrid systems.**<sup>1</sup> , GIANLUCA RASTELLI, PASCAL STADLER, WOLFGANG BELZIG, University of Konstanz — A still open challenge in nanoelectromechanical systems is the achievement of the quantum regime via active cooling and using electron transport. I will discuss active ground state cooling in a bottom-up device, viz. a carbon nanotube quantum dot suspended between two electric nano-contacts, and for two different coherent transport regimes: (i) spin-polarized current between two ferromagnets and (ii) sub-gap Andreev current between a superconductor and a normal metal. I will show that efficient ground state cooling of the resonator can be achieved for realistic parameters of the system and varying the transport parameters, e.g. gate voltage, magnetic field, etc. Finally I will discuss the signatures in the current-voltage characteristics of the non-equilibrium state of the nanoresonator.

<sup>1</sup>Zukunftskolleg of the University of Konstanz; DFG through SFB 767 and BE 3803/5.

**5:18PM P52.00015 Laser cooling of a harmonic oscillator's bath with optomechanics** , XUNNONG XU, Joint Quantum Institute, University of Maryland/National Institute of Standards and Technology, College Park, Maryland 20742, USA, JACOB TAYLOR<sup>1</sup>, Joint Quantum Institute, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, USA — Thermal noise reduction in mechanical systems is a topic both of fundamental interest for studying quantum physics at the macroscopic level and for application of interest, such as building high sensitivity mechanics based sensors. Similar to laser cooling of neutral atoms and trapped ions, the cooling of mechanical motion by radiation pressure can take single mechanical modes to their ground state. Conventional optomechanical cooling is able to introduce additional damping channel to mechanical motion, while keeping its thermal noise at the same level, and as a consequence, the effective temperature of the mechanical mode is lowered. However, the ratio of temperature to quality factor remains roughly constant, preventing dramatic advances in quantum sensing using this approach. Here we propose an efficient scheme for reducing the thermal load on a mechanical resonator while improving its quality factor. The mechanical mode of interest is assumed to be weakly coupled to its heat bath but strongly coupled to a second mechanical mode, which is cooled by radiation pressure coupling to a red detuned cavity field. We also identify a realistic optomechanical design that has the potential to realize this novel cooling scheme.

**2:30PM P53.00001 The intestine is a blender** , PATRICIA YANG, MORGAN LAMARCA, VICTORIA KRAVETS, DAVID HU, Georgia Institute of Technology — According to the U.S. Department of Health and Human Services, digestive disease affects 60 to 70 million people and costs over 140 billion annually. Despite the significance of the gastrointestinal tract to human health, the physics of digestion remains poorly understood. In this study, we ask a simple question: what sets the frequency of intestinal contractions? We measure the frequency of intestinal contractions in rats, as a function of distance down the intestine. We find that intestines contract radially ten times faster than longitudinally. This motion promotes mixing and, in turn, absorption of food products by the intestinal wall. We calculate viscous dissipation in the intestinal fluid to rationalize the relationship between frequency of intestinal contraction and the viscosity of the intestinal contents. Our findings may help to understand the evolution of the intestine as an ideal mixer.

### 2:42PM P53.00002 Confinement of Single Microswimmers in Circular Microfluidic Chambers

, TANYA OSTAPENKO, THOMAS BOEDDEKER, CHRISTIAN KREIS, FABIAN SCHWARZENDAHL, MARCO G. MAZZA, OLIVER BAEUMCHEN, Max Planck Institute for Dynamics and Self-Organization (MPIDS), 37077 Goettingen, Germany — The characteristics of active fluids, such as suspensions of biological microswimmers, may not only originate from the mutual interactions between the constituents, but also from interactions with interfaces and confining walls. In fact, the natural habitats of many living organisms are complex geometric environments, rather than bulk situations. The influence of interfaces on the dynamics was recognized as an important factor, and there are differences in the way that pusher-type swimmers (e.g. *E. coli*) and puller-type swimmers (e.g. *C. reinhardtii*) behave close to flat interfaces. Using experiments and simulations, we report on the dynamics of single puller-type swimmers in 2D circular microfluidic chambers. We find that the radial probability distribution of trajectories displays a characteristic wall hugging effect, where swimmers remain trapped at a concave interface for decreasing chamber size. For trajectories in the vicinity of the concave wall, an alignment of the local swimming direction with the local wall tangent is observed. In contrast, the swimmers tend to scatter off convex interfaces with short interaction times. Based on geometric arguments involving the swimmer's persistence length, we explain this entrapment effect at concave interfaces.

### 2:54PM P53.00003 Mirror-symmetry breakings in human sperm rheotaxis

, NORBERT STOOP, Massachusetts Inst of Tech-MIT, ANTON BUKATIN, IGOR KUKHTEVICH, Russian Academy of Sciences, St. Petersburg Academic University, JOERN DUNKEL, Massachusetts Inst of Tech-MIT, VASILY KANTSLER, University of Warwick — Rheotaxis, the directed response to fluid velocity gradients, has been shown to facilitate stable upstream-swimming of mammalian sperm cells along solid surfaces, suggesting a robust mechanism for long-distance navigation during fertilization. However, the dynamics by which a human sperm orients itself w.r.t. ambient flows is poorly understood. Here, we combine microfluidic experiments with mathematical modeling and 3D flagellar beat reconstruction to quantify the response of individual sperm cells in time-varying flow fields. Single-cell tracking reveals two kinematically distinct swimming states that entail opposite turning behaviors under flow reversal. We constrain an effective 2D model for the turning dynamics through systematic large-scale parameter scans, and find good quantitative agreement with experiments. We present comprehensive 3D data demonstrating the rolling dynamics of freely swimming sperm cells around their longitudinal axis. Contrary to current beliefs, this analysis uncovers ambidextrous flagellar waveforms and shows that the cells turning direction is not defined by the rolling direction. Instead, the different rheotactic turning behaviors are linked to a broken mirror-symmetry in the midpiece section, likely arising from a buckling instability.

### 3:06PM P53.00004 Microorganism billiards in closed plane curves

, MADISON KRIEGER, Brown University — Recent experiments and numerical simulations have demonstrated that many species of microorganisms reflect specularly from a solid surface — due to steric and hydrodynamic interactions with the wall, their outgoing angle is fixed and independent of the angle of incidence. Motivated by these results, we discuss theory and computation of the “aspecular billiard”, a modification of the classical billiard in which the outgoing angle is constant. We restrict our attention to closed plane curves, focusing on three canonical examples: the ellipse, the Bunimovich stadium, and the Sinai billiard. These systems can have a rich array of orbits, and the Lyapunov exponent is shown to be dependent on the billiard geometry and the outgoing angle. We apply these results to the design of tunable passive sorting mechanisms.

### 3:18PM P53.00005 *Helicobacter pylori* displays spiral trajectories while swimming like a corkscrew in solutions.<sup>1</sup>

, MAIRA A. CONSTANTINO, JOSEPH M. HARDCASTLE, RAMA BANSIL, Boston University, MEHDI JABBARZADEH, HENRY C. FU, University of Nevada at Reno — *Helicobacter pylori* is a helical shaped bacterium that causes gastritis, ulcers and gastric cancer in humans and other animals. In order to colonize the harsh acidic environment of the stomach *H. pylori* has evolved a unique biochemical mechanism to go across the viscoelastic gel-like gastric mucus layer. Many studies have been conducted on the swimming of *H. pylori* in viscous media. However a yet unanswered question is if the helical cell shape influences bacterial swimming dynamics or confers any advantage when swimming in viscous solution. We will present measurements of *H. pylori* trajectories displaying corkscrew motion while swimming in solution obtained by tracking single cells using 2-dimensional phase contrast imaging at high magnification and fast frame rates and simultaneously imaging their shape. We observe a linear relationship between swimming speed and rotation rate. The experimental trajectories show good agreement with trajectories calculated using a regularized Stokeslet method to model the low Reynolds number swimming behavior.

<sup>1</sup>Supported by NSF PHY 1410798 (PI: RB)

### 3:30PM P53.00006 Investigating wake patterns and propulsive frequencies of a flat plate under pitching motion.

, JOSEPH MOUBOGHA MOUBOGHA<sup>1</sup>, JACQUES ANDRE ASTOLFI<sup>2</sup>, French Naval Academy Institute - IRENav — Fundamental mechanisms of swimming are explored using a simple geometry device - flat plate - in pure-pitching motion in a hydrodynamic tunnel. The experiments are carried out at different Reynolds numbers based on the plate length  $c$ . Pitching motion is generated for reduced frequencies  $k$  between 0 and 2 and for an angular amplitude of 10 deg. Velocity fields are obtained in the wake of the plate using Particle Image Velocimetry and measurements of drag coefficients are estimated from mean velocity profiles. This study confirms the occurrence of a threshold oscillation frequency beyond which the plate enters a propulsive regime and the wake features organized structures. In this case an inversion of the typical Karman vortex street is observed. The evolution of mean transverse velocity profiles in the wake of the plate shows that the usual wake profile with velocity deficit - plate with drag - can be transformed into a jet - plate with thrust - above a certain reduced frequency.

### 3:42PM P53.00007 Continuous-flow Electrokinetic Particle Separation in a Bifurcating Microchannel.

, DI LI, XINYU LU, XIANGCHUN XUAN, Clemson University — Separating particles from a heterogeneous mixture is important and necessary in many engineering and biomedical applications. Electrokinetic flow-based continuous particle separation has so far been realized primarily by the use of particle dielectrophoresis induced in constricted and/or curved microchannels. We demonstrate in this talk that particles can be continuously separated by size when passing through a bifurcating microchannel. This sheathless label-free separation relies on the wall-induced electrical lift force that acts to focus particles to the center of the main-branch and deflect them to size-dependent flow paths in the two side-branches. We also develop a numerical model to predict and understand this separation.

**3:54PM P53.00008 Predator-prey model for the self-organization of stochastic oscillators in dual populations**<sup>1</sup>, SARA MORADI, Universit Libre de Bruxelles, 1050 Brussels, Belgium, JOHAN ANDERSON, Department of Earth and Space Sciences, Chalmers University of Technology, SE-412 96 Gteborg, Sweden, OZGUR D. GRCAN, Ecole Polytechnique, CNRS UMR7648, LPP, F-91128, Palaiseau, France — A predator-prey model of dual populations with stochastic oscillators is presented. A linear cross-coupling between the two populations is introduced that follows the coupling between the motions of a Wilberforce pendulum in two dimensions: one in the longitudinal and the other in torsional plain. Within each population a Kuramoto type competition between the phases is assumed. Thus, the synchronization state of the whole system is controlled by these two types of competitions. The results of the numerical simulations show that by adding the linear cross-coupling interactions predator-prey oscillations between the two populations appear which results in self-regulation of the system by a transfer of synchrony between the two populations. The model represents several important features of the dynamical interplay between the drift wave and zonal flow turbulence in magnetically confined plasmas, and a novel interpretation of the coupled dynamics of drift wave-zonal flow turbulence using synchronization of stochastic oscillator is discussed.

**4:06PM P53.00009 Exploring the Spatiotemporal Dynamics of Covariant Lyapunov Vectors for Chaotic Convection**<sup>1</sup>, MU XU, MARK PAUL, Virginia Tech — Covariant Lyapunov vectors provide access to fundamental features of chaos in high-dimensional systems that are driven far-from-equilibrium. We explore the spatiotemporal dynamics of covariant Lyapunov vectors for chaotic Rayleigh-Bénard convection to provide new physical insights. We use the covariant Lyapunov vectors to quantify the transition from hyperbolic to non-hyperbolic dynamics, to determine the degree of Oseledec splitting exhibited by the dynamics, and to shed light upon upon the tangled nature of the Lyapunov vectors. In this talk, we will explore the spatiotemporal dynamics of the Lyapunov vectors and their relation with the chaotic pattern dynamics of the flow field. Our results suggest that the Lyapunov vectors contain two distinct spatiotemporal features consisting of highly localized regions near defect structures and a spatially distributed checkerboard pattern. We will explore the connection between these features and the ideas of physical and spurious modes that may compose the dynamics.

**4:18PM P53.00010 Lattice-Boltzmann Simulation of Tablet Disintegration**, JIAOLONG JIANG, NING SUN, DILIP GERSAPPE, Department of Materials Science and Engineering, Stony Brook University, Stony Brook, NY, 11794, USA — Using the lattice-Boltzmann method, we developed a 2D model to study the tablet disintegration involving the swelling and wicking mechanisms. The surface area and disintegration profile of each component were obtained by tracking the tablet structure in the simulation. Compared to pure wicking, the total surface area is larger for swelling and wicking, which indicates that the swelling force breaks the neighboring bonds. The disintegration profiles show that the tablet disintegrates faster than pure wicking, and there are more wetted active pharmaceutical ingredient particles distributed on smaller clusters. Our results indicate how the porosity would affect the disintegration process by changing the wetting area of the tablet as well as by changing the swelling force propagation.

**4:30PM P53.00011 The role of the capillary force in the liquid distribution in porous media**, BOJAN MARKICEVIC, Pall Corp — The dynamics of the liquid spreading in porous media occupied by gas is investigated numerically using the capillary network models. In the numerical solution, the flow at the free interface is fully resolved from the force balance at each pore along the interface allowing for local flows to fill or empty the pores. The flow is transient and the interface shape is determined at each time step. The liquid/solid interactions are investigated for whole range from fully wetting to fully non-wetting cases, and the spread of neutral fluid is also solved. For the neutral fluid, the interface irregularity are caused by pore varying volume with the interface of specific thickness separating fully saturated and gas occupied parts of porous medium. For the capillary interactions present, the interface thickness increases and due to the gas entrapment by spreading liquid, the saturation profiles develop in the direction of the liquid flow. The profiles depend on the capillary force as liquid spreads along the paths consisting of smaller pores for wetting, and larger pores for non-wetting interactions. Finally, the influence of the capillary force is counteracted by viscous force, where for faster flows, the saturation profiles vanish and the interface of limited thickness develops.

**4:42PM P53.00012 Numerical modeling and simulation of flow through porous fabric surface**, ZHENG GAO, XIAOLIN LI, Stony Brook University — We designed a numerical scheme to model the permeability of the fabric surface in an incompressible fluid by coupling the projection method with the Ghost Fluid Method in the front tracking framework. The pressure jump condition is obtained by adding a source term to the Poisson's equation in the projection step without modifications on its coefficients. The numerical results suggest that this approach has the ability to reproduce the relationship between pressure drop and relative velocity observed in the experiments. We use this algorithm to study the effects of porosity on the drag force and stability of parachutes during its inflation and deceleration.

**4:54PM P53.00013 A Numerical Study of Shear Flow in Partially Vegetated Open Channels**, JINGFANG QU, SUNY, Stony Brook, S CHEN, North Carolina State University, JIE YU, XIAOLIN LI, SUNY, Stony Brook — Shear flow at the interface between a porous layer and an open conduit is a problem of fundamental importance to problems ranging from natural to engineered flows. Such shear flows are known to be unstable, inducing waves and coherent vortices via Kelvin-Helmholtz instability. These coherent flow structures can strongly enhance the exchange of scalar variables and vector variable such as momentum in and out of the canopy, hence playing an important role in controlling environmental quality of these system. We developed a numerical model using finite difference method for flow in open channel occupied by a vegetation canopy. We apply the method to simulate the shear flow and compare with the experimental study by White and Nepf in 2007. Preliminary comparisons with the experimental data show good agreements.

**5:06PM P53.00014 Finite Amplitude Analysis of Mixed Convection in a Vertical Annulus Filled with Porous Medium.**, PREMANANDA BERA<sup>1</sup>, MOUMITA BHOWMIK, Indian Institute of Technology Roorkee — Using the weakly nonlinear stability analysis, we have investigated the stability of stably stratified mixed convective flow in a vertical annulus filled with fluid saturated metallic foam with porosity 0.97. Since the curvature parameter ( $C$ ) plays a vital role to describe the geometry, therefore special attention has been given to understand the effect of  $C$  on the flow by considering three different values of  $C$  (0.001, 0.6, and 10). The nonlinear results are presented for the fluid as water (Prandtl number ( $Pr$ ) equal to 7) and a fixed Reynolds number  $Re$  equal to 500. In the entire weakly nonlinear analysis, only super critical bifurcation has been predicted at and beyond the critical Rayleigh number ( $Ra$ ). The equilibrium amplitude ( $|A|$ ) increases beyond the critical point and decreases on reducing the gap between the concentric cylinders. Due to nonlinear interaction, a substantial enhancement in heat transfer rate is also observed from the basic state beyond the bifurcation point, i.e. Nusselt number predicted by nonlinear analysis is much more than those predicted by fully developed basic state.

**Session P54 GERA DPOLY FIAP: Organic Systems for Photovoltaics, Including Perovskites**

Hilton Baltimore Holiday Ballroom 5 -

**2:30PM P54.00001 Ovshinsky Sustainable Energy Fellowship: Excitronics for Transparent Photovoltaics**, RICHARD LUNT, Michigan State University — Room-temperature excitonic materials offer new opportunities for low-cost photovoltaic (PV) systems and provide prospects for unique solar harvesting science and applications. In the first part of this talk, I will introduce our pioneering work on developing transparent PVs that are creating a new paradigm for seamless solar harvesting around buildings, automobiles, and mobile electronics. These devices are enabled by the manipulation of excitonic semiconductor materials with selective harvesting in the nearinfrared and ultraviolet components of the solar spectrum. I will describe key photophysical properties, outline the thermodynamic and practical limits to these new classes of materials and devices, and briefly discuss their commercial impact for a range of applications. In the second part, I will describe the development of a new series organic salts that allow tunable photoresponse from 900nm to 1600nm, an unprecedented range for smallmolecule semiconductors. These organic salts also enable precise tuning of frontier orbital levels and heterojunction interface gaps through anion alloying that result in voltages near the thermodynamic limit. This design strategy can further enable rapid development of efficient and lowcost multijunction devices (both opaque and transparent) with complimentary response across the solar spectrum.

**3:06PM P54.00002 The role of molecular layer mixing on the thermal conductance of organic-inorganic heterojunctions**, SHUBHADITYA MAJUMDAR, ALAN J.H. MCGAUGHEY, JONATHAN A. MALEN, Carnegie Mellon University — The role of interfacial properties in affecting energy transport characteristics is an extensive area of research. Hybrid materials composed of organic-inorganic heterojunctions are gaining popularity as alternatives to conventional semiconductors for various energy-generation devices, thus requiring detailed study of their interfacial properties – especially thermal transport. Previous works have isolated the organic-inorganic interface thermal properties using self-assembled monolayer (SAM) junctions between two inorganic substrates and characterized them based on interfacial bonding strength, vibrational mismatch and molecule length. Here, we investigate the effect of having a mixed SAM layer on the thermal conductance of the SAM junction. The mixed SAM layers either have molecules of the same length but different end groups (thiols and methyl) or different lengths. This creates a modifiable bonding environment at one interface either through a varying ratio of strong and weakly bonded end groups or a decreasing surface coverage of the molecule. Both these scenarios are investigated to study the cooperative nature of the molecules/interface bonds and their effect on the heat transport across the junction. We follow a combined experimental and computational approach in our investigation – we fabricate the SAM junctions (alkanethiols between two gold substrates) and measure their thermal conductance using Frequency Domain Thermoreflectance, and use molecular dynamics simulations to get a deeper understanding of the role of intermolecular cross talk.

**3:18PM P54.00003 MOVED TO X33.011 –**

**3:30PM P54.00004 Switchable Solar Window Devices Based on Polymer Dispersed Liquid Crystals<sup>1</sup>**, JOSEPH MURRAY, DAKANG MA, JEREMY MUNDAY, University of Maryland — Windows are an interesting target for photovoltaics due to the potential for large area of deployment and because glass is already a ubiquitous component of solar cell devices. Many demonstrations of solar windows in recent years have used photovoltaic devices which are semitransparent in the visible region. Much research has focused on enhancing device absorption in the UV and IR ranges as a means to circumvent the basic tradeoff between efficiency and transparency to visible light. Use of switchable solar window is a less investigated alternative approach; these windows utilize the visible spectrum but can toggle between high transparency and high efficiency as needed. We present a novel switchable solar window device based on Polymer Dispersed Liquid Crystals (PDLC). By applying an electric field to the PDLC layer, the device can be switched from an opaque, light diffusing, efficient photovoltaic cell to a clear, transparent window. In the off state (i.e. scattering state), these devices have the added benefits of increased reflectivity for reduced lighting and cooling costs and haze for privacy. Further, we demonstrate that these windows have the potential for self-powering due to the very low power required to maintain the on, or high transparency, state.

**3:42PM P54.00005 Discovery of Novel Perovskites for Solar Thermochemical Water Splitting from High-Throughput First-Principles Calculations**, ANTOINE EMERY, CHRIS WOLVERTON, Northwestern Univ — Among the several possible routes of hydrogen synthesis, thermochemical water splitting (TWS) cycles is a promising method for large scale production of hydrogen. The choice of metal oxide used in a TWS cycle is critical since it governs the rate and efficiency of the gas splitting process. In this work, we present a high-throughput density functional theory (HT-DFT) study of  $\text{ABO}_3$  perovskite compounds to screen for thermodynamically favorable two-step thermochemical water splitting materials. We demonstrate the use of two screens, based on thermodynamic stability and oxygen vacancy formation energy, on 5,329 different compositions to predict 139 stable potential candidate materials for water splitting applications. Several of these compounds have not been experimentally explored yet and present promising avenues for further research. Additionally, the large dataset of compounds and stability in our possession allowed us to revisit the structural maps for perovskites. This study shows the benefit of using first-principles calculations to efficiently screen an exhaustively large number of compounds at once. It provides a baseline for further studies involving more detailed exploration of a restricted number of those compounds.

**3:54PM P54.00006 Super-ion inspired colorful hybrid perovskite solar cells.**, HONG FANG, PURU JENA, Virginia Commonwealth Univ — Organic-inorganic hybrid perovskites, with the general formula  $\text{AMX}_3$  (A=cation; M=metal; X=halogen), have emerged as a new generation of efficient yet inexpensive photovoltaic cells. These materials show record high conversion efficiency as solar cells and have excellent light-emission properties that can also be used in other optoelectronic devices. They can be processed easily from solution with optic band gaps, tunable from visible to infrared regions and are considered to be “the next big thing in photovoltaics”. However, several important issues such as the relationship between their photoexcitation properties and the chemical structures, their stability under ambient conditions, as well as the possibility to invent their environment-friendly analogues remain unsolved. In this work, our aim is not only to gain a fundamental understanding of the structure-property relationship of organic-inorganic hybrid perovskites, but also to rationally design a new class of hybrid perovskites that have desired electronic band gaps for solar cell applications. This is accomplished by using super-ions that can mimic the properties of elementary alkali and halogen ions as building blocks. These super-ions include superalkalis –  $\text{CH}_3\text{NH}_3^+$ ,  $\text{HC}(\text{NH}_2)_2^+$ , and  $\text{Li}_3\text{O}^+$  as cations and hyperhalogens –  $\text{Ge}(\text{BH}_4)_3^-$  and  $\text{Sn}(\text{BH}_4)_3^-$  as anions. The results are compared with perovskites composed of  $\text{GeCl}_3^-$ ,  $\text{GeBr}_3^-$ ,  $\text{GeI}_3^-$ ,  $\text{SnCl}_3^-$ ,  $\text{SnBr}_3^-$ , and  $\text{SnI}_3^-$  superhalogen anions. We develop a strategy to assemble these super-ions to form environment-friendly solar cells with adjustable band gaps (covering the visible range and beyond) and with improved resistance to moisture.

**4:06PM P54.00007 High efficiency graded band gap perovskite solar cells**, ONUR ERGEN, SALLY DEMAIO-TURNER, THANG THOAN PHAM, MARK TIAN ZHI TAN, JONGMIN YUK, ALEX ZETTL, University of California at Berkeley — We report high efficiency graded band gap perovskite solar cells with very large current output and high power conversion efficiencies (PCE) by using simultaneously mixed halides ( $\text{CH}_3\text{NH}_3\text{SnI}_3$  and  $\text{CH}_3\text{NH}_3\text{PbI}_{3-x}\text{Br}_x$ ) perovskite absorber layers. An analysis of the experimental data yields a high fill factor (FF) of ~75% and high short circuit current density ( $J_{\text{sc}}$ ) of up to 46.2 mA/cm<sup>2</sup>. These devices provide the highest current output aiming above 20% PCE.

**4:18PM P54.00008 Efficient organic-inorganic hybrid perovskites and doped metal oxide heterojunction solar cells.**, XIAOJUAN FAN, Marshall University — Organic-Inorganic hybrid perovskite  $\text{CH}_3\text{NH}_3\text{PbI}_3$  has recently attracted much attention for its high efficient solar energy conversion. This semiconducting pigment with a direct bandgap of 1.55 eV has made it an interesting optical and electronic material over the whole visible solar emission spectrum. The role of hole conducting has been found in this semiconductor that allows perovskite solar cell (PSC) to be formed by  $\text{CH}_3\text{NH}_3\text{PbI}_3/\text{TiO}_2$  heterojunctions that use  $\text{TiO}_2$  as scaffold, and carbon as a back contact. We will report a double layer metal doped  $\text{TiO}_2/\text{Al}_2\text{O}_3$  mesoporous scaffold covered by the p-type semiconducting pigment to form a high efficient PSC through solution method.  $\text{TiO}_2$  and  $\text{Al}_2\text{O}_3$  are both large band gap semiconductors that affect conducting and recombination rate in solar cells. One improvement work is doping other metal elements in  $\text{TiO}_2$  to raise the mobility while extend the recombination time. It has suggested that optimal amounts of doped metals such as Cu, Co, Mn can suppress the reduction of  $\text{Ti}^{4+}$  resulting better transportation.  $\text{TiO}_2$  thin films doped with metals are subjected to the EPR analysis and the results will be correlated with measurements of electronic-optical properties.

**4:30PM P54.00009 Modeling morphology dependence of the power generation in bulk heterojunction organic photovoltaics**, TIMOTHY SCHLITTENHARDT, SELMAN HERSHFIELD, Univ of Florida - Gainesville — Bulk heterojunctions are mixtures of differently doped organic semiconducting materials that provide for a highly interconnected and complex morphology. A three dimensional simulation is conducted of these systems, where the junctions are modeled by diodes with a given j-V characteristic and the transport within a particular material is treated as ohmic. The current and potential profile are calculated throughout the sample with an iterative method that allows us to readily treat systems with  $10^4$  sites for a full range of applied voltage biases. Visualizations of the current flow and voltage profile are given. It is found that power is not generated uniformly throughout the sample, but is concentrated near the edges. As has been observed experimentally, this leads to an optimal thickness for power generation. A simple analytical model is presented which reproduces and provides understanding of our simulation results.

**4:42PM P54.00010 Reliable thermal processing of organic perovskite films deposited on ZnO**, ALEX ZAKHIDOV, CHRIS MANSPEAKER, DMITRY LYASHENKO, Texas State University, ALEX ZAKHIDOV TEAM — Zinc oxide (ZnO) is a promising semiconducting material to serve as an electron transport layer (ETL) for solar cell devices based on organo-halide lead perovskites. ZnO ETL for perovskite photovoltaics has a combination of attractive electronic and optical properties: i) the electron affinity of ZnO is well aligned with valence band edge of the  $\text{CH}_3\text{NH}_3\text{PbI}_3$ , ii) electron mobility of ZnO is  $>1 \text{ cm}^2/(\text{Vs})$ , which is a few orders of magnitude higher than that of  $\text{TiO}_2$  (another popular choice of ETL for perovskite photovoltaic devices), and iii) ZnO has a large of band gap of 3.3 eV, which ensures optical transparency and large barrier for the hole injection. Moreover, ZnO nanostructures can be printed on flexible substrates at room temperatures in cost effective manner. However, it was recently found that organic perovskites deposited on ZnO are unstable and readily decompose at  $>90^\circ\text{C}$ . In this work, we further investigate the mechanism of decomposition of  $\text{CH}_3\text{NH}_3\text{PbI}_3$  film deposited on ZnO and reveal the role of the solvent in the film during the annealing process. We also develop a restricted volume solvent annealing (RVSA) process for post annealing of the perovskite film on ZnO without decomposition. We demonstrate that RVSA enables reliable perovskite solar cell fabrication.

**4:54PM P54.00011 Charge Generation Dynamics in Efficient All-Polymer Solar Cells: Influence of Polymer Packing and Morphology**, BHOJ GAUTAM, North Carolina State University, CHANGYEON LEE, Korea Advanced Institute of Science and Technology (KAIST), ROBERT YOUNTS, North Carolina State University, WONHO LEE, Korea Advanced Institute of Science and Technology (KAIST), EVGENY DANILOV, North Carolina State University, BUMJOON KIM, Korea Advanced Institute of Science and Technology (KAIST), KENAN GUNDOGDU, North Carolina State University — All-polymer solar cells exhibit rapid progress in power conversion efficiency (PCE) from 2 to 7.7% over the last few years. While this improvement is primarily attributed to efficient charge transport and balanced mobility between the carriers, not much is known about the charge generation dynamics in these systems. Here we measured exciton relaxation and charge separation dynamics using ultrafast spectroscopy in polymer/polymer blends with different molecular packing and morphology. These measurements indicate that preferential face on configuration with intermixed nanomorphology increases the charge generation efficiency. In fact there is a direct quantitative correlation between the free charge population in the ultrafast time scales and the external quantum efficiency, suggesting not only the transport but also charge generation is key for the design of high performance all polymer solar cells.

**5:06PM P54.00012 Phonon Mode Transformation across the Orthorhombic-Tetragonal Phase Transition in a Lead-Iodide Perovskite  $\text{CH}_3\text{NH}_3\text{PbI}_3$ : a Terahertz Time-Domain Spectroscopy Approach**<sup>1</sup>, ELBERT E. M. CHIA, Nanyang Tech Univ, CHAN LA-O-VORAKIAT, King Mongkuts University of Technology Thonburi, JEANNETTE KADRO, TEDDY SALIM, DAMING ZHAO, Nanyang Tech Univ, TOWFIQ AHMED, Los Alamos National Laboratory, YENG MING LAM, Nanyang Tech Univ, JIAN-XIN ZHU, Los Alamos National Laboratory, RUDOLPH MARCUS<sup>2</sup>, California Institute of Technology, MARIA-ELISABETH MICHEL-BEYERLE, Nanyang Tech Univ — Using terahertz time-domain spectroscopy (THz-TDS), we study the temperature-dependent phonon modes of the organometallic lead iodide perovskite  $\text{CH}_3\text{NH}_3\text{PbI}_3$  thin film across the terahertz (0.5-3 THz) and temperature (20-300 K) ranges. These modes are related to the vibration of the Pb-I bonds. We found that two phonon modes in the tetragonal phase at room temperature split into four modes in the low-temperature orthorhombic phase. By use of the Lorentz model fitting, we analyze the critical behavior of this phase transition.

**Session P55 DBIO DFD GSOFT: Active Fluids in Living Matter: Collective Cell Motility** Hilton  
Baltimore Holiday Ballroom 6 - Yuhai Tu, IBM, Inc.

**2:30PM P55.00001 Collective dynamics of cell migration and cell rearrangements** , ALEXANDRE KABLA, University of Cambridge — Understanding multicellular processes such as embryo development or cancer metastasis requires to decipher the contributions of local cell autonomous behaviours and long range interactions with the tissue environment. A key question in this context concerns the emergence of large scale coordination in cell behaviours, a requirement for collective cell migration or convergent extension. I will present a few examples where physical and mechanical aspects play a significant role in driving tissue scale dynamics.

1. Geometrical confinement is one of the key external factors influencing large scale coordination during collective migration. Using a combination of in vitro experiments and numerical simulations, we show that the velocity correlation length, measured in unconfined conditions, provides a convenient length scale to predict the dynamic response under confinement. The same length scale can also be used to quantify the influence range of directional cues within the cell population.
2. Heterogeneity within motile cell populations is frequently associated with an increase in their invasive capability and appears to play an important role during cancer metastasis. Using in silico experiments, we studied the way cell invasion is influenced by both the degree of cell coordination and the amount of variability in the motile force of the invading cells. Results suggest that mechanical heterogeneity dramatically enhances the invasion rate through an emerging cooperative process between the stronger and weaker cells, accounting for a number of observed invasion phenotypes.
3. Effective convergent extension requires on a consistent orientation of cell intercalation at the tissue scale, most often in relation with planar cell polarity mechanisms to define the primary axes of deformation. Using a novel modelling approach for cells mechanical interactions, we studied the dynamics of substrate free motile cell populations. Ongoing work shows in particular that nematic order emerges from interacting cells without the need for biochemical cues setting tissue polarity.

**3:06PM P55.00002 Multicellular Streaming in Solid Tumours** , JOSEF KAS, Leipzig University — As early as 400 BCE, the Roman medical encyclopaedist Celsus recognized that solid tumours are stiffer than surrounding tissue. However, cancer cell lines are softer, and softer cells facilitate invasion. This paradox raises several questions: Does softness emerge from adaptation to mechanical and chemical cues in the external microenvironment, or are soft cells already present inside a primary solid tumour? If the latter, how can a more rigid tissue contain more soft cells? Here we show that in primary tumour samples from patients with mammary and cervix carcinomas, cells do exhibit a broad distribution of rigidities, with a higher fraction of softer and more contractile cells compared to normal tissue. Mechanical modelling based on patient data reveals that, surprisingly, tumours with a significant fraction of very soft cells can still remain rigid. Moreover, in tissues with the observed distributions of cell stiffnesses, softer cells spontaneously self-organize into lines or streams, possibly facilitating cancer metastasis.

**3:42PM P55.00003 Active unjamming of confluent cell layers**<sup>1</sup> , M CRISTINA MARCHETTI, Syracuse University — Cell motion inside dense tissues governs many biological processes, including embryonic development and cancer metastasis, and recent experiments suggest that these tissues exhibit collective glassy behavior. Motivated by these observations, we have studied a model of dense tissues that combines self-propelled particle models and vertex models of confluent cell layers. In this model, referred to as self-propelled Voronoi (SPV), cells are described as polygons in a Voronoi tessellation with directed noisy cell motility and interactions governed by a shape energy that incorporates the effects of cell volume incompressibility, contractility and cell-cell adhesion. Using this model, we have demonstrated a new density-independent solid-liquid transition in confluent tissues controlled by cell motility and a cell-shape parameter measuring the interplay of cortical tension and cell-cell adhesion. An important insight of this work is that the rigidity and dynamics of cell layers depends sensitively on cell shape. We have also used the SPV model to test a new method developed by our group to determine cellular forces and tissue stresses from experimentally accessible cell shapes and traction forces, hence providing the spatio-temporal distribution of stresses in motile dense tissues.

**4:18PM P55.00004 Modeling collective cell motility**<sup>1</sup> , WOUTER-JAN RAPPEL, Univ of California - San Diego — Eukaryotic cells often move in groups, a critical aspect of many biological and medical processes including wound healing, morphogenesis and cancer metastasis. Modeling can provide useful insights into the fundamental mechanisms of collective cell motility. Constructing models that incorporate the physical properties of the cells, however, is challenging. Here, I discuss our efforts to build a comprehensive cell motility model that includes cell membrane properties, cell-substrate interactions, cell polarity, and cell-cell interaction. The model will be applied to a variety of systems, including motion on micropatterned substrates and the migration of border cells in *Drosophila*.

**4:54PM P55.00005 Water Dynamics in Living Cells and Tumor Cell Migration in Confined Microenvironments** , SEAN SUN, Johns Hopkins University — More than 70% of the total mass in living cells is water. In most biological scenarios water serves as a passive medium responsible for solvation and proper functioning of proteins. However, it has been long recognized that there are situations where dynamic transport of water in cells is important. First, cells actively transport water in order to maintain its volume, and because cell volume directly influences cell shape and internal hydrostatic pressure, it is a critical aspect of cell mechanics. Furthermore, cell volume is coupled to protein synthesis which ultimately determines the cell size. Therefore water transport and cell volume dynamics ultimately impact cell growth and division. Second, epithelial cells in organs such as the eye and kidney actively transport water across the cell membrane and the epithelial layer. Indeed, water channels such as aquaporins increase water permeability of the membrane and facilitate this transport. Recent, we have shown that in confined microenvironments, active transport of water is responsible for actin-independent cell movement in confined spaces, especially for cancer cells. These results suggest that cells actively control its water content. The active regulation of water content is a crucial aspect of cell dynamics. We will discuss a theoretical model of cell pressure/volume control. Implications of this model for active cell dynamics in multi-cellular epithelial sheets will be discussed.

**Session Q55 FHP FOEP: A Staged Reading of the Play: No No Nobel** Hilton Baltimore Key Ballroom

9 -

**8:00PM Q55.00001 A Staged Reading of the Play: No No Nobel** — A Staged Reading of the Play: No No Nobel In Biology, what discovery is considered the most important breakthrough of the 20th century? In Chemistry, what pattern development enabled chemists and physicists to understand the nature of and ultimately the atomic physics of the elements? In Physics, what experiment and theory in nuclear physics led to the most important journalistic story of the 20th century? In Cosmology, what theory was developed that enabled the understanding of the now named Big Bang theory and the evolution of the universe? In Science Education, what graduate student made a most important observation and ultimately the identification of a remnant of a supernova explosion? Join us for a dramatic staged reading of No No Nobel and find out what unifies all the above questions. The playwright is the science historian David Cassidy and the staged reading is performed by the Baltimore Improv Group [www.bigimprov.org](http://www.bigimprov.org) . After the performance, the playwright, the director Mike Harris and the actors will be available for a talk-back audience discussion. Produced by Brian Schwartz, Brooklyn College and the Graduate Center of the City University of New York

**Thursday, March 17, 2016 8:00AM - 11:00AM –**

**Session R1 DCMP: 3D Dirac Materials** Ballroom I - Ady Stern, Weizmann Institute of Science

**8:00AM R1.00001 Weyl Semimetal Phase in Noncentrosymmetric Transition-Metal Monophosphides**, XI DAI, Institute of Physics, CAS — Based on first-principle calculations, we show that a family of nonmagnetic materials including TaAs, TaP, NbAs, and NbP are Weyl semimetals (WSM) without inversion centers. We find twelve pairs of Weyl points in the whole Brillouin zone (BZ) for each of them. In the absence of spin-orbit coupling (SOC), band inversions in mirror-invariant planes lead to gapless nodal rings in the energy-momentum dispersion. The strong SOC in these materials then opens full gaps in the mirror planes, generating nonzero mirror Chern numbers and Weyl points off the mirror planes. The transport properties obtained by the Boltzmann equation combined with the semiclassical treatments of the unique electronic structure in these materials will also be discussed in comparison with the most recent experimental data.

**8:36AM R1.00002 Chirality transfer dynamics in quantum orbits in the Dirac semi-metal  $\text{Cd}_3\text{As}_2$** , PHILIP MOLL, UC Berkeley — No abstract available.

**9:12AM R1.00003 Evidence for the chiral anomaly in the Dirac semimetal  $\text{Na}_3\text{Bi}$** <sup>1</sup>, JUN XIONG, Princeton University — Chiral symmetry describes the conservation of handedness of massless chiral fermions in high-energy physics. Such symmetry can be broken by the coexistence of electric ( $\vec{E}$ ) and magnetic ( $\vec{B}$ ) fields, known as the chiral (Adler-Bell-Jackiw) anomaly. This anomaly describes an axial current pumped between left-handed and right-handed Weyl fermions. In condensed matter physics, the recent development in both theory and experiments has confirmed the existence of Weyl nodes in the Dirac and Weyl semimetals. Generated by the  $\vec{E} \cdot \vec{B}$  term, the axial current could induce negative magnetoresistance in the Dirac and Weyl semimetals. Here we report the observation of a large, negative longitudinal magnetoresistance in the Dirac semimetal  $\text{Na}_3\text{Bi}$ . By rotating both the direction of  $\vec{E}$  and  $\vec{B}$ , we found that the small deviation of  $\vec{E}$  from  $\vec{B}$  greatly suppresses the observed negative magnetoresistance. We will discuss its consistency with the predicted chiral anomaly effect in the Dirac/Weyl semimetal.

**9:48AM R1.00004 Experimental realization of new topological phases of matter beyond topological insulators**, MADHAB NEUPANE, Department of Physics, University of Central Florida, Orlando, Florida 32816, USA — A three-dimensional (3D)  $\text{Z}_2$  topological insulator (TI) is a crystalline solid, which is an insulator in the bulk but features spin-polarized Dirac electron states on its surface. In 2007, the first 3D TI was discovered in a bismuth-based compound. The discovery of the first TI tremendously accelerated research into phases of matter characterized by non-trivial topological invariants. Not only did the 3D  $\text{Z}_2$  TI itself attract great research interest, it also inspired the prediction of a range of new topological phases of matter. The primary examples are the topological Kondo insulator, the topological 3D Dirac and Weyl semimetals, the topological crystalline insulator, topological nodal line semimetal and the topological superconductor. Each of these phases was predicted to exhibit surface states with unique properties protected by a non-trivial topological invariant. In this talk, I will discuss the experimental realization of these new phases of matter in real materials by momentum and time-resolved photoemission spectroscopy. Special attention will be given to the experimental discovery of Dirac semimetal phase in  $\text{Cd}_3\text{As}_2$  and topological nodal-line phase in  $\text{PbTaSe}_2$ . The unusual properties of the protected topological surface states can lead to potential future applications in spintronics and quantum information, which hold promise to revolutionize our electronics and energy industries. *This work is supported by start-up funds from University of Central Florida (MN) and Los Alamos National Laboratory LDRD program. The work at Princeton and Princeton-led ARPES measurements are supported by the Gordon and Betty Moore Foundations EPiQS Initiative through grant GBMF4547 (Hasan) and by U.S. Department of Energy DE-FG-02-05ER46200.*

**10:24AM R1.00005 Time-reversal symmetry breaking type II Weyl state in  $\text{YbMnBi}_2$** , SERGEY BORISENKO, IFW-Dresden, Germany — Detection of Dirac, Majorana and Weyl fermions in real materials may significantly strengthen the bridge between high-energy and condensed-matter physics. While the presence of Dirac fermions is well established in graphene and topological insulators, Majorana particles have been reported recently and evidence for Weyl fermions in non-centrosymmetric crystals has been found only a couple of months ago, the "magnetic" Weyl fermions are still elusive despite numerous theoretical predictions and intense experimental search. In order to detect a time-reversal symmetry breaking Weyl state we designed two materials with Fermi velocities superior to that of graphene and I will present the experimental evidence of realization of such a state in one of them,  $\text{YbMnBi}_2$ . We model the time reversal symmetry breaking observed by magnetization measurements by a canted antiferromagnetic state and find a number of Weyl points both above and below the Fermi level. Using angle-resolved photoemission, we directly observe these latter Weyl points and a hallmark of the exotic state – the arc of the surface states which connects these points. Our results not only provide a fundamental link between the two areas of physics, but also demonstrate the practical way to design novel materials with exotic properties.

**8:00AM R2.00001 Electrical detection of proton-spin motion in a polymer device at room temperature<sup>1</sup>**, CHRISTOPH BOEHME, Department of Physics and Astronomy, University of Utah — With the emergence of spintronics concepts based on organic semiconductors there has been renewed interest in the role of both, electron as well as nuclear spin states for the magneto-optoelectronic properties of these materials. In spite of decades of research on these molecular systems, there is still much need for an understanding of some of the fundamental properties of spin-controlled charge carrier transport and recombination processes [1]. This presentation focuses on mechanisms that allow proton spin states to influence electronic transition rates in organic semiconductors. Remarkably, even at low-magnetic field conditions and room temperature, nuclear spin states with energy splittings orders of magnitude below thermal energies are able to influence observables like magnetoresistance and fluorescence [2]. While proton spins couple to charge carrier spins via hyperfine interaction, there has been considerable debate about the nature of the electronic processes that are highly susceptible to these weak hyperfine fields. Here, experiments are presented which show how the magnetic resonant manipulation of electron and nuclear spin states in a  $\pi$ -conjugated polymer device causes changes of the device current [3]. The experiments confirm the extraordinary sensitivity of electronic transitions to very weak magnetic field changes and underscore the potential significance of spin-selection rules for highly sensitive absolute magnetic fields sensor concepts [4]. However, the relevance of these magnetic-field sensitive spin-dependent electron transitions is not just limited to semiconductor materials but also radical pair chemistry [5] and even avian magnetoreceptors [6]. **8:36AM R2.00002 Active control of magnetoresistance of organic spin valves using ferroelectricity**, JIAN SHEN, Fudan Univ — Organic spintronic devices have been appealing because of the long spin lifetime of the charge carriers in the organic materials and their low cost, flexibility and chemical diversity. In previous studies, the control of resistance of organic spin valves is generally achieved by the alignment of the magnetization directions of the two ferromagnetic electrodes, generating magnetoresistance. Here we employ a new knob to tune the resistance of organic spin valves by adding a thin ferroelectric interfacial layer between the ferromagnetic electrode and the organic spacer: the magnetoresistance of the spin valve depends strongly on the history of the bias voltage, which is correlated with the polarization of the ferroelectric layer; the magnetoresistance even changes sign when the electric polarization of the ferroelectric layer is reversed. These findings enable active control of resistance using both electric and magnetic fields, opening up possibility for multi-state organic spin valves.

**9:12AM R2.00003 Organic magnetoelectroluminescence for room temperature transduction between magnetic and optical information**, MARKUS WOHLGENANT, University of Iowa — No abstract available.

**9:48AM R2.00004 New Directions for Organic Spintronics: Novel Materials and Emergent Phenomena<sup>1</sup>**, EZEKIEL JOHNSTON-HALPERIN, Department of Physics, The Ohio State University — Organic and organic-based materials are attractive candidates for applications in magnetoelectronics and spintronics due to their low cost, ease of fabrication, and low spin-orbit coupling (and consequently long spin lifetimes). However, in comparison to the case for inorganic systems, robust intrinsic magnetic ordering in this class of materials is exceedingly rare and as a result the potential of these materials has yet to be fully realized. Here we present a series of recent breakthroughs in the synthesis, encapsulation, and measurement of organic-based magnets that lay the foundation for all organic magnetoelectronic and spintronic devices. We will discuss advances in encapsulation strategies that allow lifetimes of up to 1 month in air for functional magnetoelectronic devices, the use of ligand substitution to generate a library of related magnetic materials, the growth of all-organic and hybrid organic/inorganic magnetic heterostructures, and measurements of the magnetization dynamics that reveal ferromagnetic resonance (FMR) linewidths of  $\sim 1$  G, comparable to or narrower than corresponding measurements in yttrium iron garnet (YIG). These results establish the validity of organic-based magnets for applications in next-generation magnetoelectronics and provide unique leverage on long-standing challenges in the field of organic spintronics. For example, organic magnetic heterostructures promise to provide an exciting opportunity to explore exchange, dynamic spin injection, and spin transport in all-organic spintronic devices.

**Session R3 DCMP GSOFT GSNP: Glass and Jamming Transitions** Ballroom III - Sydney Nagel, University of Chicago

**8:00AM R3.00001 The Gardner Transition: A new approach for understanding low-temperature glasses**, PATRICK CHARBONNEAU, Duke University — Recent theoretical advances in the mean-field theory of glasses predict the existence deep in the glass phase of a novel phase transition, a so-called Gardner transition. This transition signals the emergence of a complex free energy landscape composed of a marginally stable hierarchy of sub-basins within a broad glass metabasin. It is thus the onset of marked changes in thermal and transport properties of glasses, and ultimately leads to the unusual critical behavior at jamming. The Gardner transition itself is immediately related to a diverging (i) characteristic relaxation time, (ii) caging susceptibility and (iii) correlation length of the caging heterogeneity as well as aging, even in well-thermalized glasses. We have detected some of these signatures both in a mean-field model and in standard hard-sphere glass formers. We find the results to quantitatively agree with theory in the former and qualitatively so in the latter, which suggest that the transition should be detectable in a wide array of numerical and experimental systems. Interestingly, although the Gardner transitions is primarily associated with structural glass formers, we also find features of the transition in crystals of polydisperse particles once the landscape becomes rough.

**8:36AM R3.00002 Scaling theory for the jamming transition<sup>1</sup>**, ANDREA J. LIU, University of Pennsylvania, Department of Physics and Astronomy — The existence of a critical jamming transition, which marks the onset of rigidity in athermal packings of spheres, suggests that universal physics underlies the origin and nature of rigidity in disordered solids ranging from glasses to foams and granular materials. The jamming transition was originally proposed as a zero-temperature critical point in a non-equilibrium phase diagram in packing density and shear stress. Many studies have documented critical phenomena near the jamming transition, including power-law scaling, diverging length scales and scaling collapse, and theories have been developed to understand these phenomena. However, a number of confusing features have precluded a unified critical scaling analysis of the transition. Here we resolve these issues to present a scaling ansatz for the jamming critical point in terms of density and shear stress. The theory predicts new exponents that we verify with numerical simulations.

**9:12AM R3.00003 Frustration by Shape-Designed Local Polymorphism: A Near-Equilibrium Colloidal Glass of Hard Kites**, THOMAS MASON, University of California- Los Angeles — We study glass formation in uniform Brownian dispersions of hard colloidal polygonal platelets having the shape of 72-degree achiral kites, fabricated using optical stepper lithography. These kites are confined to a plane through roughness-controlled depletion attractions, and they diffuse in two-dimensions as we very slowly raise the particle density in the system. Although the densest packing of these kites is a crystalline lattice that fully tiles the plane, remarkably, we observe that the kites do not crystallize even for such quasi-static osmotic compression. By contrast, we have previously shown that such slow compression does cause crystallization of Brownian systems of other convex 2D lithographic shapes, such as squares and rhombs. Instead, the system of kites forms a disordered glass that undergoes an ergodic to non-ergodic transition, both in a rotational and a translational sense, while remaining near-equilibrium, as we measure by video particle tracking. We show that the high diversity of few-particle local polymorphic configurations (LPCs) of kites, related to our choice of angles and lengths in the designed shape, is responsible for suppressing long range spatial order and consequently favors glass formation instead. The prevalence and diversity of 5-particle LPCs, such as the pentagonal star, frustrate crystallization because these pentagonal LPCs are topologically different than the one 4-particle LPC that corresponds to the space-filling crystal. We anticipate that this mechanism of glass formation through shape-dependent frustration by diverse and incommensurate LPCs will also be relevant for molecular systems in three dimensions.

**9:48AM R3.00004 Solution of the dynamics of high-dimensional liquids**, JORGE KURCHAN<sup>1</sup>, LPS-ENS 24 rue Lhomond, 75231 Paris — The dynamics of a liquid composed of particles with spherically symmetric potentials has been solved exactly in limit of high dimensions  $d$ . The calculation is long but straightforward. At high density, an ergodicity-breaking glass transition is found. This computation allows one to assess the validity of approximation schemes such as Mode-Coupling Theory. As a by-product, because our calculation is, if not rigorous, elementary, an improvement in the bound for sphere packings in large dimensions is now at hand.

**10:24AM R3.00005 Spinodals with Disorder: from Avalanches in Random Magnets to Glassy Dynamics**, GIULIO BIROLI, IPHT CEA Saclay and LPS ENS Paris — We revisit the phenomenon of spinodals in the presence of quenched disorder and develop a complete theory for it. We focus on the spinodal of an Ising model in a quenched random field (RFIM), which has many applications in many areas from materials to social science. By working at zero temperature in the quasi-statically driven RFIM, thermal fluctuations are eliminated and one can give a rigorous content to the notion of spinodal. We show that the spinodal transition is due to the depinning and the subsequent expansion of rare droplets. We work out the critical behavior, which, in any finite dimension, is very different from the mean-field one: the characteristic length diverges exponentially and the thermodynamic quantities display very mild non-analyticities much like in a Griffith phenomenon. Thanks to the recently established connection between the spinodal of the RFIM and glassy dynamics, our results allow us to conclusively assess the physical content and the status of the dynamical transition predicted by the mean-field theory of glass-forming liquids.

Ballroom IV - Svetlana Sukhishvili, Stevens Institute of Technology

**8:00AM R4.00001 Funny and Functional Physics: PEC Nanoparticles**, MARTIEN COHEN STUART, Physical Chemistry & Soft Matter, Wageningen University, Netherlands — When the tendency of polyelectrolyte complexes to phase separate is judiciously combined with appropriate concepts from the realms of polymer physics and supramolecular chemistry, a wealth of novel self-assembled nanoparticles with original properties can be prepared. This presentation discusses how a high degree of complexity and functionality arises spontaneously, in the form of equilibrium structures, and how these structures can be understood from physical principles. Some promising applications are mentioned as well.

**8:36AM R4.00002 Quantifying Contributions to Transport in Ionic Polymers Across Multiple Length Scales**, LOUIS MADSEN, Virginia Tech — Self-organized polymer membranes conduct mobile species (ions, water, alcohols, etc.) according to a hierarchy of structural motifs that span sub-nm to  $>10\ \mu\text{m}$  in length scale. In order to comprehensively understand such materials, our group combines multiple types of NMR dynamics and transport measurements (spectroscopy, diffusometry, relaxometry, imaging) with structural information from scattering and microscopy as well as with theories of porous media,<sup>1</sup> electrolytic transport, and oriented matter.<sup>2</sup> In this presentation, I will discuss quantitative separation of the phenomena that govern transport in polymer membranes, from intermolecular interactions ( $\leq 2\ \text{nm}$ ),<sup>3</sup> to locally ordered polymer nanochannels (a few to 10s of nm),<sup>2</sup> to larger polymer domain structures (10s of nm and larger).<sup>1</sup> Using this multi-scale information, we seek to give informed feedback on the design of polymer membranes for use in, *e.g.*, efficient batteries, fuel cells, and mechanical actuators. **References:**

**9:12AM R4.00003 Nonequilibrium Simulations of Ion Dynamics in Ionomer Melts**, AMALIE FRISCHKNECHT, Sandia National Laboratories — Ionomers, polymers containing a small fraction of covalently bound ionic groups, are of interest as possible electrolytes in batteries. However, to date ionomers do not have sufficiently high conductivities for practical application, most likely because the ions tend to form aggregates, leading to slow ion transport. To build a better understanding of the relationships among ionomer chemistry, morphology, and ion transport, we have performed a series of molecular dynamics simulations and connected aspects of these simulations with experiment. In previous work using both atomistic and coarse-grained models, we showed that precise ionomers (with a fixed spacing between ionic groups along the polymer backbone) exhibit a range of ionic aggregate morphologies, from discrete clusters to percolated aggregates. In this talk I will describe recent simulations of our coarse-grained ionomer melts in an applied electric field. From a constant applied field, we are able to extract the ion mobilities and hence conductivities. We find that ionomers with percolated ionic aggregate morphologies have higher ion mobilities and hence higher conductivities. Application of an oscillating electric field enables us to calculate the frequency-dependent conductivity of the model ionomer melts. The real part of the conductivity has a high frequency peak associated with plasma oscillations, and a very broad low frequency peak associated with ion motions in ionic aggregates. I will end with comments on the connections to atomistic simulations and to experimental probes of ion dynamics.

Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-AC04-94AL85000.

**9:48AM R4.00004 Electrostatic Assembly of Polymers and Nanoparticles at Liquid-Liquid Interfaces.**<sup>1</sup>, DAVID HOAGLAND, Univ. of Massachusetts Amherst — The electrostatic attraction between charged solutes on opposite sides of the interface between immiscible liquids offers an efficient route to the self-assembly of two-dimensional films. As implemented by us, a hydrophobic polymer with amine end(s) or block(s) is presented in an oil phase, and a negatively charged nanoparticle is presented in an aqueous phase; both solutes are insoluble in the opposite phase but efficiently driven to the liquid-liquid interface by mutual electrostatic attraction to the solute in the opposite phase. Depending on experimental conditions (salt concentration, pH, solute concentrations, etc.), a continuous, nanoscopically thin composite film builds at the oil-water interface over the timescale of minutes, often accompanied by a dramatic reduction of interfacial tension akin to that observed for a surfactant. Film formation and properties by the new route will be discussed, as principally probed through pendant drop interfacial tensiometry and pendant drop interfacial rheometry. Components of model system are toluene-dissolved amine end-capped polystyrene and water-dispersed acid-treated carbon nanotubes or citrate-treated gold nanospheres. Film structures are complicated, as are crucial electrostatic interactions near the interface. With amine end-capped polystyrene partnered with acid-treated carbon nanotubes, high pH (above 5) and high polystyrene molecular weight (above 5000 g/mol) strongly hinder film formation. These films, which are liquid-like, show two viscoelastic relaxations, a fast relaxation (about 10 s) associated with polystyrene chain rearrangements (slightly impacted by carbon nanotube association) and a slow relaxation (about 20 min) associated with polystyrene adsorption/desorption; at intermediate times (or frequencies), the two-dimensional storage and loss moduli follow approximately the same power law dependences.

**10:24AM R4.00005 Polymerized Ionic Liquids: Promising Class of Polymer Electrolytes**, ALEXEI SOKOLOV, University of Tennessee, and Oak Ridge National Laboratory — Use of polymer electrolytes instead of traditional liquid electrolytes offers an elegant solution to many problems in current battery technology. However, a major obstacle in use of polymer electrolytes is their low ionic conductivity and low transference number (percentage of charge transported by the desired ion). Polymerized ionic liquids (PolyILs), a relatively new class of polymer electrolytes, are essentially single ion conductors and provide simple solution for the increase of the transference number. However, their ionic conductivity at ambient conditions remains low. Our earlier studies demonstrated that only *strong decoupling of ionic conductivity from segmental dynamics* can lead to a 'superionic' behavior of a polymer and might provide sufficiently high conductivity [1,2]. Based on this concept, we overview recent developments in the field of polymerized ionic liquids, with the emphasis on the polymer specific decoupling of ionic conductivity from segmental dynamics. The latter is well illustrated by the comparison of ionic liquids with their polymerized analogs [3,4]. Ways to further improvement of ionic conductivity in PolyILs, and their possible limitations are discussed at the end.

## Thursday, March 17, 2016 8:00AM - 11:00AM –

**Session R5 DMP: Disorder and Substitution Studies in Fe-based Superconductors** 301 - Johnpierre Paglione, University of Maryland

**8:00AM R5.00001 Effect of electron irradiation on  $(\text{Ba}_{1-x}\text{K}_x)\text{Fe}_2\text{As}_2$  from London penetration depth measurements**, KYUIL CHO, S. TEKNOWIJOYO, M. A. TANATAR, Y. LIU, T. A. LOGRASSO, R. PROZOROV, Ames Laboratory and Iowa State University, USA, M. KONCZYKOWSKI, Ecole Polytechnique, France, S. MAITI, P. HIRSCHFELD, University of Florida, USA, V. MISHRA, Oak Ridge National Laboratory, USA — The effects of artificial disorder induced by 2.5 MeV electron irradiation on superconducting properties of single crystals of  $(\text{Ba}_{1-x}\text{K}_x)\text{Fe}_2\text{As}_2$  (fifteen different compositions covering a wide interval of  $0.20 \leq x \leq 1.0$ ) was systematically studied by tunnel-diode resonator measurements of the in-plane London penetration depth,  $\lambda(T)$ , down to 50 mK before and after irradiation. Upon electron irradiation (with total doses up to  $2 \times 10^{19} \text{ e}^-/\text{cm}^2$ ), the increase of resistivity at  $T_c$ ,  $\Delta\rho(T = T_c)$  and the decrease of  $\Delta T_c/T_{c0}$  was largest at heavily over-doped compositions. A non-exponential behavior in samples with  $x \geq 0.8$  was found from the low-temperature variation of  $\lambda(T)$  suggesting a change in the superconducting gap structure or peculiarities of (inter-, intra-) band scattering and pairing. We will discuss possible scenarios to connect a fully gapped state at the optimal doping ( $x \approx 0.40$ ) with the apparent nodal behavior in the heavily over-doped region ( $x \geq 0.8$ ).

The work performed in Ames Lab and Iowa State University was supported by the U.S. DOE, OS, MSED under contract DE-AC02-07CH11358. The work performed in University of Florida was supported by NSF-DMR-1005625.

**8:12AM R5.00002 A shift of the phase diagram in  $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$  by controlled disorder**, YUTA MIZUKAMI, KOHEI MATSUURA, University of Tokyo, MARCIN KONCZYKOWSKI, Ecole Polytechnique, TATSUYA WATASHIGE, SHIGERU KASAHARA, YUJI MATSUDA, Kyoto University, TAKASADA SHIBAUCHI, University of Tokyo — The relationship between unconventional superconductivity and quantum critical point (QCP) is one of the most important issues in strongly correlated electron systems. A systematic study on the impurity scattering is performed in iron-based superconductor  $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$ , in which clear evidence for QCP has recently been presented[1]. We introduce point defects into  $\text{BaFe}_2(\text{As}_{1-x}\text{P}_x)_2$  by electron irradiation, which has less effects on lattice constant and carrier density compared to the chemical substitution of atoms[2]. Here, we report on the changes of the magnetic and superconducting transition temperatures with electron irradiation in a wide range of substitution, from which we discuss the effect of impurity scattering on superconducting dome and QCP. [1]T. Shibauchi *et al.*, Annu. Rev. Condens. Matter Phys. **5**, 113 (2014). [2]Y. Mizukami *et al.*, Nat. Commun. **5**, 5657 (2014).

**8:24AM R5.00003 Robustness of quantum critical pairing against disorder in iron-based superconductors**<sup>1</sup>, JIAN KANG, RAFAEL FERNANDES, School of Physics and Astronomy, University of Minnesota — Several experiments in iron pnictides and cuprates reveal a superconducting (SC) state remarkably robust against non-magnetic disorder at least when compared to the simple extension of the Abrikosov-Gorkov formalism to dirty unconventional superconductors. Motivated by the fact that most of these SC states appear in proximity to a magnetic instability, here we study the impact of non-magnetic disorder on the SC state promoted by quantum critical magnetic fluctuations. We go beyond the weak coupling approach by applying a variational formalism of the Eliashberg equations of the spin-fermion model, taking into account the effects of disorder on both fermionic and bosonic degrees of freedom. We find that the reduced fermionic coherent spectral weight near the magnetic quantum critical point strongly decreases the suppression rate of  $T_c$  by weak disorder, as compared to the Abrikosov-Gor'kov universal value. Furthermore, because the bosons promoting the Cooper pairs emerge as collective modes of the fermions, they are also impacted by disorder, giving rise to an additional reduction of the suppression rate of  $T_c$  by weak disorder. Our results qualitatively agree with experiments, shedding new light on why unconventional superconductors are robust against disorder.

**8:36AM R5.00004 Numerical Studies of Doped Iron Pnictides<sup>1</sup>**, CHRISTOPHER BISHOP, SHUHUA LIANG, ADRIANA MOREO, ELBIO DAGOTTO, Univ of Tennessee, Knoxville — The phase diagram of electron-doped pnictides is studied varying the temperature, electronic density, and isotropic disorder strength and dilution via numerical studies of a three-orbital spin-fermion model with lattice degrees of freedom [1]. Doping introduces disorder but in theoretical studies the effect of the randomly located dopants is difficult to address. Numerically the effects of electronic doping, regulated by a chemical potential, and impurity disorder at randomly selected sites can be independently controlled. It was found that the reduction with doping of the Neel and the structural transition temperatures, and the stabilization of a nematic state, is mainly controlled by the magnetic dilution due to the disorder. Fermi surface changes due to doping affect only slightly both critical temperatures. Our findings are compatible with neutron scattering and STM results, unveiling a patchy network of locally magnetically ordered anisotropic clusters, despite the isotropic disorder. The fragile tendency to nematicity intrinsic of translational invariant electronic systems needs to be supplemented by disorder and dilution to stabilize the robust nematic phase experimentally found in electron-doped 122 pnictides. <sup>1</sup> National Science Foundation Grant No. DMR-1404375

**8:48AM R5.00005 Mechanically - induced disorder in  $\text{CaFe}_2\text{As}_2$ : a  $^{57}\text{Fe}$  Mössbauer study<sup>1</sup>**, XIAOMING MA, Ames Laboratory/ Iowa State University and Lanzhou University, China, SHENG RAN, PAUL C. CANFIELD, SERGEY L. BUD'KO, Ames Laboratory/Iowa State University —  $^{57}\text{Fe}$  Mössbauer spectroscopy was used to study an extremely pressure and strain sensitive compound,  $\text{CaFe}_2\text{As}_2$ , with different degrees of strain introduced by grinding and annealing. At the base temperature, in the antiferromagnetic/orthorhombic phase, compared to a sharp sextet Mössbauer spectrum of single crystal  $\text{CaFe}_2\text{As}_2$ , which is taken as an un-strained sample, an obviously broadened sextet and an extra doublet were observed for ground  $\text{CaFe}_2\text{As}_2$  powders with different degrees of strain. The Mössbauer results suggest that the magnetic phase transition of  $\text{CaFe}_2\text{As}_2$  can be inhomogeneously suppressed by the grinding induced strain to such an extent that the antiferromagnetic order in parts of the grains forming the powdered sample remain absent all the way down to 4.6 K. However, strain has almost no effect on the temperature dependent hyperfine magnetic field in the grains with magnetic order. The quadrupole shift in the magnetic phase approaches zero with increasing degrees of strain, indicating that the strain reduces the average lattice asymmetry at Fe atom position.

<sup>1</sup>Supported by US DOE under the Contract No. DE-AC02-07CH11358 and by the China Scholarship Council

**9:00AM R5.00006 Effects of Tilted Columnar Defects on  $J_c$  Behavior in  $(\text{Ba},\text{K})\text{Fe}_2\text{As}_2$** , TSUYOSHI TAMEGAI, AKIYOSHI PARK, KENGO OHARA, SUNSENG PYON, The University of Tokyo, TADASHI KAMBARA, RIKEN, HISASHI KITAMURA, National Institute of Radiological Sciences — Iron-based superconductors have very promising characteristics to be used for practical applications at high fields. We have already demonstrated a remarkable enhancement of  $J_c$  in  $(\text{Ba},\text{K})\text{Fe}_2\text{As}_2$  by irradiating swift particles [1,2]. In order to further enhance  $J_c$ , we introduced columnar defects at an angle from the  $c$ -axis. We found a novel non-monotonic field dependence of  $J_c$  as well as its enhancement in such samples at relatively high temperatures. Origins of these anomalous  $J_c$  behavior and the degree of  $J_c$  enhancement with the tilted columnar defects will be discussed. [1] T. Taen et al., Supercond. Sci. Technol. 28, 085003 (2015). [2] F. Ohtake et al., Physica C518, 47 (2015).

**9:12AM R5.00007 Magnetic penetration depth in disordered iron-based superconductors<sup>1</sup>**, ALEX LEVCHENKO, University of Wisconsin-Madison, MAXIM DZERO, Kent State University, MAXIM KHODAS, Hebrew University of Jerusalem, ALEX KLIRONOMOS, American Physical Society, MAXIM VAVILOV, University of Wisconsin-Madison — We study the effect of disorder on the London penetration depth in iron-based superconductors. The theory is based on a two-band model with quasi-two-dimensional Fermi surfaces, which allows for the coexistence region in the phase diagram between magnetic and superconducting states in the presence of intraband and interband scattering. Within the quasiclassical approximation we derive and solve Eilenberger's equations, which include a weak external magnetic field, and provide analytical expressions for the penetration depth in the various limiting cases. A complete numerical analysis of the doping and temperature dependence of the London penetration depth reveals the crucial effect of disorder scattering, which is especially pronounced in the coexistence phase. The experimental implications of our results are discussed.

**9:24AM R5.00008 The study of vortex state across the phase diagram in single crystals of  $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$  using current voltage characteristics.<sup>1</sup>**, X. Y. HUANG, Y. P. SINGH, D. J. HANEY, S. ZHANG, Kent State University, H. H. WEN, Nanjing University, T. HU, Shanghai Institute of Microsystem and Information Technology, M. DZERO, C. C. ALMASAN, Kent State University — Utilizing the current voltage (I-V) characteristic measurement, we investigate the vortex state of  $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$  single crystals across a wide doping range: under-doped ( $x = 0.042$  and  $0.056$ ), near optimally-doped ( $x = 0.06$  and  $0.072$ ), and the over-doped ( $x = 0.1$ ). We compare the nature of the I-V characteristic curves obtained in our measurements with those of conventional type II superconductors. Using our data we could find a direct relationship between the critical current and flux-flow resistivity over the whole doping range studied. The implications of the comparison between the I-V curves of a conventional type II superconductor and  $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$  will be discussed. We will also comment on the observed relationship between the critical current and the flux-flow resistivity for the  $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$  crystals studied.

**9:36AM R5.00009 The role of magnetism and disorder in superconductivity of gold-doped  $\text{BaFe}_2\text{As}_2$  crystals<sup>1</sup>**, LI LI, HUIBO CAO, MIAOFANG CHI, ATHENA S. SEFAT, Oak Ridge National Lab — We present bulk magnetic and transport properties, and find structural and magnetic transitions, in order to construct the detailed T-x phase diagram for  $\text{Ba}(\text{Fe}_{1-x}\text{Au}_x)_2\text{As}_2$  single crystals [1]. The Au substitution into the FeAs-planes is only possible up to a small amount of ~3%, probably due to the large size of gold. We find that 5d is more effective in reducing magnetism in  $\text{BaFe}_2\text{As}_2$  than its counter 3d Cu, and this relates to superconductivity. In this talk, we reveal more comprehensive neutron diffraction data in order to clarify some of the inferred  $T_N$ ,  $T_S$  points in our literature report [1]. New transmission electron microscopy results will be presented that sheds light on the role of chemical disorder for preventing high  $T_c$  in these crystals. [1] L. Li et al., Phys. Rev. B 92, 094504 (2015).

**9:48AM R5.00010 Defect-induced Superconductivity up to 49 K in  $(\text{Ca}_{1-x}\text{R}_x)\text{Fe}_2\text{As}_2$** , L.Z. DENG, B. LV, K. ZHAO, F. Y. WEI, Y. Y. XUE, Z. WU, Texas Center for Superconductivity at the University of Houston, C.W. CHU, Texas Center for Superconductivity at the University of Houston; Lawrence Berkeley National Laboratory, Berkeley, California — To explore the origin of the unusual non-bulk superconductivity with a  $T_c$  up to 49 K reported in the rare-earth-doped  $\text{CaFe}_2\text{As}_2$ , the chemical composition, magnetization, specific heat, resistivity and low temperature annealing effect are systematically investigated on nominal  $(\text{Ca}_{1-x}\text{R}_x)\text{Fe}_2\text{As}_2$  single crystals with different  $x$ 's and  $\text{R} = \text{La}, \text{Ce}, \text{Pr}$  and  $\text{Nd}$ . All display a doping independent  $T_c$  once superconductivity is induced, a doping dependent low field superconducting volume fraction  $f$ , and a large magnetic anisotropy  $\eta$  in the superconducting state, suggesting a rather inhomogeneous superconducting state in an otherwise chemically "homogeneous" superconductor. The wavelength dispersive spectroscopy, specific heat and magnetization measurements show the presence of defects which form superparamagnetic clusters for  $\text{R} = \text{Ce}, \text{Pr}$  and  $\text{Nd}$ , but not for  $\text{La}$  and display both inter and intra-cluster interactions, implying that defects are locally self-organized. Low temperature annealing reduces only the residual strain in the samples without varying  $x$  and suppresses  $f$  profoundly; however, the  $T_c$  was unaffected. The above observations are consistent with the interface-enhanced superconductivity recently proposed and also demonstrates the crucial role of defects in the occurrence of the unusually high  $T_c \sim 49$  K in  $(\text{Ca}_{1-x}\text{R}_x)\text{Fe}_2\text{As}_2$ .

**10:00AM R5.00011 Optical spectroscopy of superconducting Pt-doped  $\text{BaFe}_2\text{As}_2$** <sup>1</sup>, ZHEN XING, M. QAZILBASH, Department of Physics, College of William and Mary, SHANTA SAHA, J. PAGLIONE, Center for Nanophysics and Advanced Materials, Department of Physics, University of Maryland, College Park — Substitution of iron with platinum in  $\text{BaFe}_2\text{As}_2$  leads to suppression of the antiferromagnetic and structural transitions, and the occurrence of bulk superconductivity with superconducting transition temperature ( $T_c$ ) around 20 K. In this work, we perform optical spectroscopy study of a  $\text{BaFe}_{1.9}\text{Pt}_{0.1}\text{As}_2$  single crystal. The  $ab$ -plane optical conductivity has been obtained by performing cryogenic infrared reflectance spectroscopy and spectroscopic ellipsometry both above and below  $T_c$ . Below  $T_c$ , bulk superconductivity is directly observed as perfect reflectance in the far infrared data. We model the optical conductivity in the superconducting state using Mattis-Bardeen formalism and find that the data is best fit with two energy gaps. We also analyze the optical conductivity in the normal state and discuss the nature of charge transport.

<sup>1</sup>This work was supported by NASA / Virginia Space Grant Consortium.

**10:12AM R5.00012 Effects of single- and multi-substituted Zn ions in doped-122 type iron-based superconductors**, YUANYUAN ZHAO, BO LI, Department of Physics and Texas Center for Superconductivity, University of Houston, Houston, Texas 77204, USA, WEI LI, State Key Laboratory of Functional Materials for Informatics and Shanghai Center for Superconductivity, Shanghai Institute of Microsystem and Informat, HONG-YI CHEN, National Taiwan Normal University, Department of Physics, Taipei 116, Taiwan, KEVIN E. BASSLER, C. S. TING, Department of Physics and Texas Center for Superconductivity, University of Houston, Houston, Texas 77204, USA — Recent experiments on Zn-substituted 122-type iron-based superconductors at electron- and hole- doped region provide us with a testing ground to understand the effect of Zn impurities in the system. Here, our first-principle calculations of the electronic structure reveal the Zn 4s-orbital is partially occupied, suggesting the effect of Zn 4s-orbital could not be neglected. We focus on Zn 4s-orbital instead of its 3d-orbital. Through self-consistent lattice Bogoliubov-de Gennes (BdG) calculation on a two-orbital model, our results qualitatively agree with the experimental measurements.

**10:24AM R5.00013 From Kondo behavior to high temperature superconductivity in  $\text{Sr}(\text{Ni}_{1-x}\text{Fe}_x)_2\text{As}_2$** , NICHOLAS WAKEHAM, Los Alamos National Laboratory, NI NI, UCLA, Department of Physics and Astronomy, ERIC BAUER, JOE THOMPSON, FILIP RONNING, Los Alamos National Laboratory —  $\text{SrFe}_2\text{As}_2$  has an antiferromagnetic groundstate at ambient pressure that can be suppressed by chemical doping or pressure to produce unconventional superconductivity.  $\text{SrNi}_2\text{As}_2$  is a non-magnetic conventional superconductor with  $T_c$  of 0.6 K. It has been shown that in  $\text{Sr}(\text{Ni}_{1-x}\text{Fe}_x)_2\text{As}_2$  there is a dome of superconductivity between  $x = 0.95$  and  $x = 0.9$ . However, little is known about this doping series for small  $x$  values. We will present the study of the thermodynamic and transport properties of the doping series of  $\text{Sr}(\text{Ni}_{(1-x)}\text{Fe}_x)_2\text{As}_2$  for  $x \leq 0.6$ . In the dilute Fe limit ( $x \leq 0.01$ ) we find strong evidence for single-ion Kondo behaviour. As the concentration of Fe is increased, Fe-Fe interaction effects become significant and the Kondo scale increases. For  $0.2 \leq x \leq 0.6$  magnetic susceptibility measurements show the presence of a spin glass transition. The presence of Kondo behaviour in  $\text{Sr}(\text{Ni}_{(1-x)}\text{Fe}_x)_2\text{As}_2$  indicates the formation of local moments interacting with conduction electrons. Therefore, we will address the relevance of this result to the discussion of the itineracy of the magnetism in  $\text{SrFe}_2\text{As}_2$ , as well as the observed enhancement of the effective mass seen in many pnictide compounds.

**10:36AM R5.00014 Weak-coupling superconductivity in a strongly correlated iron pnictide**<sup>1</sup>, ALIAKSEI CHARNUKHA, Univ of California - San Diego — Iron-based superconductors have been found to exhibit an intimate interplay of orbital, spin, and lattice degrees of freedom, dramatically affecting their low-energy electronic properties, including superconductivity. Albeit the precise pairing mechanism remains unidentified, several candidate interactions have been suggested to mediate the superconducting pairing, both in the orbital and in the spin channel. Here, we employ optical spectroscopy (OS), angle-resolved photoemission spectroscopy, ab initio band-structure, and Eliashberg calculations to show that nearly optimally doped  $\text{NaFe}_{0.978}\text{Co}_{0.022}\text{As}$  exhibits some of the strongest orbitally selective electronic correlations in the family of iron pnictides. Unexpectedly, we find that the mass enhancement of itinerant charge carriers in the strongly correlated band is dramatically reduced near the  $\Gamma$  point and attribute this effect to orbital mixing induced by pronounced spin-orbit coupling. Embracing the true band structure allows us to describe all low-energy electronic properties obtained in our experiments with remarkable consistency and demonstrate that superconductivity in this material is rather weak and mediated by spin fluctuations.

**10:48AM R5.00015 In situ characterization of pulsed-laser-deposition grown Co doped  $\text{BaFe}_2\text{As}_2$  on  $\text{SrTiO}_3$  (001)**, SUNWOUK YI, SUNGMIN KIM, MINJUN LEE, HANHO LEE, HOYEON JEON, YONGCHAN YOO, INHAE ZOH, CHAO ZHANG, MYUNGCHUL OH, YOUNG KUK, Department of Physics and Astronomy, Seoul National University, Republic of Korea — We report epitaxial growth of  $\text{Ba}(\text{Fe}_{1-x}\text{Co}_x)_2\text{As}_2$  (BFCA) thin films on  $\text{SrTiO}_3$  (001) substrates using pulsed laser deposition (PLD) technique under ultrahigh vacuum. The growth was performed using a pellet with the optimal Co concentration  $x=0.08$ . The temperature dependent conductivity of BFCA films was compared with those in the pellet form. The crystallinity was monitored with reflection high-energy electron diffraction during the growth and low energy electron diffraction (LEED) patterns. Optimal growth condition was obtained at the substrate temperature of  $700 \pm 20^\circ$ . The grown sample was immediately transferred to measure the topography and spectroscopy using a scanning tunneling microscope. LEED/STM result reveals modulation of  $\sqrt{2} \times \sqrt{2}$  surface reconstruction on the top plane and STM result shows the same structure. The average sizes of terraces were  $\approx 10\text{nm}$  with a homogeneous electronic structure. The geometric and electronic structure of BFCA films will be reported.

**Thursday, March 17, 2016 8:00AM - 11:00AM –**

**Session R6 GMAG DMP: Frustrated Magnetism: Triangular Lattice Magnets** 302 - Collin Broholm, Johns Hopkins University

**8:00AM R6.00001 Frustrated quantum magnetism in the 6H-perovskites**, JEFFREY QUILLIAM, University of Sherbrooke — I will review the recent state of research on the 6H-perovskites,  $\text{Ba}_3\text{MA}_2\text{O}_9$ , a large class of materials that can accommodate many different magnetic ions on ostensibly triangular lattices. This class of materials has given rise to several important discoveries in recent years, including quantum spin liquids, a quantum spin-orbital liquid and the first perfectly triangular spin-1/2 antiferromagnet. Many of these materials also provide an interesting interplay of magnetic, orbital and charge degrees of freedom. Others suffer from high levels of site disorder, which leads to interesting physics, at least in the case of the spin-orbital liquid candidate  $\text{Ba}_3\text{CuSb}_2\text{O}_9$ . I will primarily discuss our recent work on the materials  $\text{Ba}_3\text{MSb}_2\text{O}_9$ , where  $\text{M} = \text{Cu}, \text{Ni}$  and  $\text{Co}$  using the techniques of nuclear magnetic resonance (NMR), muon spin rotation ( $\mu\text{SR}$ ) and ultrasound velocity measurements.

**8:36AM R6.00002 Spin glassy behaviors and isolated spin dimers in  $\text{BaCr}_{9p}\text{Ga}_{12-9p}\text{O}_{19}$** , JUNJIE YANG, ANJANA SAMARAKOON, KYUN WOO HONG, SEUNG-HUN LEE, Department of Physics, University of Virginia, Charlottesville, VA 22903, USA, JOHN R. D. COPLEY, QINGZHEN HUANG, NIST Center for Neutron Research, Gaithersburg, Maryland 20899, USA, TAKU J SATO, IMRAM, Tohoku University, Katahira, Sendai 980-8577, Japan — Theoretical results suggested that quantum fluctuations may induce glassy states (spin jam states) in defect-free spin systems. Recently our experimental results indicated the existence of spin jam states in  $\text{SrCr}_p\text{Ga}_{12-9p}\text{O}_{19}$  (SCGO( $p$ )) in which the  $\text{Cr}^{3+}$  ions form two-dimensional (2D) triangular lattice of bi-pyramids. Here we report a isostructural new system  $\text{BaCr}_{9p}\text{Ga}_{12-9p}\text{O}_{19}$  (BCGO( $p$ )) with  $0.4 < p < 0.9$ . Neutron diffraction results show that BCGO( $p$ ) is isostructural as SCGO( $p$ ) but with a larger lattice indicating that BCGO( $p$ ) is more 2D. BCGO( $p$ ) exhibits similar glassy behaviors as SCGO( $p$ ) but with higher freezing temperature. Very high Curie-Weiss temperature and frustration index were also observed in BCGO( $p$ ) suggesting that BCGO( $p$ ) is one of the most frustrating system. Inelastic neutron scattering results show that BCGO( $p$ ) has dispersionless magnetic excitations at an energy of 16.5(1) meV arising from  $4f_{vi}-4f_{vi}$  spin dimers. These spin dimers are adjacent spins in neighboring triangular lattice planes which separate the 2D interacting triangular lattice of bi-pyramids. These results indicate that BCGO( $p$ ) is a new good candidate for studying spin jam states.

**8:48AM R6.00003 Muon spin rotation study of spin dimers on a triangular lattice in  $\text{Ba}_3\text{MRu}_2\text{O}_9$** , DJAMEL ZIAT, AIM VERRIER, Graduate student, JEFFREY QUILLIAM, Professor, ADAM ACZEL, RYAN SINCLAIR, QIANG CHEN, HAIDONG ZHOU, PhD — The family of hexagonal perovskites,  $\text{Ba}_3\text{MA}_2\text{O}_9$  has recently been proven to be fertile ground for the discovery of new, exotic magnetic phases, including several quantum spin liquid candidates. The 6H-perovskites can also accommodate spin dimers on a triangular lattice, as in the ruthenate materials  $\text{Ba}_3\text{MRu}_2\text{O}_9$ . We will present measurements on materials containing  $\text{M}^{3+}$  ( $\text{M} = \text{Y}, \text{La}, \text{Lu}, \text{In}$ ), which give rise to mixed valence  $\text{Ru}^{4.5+}$  ions wherein the orbital and charge degrees of freedom must also be considered. In particular, muon spin rotation (SR) experiments, have allowed us to probe the nature of the magnetically ordered ground state of these materials at low temperatures.

**9:00AM R6.00004 Magnetic Correlations in the Triangular Antiferromagnet  $\text{TbInO}_3$** , GABRIELE SALA, McMaster University, LUCY CLARK, University of St Andrews, DALINI MAHARAJ, McMaster University, MATTHEW B. STONE, Oak Ridge National Laboratory, KEVIN S. KNIGHT, ISIS Neutron Facility, SANG-WOOK CHEONG, Rutgers University, BRUCE D. GAULIN, McMaster University —  $\text{TbInO}_3$  crystallizes with a hexagonal  $P6_3cm$  structure in which layers of edge-sharing triangles of magnetic  $\text{Tb}^{3+}$  ions are separated by non-magnetic  $[\text{InO}_5]^{7-}$  units.  $\text{TbInO}_3$ , therefore, realizes an excellent opportunity to explore the behavior of a two-dimensional magnetic triangular lattice, a canonical model of geometric frustration. Here we present our study of a polycrystalline sample of  $\text{TbInO}_3$ . Our high resolution powder neutron diffraction data (HRPD, ISIS) of  $\text{TbInO}_3$  confirm that the triangular layers of  $\text{Tb}^{3+}$  remain undistorted to at least 0.46 K. Magnetic susceptibility data follow Curie-Weiss behavior over a wide range of  $T$  with  $\theta = -17.19(3)$  K indicating the dominance of antiferromagnetic correlations. The susceptibility data also show an absence of conventional long-range spin order down to at least 0.55 K, reflecting the frustrated nature of  $\text{TbInO}_3$ . Elastic magnetic diffuse neutron scattering (SEQUOIA, SNS) is observed below  $\sim 15$  K, due to the presence of static two-dimensional spin correlations. The spectrum of crystal field excitations in  $\text{TbInO}_3$  appears to have an exotic form due to the existence of two crystallographically distinct  $\text{Tb}^{3+}$  sites and leads to a strong Ising anisotropy of the spin symmetry.

**9:12AM R6.00005 ABSTRACT WITHDRAWN —**

**9:24AM R6.00006 A spin-orbit coupled triangular lattice quantum spin liquid in  $\text{YbMgGaO}_4$ : a semiclassical study**, YAO-DONG LI, Department of Computer Sciences, Fudan University, GANG CHEN<sup>1</sup>, Department of Physics, State Key Laboratory of Surface Physics, Fudan University; Perimeter Institute for Theoretical Physics — Recently  $\text{YbMgGaO}_4$  is proposed to be the first strong spin-orbit coupled quantum spin liquid candidate system that contains odd number of electron per unit cell with effective spin 1/2 local moments. In this talk we analyze the classical phase diagram of the most generic model that describes the Yb effective spin 1/2 local moments on the triangular lattice. We show the frustration is strong near the phase boundary between the 120 degree state and the stripe ordered phase. Further, we study the quantum fluctuation of the spin momentum by the linear spin wave theory and find that the magnetic order is destroyed in the strongly frustrated regimes of the phase diagram. Our result is compatible with the experimental results that suggest a quantum spin liquid ground state.

<sup>1</sup> Collaborative Innovative Center of Advanced Microstructures, Fudan University

**9:36AM R6.00007 Magnetic Ground State of the Ideal Triangular-Lattice Antiferromagnets Tuned by the Inter-layer Interactions<sup>1</sup>**, JIE MA, University of Tennessee, M MATSUDA, Oak Ridge National Laboratory, Y. KAMIYA, RIKEN, Z. L. DUN, University of Tennessee, C. DELA CRUZ, Oak Ridge National Laboratory, C. D. BATISTA, Los Alamos National Laboratory, Y. QIU, N BUTCH, J. R. D. COPLEY, NIST, H. D. ZHOU, University of Tennessee — Neutron inelastic scattering and diffraction techniques have been applied to investigate both structures and spin wave excitations of the tri-perovskite  $\text{Ba}_3\text{MM}'_2\text{O}_9$ , which is antiferromagnetic with the equilateral-triangular lattice M layers. Although the magnetic structure of the system is non-collinear 120 in ab-plane, the c-axis canting appears by increasing the spin momentum from  $S(\text{Co}^{2+}) = 1/2$  to  $S(\text{Mn}^{2+}) = 5/2$ . Our measurements clearly show that the magnetic ground state and excitations could be modified by the inter-layer interaction, which is strongly interfered by the type and staggering method of the nonmagnetic  $\text{M}'\text{O}_6$  clusters. In addition, the lattice-related quantum phenomena were discussed, such as the temperature-dependent acoustic mode in  $\text{Ba}_3\text{NiNb}_2\text{O}_9$ , and the pressure-effect on the magnetic dynamics of the Fermi-liquid-like ground state,  $\text{Ba}_3\text{NiSb}_2\text{O}_9(6\text{H-B})$ .

<sup>1</sup> Magnetic Ground State of the Ideal Triangular-Lattice Antiferromagnets Tuned by the Inter-layer Interactions

**9:48AM R6.00008 An indirect RIXS study of roton excitation in triangular lattice antiferromagnet**, TRINANJAN DATTA, Georgia Regents University, CHENG LUO, DAO-XIN YAO, Sun Yat-Sen University — The antiferromagnetic triangular lattice is characterized by the presence of roton excitations. We propose that the K-edge indirect resonant inelastic x-ray scattering (RIXS) spectrum of a triangular lattice antiferromagnet can serve as a novel spectroscopic tool to detect the presence of roton excitations. By considering self-energy corrections to the spin-wave spectrum and magnon decay rates in its ordered coplanar three-sublattice 120 degree magnetic state, we find that a single-peak RIXS spectrum forms at the roton momentum, Luo et. al. Phys. Rev. B 92, 035109 (2015). The single peak feature is in sharp contrast to the other high symmetry points where the RIXS spectrum splits into a multipeak structure. It is this contrast which can be utilized as an experimental signature to detect the presence of rotons. We also investigate the effect of XXZ spin anisotropy, orthorhombic spatial anisotropy, and DM interaction in the triangular lattice and find that the roton peak is affected.

**10:00AM R6.00009 2D Heisenberg Triangular Antiferromagnet in  $\text{Ba}_3\text{CoSb}_2\text{O}_9$** , ALUN BIFFIN, Laboratory for Neutron Scattering, Paul Scherrer Institute, CH-5232 Villigen PSI, Switzerland, FRANZ DEMMEL, HELEN WALKER, ISIS Facility, Didcot, Oxfordshire, OX11 0QX, U.K., MICHAEL HAYWARD, Department of Chemistry, Inorganic Chemistry Laboratory, University of Oxford, South Parks Road, Oxford OX1 3QR, United Kingdom, RADU COLDEA, Clarendon Laboratory, University of Oxford, Parks Road, Oxford OX1 3PU, U.K. — We present inelastic neutron scattering (INS) experiments on the triangular antiferromagnet (TAF)  $\text{Ba}_3\text{CoSb}_2\text{O}_9$ . High energy INS measurements allowed the crystal field levels of  $\text{Co}^{2+}$  ions to be resolved, and subsequently the terms relevant to its single ion Hamiltonian to be derived with the conclusion that the ions have a  $J_{\text{eff}} = 1/2$  doublet as their groundstate with relatively weak local trigonal distortion of  $\text{CoO}_6$  octahedra. The result is a system which is a rare realisation of the canonical spin 1/2 Heisenberg TAF. Following this, low energy, high-resolution INS experiments have been performed which reveal the spin wave excitations emanating from the  $120^\circ$  ordered phase below  $T_N = 3.8\text{K}$ . However, as will be seen, linear spin wave calculations are not sufficient to describe all the features of the data, and these anomalies hint at quantum dynamics beyond linear spin wave theory within this realisation of the canonical  $S=1/2$  TAF system.

**10:12AM R6.00010 Quantum phase transitions in triangular lattice Heisenberg antiferromagnet in a magnetic field**, MENGXING YE, ANDREY CHUBUKOV, Univ of Minnesota - Twin Cities — We present the zero temperature phase diagram of a large  $S$  Heisenberg anti-ferromagnet on a frustrated triangular lattice with the nearest neighbor ( $J_1$ ) and the next nearest neighbor ( $J_2$ ) interactions, in a magnetic field. We show that the classical model has an accidental degeneracy for all  $J_2/J_1$  and all fields below the saturation field, which gives rise to the extended manifold of the ground state spin configurations. Quantum fluctuations, however, lift this degeneracy. For small  $J_2/J_1$ , they select one of three different co-planar states, depending on the field value. We argue that above some critical ratio of  $J_2/J_1$ , which weakly depends on a magnetic field, these fluctuations select the stripe phase. We analyze in detail the mechanism of the selection of the stripe phase and explore the nature of the quantum phase transition in a magnetic field between the ordered phases as  $J_2/J_1$  passes through a critical value.

**10:24AM R6.00011 Neutron diffraction study of low dimensional magnetic system: single crystal  $\alpha\text{-NaMnO}_2$** , REBECCA DALLY, Boston College, STEPHEN WILSON, University of California, Santa Barbara, JEFFREY LYNN, ROBIN CHISNELL, LELAND HARRIGER, NIST Center for Neutron Research, MICHAEL GRAF, Boston College —  $\alpha\text{-NaMnO}_2$  contains complex, low dimensional interactions and is magnetically frustrated due to the triangular arrangement of  $\text{Mn}^{3+}$  ( $S=2$ ,  $t_{2g}^3 e_g^1$ ) atoms in the crystal. Nearest neighbor Mn atoms lie along the  $b$ -axis in a chain; these chains span the  $ab$ -plane, where a mean-field approach to the interchain exchange predicts the cancellation of interactions, giving rise to quasi-1D behavior. Here we will present the results of our recent single crystal neutron diffraction measurements of correlated spin behavior in this  $\text{Na}_x\text{MnO}_2$ . A complex evolution of the ordering wave vector, spin anisotropy, and dimensionality is observed as the system approaches the antiferromagnetic phase transition. The implications for the inherent dimensionality of this system and its coupling to the lattice will be discussed.

**10:36AM R6.00012 Giant magnon-phonon coupling in  $\text{LiCrO}_2$** , SNDOR TTH, Paul Scherrer Institut, Laboratory for Neutron Scattering and Imaging, KATHARINA ROLFS, Paul Scherrer Institut, Laboratory for Scientific Developments and Novel Materials, BJRN WEHINGER, University of Geneva, Department of Quantum Matter Physics, TURAN BIROL, Rutgers University Department of Physics and Astronomy, UWE STUHR, Paul Scherrer Institut, Laboratory for Neutron Scattering and Imaging, BJRN FK, Institut Laue Langevin, KENTA KIMURA, Osaka University, Department of Materials Engineering Science, HIROSHI TAKATSU, Tokyo Metropolitan University, Department of Physics, CHRISTIAN REGG, Paul Scherrer Institut, Laboratory for Neutron Scattering and Imaging — The study of low dimensional and frustrated quantum magnets has been a central problem in condensed matter physics over the past decades. The main feature of frustrated magnets is the macroscopic degeneracy of the ground state that can be lifted by weak additional effects such as quantum fluctuations. This can lead to new exotic ground states without long-range order and novel excitations. Here we present an example,  $\text{LiCrO}_2$ , where frustration (and electronic properties) leads to strong coupling between magnons and phonons in a triangular lattice antiferromagnet. This coupling leads to a novel magnon dispersion with a roton minima at the zone boundary [1]. We show direct evidence using inelastic neutron and X-ray scattering that the roton is the direct result of the magnon-phonon coupling. Furthermore the discovered effect could shed light on the underlying physics of other  $\text{Cr}^{3+}$  compounds with strange properties, such as the observed flat magnetic modes in the pyrochlore lattice antiferromagnet  $\text{MgCr}_2\text{O}_4$ . [1] S. Toth, et al., PRL 109, 127203 (2012).

**10:48AM R6.00013 Nanosized helical magnetic domains in strongly frustrated  $\text{Fe}_3\text{PO}_4\text{O}_3$** <sup>1</sup>, MITCHELL BORDELON, KATE ROSS, GREG TERHO, JAMES NEILSON, Colorado State University — Non-centrosymmetric  $\text{Fe}_3\text{PO}_4\text{O}_3$  (space group  $R\bar{3}m$ ) contains triangular motifs of  $\text{Fe}^{3+}$  ions coupled by strong antiferromagnetic interactions ( $|\Theta_{CW}| > 900\text{K}$ ). Neutron powder diffraction below  $T_N = 163\text{K}$  reveals the formation of an ordered helical incommensurate magnetic structure, with helical axis in the hexagonal  $ab$  plane and modulation length of  $\sim 100$ . The magnetic structure forms needle-like correlation volumes perpendicular to the  $ab$  plane that extend at least to 900 along the  $c$ -axis, but are confined to  $\sim 70$  in the  $ab$  plane. The refined magnetic moment, supported by magnetization measurements of a magnetically diluted series ( $\text{Fe}_{3-x}\text{Ga}_x\text{PO}_4\text{O}_3$ ), indicates a reduced  $\text{Fe}^{3+}$  moment, suggesting metal-ligand charge transfer. High-resolution synchrotron X-ray diffraction reveals no lattice symmetry change below  $T_N$ . Absence of long-range in-plane order below  $T_N$  signifies the formation of a high density of defects in the magnetic structure. The defect-rich helical magnetic phase in  $\text{Fe}_3\text{PO}_4\text{O}_3$  offers insight into the stabilization of topological spin textures in antiferromagnets.

**Session R7 FEd: Physics Education Student Retention** 303 - Michael Falk, Johns Hopkins University

**8:00AM R7.00001 From Start to Finish: Retention of Physics Undergraduates** , DONNA HAMMER, TIM UHER, University of Maryland — The University of Maryland Physics Department's NSF Scholarships in Science Technology, Engineering and Mathematics (S-STEM) project is a unique program that aims to reduce the attrition of students that occurs in the "pre-major-to-major" gap – i.e., students who begin at the university intending to study physics, but do not graduate with a physics degree. To increase the retention of admitted students, the UMD S-STEM program is designed to provide student with financial assistance, a strong sense of community, academic support, and career planning. We will discuss how the program has been integrated into the curriculum and culture of the physics department, and focus on developing key components of the program: a nurturing environment, dedicated mentorship, early research experience, and professional development.

**8:12AM R7.00002 GRAD-MAP: A Joint Physics and Astronomy Diversity Initiative at the University of Maryland<sup>1</sup>** , PETER MEGSON, NEIL ANDERSON, KATIE JAMESON, LORA PRICE, GARETH ROBERG-CLARK, ZEEVE ROGOSZINKSI, KYLE SHEPPARD, CORBIN TAYLOR, TIM UHER, ASHLEE WILKINS, DONNA HAMMER, University of Maryland — Graduate Resources for Advancing Diversity with Maryland's Astronomy and Physics (GRAD-MAP), builds connections between UMD and mid-Atlantic HBCUs, Minority-Serving Institutions, and community colleges, and uses seminars, forums, and workshops to foster a diverse community of undergraduates prepared to succeed in graduate school, and is now in its third year. GRAD-MAP launched with a three-pronged approach: 1) Collaborative Seminars, 2) A Winter Workshop, and 3) A Spring Symposium. This program allows GRAD-MAP to do more than just increase the numbers of minority students participating in astronomy and physics research (or, worse, simply shuffle around students who already are or would be); it is committed to identifying students who are otherwise underserved or overlooked by the traditional academic pipeline, not only to get them on the path to be successful undergraduate researchers and eventual graduate applicants, but also to make the climate of academic physics and astronomy more inclusive to them and all other underrepresented minority students. We will describe the key elements of our program, and highlight successes and lessons learned; GRAD-MAP can serve as a model for other universities committed to diversity and inclusion.

<sup>1</sup>Supported by NSF PIRE and CAREER programs, Maryland Space Grant Consortium, and UMD Departments of Physics and Astronomy

**8:24AM R7.00003 Explaining the Gender Gap: Comparing Undergraduate and Graduate/Faculty Beliefs about Talent Required for Success in Academic Fields** , KIMBERLYN BAILEY, AMPALAVANAR NANTHAKUMAR, SCOTT PRESTON, CAROLINA C. ILIE, State University of New York at Oswego — Recent research has proposed that the gender gap in academia is caused by differing perceptions of how much talent is needed to succeed in various fields. It was found that, across the STEM/non-STEM divide, the more that graduate students and faculty see success in their own field as requiring as requiring talent, the fewer women participate in that field. This research examines whether undergraduate students share these attitudes. If these attitudes trickle down to the undergraduate population to influence students to choose different fields of study, then undergraduate beliefs should reflect those of graduate students and faculty. Using a large survey of undergraduates across the country, this study aims to characterize undergraduate attitudes and to determine variables that explain the differences between the attitudes of these two populations. Our findings suggest that the two populations have similar beliefs, but that undergraduate beliefs are strongly influenced by information about the gender ratio in each field and that this strong influence greatly differs between STEM and non-STEM fields. These findings seek to help direct future research to ask the right questions and propose plausible hypotheses about gender the imbalance in academia.

**8:36AM R7.00004 Perception, Attitude and Instructional Preferences on Physics in High School Students: An Exploration in an International Setting** , MINI NARAYANAN, ABDUL GAFOOR, Department of Education, Calicut University, India — Questionnaire survey explored perception, attitude and instructional preferences with respect to gender and nationality in high school students of India and USA, a sample of 1101 Indian and 458 US students. Descriptive Statistics techniques were adopted for analysis. Male and female students in USA were at the high and low ends of the spectrum, respectively, in perception and attitude. Preference on instructional strategies was found to be independent of nationality, exposed strategies, opting science, class size and facilities. Responses from both countries indicate preference for an integrated instructional strategy that has strong teacher involvement in a student-centered framework. A thoughtful and properly designed instructional strategy could provide sufficient elements in modifying students' epistemological beliefs. Understanding the nature and process of physics along with a better learning outcome is usually not possible by administering student-centered or teacher-centered strategies alone in their purest form. This study provides adequate support in obtaining two equally significant but contrasting goals in Physics Education Research, to gain conceptual development with increased interest and attainment in learners, through integration.

**8:48AM R7.00005 Examining the Needs and Dispositions of Sumter School District High School Students with Regards to Studying Physics, Part 1** , JESSICA KOHLER, University of South Carolina Sumter — Out of a total student population of 4740 in the Sumter School District (SSD) in Sumter, SC, only 167 were enrolled in a physics course in Spring 2015. That was 3.52% of the total student population in the district. As advised by Lori Smith, Coordinator of Science and Fine Arts of SSD, enrollment in physics courses was insufficient. Since physics is the basis of all sciences and a prerequisite for engineering courses, not having enrolled and succeeded in a physics course during high school could impede a students success in such majors during college. This project aimed to examine the needs and dispositions of high school students in SSD with regards to studying physics by exploring the reasons behind their decisions to enroll or not enroll in a physics course during their high school careers. The project also found out how they believe their physics classes could be improved. This was achieved by conducting an electronic survey among voluntary participants from the seniors. A quantitative analysis of the results is presented. These results are intended to help to improve the physics program in SSD as well as shape The University of South Carolina Sumters outreach efforts in the local high schools to encourage students to enroll in college physics courses.

**Session R8 DMP: Hybrid Organic Inorganic Perovskite Photovoltaics** 304 - Dali Sun, University of Utah

**8:00AM R8.00001 Understanding the Unique Properties of Organometal Trihalide Perovskite with Single Crystals<sup>1</sup>** , JINSONG HUANG, University of Nebraska Lincoln — Organometal Trihalide Perovskite has been discovered to be all-round optoelectronic materials many types of electronic devices. The understanding of this family of materials is however limited yet due to the complicated grain structures in polycrystalline films which are generally used in most of the devices. In this contribution, I will present our recent progress in understanding the fundamental properties, including optoelectronic properties and electromechanical properties, using the high quality organometal trihalide perovskite single crystals. I will report the crystallographic orientation dependent charge transport and collection, surface and bulk charge recombination process, and direction measuring of carrier diffusion length using the lasing induced photocurrent scanning. The polarity of the organometal trihalide perovskite crystals will also be examined.

<sup>1</sup>We thank financial support from SunShot Initiative at Department of Energy under Award DE-EE0006709, and from National Science Foundation Grant DMR-1505535 and Grant DMR-1420645, and from Office of Naval Research under award N00014-15-1-2713.

**8:36AM R8.00002 High Performance Tandem Perovskite/Polymer Solar Cells<sup>1</sup>** , YAO LIU, MONOJIT BAG, ZACHARIAH PAGE, LAWRENCE RENNA, PAUL KIM, JAEWON CHOI, TODD EMRICK, D. VENKATARAMAN, THOMAS RUSSELL<sup>2</sup>, UMASS — Combining perovskites with other inorganic materials, such as copper indium gallium diselenide (CIGS) or silicon, is enabling significant improvement in solar cell device performance. Here, we demonstrate a highly efficient hybrid tandem solar cell fabricated through a facile solution deposition approach to give a perovskite front sub-cell and a polymer:fullerene blend back sub-cell. This methodology eliminates the adverse effects of thermal annealing during perovskite fabrication on polymer solar cells. The record tandem solar cell efficiency of 15.96% is 40% greater than the corresponding perovskite-based single junction device and 65% greater than the polymer-based single junction device, while mitigating deleterious hysteresis effects often associated with perovskite solar cells. The hybrid tandem devices demonstrate the synergistic effects arising from the combination of perovskite and polymer-based materials for solar cells.

**8:48AM R8.00003 Nanoimprinted Perovskite Solar Cells With Enhanced Photocurrent** , ROSS HAROLDSON, BALASUBRAMANIAM BALACHANDRAN, YIXIN REN, ANVAR ZAKHIDOV, WENCHUANG HU, Univ of Texas - Dallas, UTD NANOIM-PRINT TEAM — We have developed a new method of Nanoimprint Lithography (NIL) to shape the morphology of organolead trihalide perovskite. With this hot stamping process we created ordered gratings or other micro or nanostructures of perovskite resembling 2D photonic crystals on the scale of 200 to 600 nm from a starting small grain spin-coated film of the same scale. With this new method of nanoimprinting, we demonstrate that perovskite PV device performance can be improved and controlled. Initial results comparing flat vs. NIL-PV structure devices show dramatic increase in photocurrent as well as better crystallinity. The origin of Isc enhancement is explained in terms of better morphology and larger grains, resulting in longer diffusion length of carriers, while better light absorption by photonic crystal nanopatterns cannot be excluded.

**9:00AM R8.00004 Designing lead-free and stable perovskite materials for photovoltaic applications.** , YIYANG SUN, SHENGBAI ZHANG, Department of Physics, Rensselaer Polytechnic Institute — A critical barrier for large-scale deployment of the current perovskite solar materials is the use of Pb to achieve high power conversion efficiency. While this appears to be a technical issue, there are more fundamental reasons behind. The current research has mainly focused on the replacement of Pb by other elements, in particular, Sn. However, in halide perovskites (i.e., I-II-VI<sub>3</sub> composition), Sn is in its less stable 2+ state. The formation of more stable 4+ centers in the Sn(II)-based materials under ambient conditions makes the device efficiency very low. Worse, there might be no other elements across the Periodic Table that can replace Pb while maintaining the desirable properties, such as band gap. Out-of-the-box ideas are therefore called for to stimulate the research in this field. In this talk, two approaches are proposed based on state-of-the-art first-principles calculations. Through a screening of chalcogenide perovskite materials, CaTiS<sub>3</sub>, BaZrS<sub>3</sub>, CaZrSe<sub>3</sub>, and CaHfSe<sub>3</sub> have been predicted to have suitable band gaps for making solar cells. Among these materials, BaZrS<sub>3</sub> have been synthesized experimentally. Another proposed approach is to introduce dual anions (i.e., splitting the anion sites) that allow the composition to satisfy charge neutrality, while replacing Pb by more environmentally benign elements. One of the candidate materials is CH<sub>3</sub>NH<sub>3</sub>BiS<sub>2</sub>, which is predicted to have band gap around 1.4 eV and high optical absorption.

**9:12AM R8.00005 Light induced polaron formation in perovskite solar cell devices** , AMANDA NEUKIRCH, WANYI NIE, JEAN-CHRISTOPHE BLANCON, LANL, KANNATASSEN APPAVOO, BNL, HSINHAN TSAI, LANL, MANISH CHHOWALLA, Rutgers University, MUHAMMAD ALAM, Purdue University, MATTHEW SFEIR, BNL, CLAUDINE KATAN, ISCR, JACKY EVEN, FOTON, JARED CROCHET, GAUTAM GUPTA, ADITYA MOHITE, SERGEI TRETIKOV, LANL — The need for a low-cost, clean, and abundant source of energy has generated large amounts of research in solution processed solar cell materials. The lead halide perovskite has rapidly developed as a serious candidate for the active layer of photovoltaic devices. The efficiencies of devices made with this material have increased from 3.5% to over 20% in around 5 years. Despite the remarkable progress associated with perovskite materials, there are still fundamental questions regarding their lack of photo-stability over prolonged solar irradiation that need to be addressed. Recent experiments on photo-degradation under constant illumination have found fast self-healing by resting the device in the dark for less than 1 minute. Density functional theory and symmetry analysis show that localized charge states couple to local structural lattice distortions and methyl ammonium quasistatic configurations. Once translational symmetry is lost, additional bonding configurations become symmetry allowed, triggering localized charges in the vicinity over time under constant illumination, thus seeding the formation of macroscopic charged domains and preventing efficient charge extraction. Here we present an in-depth study of polaron formation and binding energy at the atomistic level.

### 9:24AM R8.00006 Electric polarization of $CH_3NH_3PbI_3$ and enhancement by Cl substitution<sup>1</sup>

, WEN-LI YAN, Beihang University, University of Utah, GUANG-HONG LU, Beihang University, FENG LIU, University of Utah — As a prototype of organic-inorganic hybrid perovskite,  $CH_3NH_3PbI_3$  has attracted extensive attention recently due to its applications in high power-conversion-efficiency solar cells. In comparison with its inorganic perovskite counterparts such as  $CsPbI_3$ , the organic cation  $CH_3NH_3^+$  is expected to play multiple important roles in distorting crystal structures and thus band structures as well as creating local electrically polarized domains to help separate charge carriers. Using first-principles method and berry phase theory, the electric polarization vectors of  $CH_3NH_3PbI_3$  have been calculated. The off-center displacement of Pb within the  $PbI_6$  octahedral is shown to introduce major intrinsic polarization, with additional contributions from off-center displacement of  $CH_3NH_3^+$  within  $PbI_3$  cage and charge polarization within the organic cation. With chlorine substitution of iodine, the electronegativity difference between halogen and Pb becomes larger, and the lattice distortion and hence the electric polarization increases, which provides a possible mechanism to further assist charge carrier separation in solar cell devices. This is consistent with enhanced photovoltaics properties of  $CH_3NH_3PbI_{3-x}Cl_x$  found in recent experiments.

### 9:36AM R8.00007 Hybrid organic-inorganic halide perovskites: Electronic structure, dielectric properties, native defects, and the role of $ns^2$ ions

, MAOHUA DU, Oak Ridge National Laboratory, DONGWEN YANG, College of Materials Science and Engineering, Jilin University, China, HONGLIANG SHI, Oak Ridge National Laboratory, LIJUN ZHANG, College of Materials Science and Engineering, Jilin University, China —  $CH_3NH_3PbI_3$  possesses an interesting combination of properties, i.e., efficient carrier transport, high density of defects (which are nevertheless benign in terms of carrier trapping), large static dielectric constant, and significant ion migration. These properties have important effects on the solar cell performance and are unusual for a photovoltaic material. However, they are not unique; they have been reported for other halides. In the talk, we discuss the underlying physics behind these material properties in  $CH_3NH_3PbI_3$  and other halide electronic materials. The large static dielectric constant resulting from the presence of the  $ns^2$  ions and the molecular dipoles is related to the high defect concentration, defect tolerance, and the defect diffusion. We will also show the calculations of the defect and impurity diffusion and discuss their impact on the solar cell performance.

### 9:48AM R8.00008 Quasiparticle band gap of organic-inorganic hybrid perovskites: Crystal structure, spin-orbit coupling, and self-energy effects<sup>1</sup>

, WEIWEI GAO, State Univ of NY - Buffalo, XIANG GAO, Beijing Computational Science Research Center, TESFAYE ABTEW, State Univ of NY - Buffalo, YIYANG SUN, SHENGBAI ZHANG, Rensselaer Polytechnic Institute, PEIHONG ZHANG, State Univ of NY - Buffalo — The quasiparticle band gaps of organic-inorganic hybrid perovskites are often determined (and can be controlled) by various factors, complicating predictive materials optimization. Here we report a comprehensive investigation on the band gap formation mechanism in  $CH_3NH_3PbI_3$  by decoupling various contributing factors which ultimately determine their electronic structure and quasiparticle band gap. Four major factors, namely, quasiparticle self-energy, spin-orbit coupling, volume (lattice constant) effects, and structural distortions due to the presence of organic molecules, and their influences on the quasiparticle band structure of organometal hybrid perovskites are illustrated. We find that although methylammonium cations do not contribute directly to the electronic states near band edges, they play an important role in defining the band gap through a lattice distortion mechanism and by controlling the overall lattice constants (thus the chemical bonding of the optically active  $PbI_3^-$ ). The spin-orbit coupling effects drastically reduce the electron and hole effective masses in these systems, which is beneficial for high carrier mobilities and small exciton binding energies.

### 10:00AM R8.00009 Light-induced defects in hybrid lead halide perovskite

, ONISE SHARIA, WILLIAM SCHNEIDER, University of Notre Dame — One of the main challenges facing organohalide perovskites for solar application is stability. Solar cells must last decades to be economically viable alternatives to traditional energy sources. While some causes of instability can be avoided through engineering, light-induced defects can be fundamentally limiting factor for practical application of the material. Light creates large numbers of electron and hole pairs that can contribute to degradation processes. Using *ab initio* theoretical methods, we systematically explore first steps of light induced defect formation in methyl ammonium lead iodide,  $MAPbI_3$ . In particular, we study charged and neutral Frenkel pair formation involving Pb and I atoms. We find that most of the defects, except negatively charged Pb Frenkel pairs, are reversible, and thus most do not lead to degradation. Negative Pb defects create a mid-gap state and localize the conduction band electron. A minimum energy path study shows that, once the first defect is created, Pb atoms migrate relatively fast. The defects have two detrimental effects on the material. First, they create charge traps below the conduction band. Second, they can lead to degradation of the material by forming Pb clusters.

### 10:12AM R8.00010 Ab initio study of the polarization dependence of the optoelectronic properties of hybrid halide perovskites

, LINN LEPPERT, SEBASTIAN E. REYES-LILLO, Molecular Foundry, Lawrence Berkeley National Lab; Department of Physics, University of California Berkeley, JEFFREY B. NEATON, Molecular Foundry, Lawrence Berkeley National Lab; Department of Physics, University of California Berkeley; Kavli Energy NanoSciences Institute, NEATON TEAM — With efficiencies as high as 20%, hybrid organic-inorganic halide perovskites have garnered much of the photovoltaic community's attention. In light of recent experimental results [1], we investigate the coupling mechanism between polarization and optoelectronic properties of methylammonium (MA) lead iodide,  $(CH_3NH_3)PbI_3$ , and related halide perovskites. In particular, we study the conditions that promote a combined effect of strong spin-orbit coupling and inversion symmetry breaking and that lead to a sizable Rashba/Dresselhaus effect. Using density functional theory calculations, we elucidate the emergence of Rashba/Dresselhaus splitting associated with local distortions and long-range coherent alignment of MA moieties in the material. We examine the extent to which the magnitude of the splitting, as well as other important electronic and optical properties [1], can be altered by increasing the macroscopic polarization. This opens avenues for manipulation of optoelectronic properties by an external electric field and/or chemical substitution of the MA molecule.

### 10:24AM R8.00011 Degradation of Co-evaporated Perovskite Thin Films<sup>1</sup>

, CONGCONG WANG, Univ of Rochester, YOUZHEN LI, XUEMEI XU, Central South University, CHENGCONG WANG, Univ of Rochester, FANGYAN XIE, Sun Yat-Sen University, YONGLI GAO, Univ of Rochester — Methylammonium lead halide perovskites have been developed as highly promising materials to fabricate efficient solar cells in the past few years. We have investigated degradation of co-evaporated  $CH_3NH_3PbI_3$  films using x-ray photoelectron spectroscopy (XPS), small angle x-ray diffraction (XRD), and atomic force microscopy (AFM). The  $CH_3NH_3PbI_3$  films have an excellent atomic ratio and crystal structure. The films were exposed to oxygen, air and water, respectively. The results indicate that  $CH_3NH_3PbI_3$  film is not sensitive to oxygen and dry air. The XPS results of  $H_2O$  exposure are similar to those of ambient exposure except for the higher intensity of C and O. The XRD results indicate that the perovskite turned to  $PbI_2$  after ambient exposure. The AFM measurements reveal that the morphology of the film changed drastically from smooth to rough by ambient exposure. The experiment indicated that  $H_2O$  plays a dominated role in the degradation of  $CH_3NH_3PbI_3$  films. The degradation can be characterized by almost complete removal of N, substantial reduction of I, residual of  $PbI_2$ , C, O, and I compounds on the surface.

**10:36AM R8.00012 Use of Nanoconfinement to Control Metal-Halide Perovskite Crystallization and Stability**, SANGCHUL LEE, JOSHUA FELDMAN, STEPHANIE LEE, Department of Chemical Engineering and Materials Science, Stevens Institute of Technology — We present a systematic study of the effect of nanoconfinement on the crystallization of methylammonium lead halide (MAPbI<sub>3</sub>) perovskite crystallization. MAPbI<sub>3</sub> was spin coated onto anodized aluminum oxide (AAO) templates with uniaxially-aligned pores ranging from 20 – 200 nm in diameter and examined using 2-D X-ray diffraction and scanning electron microscopy. X-ray diffraction patterns revealed the presence of a transient precursor phase that converts to the MAPbI<sub>3</sub> crystal structure upon thermal annealing. The orientation of the precursor phase and conversion rate to the MAPbI<sub>3</sub> crystal structure were found to depend on the pore size of the AAO template. The stability of MAPbI<sub>3</sub> in air also depends on the extent of nanoconfinement. When deposited on flat SiO<sub>2</sub> surfaces, MAPbI<sub>3</sub> degraded into PbI<sub>2</sub> and MA after 21 days. When deposited in AAO templates exhibiting 20-nm pore sizes, however, MAPbI<sub>3</sub> crystals were stable for longer than 16 days. These findings suggest that nanoconfinement of MAPbI<sub>3</sub> crystals may be a promising strategy for improving the stability of perovskite-based solar cells.

**10:48AM R8.00013 Structural Effects on the Bandstructure of Methylammonium Lead Iodide**, MARCO BERNARDI, California Institute of Technology, BRADFORD A BARKER, DEREK VIGIL-FOWLER, JEFFREY B NEATON, STEVEN G LOUIE, University of California at Berkeley, LOUIE TEAM — Metal-organic halide perovskites possess peculiar physical properties. The carrier diffusion length in methylammonium lead iodide (MAPbI) exceeds 1  $\mu\text{m}$ , but this unusually high value for a solution-processed material is poorly understood. We developed first-principles calculations of carrier lifetimes and diffusion lengths in semiconductors, which require accurate knowledge of the bandstructure. In this talk, we show that in MAPbI the structure strongly affects the bandstructure and band edges, and that density functional theory (DFT) is unable to predict the room temperature tetragonal structure due to the polymorphism of MAPbI. The Rashba splitting induced by the spin-orbit interaction, and the DFT band gap and effective masses, all depend strongly on the chosen structure, a point that previous work failed to address. Working with multiple stochastic realizations of large unit cells with random methylammonium orientations, we compute average effective masses and show that the effective mass depends linearly on the band gap. The average Rashba coefficient we find is an order of magnitude smaller than previously reported, and the band edges are almost parabolic. Our structures possess the correct symmetry and are free of the spurious Pb off-centering assumed in previous work. We identify the correct starting point for GW bandstructure calculations and to compute the carrier lifetime and diffusion length.

**Thursday, March 17, 2016 8:00AM - 11:00AM –**  
**Session R11 GMAG DMP FIAP: Spin-Hall IV** 307 - Igor Barsukov, UC Irvine

**8:00AM R11.00001 Magnonic charge-pumping and spin-orbit torques in conducting ferromagnets**, ARNE BRATAAS, Norwegian University of Science and Technology — In conducting ferromagnets, the spin-transfer torque and spin-motive force are known to exhibit a reciprocal relationship. Recent works on ferromagnets with strong spin-orbit coupling have revealed a rich complexity of the interaction between itinerant charge carriers and magnetization. As a result, currents can also induce magnetization excitations via spin-orbit torques, sometimes in more efficient ways than via spin-transfer torques. The reciprocal phenomenon of spin-orbit torques is magnonic charge-pumping. We will discuss how the material symmetry governs spin-orbit torques and magnonic charge-pumping. We will also relate magnonic charge pumping and spin-orbit torques via the Onsager reciprocal relations. Finally, we will give examples for important classes of systems including isotropic ferromagnets with nonuniform magnetization.

**8:36AM R11.00002 The Spin Hall Effect in Rare Earth Thin Films**, NEAL REYNOLDS, JONATHAN GIBBONS, JOHN HERON, Physics Department Cornell University, DARRELL SCHLOM, Materials Science and Engineering Cornell University, DANIEL RALPH, Physics Department Cornell University — The spin Hall effect results in a spin current which flows transverse to an applied electric field in non-magnetic materials. We report measurements of the strength of the spin Hall effect in a series of lanthanide rare earth materials in order to determine whether the large spin and orbital moments in f-electron materials might enhance the spin Hall effect. To ensure trustworthy results, we compare the results of several complementary measurement techniques: off-resonant electrical and optical second harmonic detection of current-induced magnetic tilting, spin-torque ferromagnetic resonance, and spin pumping. We compare the results to ab-initio calculations of the intrinsic Berry curvature contribution to spin Hall effect.

**8:48AM R11.00003 Towards brain-inspired computing with spin-torque nano-oscillators**, JULIE GROLLIER, JACOB TORREJON, MATHIEU RIOU, CNRS/Thales, Palaiseau, France, VINCENT CROS, CNRS/Thales lab, DAMIEN QUERLIOZ, Institut d'Electronique Fondamentale, Orsay, France, SUMITO TSUNEGI, AKIO FUKUSHIMA, HITOSHI KUBOTA, SHINJI YUASA, National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan, GURU KHALSA, MARK D. STILES, National Institute of Science and Technology (NIST), Gaithersburg, USA — The brain displays many features typical of non-linear dynamical networks, such as synchronization or chaotic behaviour. These observations have inspired a whole class of models that harness the power of complex non-linear dynamical networks for computing. In this framework, neurons are modeled as non-linear oscillators, and synapses as the coupling between oscillators. These abstract models are very good at processing waveforms for pattern recognition or at generating precise time sequences useful for robotic motion. However there are very few hardware implementations of these systems, because large numbers of interacting non-linear oscillators are indeed. In this talk, I will show that coupled spin-torque nano-oscillators are very promising for realizing cognitive computing at the nanometer and nanosecond scale, and will present our first results in this direction.

**9:00AM R11.00004 Oscillatory spin transport in spin Hall multilayers**, IGOR BARSUKOV, University of California, Irvine, A. M. GONALVES, P. SOLEDADE, C. A. C. PASSOS, M. COSTA, CBPF, Rio de Janeiro, Brazil, N. M. SOUZA-NETO, LNLS, Campinas, Brazil, F. GARCIA, CBPF, Rio de Janeiro, Brazil, H. K. LEE, A. SMITH, University of California, Irvine, O. TRETIAKOV, Tohoku University, Sendai, Japan, I. N. KRIVOROTOV, University of California, Irvine, L. C. SAMPAIO, CBPF, Rio de Janeiro, Brazil — We study multilayers of sputtered Pt/(d)Cu/Py as a function of the Cu thickness  $d$  using ferromagnetic resonance (FMR). The FMR linewidth reveals a linear dependence on the frequency with negligible inhomogeneous contribution. The Gilbert damping falls smoothly with increasing  $d$ , but presents a strong superimposed oscillation with a period of  $\sim 1.5\text{nm}$ . We attribute this behavior to RKKY-like spin transport in the confinement of the Cu layer. The induced perpendicular anisotropy due to the proximity effect shows a similar behavior. We evaluate the induced magnetic moment on Pt using x-ray magnetic circular dichroism and find that it decreases with increasing Cu thickness smoothly. Again, we see oscillations of the magnetic moment and show that the oscillatory spin transport affects proximity induced magnetism in Pt. We extend our study to multilayer systems with increased oxidation levels and with out-of-plane crystal texture, in order to investigate the effects of disorder and electron's k-vectors that are responsible for the oscillatory spin transport.

**9:12AM R11.00005 Magnon emission and radiation induced by spin-polarized current.**<sup>1</sup>, ANDREI ZHOLUD, RYAN FREEMAN, RONGXING CAO, SERGEI URAZHIDIN, Emory University — The spin-torque effect due to spin injection into ferromagnets can affect their effective dynamical damping, and modify the magnon populations. The latter leads to the onset of nonlinear damping that can prevent spontaneous current-induced magnetization oscillations. It has been argued that these nonlinear processes can be eliminated by the radiation of magnons excited by local spin injection in extended magnetic films. To test these effects, studies of the effects of spin injection on the magnon populations in nanoscale spin valves and magnetic point contacts. Measurements of the giant magnetoresistance show a significant resistance component that is antisymmetric in current, and linearly dependent on temperature  $T$ . This component is significantly larger for the nanopatterned ferromagnets than for point contacts. We interpret our observations in terms of stimulated generation of magnons by the spin current, and their radiation in point contacts. 1. V.E. Demidov, S. Urazhdin, H. Ulrichs, V. Tiberkevich, A. **9:24AM R11.00006 Electric probe for spin transition and fluctuation**, ZHIYONG QIU, Tohoku University, JIA LI, University of California at Berkeley, DAZHI HOU, Tohoku University, ELKE ARENHOLZ, ALPHA T. NDIAYE, ALI TAN, Lawrence Berkeley National Laboratory, KEN-ICHI UCHIDA, KOJI SATO, Tohoku University, YAROSLOV TSERKOVNIAK, University of California, Z. Q. QIU, University of California at Berkeley, EIJI SAITOH, Tohoku University — Spin fluctuation and transition have always been one of central topics of magnetism and condensed matter science. To probe them, neutron scatterings have been used as powerful tools. A part of neutrons injected into a sample is scattered by spin fluctuation inside the sample. This process transcribes the spin fluctuation onto scattering intensity, which is commonly represented by dynamical magnetic susceptibility of the sample and is maximized at magnetic phase transitions. Importantly, a neutron carries spin without electric charge, and it thus can bring spin into a sample without being disturbed by electric energy: an advantage of neutrons, although large facilities such as a nuclear reactor is necessary. Here we show that spin pumping, frequently used in nanoscale spintronic devices, provides a desktop micro probe for spin fluctuation and transition; not only a neutron beam, spin current is also a flux of spin without an electric charge and its transport reflects spin fluctuation in a sample. We demonstrate detection of anti-ferromagnetic transition in ultra-thin CoO films via frequency dependent spin-current transmission measurements.

**9:36AM R11.00007 Electrical manipulation of a ferromagnet by an antiferromagnet**, V TSHITOYAN, C CICCARELLI, Cavendish Laboratory, University of Cambridge, UK, A P MIHAL, M ALI, School of Physics and Astronomy, University of Leeds, UK, A C IRVINE, Cavendish Laboratory, University of Cambridge, UK, T A MOORE, School of Physics and Astronomy, University of Leeds, UK, T JUNGWIRTH, Institute of Physics ASCR, Prague, CZ and School of Physics and Astronomy, University of Nottingham, UK, A J FERGUSON, Cavendish Laboratory, University of Cambridge, UK — Several recent studies of antiferromagnetic (AFM) spintronics have focused on transmission and detection of spin-currents in AFMs. Efficient spin transmission through AFMs was inferred from experiments in FM/AFM/NM (normal metal) structures. Measurements in FM/AFM bilayers have demonstrated that a metallic AFM can also act as an efficient ISHE detector of the spin-current, with spin-Hall angles comparable to heavy NMs. Here we demonstrate that an antiferromagnet can be employed for a highly efficient electrical manipulation of a ferromagnet. We use an all-electrical excitation and detection technique of ferromagnetic resonance in a NiFe/IrMn bilayer. We observe antidamping-like spin torque acting on the NiFe generated by the in-plane current driven through the IrMn antiferromagnet. A large enhancement of the torque, characterized by an effective spin-Hall angle exceeding most heavy transition metals, correlates with the presence of the exchange-bias field at the NiFe/IrMn interface. It highlights that, in addition to strong spin-orbit coupling, the AFM order in IrMn governs the observed phenomenon.

**9:48AM R11.00008 Spin pumping and inverse spin Hall effects in heavy metal/antiferromagnet/Permalloy trilayers**<sup>1</sup>, HILAL SAGLAM, WEI ZHANG, M. BENJAMIN JUNGFLISCH, WANJUN JIANG, JOHN E. PEARSON, AXEL HOFFMANN, Argonne National Laboratory — Recent work shows efficient spin transfer via spin waves in insulating antiferromagnets (AFMs) [1], suggesting that AFMs can play a more active role in the manipulation of ferromagnets. We use spin pumping and inverse spin Hall effect experiments on heavy metal (Pt and W)/AFMs/Py (Ni<sub>80</sub>Fe<sub>20</sub>) trilayer structures, to examine the possible spin transfer phenomenon in metallic AFMs, *i.e.*, FeMn and PdMn. Previous work has studied electronic effects of the spin transport in these materials, yielding short spin diffusion length on the order of 1 nm [2]. However, the work did not examine whether besides diffusive spin transport by the conduction electrons, there are additional spin transport contributions from spin wave excitations [1]. We clearly observe spin transport from the Py spin reservoir to the heavy metal layer through the sandwiched AFMs with thicknesses well above the previously measured spin diffusion lengths, indicating that spin transport by spin waves may lead to non-negligible contributions. **10:00AM R11.00009 Phase-sensitive inductive detection of ac currents due to spin-pumping/inverse spin Hall effect in unpatterned Permalloy/Pt bilayers**, THOMAS SILVA, NIST, HANS NEMBACH, University of Colorado, JUSTIN SHAW, NIST, ALEXY KARENOWSKA, Oxford University, MATHIAS WEILER, WMI — We present a new method to measure the ac inverse spin Hall effect at GHz frequencies. Unlike previous methods [1-3], our does not rely on any patterning or electrical contacts. We utilize phase-sensitive, broad-band, perpendicular-field ferromagnetic resonance to detect the ac current by the inverse spin Hall effect (ISHE) in Py/Pt bilayers. The ISHE component of the signal is non-linear in the excitation frequency; while the inductive FMR response scales linearly with frequency, the ISHE signal scales quadratically because the ISHE current itself is proportional to  $dm/dt$ . This differential gain affords us detection of previously unreported higher order contributions to the ISHE signal. We compare FMR measurements with a control samples that do not include the high spin-orbit layer, *e.g.* Pt. Data sets with and without Pt are normalized by the complex Polder susceptibility, which nullifies any effects due to differences in line-width and anisotropy. The complex ratio of the normalized inductive amplitudes is analyzed with a simple model that considers how the ac currents generated by the ISHE couple inductively back into the excitations waveguide. The linear ISHE signal agrees with previous reported values. The nonlinear ISHE signal is 3-4 orders of magnitude weaker, but is easily detected over the frequency range of 5-45 GHz. [1] M. Weiler, et al., *PRL* **113**, 157204 (2014), [2] C. Hahn, et al., *PRL* **111**, 217204 (2013) [3] D. Wei, et al., *Nat. Comm.* **5**, (2014)

**10:12AM R11.00010 Extrinsic Spin Hall effect of AuW alloys**, PIOTR LACZKOWSKI, JUAN CARLOS ROJAS-SANCHEZ, UMPHY CNRS-Thales - 1-Avenue Augustin Fresnel - 91767 PALAISEAU, WILLIAMS SAVERO-TORRES, INAC-SP2M, CEA-Universit Joseph Fourier, F-38054 Grenoble, France, NICOLAS REYREN, CYRIL DERANLOT, JEAN-MARIE GEORGE, HENRI JAFFRES, UMPHY CNRS-Thales - 1-Avenue Augustin Fresnel - 91767 PALAISEAU, CYRIL BEIGN, LUCIEN NOTIN, INAC-SP2M, CEA-Universit Joseph Fourier, F-38054 Grenoble, France, SOPHIE COLLIN, UMPHY CNRS-Thales - 1-Avenue Augustin Fresnel - 91767 PALAISEAU, ALAIN MARTY, JEAN-PHILIPPE ATTAN, LAURENT VILA, INAC-SP2M, CEA-Universit Joseph Fourier, F-38054 Grenoble, France, FREDERIC PETROFF, ALBERT FERT, UMPHY CNRS-Thales - 1-Avenue Augustin Fresnel - 91767 PALAISEAU, UMPHY CNRS-THALES PALAISEAU TEAM, CEA-SP2M-INAC GRENOBLE TEAM — The spin Hall effect (SHE) allows a reciprocal conversion between charge and spin currents using spin orbit interactions. Large Spin Hall angle have been reported in transition metals (Pt, W, Beta-Ta) and in alloys made of heavy metals [1]. We will report on SHA in AuW alloys [2] exhibiting a non-monotonic relation with W content. In this regime, it suggests a skew-scattering to side-jump dominant contribution to the spin Hall resistivity, thus allowing precise tuning of SHA vs. W content. We will present experiments by using Lateral Spin Valves with refined spin-absorption model adapted to strong spin-orbit interactions. By using complementary FMR/Spin-Pumping techniques, we demonstrate very large SHA of the order of 15 % at rather high W concentration in rather good agreement with the previous method. **10:24AM R11.00011 Chiral damping in magnetic domain walls dynamics** , EMILIE JUÉ, SPINTEC - Grenoble, now: NIST - Boulder — Domain wall (DW) motion in materials with structural inversion asymmetry (SIA) and high spin-orbit coupling has attracted much interest in the recent years due to the discovery of unexpected physical mechanisms. Especially, it has been shown that the DW dynamics in such materials can be explained by chiral DWs with (partly or fully) Néel structure, whose stability derives from an interfacial Dzyaloshinskii-Moriya interaction (DMI) [1]. In this work, we show that DMI is not the only effect inducing chiral dynamics and demonstrate the existence of a chiral damping. This result is supported by the study of the asymmetry induced by an in-plane magnetic field on field induced domain wall motion in perpendicularly magnetized asymmetric Pt/Co/Pt trilayers. Using time reversal properties, we show that this asymmetry cannot be attributed to an effective field but originates from a purely dissipative mechanism. The observation of chiral damping, not only enriches the spectrum of physical phenomena engendered by the SIA, but since it can coexist with DMI it is essential for conceiving DW and skyrmion devices. **Session R12 DCOMP: Recent Computational Advances in the Understanding of Complex Oxides** 308 - James Rondinelli, Northwestern University

**8:00AM R12.00001 The role of Coulomb correlations in complex oxides** , SILKE BIERMANN, cole Polytechnique — No abstract available.

**8:30AM R12.00002 Strong correlations in new multiferroics** , DANIEL PUGGIONI, Northwestern University — No abstract available.

**9:00AM R12.00003 Hybrid functionals for simulating complex oxides** , CESARE FRANCHINI, University of Vienna — Hybrid functionals are a class of exchange-correlation (XC) functionals in density functional theory (DFT) that are constructed by a suitable mixing of local/semi-local XC functionals (LDA/GGA) with a certain portion of the exact Hartree-Fock exchange. After being used for years in the chemistry community for studying molecular properties, hybrid functionals are being increasingly widely used for solid state problems, for which standard LDA/GGA approximations provide a defective description. In particular, hybrid functionals appear to account well for the complicated coupling between lattice, charge and spin degrees of freedom in transition metal oxides, a class of materials that has recently attracted a lot of interest due to its technological relevance (all-oxides electronics), the large spectrum of functionalities, and the many challenging issues related to strong electronic correlation [1,2]. The purpose of this talk is to present the essential ideas and physical picture of hybrid functionals and to present a map of recent applications to complex oxides aiming to cover an ample spectra of cases (*sp*, *3d*, *4d* and *5d* compounds) and to discuss an extended array of physical phenomena including: metal-to-insulator transitions, electron localization, bandgap prediction, polarons, multiferroism, and spin-orbit coupling. [1] C. Franchini, J. Phys. Condens. Matter 26, 253202 (2014). [2] J. G. He and C. Franchini, Phys. Rev. B 86, 235117 (2012).

**9:30AM R12.00004 Electron-electron interactions and lattice distortions in the perovskite titanates** , LARS BJAALIE, University of California, Santa Barbara — A two-dimensional electron gas (2DEG) with the unprecedented high density of  $3 \times 10^{14}$  (corresponding to 1/2 electron per interface unit cell area) can be formed at the interface between  $\text{SrTiO}_3$  and a rare-earth titanate ( $\text{RTiO}_3$ ). The 2DEG resides in the  $\text{SrTiO}_3$ , and arises from a polar discontinuity at the interface. The formation of this 2DEG has led us to study these perovskite titanates in detail. Some of these compounds are Mott insulators, where a Mott-Hubbard gap opens up between partially filled Ti *3d* bands. This talk focuses on the importance of the interplay between electron-electron interactions and lattice distortions in these complex oxides, which we study with density functional theory using a hybrid functional, capable of correctly describing electron localization and Mott-insulating behavior. These effects are crucial to understanding the metal-to-insulator transition as a function of electron density. Indeed, very thin  $\text{SrTiO}_3$  layers inserted in  $\text{GdTiO}_3$  show insulating behavior, in contrast to the metallic character of thicker layers in which the electrons form a 2DEG. The same physics is observed in bulk  $\text{SrTiO}_3$  when doped with 1/2 electron per Ti atom <sup>1</sup>. Charge localization and lattice distortions also govern the formation of small hole polarons in the rare-earth titanates. We demonstrate that these polarons impact the optical absorption measurements commonly used to determine the value of the Mott-Hubbard gap <sup>2</sup>. Work performed in collaboration with Anderson Janotti, Burak Himmetoglu, and Chris G. Van de Walle, and supported by NSF and ARO.

**10:00AM R12.00005 Transport Properties of Complex Oxides: New Ideas and Insights from Theory and Simulation** , NICOLE BENEDEK, Cornell University — Complex oxides are one of the largest and most technologically important materials families. The  $\text{ABO}_3$  perovskite oxides in particular display an unparalleled variety of physical properties. The microscopic origin of these properties (how they arise from the structure of the material) is often complicated, but in many systems previous research has identified simple guidelines or 'rules of thumb' that link structure and chemistry to the physics of interest. For example, the tolerance factor is a simple empirical measure that relates the composition of a perovskite to its tendency to adopt a distorted structure. First-principles calculations have shown that the tendency towards ferroelectricity increases systematically as the tolerance factor of the perovskite decreases. Can we uncover a similar set of simple guidelines to yield new insights into the ionic and thermal transport properties of perovskites? I will discuss recent research from my group on the link between crystal structure and chemistry, soft phonons and ionic transport in a family of layered perovskite oxides, the  $\text{Ln}_2\text{NiO}_{4+\delta}$  Ruddlesden-Popper phases. In particular, we show how the lattice dynamical properties of these materials (their tendency to undergo certain structural distortions) can be correlated with oxide ion transport properties. Ultimately, we seek new ways to understand the microscopic origins of complex transport processes and to develop first-principles-based design rules for new materials based on our understanding.

**Thursday, March 17, 2016 8:00AM - 11:00AM –**  
**Session R13 DAMOP: Atomtronics** 309 - Mark Edwards, Georgia Southern University

**8:00AM R13.00001 Magnon optics and thermodynamics in a degenerate spinor Bose gas** , DAN STAMPER-KURN, Univ of California - Berkeley — At low temperature, spinor Bose gases form magnetically ordered superfluids. Like other magnetic materials, such a fluid supports magnons, the Nambu-Goldstone bosons corresponding to the spontaneous breaking of rotational symmetry. We have developed methods to produce and detect such excitations in a  $^{87}\text{Rb}$   $F = 1$  spinor Bose gas. I will discuss precise measurements of the magnon recoil energy using coherent magnon interferometry, the use of thermalized magnons to measure and lower the temperature of quantum gases, and the phenomenon of magnon condensation in a quantum gas.

**8:36AM R13.00002 Atomtronics with Ultracold Bose Gases** , HERWIG OTT, University of Kaiserslautern — Neutral atom systems can exhibit similar transport properties like solid state devices. For instance, a neutral atom current is induced by a difference in chemical potential very much in the same way as a voltage drives an electric current. Employing Bose-Einstein condensed atomic gases allows observing superfluid transport phenomena, thus drawing connections to superconductivity. With help of light fields, the atomic current can additionally be guided in engineered potential landscapes in which one can also incorporate tunneling junctions. Eventually, the different components and elements can be integrated in atomtronic circuits which shed light on fundamental transport properties of many-body quantum systems. In this talk, I will present two fundamental atomtronic devices. The first is the observation of negative differential conductivity, which occurs at a multimode tunneling junction for ultracold atoms [1]. The second is the appearance of a DC Josephson current in a biased tunneling junction [2], which features bistable transport characteristics. I will discuss the prospects of these basic elements for more complex atomtronic circuits. References [1] R. Labouvie, B. Santra, S. Heun, S. Wimberger, and H. Ott “Negative Differential Conductivity in an Interacting Quantum Gas” Phys. Rev. Lett. 115, 050601 (2015). [2] R. Labouvie, B. Santra, Simon Heun, and H. Ott “Nonequilibrium steady states in a driven-dissipative superfluid” arXiv:1507.05007

**9:12AM R13.00003 Dynamics of quantum impurities in many-body systems of ultracold atoms** , EUGENE DEMLER, Harvard University — Recent theoretical and experimental progress in the study of dynamics of quantum impurities in ensembles of ultracold atoms will be reviewed. Examples include RF spectroscopy of Bose and Fermi polarons, interferometric measurements of ultrafast dynamics of impurities in an atomic Fermi sea, exploring crossover from few- to many-body dynamics in Rydberg excitations. New directions including realizations of Kondo type models and Shiba states in Fermi superfluids will be discussed.

**9:48AM R13.00004 Transport dynamics and dissipation in polariton ring condensates and cold atoms** , ANDREW DALEY, Univ of Strathclyde — Recent progress in experiments has opened new contexts in which to observe and explore out-of-equilibrium quantum transport dynamics. On the side of cold atoms, significant advances are made possible by the ability to control and measure atomic dynamics time-dependently, as well as to explore the effects of strong interactions. This is especially true in recent experiments with quantum gas microscopes, which now provide single-site and single atom measurement and control. At the same time, new methods for control and longer coherence times have been realised in condensates of exciton polaritons. This has enabled the development of ring geometries for these systems, and corresponding quantised circulation. I will discuss our recent theoretical work looking at the interplay between coherent dynamics and dissipation in these systems. For polaritons in a ring trap, half-quantum vortices are allowed in which there is a phase rotation of  $\pi$  and a corresponding polarisation vector rotation of  $\pi$  around the ring. The observed half-quantum state in current experiments is novel, in that the handedness of the spin flips from one side of the ring to the other side in addition to the rotation of the linear polarization component. This type of state is not possible for vortices in a simply connected geometry, and we investigate how the interplay between the polariton production and dissipation can give rise to this state in a ring trap. I will also discuss the transport dynamics of cold atoms in tilted optical lattices, in the presence of decoherence from sources including spontaneous emissions.

**10:24AM R13.00005 Driving transitions between quantized flow states in an atomtronic circuit** , STEPHEN ECKEL, Joint Quantum Institute (NIST/UMD) — Superfluidity, or flow without resistance, is a macroscopic quantum effect that is present in a multitude of systems, including liquid helium, superconductors, and ultra-cold atomic gases. In superconductors, flow without resistance has led to the development of a number of useful devices. Here, I will present our work studying a superfluid analog to the rf-superconducting interference device (SQUID). Our atomtronic analog is formed in a ring-shaped Bose-Einstein condensate (BEC) of sodium atoms. Ring condensates are unique in that they can support persistent currents that are quantized. We drive transitions between persistent current states using a rotating perturbation, or weak link. Here, rotation acts as the analog to magnetic field in superconductors. In our system, a current (as viewed in the frame co-rotating with the perturbation) develops to oppose any change in rotation. If the rotation rate is sufficiently large, the critical current of the superfluid is exceeded in the weak link region, causing a transition to a state of larger persistent current. The strength of the perturbation tunes the critical rotation rates. Like the rf-SQUID, the transitions show hysteresis rotation rates that increase the quantized current are different from those that decrease the current. The size of the hysteresis loop allows us to explore the microscopic mechanisms responsible for the transitions. In a more recent experiment, we have observed the time it takes for the first persistent current state to decay in the presence of a stationary perturbation. The measured timescales depend strongly on temperature, but in a way that suggests that other physical effects, like quantum coherence, could also play a role in the transitions between current states.

**Session R14 GSNP GSOF: Geometry and Mechanics of Folded Filaments, Writhing Ribbons and Braided Bundles** 310 - Gregory Grason, Univeristy of Massachusetts-Amherst

**8:00AM R14.00001 Collective Behavior of Hair, and Ponytail Shape and Dynamics.**<sup>1</sup> , ROBIN BALL, Dept of Physics, University of Warwick — I will discuss how we can build a mathematical model of the behaviour of a bundle of hair, comparing the results with experimental studies of the shape and dynamics of human ponytails. We treat the individual fibers as elastic filaments with random intrinsic curvature, in which the balance of bending elasticity, gravity, orientational disorder and inertia is recast as a differential equation for the envelope of the fibre bundle. The static elements of this work were first reported in R.E. Goldstein, P.B. Warren and R.C. Ball, Physical Review Letters 108, 078101 (2012). The compressibility of the bundle enters through an equation of state whose empirical form is shown to arise from a Confined Helix Model, in which the constraint of the surrounding hair is on a given fibre is represented as a confining cylinder. Using this model we find the ponytail shape is well fit with only one adjustable parameter, which is the degree to which the confining cylinders over fill space. The dynamics of driven vertical ponytail motion is well reproduced provided we introduce some damping, and we find the level of damping required is consistent with that arising from viscous drag of the lateral motion of the hair fibres through the interstitial air. Most of our match with experiment is achieved by approximating the fibre density of the ponytail to be uniform across its cross-section, and to vary only length-wise. However we show that detail near the exit from a confining clamp (aka hairband) is only captured by computing the full cross-sectional variation.

<sup>1</sup>The work reported is joint with RE Goldstein (Cambridge UK) and PB Warren (Unilever Research).

**8:36AM R14.00002 Equilibrium theory for braided elastic filaments** , GERT VAN DER HEIJDEN, University College London — Motivated by supercoiling of DNA and other filamentous structures, we formulate a theory for equilibria of 2-braids, i.e., structures formed by two elastic rods winding around each other in continuous contact and subject to a local interstrand interaction. Unlike in previous work no assumption is made on the shape of the contact curve. Rather, this shape is found as part of the solution. The theory is developed in terms of a moving frame of directors attached to one of the strands with one of the directors pointing to the position of the other strand. The constant-distance constraint is automatically satisfied by the introduction of what we call braid strains. The price we pay is that the potential energy involves arclength derivatives of these strains, thus giving rise to a second-order variational problem. The Euler-Lagrange equations for this problem give balance equations for the overall braid force and moment referred to the moving frame as well as differential equations that can be interpreted as effective constitutive relations encoding the effect that the second strand has on the first as the braid deforms under the action of end loads. Simple analytical cases are discussed first and used as starting solutions in parameter continuation studies to compute classes of both open and closed (linked or knotted) braid solutions.

### 9:12AM R14.00003 Deformation and transport of micro-fibers and helices in viscous flows ,

ANKE LINDNER, PMMH-ESPCI, Paris, France — Fluid-structure interactions between flexible objects and viscous flows are, to a large extent, governed by the shape of the flexible object. Using microfabrication methods, we obtain complex “particles” in fiber and helix form with perfect control not only over the material properties, but also the particle geometry. We then perform an experimental study on the deformation and transport of these particles in microfluidic flows. Fibers are shown to drift laterally in confined flows due to the transport anisotropy of the elongated object. When these fibers interact with lateral walls, complex dynamics are observed, such as fiber oscillation. Fiber flexibility modifies these dynamics. Flexible microhelices are easily stretched by a viscous flow and we characterize the overall shape as a function of the frictional properties. The deformation of these helices is well-described by non-linear finite extensibility. Due to the non-uniform distribution of the pitch of a helix subject to viscous drag, linear and nonlinear behavior is identified along the contour length of a single helix. When a polymer solution is used for the viscous flow, an interesting multiscale problem arises and the typical polymer size needs to be compared not only to the global size of the helix, but also to the dimensions of the ribbon.

### 9:48AM R14.00004 Wrinkles, loops, and topological defects in twisted ribbons , JULIEN CHOPIN,

ESPCI ParisTech — Nature abounds with elastic ribbon like shapes including double-stranded semiflexible polymers, graphene and metal oxide nanoribbons which are examples of elongated elastic structures with a strongly anisotropic cross-section. Due to this specific geometry, it is far from trivial to anticipate if a ribbon should be considered as a flat flexible filament or a narrow thin plate. We thus perform an experiment in which a thin elastic ribbon is loaded using a twisting and traction device coupled with a micro X-ray computed tomography machine allowing a full 3D shape reconstruction. A wealth of morphological behaviors can be observed including wrinkled helicoids, curled and looped configurations, and faceted ribbons. In this talk, I will show that most morphologies can be understood using a far-from-threshold approach and simple scaling arguments. Further, we find that the various shapes can be organized in a phase diagram using the twist, the tension, and the geometry of the ribbon as control parameters. Finally, I will discuss the spontaneous formation of topological defects with negatively-signed Gaussian charge at large twist and small but finite stretch.

### 8:00AM R15.00001 Universal increase in the superconducting critical temperature of two-dimensional semiconductors at low doping by the electron-electron interaction<sup>1</sup> , MATTEO CALANDRA,

CNRS — In two-dimensional multivalley semiconductors, at low doping, even a moderate electron-electron interaction enhances the response to any perturbation inducing a valley polarization. If the valley polarization is due to the electron-phonon coupling, the electron-electron interaction results in an enhancement of the superconducting critical temperature. By performing first-principles calculations beyond density functional theory, we prove that this effect accounts for the unconventional doping dependence of the superconducting transition temperature ( $T_c$ ) and of the magnetic susceptibility measured in  $\text{LiZrNCl}$ . Finally, we discuss what are the conditions for a maximal  $T_c$  enhancement in weakly doped two-dimensional semiconductors. References: M. Calandra, P. Zoccante and F. Mauri, Pys. Rev. Lett. 114, 077001 (2015) B. Pamuk, J. Baima, R. Dovesi, M. Calandra and F. Mauri, in preparation.

### 8:36AM R15.00002 Superconducting phases of monolayer transition-metal dichalcogenides<sup>1</sup> ,

EVAN SOSENKO, VIVEK AJI, Univ of California - Riverside — Layered group-VI dichalcogenides, e.g.,  $\text{MoS}_2$ , are two dimensional materials that engender novel coupled spin and valley physics. Characterized by strong spin-orbit coupling and inversion symmetry breaking, they give rise to novel phenomena such as the spin Hall and valley Hall effect. In this talk, I focus on the intrinsic and substrate induced superconducting phases expected in this new class of materials. We will discuss the nature of the quasiparticles resulting from valley discriminating, pair breaking processes, and the effect of the BCS phase on the nature of opto-electronic coupling and nontrivial Berry curvature associated with the bands near each valley.

<sup>1</sup>We would like to acknowledge support from ARO W911NF1510079.

### 8:48AM R15.00003 Two Dimensional Ising Superconductivity in Gated $\text{MoS}_2$ , NOAH

Univ of Sci & Tech, JIANMING LU, Zernike Institute for Advanced Materials, KAM TUEN LAW, Hong Kong Univ of Sci & Tech, OLIVIERO ZERNIKE, Zernike Institute for Advanced Materials, INGE LEERMAKERS, ULRICH ZEITLER, Radboud University, JIANTING YE, Zernike Institute for Advanced Materials — The Zeeman effect, which is usually considered to be detrimental to superconductivity, can surprisingly protect the superconducting state in layered transition metal dichalcogenide. This effective Zeeman field, which is originated from intrinsic spin orbit coupling induced by broken inversion symmetry, can reach nearly a hundred Tesla in magnitude. It strongly pins the spin orientation of the electrons to the out-of-plane direction, protecting superconductivity from being destroyed by an in-plane external magnetic field. In magnetotransport experiments of ionic-gate  $\text{MoS}_2$  transistors, we prepare individual superconducting state with different carrier doping, we indeed observe a spin-protected superconductivity by measuring the critical field  $B_{c2}$  far beyond the Pauli paramagnetic limit. The gating-enhanced  $B_{c2}$  is more than an order of magnitude larger compared to the phases where the effective Zeeman field is weakened by interlayer coupling. Our study gives the first experimental evidence of an Ising superconductivity where the spins of the pairing electrons are strongly pinned by an effective Zeeman field.

### 9:00AM R15.00004 Disorder-enhanced superconductivity in Li intercalated $\text{ZrNCl}$ , YUJI NAKA-

GAWA, YU SAITO, The University of Tokyo, WU SHI, University of California at Berkeley, YUICHI KASAHARA, Kyoto University, YOSHIHIRO IWASA, The University of Tokyo — Electrolyte gating, as represented by electric-double-layer transistor (EDLT), possesses various functionalities; forming of  $p-n$  junction, electrostatic control of phase transitions, electrochemical etching and intercalation. These different functions, namely, electrostatic function or electrochemical function, strongly depends on the geometry of the device and the temperature in which a gate voltage is applied, and are considerably useful to unveil hidden intrinsic properties of a system. In this talk, we report a study on the transport properties in Li intercalated  $\text{ZrNCl}$ , which exhibits a maximum transition temperature of 15.2 K in lightly doped regime near the superconductor-insulator transition point. By the application of gate voltages in an EDLT configuration, we succeeded in *in-situ* resistance measurement in the electrochemical intercalation process, and thereby superconductivity in a single crystal. We found that superconductivity in Li intercalated  $\text{ZrNCl}$  changed from 2D to anisotropic 3D. Furthermore, enhancement of  $T_c$  in the lightly doped regime is accompanied by the increase of disorder and superconducting fluctuation. These results suggest that superconductivity of  $\text{ZrNCl}$  in the lightly doped regime is enhanced by disorder.

**9:12AM R15.00005 Magnetic response and pair-breaking effect in superconducting transition metal dichalcogenides<sup>1</sup>**, JUNHUA ZHANG, EVAN SOSENKO, VIVEK AJI, University of California, Riverside — The low-energy physics of monolayer transition metal group-VI dichalcogenides is significantly affected by the strong spin-orbit interaction in company with inversion symmetry breaking. As a result, the superconducting state in this system exhibits different physical behaviors compared to the conventional superconductors. Motivated by this, we study in detail the effects of the in-plane magnetic field and the non-magnetic disorder on this superconducting state. In particular, we discuss the unusual magnetic response and the pair-breaking effect in this system and their indication to experiments.

<sup>1</sup>We acknowledge support from ARO W911NF1510079.

**9:24AM R15.00006 Numerical study of giant nonlocal resistance in 2D spin orbital coupling system**, ZIBO WANG, Peking University, HUA JIANG, Soochow University, XINCHEG XIE, Peking University — Recent experiments find the signal of giant nonlocal resistance  $R_{NL}$  in H-shaped graphene sample due to the Spin/Valley Hall Effect. Interestingly, compared with the local resistance  $R_L$ ,  $R_{NL}$  decreases much more quickly when the Fermi energy deviates from the Dirac point, which does not satisfy the classical relation:  $R_{NL} \propto R_L^3$ . In this work, we simulate such transport phenomenon in H-shaped graphene based on the non-equilibrium Green function method. Near the Dirac point, there does exist a large nonlocal resistance signal, which exhibits much sharper than the local one. Moreover, we investigate the relationship between  $R_L$  and  $R_{NL}$ , which can be affected by spin-orbital coupling strength, Fermi energy, sample size, etc. At last, we discuss the possible mechanism that leads to the deviation of  $R_{NL}$  from classical  $R_{NL} \propto R_L^3$ .

**9:36AM R15.00007 Thermoelectric Powerfactor and Density of States in 2D MoS<sub>2</sub>**, KEDAR HIPPAL-GAONKAR, Institute of Materials Research and Engineering, YING WANG, YU YE, HANYU ZHU, YUAN WANG, JOEL MOORE, XIANG ZHANG, University of California, Berkeley — Efficient thermoelectric devices require high voltage generation from a temperature gradient and a large electrical conductivity, while maintaining a low thermal conductivity. For a given thermal conductivity and temperature, thermoelectric powerfactor is determined by the electronic structure of the material. Low dimensionality (1D and 2D) opens new routes to high powerfactor due to unique density of states (DOS) of confined electrons and holes. Emerging 2D transition metal dichalcogenide (TMDC) semiconductors represent a new class of thermoelectric materials not only because of their discretized density of states, but also due to their large effective masses and high carrier mobilities. We report a measured powerfactor of MoS<sub>2</sub> as large as  $8.5 \text{ mWm}^{-1}\text{K}^{-2}$  at room temperature, which is amongst the highest among all thermoelectric materials and we show that the powerfactor scales with mobility for 1L and 2L samples. Moreover, measurement of thermoelectric properties of monolayer MoS<sub>2</sub> allows us to determine the confined 2D DOS near the conduction band edge and in the insulating state, which cannot be measured by electrical conductivity alone. The demonstrated record high electronically tunable powerfactor in 2D TMDCs holds promise for efficient thermoelectric energy conversion.

**9:48AM R15.00008 Thermoelectric Transport Measurements of Graphene on hBN<sup>1</sup>**, JUNXI DUAN, Department of Physics and Astronomy, Department of Mechanical Engineering, XIAOMING WANG, Department of Mechanical Engineering, GUOHONG LI, XINYUAN LAI, Department of Physics and Astronomy, MONA ZEBARJADI, Department of Mechanical Engineering, Rutgers University, EVA Y. ANDREI, Department of Physics and Astronomy, Rutgers University — The unique electronic transport properties of graphene, arising from massless charge carriers whose sign and density can be tuned by gating, have been studied extensively. Much less work was devoted to graphene's thermal properties. Unlike electrical transport which depends on total carrier density, the thermopower is determined by the net charge transferred and not by the carrier density. This leads to profound differences between the two phenomena. For example, when the Fermi level is close to the Dirac point (DP) where electron-hole (e-h) puddles are populated symmetrically, the electron and hole contributions to the thermopower cancel out. In contrast, their contributions to the electrical current add up. We studied the thermoelectric properties of high quality graphene supported on an hBN substrate, where the e-h puddle regime is significantly reduced compared to that on SiO<sub>2</sub> substrates, which allows closer access to the DP. At room temperature we find that the maximum Seebeck coefficient close to the DP reaches up to twice the values on SiO<sub>2</sub> substrates. Upon cooling down to 77K it decreases in a non-linear fashion with temperature. We will discuss possible origins of this behavior.

**10:00AM R15.00009 Gate-induced Gap in Bilayer Graphene Suppressed by Coulomb Repulsion**, YU-ZHONG ZHANG, JIN-RONG XU, ZE-YI SONG, Tongji Univ, HAI-QING LIN, Beijing Computational Science Research Center — We investigate the effect of on-site Coulomb repulsion  $U$  on the band gap of the electrically gated bilayer graphene by employing coherent potential approximation in the paramagnetic state, based on an ionic two-layer Hubbard model. We find that, while either the on-site Coulomb repulsion  $U$  or the external perpendicular electric field  $E$  alone will favor a gapped state in the bilayer graphene, competition between them will surprisingly lead to a suppression of the gap amplitude. Our results can be applied to understand the discrepancies of gap size reported from optical and transport measurements, as well as the puzzling features observed in angular resolved photoemission spectroscopic study.

**10:12AM R15.00010 A comparative study of the tunable spin-orbit coupling in graphene proximity coupled to topological insulators**, ZHUONAN LIN, Wuhan University, WEI QIN, JIANG ZENG, ICQD, HFNL, University of Science and Technology of China, WEI CHEN, ICQD, HFNL, University of Science and Technology of China and Harvard University, PING CUI, ICQD, HFNL, University of Science and Technology of China, JUN-HYUNG CHO, Hanyang University, ZHENYU ZHANG, ICQD, HFNL, University of Science and Technology of China — We present a comparative study of the electronic properties of the heterostructures consisting of a graphene sheet proximity coupled to the surfaces of three-dimensional topological insulators (TIs). Using density functional theory method, we first calculate the band structures of a single-layer graphene on the Bi<sub>2</sub>Te<sub>3</sub> thin film. Counterintuitively, the spin-orbit coupling (SOC) can be barely induced in the graphene even though the intrinsic SOC strength of Bi<sub>2</sub>Te<sub>3</sub> is stronger than that of Sb<sub>2</sub>Te<sub>3</sub>, which can readily introduce a giant SOC interaction into the graphene through proximity effect. In order to understand this exotic phenomenon, we next investigate the differences of the work functions and the charge transfers between the graphene and the TI substrates. It is found that the proximity-induced SOC in the graphene sheet can be enhanced by reducing the work function difference. These findings provide a simple work-function criterion for searching realistic materials that can be utilized as substrates to induce a large SOC gap in the graphene. Our criterion extends the possibilities of experimental realization of quantum spin Hall state in graphene.

**10:24AM R15.00011 Odd frequency pairing of interacting Majorana fermions<sup>1</sup>**, ZHOUSHEN HUANG, Los Alamos National Laboratory, USA, PETER WOELFLE, Karlsruhe Institute of Technology, Germany, ALEXANDAR BALATSKY, Los Alamos National Laboratory, USA — Majorana fermions are rising as a promising key component in quantum computation. While the prevalent approach is to use a quadratic (i.e. non-interacting) Majorana Hamiltonian, when expressed in terms of Dirac fermions, generically the Hamiltonian involves interaction terms. Here we focus on the possible pair correlations in a simple model system. We study a model of Majorana fermions coupled to a boson mode and show that the anomalous correlator between different Majorana fermions, located at opposite ends of a topological wire, exhibits odd frequency behavior. It is stabilized when the coupling strength  $g$  is above a critical value  $g_c$ . We use both, conventional diagrammatic theory and a functional integral approach, to derive the gap equation, the critical temperature, the gap function, the critical coupling, and a Ginzburg-Landau theory allowing to discuss a possible subleading admixture of even-frequency pairing.

**10:36AM R15.00012 Indirect bonding mechanism for proximity-induced giant spin-orbit coupling in graphene-topological insulator van der Waals heterostructure<sup>1</sup>**, SHIVANI RAJPUT, YAOYI LI, MICHAEL WEINERT, LIAN LI, Univ of Wisconsin, Milwaukee — We demonstrate proximity-induced spin-orbit coupling in graphene/topological insulator van der Waals (vdW) heterostructures fabricated by transferring chemical vapor deposited graphene onto Bi<sub>2</sub>Se<sub>3</sub> film grown by molecular beam epitaxy. Using scanning tunneling microscopy/spectroscopy, we observe a spin-orbit splitting of the graphene Dirac states up to 80 meV, with a spatial variation of 20 meV due to the inherent lack of epitaxial relation in the graphene/Bi<sub>2</sub>Se<sub>3</sub> vdW junction. Density functional theory calculations further reveal that this giant spin-orbit splitting of the graphene bands is a consequence of the orthogonalization requirement on the overlapping wave functions, rather than simple direct bonding at the interface. This revelation of an indirect bonding mechanism of the proximity effect will facilitate more effective engineering of desired properties in vdW heterostructures.

**10:48AM R15.00013 Magnetic field induced suppression of the forward bias current in Bi<sub>2</sub>Se<sub>3</sub>/Si Schottky barrier diodes<sup>1</sup>**, HAOMING JIN, ARTHUR HEBARD, University of Florida — Schottky diodes formed by van der Waals bonding between freshly cleaved flakes of the topological insulator Bi<sub>2</sub>Se<sub>3</sub> and doped silicon substrates show electrical characteristics in good agreement with thermionic emission theory. The motivation is to use magnetic fields to modulate the conductance of the topologically protected conducting surface state. This surface state in close proximity to the semiconductor surface may play an important role in determining the nature of the Schottky barrier. Current-voltage (I-V) and capacitance-voltage (C-V) characteristics were obtained for temperatures in the range 50-300 K and magnetic fields, both perpendicular and parallel to the interface, as high as 7 T. The I-V curve shows more than 6 decades linearity on semi-logarithmic plots, allowing extraction of parameters such as ideality ( $\eta$ ), zero-voltage Schottky barrier height (SBH), and series resistance ( $R_s$ ). In forward bias we observe a field-induced decrease in current which becomes increasingly more pronounced at higher voltages and lower temperature, and is found to be correlated with changes in  $R_s$  rather than other barrier parameters. A comparison of changes in  $R_s$  in both field direction will be made with magnetoresistance in Bi<sub>2</sub>Se<sub>3</sub> transport measurement.

## Thursday, March 17, 2016 8:00AM - 11:00AM – Session R16 DCMP DMP: Transport in Transition Metal Dichalcogenides 315 -

**8:00AM R16.00001 Memristive Phenomena in Polycrystalline Single Layer MoS<sub>2</sub>**, VINOD SANGWAN, DEEP JARIWALA, IN-SOO KIM, KAN-SHENG CHEN, TOBIN MARKS, LINCOLN LAUHON, MARK HERSAM, Northwestern University, HERSAM LABORATORY TEAM — Recently, a new class of layered two-dimensional semiconductors has shown promise for various electronic applications. In particular, single layer transition metal dichalcogenides (e.g. MoS<sub>2</sub>) present a host of attractive features such as high electrical conductivity, tunable band-gap, and strong light-matter interaction. However, available growth methods produce large-area polycrystalline films with grain-boundaries and point defects that can be detrimental in conventional electronic devices. In contrast, we have developed unconventional device structures that exploit these defects for useful electronic functions.[1] In particular, we observe grain-boundary mediated memristive phenomena in single layer MoS<sub>2</sub> transistors. Memristor current-voltage characteristics depend strongly on the topology of grain-boundaries in MoS<sub>2</sub>. A grain boundary directly connecting metal electrodes produces thermally assisted switching with dynamic negative differential resistance, whereas a grain boundary bisecting the channel shows non-filamentary soft-switching. In addition, devices with intersecting grain boundaries in the channel show bipolar resistive switching with high on/off ratios up to  $\sim 10^3$ . [1] Furthermore, the gate electrode in the field-effect geometry can be used to control the absolute resistance of the on and off states. Complementary electrostatic force microscopy, photoluminescence, and Raman microscopy reveal the role of sulfur vacancies in the switching mechanism. *References: 1. Sangwan et al., Nature Nanotechnology, 10 403-406 (2015)*

**8:12AM R16.00002 Transport measurements on monolayer and few-layer WSe<sub>2</sub>**, TAUNO PALOMAKI, WENJIN ZHAO, JOE FINNEY, ZAIYAO FEI, PAUL NGUYEN, FRANK MCKAY, DAVID COBDEN, University of Washington — The behavior of the electrical contacts often dominates transport measurements in mono and few-layer transition metal dichalcogenide (TMD) devices. Creating good contacts for some TMDs is particularly challenging since the fabrication procedure should prevent the TMD from oxidizing or chemically interacting with the contacts. In this talk, we discuss our progress on creating mono and few-layer WSe<sub>2</sub> devices with both good electrical contacts and minimal effects from the substrate, polymer contamination, oxidation and other chemistry. For example, we have developed a technique for encapsulating metallic contacts and WSe<sub>2</sub> flakes together in hexagonal boron nitride with multiple gates to separate and control the contributions from the channel and the Schottky barriers at the contacts. Research supported in part by Samsung GRO grant US 040814

**8:24AM R16.00003 Negative to Positive Crossover of Magnetoresistance in WS<sub>2</sub> nanoflakes with Ohmic Contact**, YANGWEI ZHANG, HONGLIE NING, YANAN LI, YANZHAO LIU, JIAN WANG<sup>1</sup>, — We report studies on the transport measurements of WS<sub>2</sub> nanoflakes including contact optimization and magnetoresistance measurement. We find that the platinum electrodes deposited by focused ion beam (FIB) technology on WS<sub>2</sub> exhibit an ohmic contact, which provides a pathway to solve the dilemma of Shottky barrier for WS<sub>2</sub> devices. A temperature-modulated negative-to-positive crossover of magnetoresistance (MR) is also observed, replenishing the existing data which mainly emphasizes field effect transistor (FET) related transport. Our work may stimulate further studies and potential electronic and optoelectronic applications on transition-metal dichalcogenides.

**8:36AM R16.00004 Shubnikov-de Haas oscillations of high mobility holes in monolayer and bilayer WSe<sub>2</sub>: spin-valley locking, effective mass, and inter-layer coupling<sup>1</sup>**, BABAK FALLAHAZAD, HEMA CHANDRA PRAKASH MOVVA, KYOUNGHWAN KIM, STEFANO LARENTIS, Univ of Texas, Austin, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, 1-1 Namiki Tsukuba, Ibaraki 305-0044, Japan, SANJAY K. BANERJEE, EMANUEL TUTUC, Univ of Texas, Austin — We study the magnetotransport properties of high mobility holes in monolayer and bilayer WSe<sub>2</sub>, measured in dual-gated samples with top and bottom hexagonal boron-nitride dielectrics, and using platinum bottom contacts. Thanks to the Pt high work-function combined with the a high hole density induced electrostatically by an applied top gate bias, the contacts remain ohmic down to low (1.5 K) temperatures. The samples display well defined Shubnikov-de Haas (SdH) oscillations, and quantum Hall states (QHS) in high magnetic fields. In both mono and bilayer WSe<sub>2</sub>, the SdH oscillations and the QHSs occur predominantly at even filling factors, evincing a two-fold Landau level degeneracy consistent with spin-valley locking. The Fourier transform analysis of the SdH oscillations in dual-gated bilayer WSe<sub>2</sub> reveal the presence of two subbands, each localized in the top or the bottom layer, as well as negative compressibility. From the temperature dependence of the SdH oscillation amplitude we determine a hole effective mass of 0.45m<sub>0</sub> for both mono and bilayer WSe<sub>2</sub>. The top and bottom layer densities can be independently tuned using the top and bottom gates, respectively, evincing a weak interlayer coupling.

**8:48AM R16.00005 The suppression of the large magnetoresistance in thin WTe<sub>2</sub>.** , JIE SHEN, JOHN WOODS, JUDY CHA, Yale Univ — The layered nature of WTe<sub>2</sub> suggests the possibility of making a single layer WTe<sub>2</sub> memory device that exploits the recently observed large magnetoresistance. Presently, the origin of the magnetoresistance is attributed to the charge balance between the electron and hole carriers, yet the exact underlying physical mechanism is unclear. Here we show a systematic suppression of the large magnetoresistance, as well as turn-on temperature, with decreasing thickness of WTe<sub>2</sub>. We attribute the thickness-dependent transport properties to undesirable parasitic effects that become dominant in thin films of WTe<sub>2</sub>. Our results highlight the increasing importance of characterizing the parasitic effects for 2D layered materials in a single- to a few-layer thick limit. Finally, our observations support the hypothesis that the origin of the large magnetoresistance may be due to the charge balance between the electron and the hole carriers.

**9:00AM R16.00006 Landau levels and Shubnikov-de Haas oscillations in monolayer transition metal dichalcogenide semiconductors** , ANDOR KORMANYOS, University of Konstanz, PETER RAKYTA, Budapest University of Technology and Economics, GUIDO BURKARD, University of Konstanz — We study the Landau level (LL) spectrum using a multi-band  $\mathbf{k} \cdot \mathbf{p}$  theory in monolayer transition metal dichalcogenide semiconductors [1]. We find that in a wide magnetic field range the LL can be characterized by a harmonic oscillator spectrum and a linear-in-magnetic field term which describes the valley degeneracy breaking. The effect of the non-parabolicity of the band-dispersion on the LL spectrum is also discussed. Motivated by recent magnetotransport experiments, we use the self-consistent Born approximation and the Kubo formalism to calculate the Shubnikov-de Haas oscillations of the longitudinal conductivity. We investigate how the doping level, the spin-splitting of the bands and the broken valley degeneracy of the LLs affect the magnetoconductance oscillations. We consider monolayer MoS<sub>2</sub> and WSe<sub>2</sub> as concrete examples and compare the results of numerical calculations and an analytical formula which is valid in the semiclassical regime. Finally, we briefly analyze the recent experimental results [Cui et al., Nat. Nanotechnol. 10 534 (2015)] using the theoretical approach we have developed. [1] New J. Phys. 17, 103006 (2015).

**9:12AM R16.00007 Anisotropic Electron transport and device applications of atomically thin ReS<sub>2</sub>** , ERFU LIU, YAJUN FU, YAOJIA WANG, YANQING FENG, HUIMEI LIU, XIANGANG WAN, WEI ZHOU, BAIGENG WANG, JUNWEN ZENG, Nanjing University, CHING-HWA HO, YING-SHENG HUANG, National Taiwan University of Science and Technology, HONGTAO YUAN, HAROLD Y. HWANG, YI CUI, Stanford University, DINGYU XING, FENG MIAO, Nanjing University — Semiconducting two-dimensional transition metal dichalcogenides are emerging as top candidates for post-silicon electronics. While most of them exhibit isotropic behavior, lowering the lattice symmetry could induce anisotropic properties, which are both scientifically interesting and potentially useful. In this talk, we will present atomically thin rhenium disulfide (ReS<sub>2</sub>) flakes with unique distorted 1T structure, which exhibit in-plane anisotropic properties. We first fabricated mono- and few-layer ReS<sub>2</sub> field effect transistors, which exhibit competitive performance with large current on/off ratios ( $\sim 10^7$ ) and low subthreshold swings (100 mV dec<sup>-1</sup>). The observed anisotropic ratio along two principle axes reaches up to 3.1. Furthermore, we successfully demonstrated an integrated digital inverter with good performance by utilizing two ReS<sub>2</sub> anisotropic field effect transistors, suggesting the promising implementation of large-scale two-dimensional logic circuits. Recent results on ultra-high responsivity (as high as 88,600 A W<sup>-1</sup>) phototransistors based on few-layer ReS<sub>2</sub> will also be discussed. Our results underscore the unique properties of two-dimensional semiconducting materials with low crystal symmetry for future electronic and optoelectronic applications.

**9:24AM R16.00008 Hidden symmetry and enhanced Rudermann-Kittel-Kasuya-Yosida interaction in P-N junctions of two-dimensional materials<sup>1</sup>** , WEN YANG, SHUHUI ZHANG, 1Beijing Computational Science Research Center, Beijing 100094, China, JIAJI ZHU, Institute for quantum information and spintronics, College of Science, Chongqing University of Posts and Telecommunications, Chongqing 400065, China, KAI CHANG, SKLSM, Institute of Semiconductors, Chinese Academy of Sciences, P.O. Box 912, Beijing 100083, China — Correlation between magnetic atoms (spins) in non-magnetic two-dimensional (2D) systems and materials is one of the central issues in condensed matter physics. Engineering this correlation relies heavily on the carrier-mediated Rudermann-Kittel-Kasuya-Yosida (RKKY) interaction. However, tailoring and direct detection of spin-spin correlation has been limited to spins separated by a few nanometers due to the rapid  $1/R^2$  decay of RKKY interaction with inter-spin distance R. Here we reveal a hidden symmetry – absent from the Hamiltonian – in planar P-N junctions, which could qualitatively change the spatial scaling of various response functions in a wide range of 2D systems and materials. In particular, it allows RKKY interaction to attain  $1/R$  decay, the slowest decay in extended systems. This dramatically enhances RKKY interaction and enables long-range correlation between distant spins, with applications in nanoscale magnetism, spintronics, and solid-state quantum computation.

**9:36AM R16.00009 Measurements of Schottky barrier heights formed from metals and 2D transition metal dichalcogenides** , CHANGSIK KIM, INYONG MOON, Sungkyunkwan university Advanced Institute of Nano-Technology (SAINT), SEUNGGEOL NAM, YEONCHOO CHO, HYEON-JIN SHIN, SEONGJUN PARK, Device & System Research Center, Samsung Advanced Institute of Technology (SAIT), WON JONG YOO, Sungkyunkwan university Advanced Institute of Nano-Technology (SAINT) — Schottky barrier height (SBH) is an important parameter that needs to be considered for designing electronic devices. However, for two dimensional (2D) materials based devices, SBH control is limited by 2D structure induced quantum confinement and 2D surface induced Fermi level pinning. In this work, we explore differences in measuring SBH between 2D and 3D materials. Recently, low temperature I-V measurement has been reported to extract SBH based on thermionic emission equation for Schottky diode. However, 2D devices are not real Schottky diode in that both source and drain metal electrodes make Schottky contact. According to our experimental results, SBH extracted from linear slope of  $\ln(I/T^{3/2})$  against  $1/T$  show widely diverse values, dependent on applied voltage bias and tested temperature which affect carrier transport including tunneling or thermionic emission across the metal-2D material interface. In this work, we wish to demonstrate the method to determine SBH and Fermi level pinning which are attributed to 2D transition metal dichalcogenides, differently from conventional 3D materials. .

**9:48AM R16.00010 Fermi Level Pinning at the Interface of Molybdenum Based Chalcogenides and Metals** , INYONG MOON, CHANGSIK KIM, Samsung-SKKU Graphene Center, SKKU Advanced Institute of Nano-Technology, Sungkyunkwan University, 2066, Seobu-ro, Jangan-gu, Suwon-si, Korea, SEUNGGEOL NAM, YEONCHOO CHO, HYEON-JIN SHIN, SEONGJUN PARK, Device & System Research Center, Samsung Advanced Institute of Technology (SAIT), 130 Samsung-ro, Yeongtong-gu, Suwon-si, Gyeonggi-do 443-803, Korea, WON JONG YOO, Samsung-SKKU Graphene Center, SKKU Advanced Institute of Nano-Technology, Sungkyunkwan University, 2066, Seobu-ro, Jangan-gu, Suwon-si, Korea — MoS<sub>2</sub> and MoTe<sub>2</sub> as the layered two dimensional materials have a sizable band gap suitable for future semiconductor application. However, their Schottky/ohmic contact engineering is found difficult to perform when varying contact metals due to Fermi level pinning at their metal interface. In this work, we investigate Schottky barrier heights at the interfaces formed between mono- or bi-layer MoS<sub>2</sub>, MoTe<sub>2</sub> and Ti, Cr, Au, Pd. By varying temperature in the range from 200 to 500 K, we obtained their current – voltage and hysteresis characteristics so as to determine accurate Schottky barrier heights. It is found that the Pd contact with MoS<sub>2</sub> and MoTe<sub>2</sub> shows the most pronounced Fermi level pinning; -0.8 and -1.2 eV respectively. Furthermore, the pinned energy level is found to be located near the conduction band edge for MoS<sub>2</sub> whereas it is near the intrinsic level for MoTe<sub>2</sub>. These results are found to be crucial to understand the Fermi level pinning mechanism of two dimensional materials, which can be used for developing future MoS<sub>2</sub> and MoTe<sub>2</sub> based transistor devices.

**10:00AM R16.00011 Weak Fermi Level Pinning Effect in Schottky Junction of  $\alpha$ -MoTe<sub>2</sub>**, SHU NAKAHARAI, MAHITO YAMAMOTO, Natl Inst for Materials Sci, KEIJI UENO, Saitama Univ, KAZUHIITO TSUKAGOSHI, Natl Inst for Materials Sci — Difficulty in hole injection from metal contacts to transition metal dichalcogenide (TMDC) semiconductors has been one of the most serious issues in the application of these 2D materials to future nanoelectronics, which is caused by the strong Fermi level pinning effect in the metal/TMDC Schottky junction. In this work, we found that the holes can be injected efficiently from a large work function metal of Pt to  $\alpha$ -molybdenum ditelluride ( $\alpha$ -MoTe<sub>2</sub>; 2H-type), a TMDC semiconductor. The Schottky barrier height for holes at the Pt/ $\alpha$ -MoTe<sub>2</sub> interface was extracted to be 40 meV by the temperature dependence of back-gate modulated currents under the flat band condition at the junction, while the Schottky barrier for electrons in the junction with a small work function metal of Ti was found to be 50 meV. Considering the difference in the work functions of Pt and Ti, the Fermi level pinning effect in  $\alpha$ -MoTe<sub>2</sub> was found to be much weaker than that in other TMDC semiconductors such as MoS<sub>2</sub>. These results open a way to the realization of complementary type circuits in the 2D materials for future low-power consumption electronics. This work was supported by JSPS KAKENHI Grant Numbers 15K06006, 25107004.

**10:12AM R16.00012 Experimental determination of the massive Dirac-fermion parameters in MoS<sub>2</sub>, MoSe<sub>2</sub>, WS<sub>2</sub>, and WSe<sub>2</sub>**, BEOM SEO KIM, Seoul Natl Univ, JUN-WON RHIM, Max Planck Institute, BEOMYOUNG KIM, Pohang Univ of Science and Technology, CHANGYOUNG KIM, Seoul Natl Univ, SEUNG RYONG PARK, Incheon Natl Univ — The physics associated with group 6 transition metal dichalcogenides (TMDs) MX<sub>2</sub> (M = Mo, W; X = S, Se) is one of the most intriguing issues in condensed matter physics. These materials have several interesting aspects, especially the direct to indirect band gap transition and spin-orbit interaction (SOI) induced spin band splitting at the K point. Recently, one reported a minimal band model, called massive Dirac-fermion model, for K point of the monolayer MX<sub>2</sub> Brillouin zone. There are several parameters in this model obtained by calculations, not by experiment, until now. Here we report the parametric studies on MX<sub>2</sub> using angle resolved photoemission spectroscopy (ARPES). We factor out the massive Dirac-Fermion parameters from the bulk MX<sub>2</sub>, not monolayer. For confirming the accurate experimental values, we performed the photon energy dependence experiment to find the exact  $\Gamma$  point and in-situ potassium-dosing experiment were performed for each MX<sub>2</sub>.

**10:24AM R16.00013 Electrical transport properties of ReS<sub>2</sub> with polymer electrolyte gating in the high-doping limit**, DMITRY OVCHINNIKOV, ADRIEN ALLAIN, DIEGO PASQUIER, DUMITRU DUMCENCO, Ecole Polytech Fed de Lausanne, CHING-HWA HO, YING-SHENG HUANG, National Taiwan University of Science and Technology, OLEG YAZYEV, ANDRAS KIS, Ecole Polytech Fed de Lausanne — Two-dimensional (2D) materials have emerged as promising candidates for future electronic applications. Among them, transition metal dichalcogenides (TMDs) demonstrate not only potential as ultrathin transistor channel material, but also intriguing spin and valley physics, which in principle could allow new types of devices and circuits. Here we report on the first study of two-dimensional anisotropic ReS<sub>2</sub> at high doping levels, enabled by polymer electrolyte gating. Significantly increasing the doping level using electrolyte instead of standard solid gate, we measured an unusual modulation of the conductivity at high carrier densities in monolayer ReS<sub>2</sub>. In the case of thicker flakes, the effect is milder and an insulator-metal-insulator sequence with increasing doping is observed. Transport measurements provide the evidence of major influence of ionic disorder. Furthermore, we discuss possible band structure effects.

**10:36AM R16.00014 Tempo-spatially resolved dynamics of electrons and holes in bilayer MoS<sub>2</sub>-WS<sub>2</sub>**<sup>1</sup>, J.M. GALICIA-HERNANDEZ, University of Puebla, Puebla 72550, Mexico and University of Central Florida, Orlando, FL 32816, V. TURKOWSKI, University of Central Florida, Orlando, FL 32816, G. HERNANDEZ-COCOLETZI, University of Puebla, Puebla 72550, Mexico, T.S. RAHMAN, University of Central Florida, Orlando, FL 32816 — We have performed a Density-Matrix Time-Dependent Density-Functional Theory analysis of the response of bilayer MoS<sub>2</sub>-WS<sub>2</sub> to external laser-pulse perturbations. Time-resolved study of the dynamics of electrons and holes, including formation and dissociation of strongly-bound intra- and inter-layer excitonic states, shows that the experimentally observed [1] ultrafast inter-layer MoS<sub>2</sub> to WS<sub>2</sub> migration of holes may be attributed to unusually large delocalization of the hole state which extends far into the inter-layer region. We also argue that the velocity of the hole transfer may be further enhanced by its interaction with transfer phonon modes. We analyze other possible consequences of the hole delocalization in the system, including reduction of the effects of the electron-electron and hole-hole repulsion in the trions and biexcitons as compared to that in the monolayers. [1] X. Hong et al., Nature Nano 9, 682 (2014).

**10:48AM R16.00015 Giant Photocurrent Generation at Topological Singularities in Graphene Superlattices**, SANFENG WU, University of Washington, LEI WANG, Columbia University, YOU LAI, NHMFL, WENYU SHAN, Carnegie Mellon University, GRANT AIVAZIAN, University of Washington, XIAN ZHANG, Columbia University, TAKASHI TANIGUCHI, KENJI WATANABE, NIMS, DI XIAO, Carnegie Mellon University, CORY DEAN, JAMES HONE, Columbia University, ZHIQIANG LI, NHMFL, XIAODONG XU, University of Washington — The energy spectrum of graphene away from the Dirac point contains topological critical points where Van Hove singularities (VHSs) appear and are predicted to host fascinating phenomena. However, the required extreme doping has prevented the experimental access to these VHSs. Alternatively, the formation of Moiré superlattices in twisted graphene bilayers or graphene on hexagonal boron-nitride (hBN) heterostructures generates electronic mini-bands that mimic graphene's energy spectrum but with reduced energy scale, providing a remarkable opportunity to study a variety of physics previously inaccessible. Here we reveal that the formation of saddle point VHSs in the mini-bands of graphene/hBN superlattice enables anomalously enhanced photocurrent generation through a photo-Nernst effect at low magnetic fields. We establish that this enhancement is unambiguously linked to the electronic topological transition at VHSs. The obtained zero-bias photocurrent is giant, with a photoresponsivity as high as about 0.3 ampere per watt, corresponding to an external quantum efficiency exceeding 50%.

**Session R17 DMP: 2D Semiconductor Physics I** 316 - John Schaibley, University of Washington

**8:00AM R17.00001 2D semiconductor optoelectronics**, KOSTYA NOVOSELOV, University of Manchester — The advent of graphene and related 2D materials has recently led to a new technology: heterostructures based on these atomically thin crystals. The paradigm proved itself extremely versatile and led to rapid demonstration of tunnelling diodes with negative differential resistance, tunnelling transistors, photovoltaic devices, etc. By taking the complexity and functionality of such van der Waals heterostructures to the next level we introduce quantum wells engineered with one atomic plane precision. Light emission from such quantum wells, quantum dots and polaritonic effects will be discussed.

**8:36AM R17.00002 Tuning the trion photoluminescence polarization in monolayer WS<sub>2</sub>**<sup>1</sup>, A.T. HANBICKI, K.M. MCCREARY, M. CURRIE, Naval Research Laboratory, G. KIOSEOGLOU, University of Crete, C.S. HELLBERG, A.L. FRIEDMAN, B.T. JONKER, Naval Research Laboratory — Monolayer transition metal dichalcogenides (TMDs) such as MoS<sub>2</sub> or WS<sub>2</sub> are semiconductors with degenerate, yet inequivalent k-points labeled K and K' that define the direct gap. The valence band maximum in each valley has only one spin state of opposite sense for K and K'. Consequently, one can selectively populate each valley independently with circularly polarized light, and determine the valley populations via the polarization of emitted light. Optical emission is dominated by neutral and charged exciton (trion) features, and changes in emitted polarization provide insight into the fundamental processes of intervalley scattering. We prepare single-layer WS<sub>2</sub> films such that the photoluminescence is from the negatively charged trion and observe a room temperature optical polarization in excess of 40

<sup>1</sup>This work was supported by core programs at NRL and the NRL Nanoscience Institute, and by the Air Force Office of Scientific Research AOARD 14IOA018-134141.

**8:48AM R17.00003 High circular polarization in a MoSe<sub>2</sub> light-emitting transistor**, MASARU ONGA, YIJIN ZHANG, RYUJI SUZUKI, YOSHIHIRO IWASA, Quantum-Phase Electronics Center (QPEC) and Department of Applied Physics, The University of Tokyo — The exclusive coupling between the valley degree of freedom and the optical helicity is a unique phenomenon in transition metal dichalcogenides (TMDs), and thus the circularly polarized luminescence is one of the main research topics in these materials. MoSe<sub>2</sub>, however, is known to exhibit exceptionally low polarization in photoluminescence (PL). Here, we report electroluminescence (EL) properties of MoSe<sub>2</sub> demonstrating electrical switching of the optical helicity in the same manner as WSe<sub>2</sub> [1]. More importantly, the observed polarization in EL is one order of magnitude higher than that in PL. The present results reveal that the mechanism of EL polarization possesses the intrinsic robustness against intervalley scattering. [1] Y. J. Zhang, et.al., Science 344, 725 (2014).

**9:00AM R17.00004 Single Quantum Emitters in Monolayer Tungsten Diselenide**, GENEVIEVE CLARK, JOHN SCHABLEY, JASON ROSS, University of Washington, YU-MING HE, YU HE, University of Science and Technology of China, WANG YAO, The University of Hong Kong, CHAOYANG LU, JIANWEI PAN, University of Science and Technology of China, XIAODONG XU, University of Washington — Single quantum emitters are essential for developing photonic quantum technologies, providing single photon sources as well as stationary quantum bits. While they have been realized in a variety of solid state systems including single quantum dots and color centers in diamond, their three dimensional bulk matrix will be difficult to integrate with emerging nanoscale devices. We present single quantum emitters in a two-dimensional semiconductor, in the form of excitons localized to defects within atomically thin Tungsten Diselenide monolayers. These localized excitons show strong photoluminescence with 130 eV emission lines from two non-degenerate, cross-polarized transitions. Second-order correlation measurements show strong photon anti-bunching, establishing that these localized excitons are single photon emitters. Magneto-optical measurements reveal an exciton g-factor of 8.7, significantly larger than that of delocalized excitons. In addition to potential advantages such as efficient photon extraction and in-situ control of local environment, the two-dimensional matrix can be incorporated into more complex van-der-Waals heterostructure devices. This enables external control of emitters in the semiconductor, while integrating seamlessly with nanoscale device architectures.

**9:12AM R17.00005 Quantum confined stark effect of single photon emitters in atomically thin semiconductors**, CHITRALEMA CHAKRABORTY, Materials Science, University of Rochester, KENNETH GOODFELLOW, SAJAL DHARA, NICK VAMIVAKAS, The Institute of Optics, University of Rochester — The optical properties of semiconducting monolayer materials have been widely studied since the isolation of monolayer transition metal dichalcogenides (TMDCs). They have rich opto-electronic properties owing to their large direct bandgap, the interplay between the spin and the valley degree of freedom of charge carriers, and the recently discovered localized excitonic states giving rise to single photon emission. We study quantum confined Stark shift from these localized emitters present on the edges of monolayer tungsten diselenide. We employ a vertically stacked van der Waal's heterostructure to fabricate a field effect device using hexagonal boron nitride as the tunnel barrier on either side of the TMDC and few layer graphene as top and bottom electrical contacts. We report the Stark shift of different defect centers to have linear or both linear and quadratic behavior with electric field. Further, evaluation of the spectral shift in the photoluminescence signal as a function of the applied voltage enables us to extract the polarizability as well as information on the dipole moment of an individual defect center.

**9:24AM R17.00006 Optical studies of dual gated WSe<sub>2</sub> transistors**, ZEFANG WANG, JIE SHAN, KIN FAI MAK, Penn State University — Recent advances in the development of atomically thin layers of transition metal dichalcogenides (TMDs) have opened up new possibilities for the exploration of novel 2D physics as well as materials for applications. The atomic thickness of these materials allows effective control of their optical and electronic properties by electrostatic gates. In this work, we fabricate dual-gate transistors of monolayer WSe<sub>2</sub> and investigate the optical and electronic properties as a function of doping and fields by the absorption and photoluminescence spectroscopy. The combination of the top and bottom gates allows us to independently vary the electric field and doping density in the monolayer over a large range. As a function of doping density, we observe the evolution of the electronic excitations from locally bound excitons, to excitons and charged excitons, to the Fermi edge singularity. We will discuss the effects of external fields on these excitations and the effects of strong Coulomb interactions in 2D semiconductors.

**9:36AM R17.00007 Photocurrent measurements in Coupled Quantum Well van der Waals Heterostructures made of 2D Transition Metal Dichalcogenides.**, ANDREW JOE, LUIS JAUREGUI, ALEX HIGH, ALAN DIBOS, ELGIN GULPINAR, KATERYNA PISTUNOVA, HONGKUN PARK, PHILIP KIM, Harvard University, Physics Department — , Luis A. Jauregui, Alex A. High, Alan Dibos, Elgin Gulpinar, Kateryna Pistunova, Hongkun Park, Philip Kim Harvard University, Physics Department -abstract- Single layer transition metal dichalcogenides (TMDC) are 2-dimensional (2D) semiconductors van der Waals (vdW) characterized by a direct optical bandgap in the visible wavelength (~2 eV). Characterization of the band alignment between TMDC and the barrier is important for the fabrication of tunneling devices. Here, we fabricate coupled quantum well (CQW) heterostructures made of 2D TMDCs with hexagonal Boron nitride (hBN) as an atomically thin barrier and gate dielectric and with top and bottom metal (or graphite) as gate electrodes. We observe a clear dependence of the photo-generated current with varying hBN thickness, electrode workfunctions, electric field, laser excitation power, excitation wavelength, and temperature. We will discuss the implication of photocurrent in relation to quantum transport process across the vdW interfaces.

**9:48AM R17.00008 Multi-terminal Monolayer WSe<sub>2</sub> devices**, WENJIN ZHAO, TAUNO PALOMAKI, JOE FINNEY, ZAIYAO FEI, PAUL NGUYEN, Univ of Washington, FRANK MCKAY, Retired, DAVID COBDEN, Univ of Washington — Two-dimensional transition-metal dichalcogenide (TMD) semiconductors are promising materials for next-generation electronic and optoelectronic devices. WSe<sub>2</sub> in particular has shown excellent optical properties, but it has proven difficult to make reliable electrical contacts to this material. We use a new chemical vapor deposition technique to grow monolayer single crystal WSe<sub>2</sub> reliably on a large scale with edges up to 15 microns long. We then fabricate these crystals into multi-terminal devices encapsulated in boron nitride using dry transfer techniques. We achieve sufficiently good electrical contacts reproducibly to allow comprehensive study of the intrinsic optical and electrical properties of gated WSe<sub>2</sub> monolayers as a function of temperature and magnetic field.

**10:00AM R17.00009 Gate-defined Single Electron Transistor in a Graphene-MoS<sub>2</sub> van der Waals Heterostructure**, KE WANG, Department of Physics, Harvard University, Cambridge, MA 02138, USA, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Materials Science, Namiki 1-1, Tsukuba, Ibaraki 305-0044, Japan, PHILIP KIM, Department of Physics, Harvard University, Cambridge, MA 02138, USA — We report experimental demonstration of fabrication of laterally confined single electron transistor (SET) on MoS<sub>2</sub> transition metal dichalcogenide (TMDC) semiconductor. A few atomic layers of MoS<sub>2</sub> single crystals are encapsulated in hBN layers in order to improve mobility of 2-dimensional (2D) electron channel. Graphene layers are employed to provide Ohmic contact to the TMDC channels. The laterally confined quantum dots are formed by electrostatically depleting the near-by 2D channel employing local gate fabricated by electron lithography. Typical SET transport signatures such as gate-tunable Coulomb blockade have been observed. We have demonstrated the quantum confinement can be sensitively tuned to adjust the dot-reservoir coupling. The work paves way for more complicated device structure such as valley-spin filter and vertically coupled quantum dots in Coulomb drag devices.

**10:12AM R17.00010 Probing interlayer interactions in WS<sub>2</sub>-graphene van der Waals heterostructures**, TING FUNG CHUNG, LONG YUAN, LIBAI HUANG, YONG P. CHEN, Purdue University — Two-dimensional crystals based van der Waals coupled heterostructures are of interest owing to their potential applications for flexible and transparent electronics and optoelectronics. The interaction between the 2D layered crystals at the interfaces of these heterostructures is crucial in determining the overall performance and is strongly affected by contamination and interfacial strain. We have fabricated heterostructures consisting of atomically thin exfoliated WS<sub>2</sub> and chemical-vapor-deposited (CVD) graphene, and studied the interaction and coupling between the WS<sub>2</sub> and graphene using atomic force microscopy (AFM), Raman spectroscopy and femtosecond transient absorption measurement (TAM). Information from Raman-active phonon modes allows us to estimate charge doping in graphene and interfacial strain on the crystals. Spatial imaging probed by TAM can be correlated to the heterostructure surface morphology measured by AFM and Raman maps of graphene and WS<sub>2</sub>, showing how the interlayer coupling alters exciton decay dynamics quantitatively.

**10:24AM R17.00011 Coherently stacked MoS<sub>2</sub>/WSe<sub>2</sub> heterostructures: Moiré pattern and its effect on interlayer couplings**, CHENDONG ZHANG, UT at Austin, MING-YANG LI, Academia Sinica; KAUST, CHIH-PIAO CHUU, Academia Sinica, MEI-YIN CHOU, Academia Sinica; Georgia Institute of Technology; NTU, Taiwan, LAIN-JONG LI, KAUST, CHIH-KANG SHIH, UT at Austin — Vertically stacked heterojunctions (HJs) of transition metal dichalcogenides (TMDs) have been proposed as fundamental building blocks for several novel electronic and photonic devices. Although such HJs can be easily achieved by sequential transferring of different TMDs, this approach is not scalable, and the orientation relationship between the layers is difficult to control. A much more desirable approach is to directly grow one kind of TMD on top of the other. In addition to being a scalable platform, the epitaxial approach also results in a well-defined orientation relationship. A very important question to ask is “What is the role of the interlayer coupling on the electronic structures of such a bilayer stack?” By using scanning tunneling microscopy/spectroscopy (STM/S) and first-principles calculations, we investigate the MoS<sub>2</sub>/WSe<sub>2</sub> vertical heterojunctions formed by direct epitaxial growth. The different lateral lattice constants between MoS<sub>2</sub> and WSe<sub>2</sub> lead to the formation of a well-ordered Moiré pattern with a superlattice constant of ~8.5 nm. This superlattice reflects the variation of the lateral alignment between the MoS<sub>2</sub> and WSe<sub>2</sub> lattices. STS shows very large variations of interlayer coupling, as a function of the lateral alignment. More interestingly, depending on the location in the BZ, the interlayer coupling has very different consequences on the electronic structures.

**10:36AM R17.00012 Interface exciton at lateral heterojunction of monolayer semiconductors<sup>1</sup>**, KA WAI LAU, The Univ of Hong Kong, ZHIRUI GONG, Shenzhen University, HONGYI YU, WANG YAO, The Univ of Hong Kong — Heterostructures based on 2D transition metal dichalcogenides (TMDs) have attracted extensive research interest recently due to the appealing physical properties of TMDs and new geometries for forming heterostructures. One such heterostructure is the lateral heterojunctions seamlessly formed in a monolayer crystal between two different types of TMDs, e.g. WSe<sub>2</sub> and MoSe<sub>2</sub>. Such heterojunction exhibits a type II band alignment, with electrons (holes) having lower energy on the MoSe<sub>2</sub> (WSe<sub>2</sub>) region. Here we present the study of an interface exciton at the 1D lateral junction of monolayer TMDs. With the distance dependent screening, we find that the interface exciton can have strong binding even though the electron-hole separation is much larger compare to the 2D excitons in TMDs. Neutral excitons are studied using two different approaches: the solution based on a real-space tight binding model, and the perturbation expansion in a hydrogen-like basis in an effective mass model. We have also used the latter method to study charged excitons at a MoSe<sub>2</sub>-WSe<sub>2</sub>-MoSe<sub>2</sub> nanoscale junction.

<sup>1</sup>The work is supported by the Research Grant Council of Hong Kong (HKU705513P, HKU9/CRF/13G), the Croucher Foundation, and the HKU OYRA.

**10:48AM R17.00013 Indirect Band Gap Emission by Hot Electron Injection in Metal/MoS<sub>2</sub> and Metal/WSe<sub>2</sub> Heterojunctions**, ZHEN LI, University of Southern California, GOUTHAM EZHILARASU, College of Engineering Guindy, Anna University, IOANNIS CHATZAKIS, ROHAN DHALL, CHUN-CHUNG CHEN, STEPHEN CRONIN, University of Southern California — Transition metal dichalcogenides (TMDCs), such as MoS<sub>2</sub> and WSe<sub>2</sub>, are free of dangling bonds, therefore make more ‘ideal’ Schottky junctions than bulk semiconductors, which produce recombination centers at the interface with metals, inhibiting charge transfer. Here, we observe a more than 10X enhancement in the indirect band gap PL of TMDCs deposited on various metals, while the direct band gap emission remains unchanged. We believe the main mechanism of light emission arises from photoexcited hot electrons in the metal that are injected into the conduction band of MoS<sub>2</sub> and WSe<sub>2</sub>, and subsequently recombine radiatively with minority holes. Since the conduction band at the K-point is 0.5eV higher than at the  $\Sigma$ -point, a lower Schottky barrier of the  $\Sigma$ -point band makes electron injection more favorable. Also, the  $\Sigma$  band consists of the sulfur  $p_z$  orbital, which overlaps more significantly with the electron wavefunctions in the metal. This enhancement only occurs for thick flakes, and is absent in monolayer and few-layer flakes. Here, the flake thickness must exceed the depletion width of the Schottky junction, in order for efficient radiative recombination to occur in the TMDC. The intensity of this indirect peak decreases at low temperatures. Reference: DOI: 10.1021/acs.nanolett.5b00885

**Session R18 GMAG DMP FIAP: Spintransport Phenomena II** 317 - See-Hun Yang, IBM Almaden

**8:00AM R18.00001 Magnetic and electron-transport properties of spin-gapless semiconducting CoFeCrAl films.<sup>1</sup>**, DAVID SELLMYER, YUNLONG JIN, University of Nebraska Lincoln, PARASHU KHAREL, South Dakota State University, SHAH VALLOPPILLY, TOM GEORGE, BALAMURUGAN BALASUBRAMANIAN, RALPH SKOMSKI, University of Nebraska Lincoln — Recently, spin-gapless semiconductors (SGS) with a semiconducting or insulating gap in one spin channel and zero gap in the other at the Fermi level have attracted much attention due to their new functionalities such as voltage-tunable spin polarization, the ability to switch between spin-polarized n-type and p-type conduction, high spin polarization and carrier mobility. For the development of spintronic devices utilizing SGS, it is necessary to have a better understanding of the magnetic and transport properties of the thin films of these materials. In this study, the structural, magnetic, and electron-transport properties of a SGS material CoFeCrAl in the thin film geometry have been investigated. CoFeCrAl films were grown on atomically flat SiO<sub>2</sub> substrates using magnetron sputtering. The Curie temperature was measured to be 550 K very close to the value reported for bulk CoFeCrAl. Electron-transport measurements on the oriented films revealed a negative temperature coefficient of resistivity, small anomalous Hall conductivity and linear field dependence of magnetoresistance, which are transport signatures of SGS. The effect of elemental compositions and structural ordering on the SGS properties of the CoFeCrAl films will be discussed.

**8:12AM R18.00002 Theory of spin relaxation at metallic interfaces<sup>1</sup>**, K. D. BELASHCHENKO, ALEXEY A. KOVALEV, University of Nebraska-Lincoln, MARK VAN SCHILFGAARDE, King's College London — Spin-flip scattering at metallic interfaces affects transport phenomena in nanostructures, such as magnetoresistance, spin injection, spin pumping, and spin torques. It has been characterized for many material combinations by an empirical parameter  $\delta$ , which is obtained by matching magnetoresistance data for multilayers to the Valet-Fert model [J. Bass and W. P. Pratt, J. Phys.: Condens. Matter **19**, 183201 (2007)]. However, the relation of the parameter  $\delta$  to the scattering properties of the interface remains unclear. Here we establish this relation using the scattering theory approach and confirm it using a generalization of the magnetoelectronic circuit theory, which includes interfacial spin relaxation. The results of first-principles calculations of spin-flip scattering at the Cu/Pd and Cu/Pt interfaces are found to be in reasonable agreement with experimental data.

<sup>1</sup>Supported by NSF Grant DMR-1308751.

**8:24AM R18.00003 Spin relaxation through Kondo scattering in Cu/Py lateral spin valves.**, J. T. BATLEY, M. C. ROSAOND, M. ALI, E. H. LINFIELD, G. BURNELL, B. J. HICKEY, University of Leeds — Within non-magnetic metals it is reasonable to expect the Elliot-Yafet mechanism to govern spin-relaxation and thus the temperature dependence of the spin diffusion length might be inversely proportional to resistivity. However, in lateral spin valves, measurements have found that at low temperatures the spin diffusion length unexpectedly decreases. We have fabricated lateral spin valves from Cu with different concentrations of magnetic impurities. Through temperature dependent charge and spin transport measurements we present clear evidence linking the presence of the Kondo effect within Cu to the suppression of the spin diffusion length below 30 K. We have calculated the spin-relaxation rate and isolated the contribution from magnetic impurities. At very low temperatures electron-electron interactions play a more prominent role in the Kondo effect. Well below the Kondo temperature a strong-coupling regime exists, where the moments become screened and the magnetic dephasing rate is reduced. We also investigate the effect of this low temperature regime ( $>1$  K) on a pure spin current. This work shows the dominant role of Kondo scattering, even in low concentrations of order 1 ppm, within pure spin transport.

**8:36AM R18.00004 Electronic structure and magnetocrystalline anisotropy of the Bi<sub>2</sub>Se<sub>3</sub> topological insulator/ferromagnet interface**, JIA ZHANG, Physics and Astronomy, University of Nebraska, Lincoln, Nebraska 68588, USA, JULIAN P. VELEV, Department of Physics, University of Puerto Rico, San Juan, Puerto Rico 00931, USA, EVGENY Y. TSYMBAL, Physics and Astronomy, University of Nebraska, Lincoln — Interesting spin-dependent phenomena are expected to emerge when a topological insulator is interfaced with a magnetic material. In this work the magnetic properties of the interface between a topological insulator Bi<sub>2</sub>Se<sub>3</sub> and ferromagnetic metals (FM) fcc (111) Ni and Co are investigated by first-principles calculations. Different interface terminations are considered, and the most stable interface termination is identified to be an interface Ni (Co) atom located atop the hollow site of the interfacial Se monolayer. We find that the proximity effect induces a small magnetic moment on the interface Se atom (0.028  $\mu_B$  for Ni and 0.023  $\mu_B$  for Co). The surface state in Bi<sub>2</sub>Se<sub>3</sub> disappears due to the strong interface hybridization between FM and Bi<sub>2</sub>Se<sub>3</sub> and metal induced gap states appear in the bandgap region of Bi<sub>2</sub>Se<sub>3</sub>. We find that both the Bi<sub>2</sub>Se<sub>3</sub>/Ni(111) and Bi<sub>2</sub>Se<sub>3</sub>/Co(111) interfaces exhibit an in-plane easy axis with the magnetic anisotropy energy of around 2 erg/cm<sup>2</sup> per interface. An interesting feature resulting from our calculations is a non-collinear k-dependent spin texture at the interface which may have important consequences for the spin-dependent transport properties, such as the spin transfer torque.

**8:48AM R18.00005 Observation of thermal spin transfer torque via ferromagnetic resonance in magnetic tunnel junctions<sup>1</sup>**, ZHAOHUI ZHANG, LIHUI BAI, CAN-MING HU, Department of Physics and Astronomy, University of Manitoba, XIAOBIN CHEN, HONG GUO, Centre for the Physics of Materials and Department of Physics, McGill University, XIAOLONG FAN, DESHENG XUE, The Key Lab for Magnetism and Magnetic Materials of Ministry of Education, Lanzhou University, DIMITRI HOUSSEMEDDINE, Everspin Technologies — The temperature gradient driven spin-transfer torque, called the thermal spin-transfer torque (TSTT) attracts people's attention since it has potential in magnetization switching by utilizing wasted heat as well as in the study of spin transportation. We observed the effects of TSTT on magnetic tunnel junction (MTJ) via analysis of the ferromagnetic resonance (FMR) spectra. We used an external laser beam to heat the MTJ in order to establish a temperature gradient effectively. A TSTT was driven by the temperature gradient and applied to the magnetization of the free FM layer of the MTJ. By measuring and analyzing the FMR spectra, after excluding the effects caused by the temperature rise, we conclude that the FMR line-shape change is a result of the TSTT generated by a temperature gradient via laser heating. The most interesting result is that the angular dependence of the TSTT and DC-bias spin-transfer torque are very different. A modified or new theory may be needed to explain this in the future.

**9:00AM R18.00006 Intrinsic Gilbert Damping in Metallic Ferromagnets in Ballistic Regime and the Effect of Inelastic Electron Scattering from Magnetic Moments: A Time Dependent Keldysh Green Function Approach**, FARZAD MAHFOUZI, NICHOLAS KIOUSSIS, California State University, Northridge — Gilbert damping in metallic ferromagnets is mainly governed by the exchange coupling between the electrons and the magnetic degree of freedom, where the time dependent evolution of the magnetization leads to the excitation of electrons and loss of energy as a result of flow of spin and charge currents. However, it turns out that when the magnetization evolves slowly in time, in the presence of spin-orbit interaction (SOI), the resonant electronic excitations has a major contribution to the damping which leads to infinite result in ballistic regime. In this work we consider the inelastic spin-flip scattering of electrons from the magnetic moments and show that in the presence of SOI it leads to the relaxation of the excited electrons. We show that in the case of clean crystal systems such scattering leads to a linear dependence of the Gilbert on the SOI strength and in the limit of diffusive systems we get the Gilbert damping expression obtained from Kambersky's Fermi breathing approach. This research was supported by NSF-PREM Grant No. DMR-1205734

**9:12AM R18.00007 Carbon Tetragons as Definitive Spin Switches in Narrow Zigzag Graphene Nanoribbons<sup>1</sup>**, ZHENYU ZHANG, PING CUI, QIANG ZHANG, HONGBIN ZHU, XIAOXIA LI, WEIYI WANG, QUNXIANG LI, CHANGGAN ZENG, University of Science and Technology of China — Precise spatial control of the spin propagation channels is of fundamental and practical importance in future graphene-based spintronic devices. Here we use first-principles calculations to show that when narrow zigzag graphene nanoribbons are connected to form junctions or superlattices, properly placed square-shaped carbon tetragons not only serve as effective bundles of the two incoming spin edge channels, but also act as definitive topological spin switches for the two outgoing channels. The nanoribbon segments are largely drawn from different acene molecules. We further show that such spin switches can lift the degeneracy between the two spin propagation channels, which enables tunability of different magnetic states upon charge doping. Preliminary experimental supports for the realization of such tetragons connecting nanoribbon segments are also presented.

<sup>1</sup>Supported by MOST, CAS, and NNSF of China.

**9:24AM R18.00008 Spin Transport and Giant Electroresistance in Ferromagnetic Graphene Vertical Heterostructures<sup>1</sup>**, HEE CHUL PARK, Center for Theoretical Physics of Complex Systems, IBS, NOJOON MYUNG, Department of Material Science and Engineering, University of Ioannina, SEUNG JOO LEE, Quantum-functional Semiconductor Research Center, Dongguk University — We investigate spin transport through ferromagnetic graphene vertical heterostructures where a sandwiched tunneling layer is either a normal or ferroelectric insulator. We show that the spin-polarization of the tunneling current is electrically controlled via gate voltages. We also demonstrate that the tunneling current of Dirac fermions can be prohibited when the spin configuration of ferromagnetic graphene sheets is opposite. Giant electroresistance can thus be developed by using the proposed heterostructure in this study. The effects of temperature on spin transport and the giant electroresistance ratio are also investigated. Our findings discover the prospect of manipulating the spin transport properties in vertical heterostructures through electric fields via gate and bias electrodes.

<sup>1</sup>The research leading to these results has received funding from the European Union Seventh Framework Programme under grant agreement No604391 Graphene Flagship, Project Code (IBS-R024-D1), and the NRF grant funded by MSIP(No. 2014-066298).

**9:36AM R18.00009 Spin relaxation mechanism in graphene spin valves with Al<sub>2</sub>O<sub>3</sub> and MgO tunnel barriers<sup>1</sup>**, WALID AMAMOU, ZHISHENG LIN, JEREMIAH VAN BAREN, JING SHI, UC Riverside, ROLAND KAWAKAMI, Ohio State University — Contact induced spin relaxation in graphene lateral spin valves is one of major limiting factors for obtaining long spin lifetimes in graphene. There are various spin relaxation mechanisms, including spin absorption, interfacial spin scattering, and fringe field effects, which may account for the observed short spin lifetimes. One possible solution is to introduce a tunnel barrier between graphene and the ferromagnetic electrode, which should reduce contact induced spin relaxation and allow for longer spin lifetimes. We study the spin relaxation mechanisms in our graphene spin valves with two different types of tunnel barriers, aluminum oxide and MgO/TiO<sub>2</sub> using the standard non-local measurement geometry. To extract the spin lifetime from Hanle spin precession data, we perform fits based on Bloch equation models that include the effects of spin absorption into the magnetic contacts. We observe a strong dependence of the extracted spin lifetime on the resistance-area (RA) product of the contacts. To understand the role of spin absorption, we compare these results to fits obtained using Hanle models that do not take spin absorption into account. Analysis shows that spin absorption might not be the dominant source of contact induced spin relaxation for graphene spin valves with sputtered Al<sub>2</sub>O<sub>3</sub> and MgO/TiO<sub>2</sub> barriers. Interfacial spin-flip scattering or spin dephasing resulting from local magnetostatic fields due to contact roughness are likely to be more important.

**9:48AM R18.00010 Spin fluctuations in 3d paramagnetic metals**, ALEKSANDER WYSOCKI, ANDREY KUTEPOV, VLADIMIR ANTROPOV, Ames Laboratory, U.S. Department of Energy, Ames, Iowa 50011, USA — Spin fluctuations (SFs) in 3d paramagnetic metals were investigated using the linear response formalism within the time dependent density functional theory. An efficient scheme of frequency integration using the Matsubara technique has been implemented and tested. The SFs spectrum in 3d paramagnets is analyzed in real and reciprocal spaces as a function of frequency and temperature. For all materials the SFs are characterized by the coexistence of low and high energy branches which originate from different regions of the Brillouin zone. The low-energy ones can be measured by neutron scattering experiments while the high-energy SFs appear to be more localized. Further, we studied the nature of square of fluctuating magnetic moment in these materials. This work was supported, in part, by the Critical Materials Institute, an Energy Innovation Hub funded by the U.S. Department of Energy (DOE), and by the Office of Basic Energy Science, Division of Materials Science and Engineering. The research was performed at Ames Laboratory, which is operated for the U.S. DOE by Iowa State University under contract # DE-AC02-07CH11358.

**Session R19 GMAG DMP: Magnetic Bulk Materials** 318 - James Lee, Lawrence Berkeley Laboratory

**8:00AM R19.00001 Field induced spin density and spiral phases in a layered antiferromagnet<sup>1</sup>**, MATTHEW STONE, MARK LUMSDEN, VASILE GARLEA, Quantum Condensed Matter Division, Oak Ridge National Laboratory, BEATRICE GRENIER, ERIC RESSOUCHE, INAC-SPSMS, CEA & Universite Grenoble Alpes, ERIC SAMULON, IAN FISHER, Department of Applied Physics and Geballe Laboratory for Advanced Materials Stanford University, LISA DEBEER-SCHMITT, Chemical & Engineering Materials Division, Oak Ridge National Laboratory, ALEXANDER HRISTOV, Department of Applied Physics and Geballe Laboratory for Advanced Materials Stanford University, JORGE GAVILANO, Paul Scherrer Institute, Villigen, Switzerland — We will present neutron scattering measurements examining the low-field ordered magnetic phases of the  $S = 1$  dimerized antiferromagnet Ba<sub>3</sub>Mn<sub>2</sub>O<sub>8</sub>. We have found that for magnetic both spin density wave order with incommensurate wave vectors and a higher field spiral phase with incommensurate wave vectors only along the  $[hh0]$  direction. For both field induced ordered phases, the magnetic moments are lying in the plane perpendicular to the field direction. The nature of these two transitions is fundamentally different: the low-field transition is a second order transition to a spin-density wave ground state, while the one at higher field, toward the spiral phase, is of first order. More recent SANS measurements of the magnetic phases with  $H \parallel c$  will be presented if available at the time of the meeting.

**8:12AM R19.00002 Incommensurate Spin Density Wave state in metamagnetic Fe<sub>3</sub>Ga<sub>4</sub>**, YAN WU, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803, HUIBO CAO, ANTONIO DOS SANTOS, Quantum Condensed Matter Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, GREG MCCANDLESS, JULIA CHAN, Department of Chemistry, University of Texas at Dallas, Richardson, TX 75080, AMAR KARKI, RONGYING JIN, JOHN DITUSA, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, LA 70803 — Fe<sub>3</sub>Ga<sub>4</sub> displays a rich competition between magnetic states without structural transitions: a ferromagnetic(FM) ground state transitions to an antiferromagnetic(AFM) intermediate state above 68 K followed by a reemergence of the FM state above room temperature(T). The reentrance of the FM state hints of a coupling of the magnetic degrees of freedom to other modes. To explore the nature of the magnetic states, we have performed extensive single crystal neutron diffraction measurements over a wide range of T and pressure. These measurements revealed two very different magnetic states with the low T FM state having magnetic moments along the c-axis while we discovered that the AFM state is in an incommensurate spin density wave(SDW) order with moments mostly along the a-axis. However, there is still considerable non-collinear and non-coplanar contributions along the b- and c-axial directions. This non-coplanar moment is likely to be the origin of the very large anomalous Hall effect(HE) including a substantial topological HE that we discovered in Fe<sub>3</sub>Ga<sub>4</sub>. Study of the effect of hydrostatic pressure indicates a reduction of the T<sub>c</sub> and a destabilization of the SDW phase.

**8:24AM R19.00003 Increased operational temperature of Cr<sub>2</sub>O<sub>3</sub>-based spintronic devices<sup>1</sup>**, MICHAEL STREET, WILL ECHTENKAMP, TAKASHI KOMESU, SHI CAO, University of Nebraska-Lincoln, JIAN WANG, University of Saskatchewan, PETER DOWBEN, CHRISTIAN BINEK, University of Nebraska-Lincoln — Spintronic devices have been considered a promising path to revolutionizing the current data storage and memory technologies. This work is an effort to utilize voltage-controlled boundary magnetization of the magnetoelectric chromia (Cr<sub>2</sub>O<sub>3</sub>) to be implemented into a spintronic device. The electric switchable boundary magnetization of chromia can be used to voltage-control the magnetic states of an adjacent ferromagnetic layer. For this technique to be utilized in a spintronic device, the antiferromagnetic ordering temperature of chromia must be enhanced above the bulk value of  $T_N = 307\text{K}$ . Previously, based on first principle calculations, boron doped chromia thin films were fabricated via pulsed laser deposition showing boundary magnetization at elevated temperatures. Measurements of the boundary magnetization were also corroborated by spin polarized inverse photoemission spectroscopy. Exchange bias of B-doped chromia was also investigated using magneto-optical Kerr effect, showing an increased blocking temperature from 307K. Further boundary magnetization measurements and spin polarized inverse photoemission measurements indicate the surface magnetization to an in-plane orientation from the standard perpendicular orientation.

<sup>1</sup>This project was supported by the SRC through CNFD, an SRC-NRI Center under Task ID (2398.001) and by C-SPIN, part of STARnet, sponsored by MARCO and DARPA (No. SRC 2381.001)

**8:36AM R19.00004 "Switching" of Magnetic Anisotropy in Magnets with Strong Spin-Orbit Coupling**, HIROAKI ISHIZUKA, LEON BALENTS, Univ of California - Santa Barbara — Motivated by recent studies on heavy-element magnetic oxides, we theoretically study a spin model on a fcc lattice with bond-dependent anisotropic interactions. Strong spin-orbit coupling in heavy elements often gives rise to bond-dependent anisotropic interactions in magnetic compounds. Such anisotropic interactions are known to induce peculiar magnetic behavior such as quantum spin-liquid and order-by-disorder. In this study, we investigate magnetic anisotropy of a fcc lattice antiferromagnet with bond-dependent interactions. We show that, in this model, the magnetic anisotropy is induced by fluctuations in both high-temperature paramagnetic and low-temperature magnetically-ordered phases. Furthermore, they show strong temperature dependence and switching of the magnetic anisotropy as the temperature decreases;  $j_{111}$  direction is favored in high-temperature above magnetic transition, while  $j_{100}$  or  $j_{110}$  is favored in the ordered phase, depending on the parameter. This is in contrast to the magnetic anisotropy induced by crystal field, which is independent of temperature. Observation of this temperature dependent anisotropy may provide a way to experimentally determine the anisotropic interaction in heavy-element magnets.

**8:48AM R19.00005 Lattice Dynamics and Magnetoelastic Coupling in a Frustrated Shape Memory Alloy**, PAUL STONAH, MIKE MANLEY, Oak Ridge National Lab, NICK BRUNO, IBRAHIM KARAMAN, RAYMUNDO ARROYAVE, Texas AM University, NAVDEEP SINGH, University of Houston, ELIOT SPECHT, DOUG ABERNATHY, SONGXUE CHI, XIAOPING WANG, Oak Ridge National Lab, CRYSTAL FABRICATION TEAM, SCATTERING EXPERIMENTS TEAM, THEORY TEAM — Magnetocaloric (MC) materials present an avenue for chemical-free, solid state refrigeration through cooling via adiabatic demagnetization. We have used inelastic neutron scattering to measure the lattice dynamics in the MC shape memory alloy Ni<sub>45</sub>Co<sub>5</sub>Mn<sub>36.6</sub>In<sub>13.4</sub>. In this presentation, we present the results of inelastic neutron scattering near the Curie temperature. We find that there is an unaccounted-for change in phonon entropy of 0.22 kJ atom<sup>-1</sup> (26 J kg<sup>-1</sup> K<sup>-1</sup>), which we attribute to phonon-magnon coupling. We identify an anomalous softening of the TA[100] phonon mode. We also present the results of diffuse neutron and X-ray diffraction experiments and provide an interpretation on the implied local order.

**9:00AM R19.00006 Magnetotransport anisotropy in microstructures of Yb<sub>2</sub>Pt<sub>2</sub>Pb**, TONI HELM, PHILIP J.W. MOLL, NoneMax-Planck-Institute for Chemical Physics of Solids, Dresden, Germany — The Yb<sup>3+</sup> moments in Yb<sub>2</sub>Pt<sub>2</sub>Pb (YPP) form a strongly frustrated Shastry-Sutherland lattice (SSL) [1]. Below 2 K, a dimerized antiferromagnetic order consisting of two AF sublattices has been recently identified by neutron diffraction [2]. Unlike other quantum magnets, YPP is a highly conductive metal and the large Sommerfeld coefficient  $\Gamma \sim 300$  mJ/molK<sup>2</sup> suggests hybridization of the Yb-4f states with the conduction band [3]. This opens the possibility to search for signatures of the metamagnetism associated with the plateaus at fractions of the saturation magnetization, a characteristic of SSL systems. To study the influence of YPPs rich magnetic structure on the anisotropic charge transport, we fabricated micron-sized transport devices from single crystalline YPP by Focused Ion Beam etching. This technique enables thickness and length dependent magnetotransport measurements along the most relevant lattice directions. [1] M. S. Kim et al. PRB 77,144425 (2008) [2] W. Müller et al. arXiv:1408.0209v1 (2014) [3] M. S. Kim, M. C. Aronson, PRL 110, 017201 (2013)

**9:12AM R19.00007 Magnetic anisotropy of rare-earth magnets calculated by SIC and OEP<sup>1</sup>**, HISAZUMI AKAI, ISSP, Univ of Tokyo, MASAKO OGURA, PGI, Juelich Research Center — We have pointed out in our previous study that the chemical bonding between N and Sm plays an important role in the magnetic anisotropy change of Sm<sub>2</sub>Fe<sub>17</sub> from in-plane to uniaxial ones caused by the introducing of N. This effect of N insertion was discussed in terms of change in the electronic structure calculated in the framework of LDA+SIC. The main issue here is whether the 4f states are dealt with properly in SIC. In the present study, we examine the applicability of SIC for the evaluation of the magnetic anisotropy of rare-earth (RE) magnets by comparing the results with various methods, in particular, the optimized effective potential (OEP) method. In this study, OEP is applied only on the RE sites. Admittedly, this is a drawback from the viewpoint of the consistent treatment of uncertainly inherent in the so-called KLI (Krieger-Li-Iafrate) constants. Putting this aside for the moment, we have calculated the electronic structure of RE magnets R<sub>2</sub>Fe<sub>17</sub>N<sub>x</sub> and RCo<sub>5</sub> (R=light RE), by OEP with exact-exchange (EXX) combined with Colle-Salvetti correlation. Our preliminary results have shown considerable differences between the SIC and OEP calculations. We will discuss the meaning of this discrepancy.

**9:24AM R19.00008 Domain wall order and motion in Mn<sub>3</sub>O<sub>4</sub>**, ALEXANDER THALER, Oak Ridge National Lab, Oak Ridge, TN, ALEXANDER ZAKJEVSKII, BRIAN NGUYEN, YEWON GIM, Physics Illinois & Seitz MRL, University of Illinois, Urbana, IL, ADAM ACZEL, LISA DEBEER-SCHMITT, Oak Ridge National Lab, Oak Ridge, TN, S. LANCE COOPER, GREGORY MACDOUGALL, Physics Illinois & Seitz MRL, University of Illinois, Urbana, IL — Mn<sub>3</sub>O<sub>4</sub> is an orbitally ordered, magnetically frustrated spinel with strong spin-lattice coupling, which exhibits a series of low temperature magnetic and structural transitions. Transverse field  $\mu$ SR has shown that ordered and disordered volumes coexist within this material, while MFM measurements have further shown that the magnetic domain walls themselves order in specific crystallographic directions, with a typical length scale of 100's of nm. In order to directly study these phenomena, we have performed small angle neutron scattering (SANS) measurements at both zero and applied magnetic field. We will present the results of these measurements and discuss what they show as far as the formation of domains, as well as the motion of the domain walls. We will also discuss the effects of internal disorder on the behavior of the material. This work was sponsored by the National Science Foundation, under grant number DMR-1455264.

**9:36AM R19.00009 Nanoscale Magnetic Structure of Non-Joulian Magnets**, RAVINI CHANDRASENA, WEIBING YANG, Department of Physics, Temple University, ANDREAS SCHOLL, Advanced Light Source, LBNL, JAN MINAR, Department of Chemistry, Ludwig Maximilian University, PADRAIC SHAFER, ELKE ARENHOLZ, Advanced Light Source, LBNL, HUBERT EBERT, Department of Chemistry, Ludwig Maximilian University, ALEXANDER GRAY, Department of Physics, Temple University, HARSH DEEP CHOPRA, Mechanical Engineering Department, Temple University — Strain dependence of magnetic anisotropy energy produces Joule magnetostriction that is a volume conserving process, whereas sensitivity of isotropic exchange energy to interatomic distance is the cause of volume magnetostriction. In a typical magnet, Joule magnetostriction dominates as the volume fraction occupied by regions of uniform spin alignment (domains) is 2-4 orders of magnitude higher than that which is occupied by regions with magnetoelastic gradients (domain walls). Recently, 'giant' non-volume conserving or non-Joulian magnetostriction has been discovered in iron-gallium alloys. Here we show using high-resolution polarization-dependent photoelectron microscopy that non-Joulian magnetism arises from an unusual partition of the crystal into nm-scale lamellar domains and domain walls within highly periodic magnetic microcells. High-resolution x-ray circular dichroism measurements at the Fe and Ga L absorption edges further provide evidence of weak iron-induced magnetism on gallium atoms via negative exchange. The results are in excellent agreement with the state-of-the-art theoretical electronic-structure calculations.

**9:48AM R19.00010 Control over magnetic properties in bulk hybrid materials<sup>1</sup>**, CHRISTIAN URBAN, University of California San Diego, ADRIAN QUESADA, Instituto de Cerámica y Vidrio, CSIC, 28049, Madrid, Spain, THOMAS SAERBECK, Institut Laue-Langevin, 71 Av. Des Martyrs, 38000 Grenoble, France, MIGUEL ANGEL DE LA RUBIA, MIGUEL ANGEL GARCIA, JOSE FRANCISCO FERNANDEZ, Instituto de Cerámica y Vidrio, CSIC, 28049, Madrid, Spain, IVAN K. SCHULLER, University of California San Diego, UCSD COLLABORATION, INSTITUTO DE CERAMICA, MADRID COLLABORATION, INSTITUT LAUE-LANGEVIN, GRENoble COLLABORATION — We present control of coercivity and remanent magnetization of a bulk ferromagnetic material embedded in bulk vanadium sesquioxide (V<sub>2</sub>O<sub>3</sub>) by using a standard bulk synthesis procedure. The method generalizes the use of structural phase transitions of one material to control structural and magnetic properties of another. A structural phase transition (SPT) in the V<sub>2</sub>O<sub>3</sub> host material causes magnetic properties of Ni to change as function of temperature. The remanent magnetization and the coercivity are reversibly controlled by the SPT without additional external magnetic fields. The reversible tuning shown here opens the pathway for controlling the properties of a vast variety of magnetic hybrid bulk systems.

**10:00AM R19.00011 A Study of Phase Stability and Properties of TiO<sub>2</sub> Polymorphs with Diffusion Monte Carlo**, YE LUO, ANOUAR BENALI, Argonne National Laboratory, LUKE SHULENBURGER, Sandia National Laboratories, JARON KROGEL, Oak Ridge National Laboratory, OLLE HEINONEN, Argonne National Laboratory, PAUL KENT, Oak Ridge National Laboratory — In the past decades, many studies have focused on the fundamental properties of TiO<sub>2</sub> due to its important role in effectively converting solar energy such as in photovoltaic batteries and photocatalytic water splitting. TiO<sub>2</sub> presents many stable and metastable phases of which, Rutile Anatase and Brookite are the most studied. Using density functional theory (DFT), the energy ordering of these phases depends strongly on the scheme describing the electronic correlation, for instance GGA+U and Hybrid functionals, often tied to an empirical parameter for reproducibility with no guarantee of predictability. We present the first analysis of the polymorphic energy ordering and properties of three naturally existing phases Rutile, Anatase and Brookite, by performing the highly accurate ab initio calculation with fixed node diffusion Monte Carlo (DMC) implemented in QMCPACK[1]. [1] QMCPACK, <http://www.qmcpack.org>

**10:12AM R19.00012 On the Electronic and Magnetic Properties of the ionic superatomic solid Ni<sub>9</sub>Te<sub>6</sub>(PEt<sub>3</sub>)<sub>8</sub>C<sub>60</sub><sup>1</sup>**, VIKAS CHAUHAN, SANJUBALA SAHOO, SHIV KHANNA, Virginia Commonwealth University, PHYSICS DEPARTMENT VCU COLLABORATION — We have carried out first principles electronic structure studies to examine the atomic structure, stability, and electronic and magnetic properties of the recently synthesized Ni<sub>9</sub>Te<sub>6</sub>(PEt<sub>3</sub>)<sub>8</sub>C<sub>60</sub> ionic material consisting of Ni<sub>9</sub>Te<sub>6</sub>(PEt<sub>3</sub>)<sub>8</sub> superatoms and C<sub>60</sub>. It is shown that the PEt<sub>3</sub> ligands result in an internal coulomb well that lifts the quantum states of the Ni<sub>9</sub>Te<sub>6</sub> cluster lowering its ionization potential to 3.39 eV thus creating a superatomic alkali motif. The metallic core has a spin magnetic moment of 5.3  $\mu_B$  in agreement with experiment. The clusters are marked by low magnetic anisotropy energy (MAE) of 2.72 meV and a larger intra-exchange coupling exceeding 0.2 eV indicating that the observed paramagnetic behavior around 10K is due to superparamagnetic relaxations. The magnetic motifs separated by C<sub>60</sub> experience a weak superexchange that stabilizes a ferromagnetic ground state as observed around 2K. The calculated MAE is sensitive to the charged state that could account for the observed change in magnetic transition temperature with size of the ligands or anion.

<sup>1</sup>We gratefully acknowledge funding support from the Department of Energy under Award Number DE-SC0006420.

**10:24AM R19.00013 Submicron sized R<sub>2</sub>Fe<sub>14</sub>B particles fabricated by mechanochemical process<sup>1</sup>**, OZLEM KOYLU-ALKAN, Department of Physics and Astronomy, University of Delaware, Newark, DE, USA, JOSE MANUEL BARANDI-ARAN, BCMaterials, Technology Park of Biscay E-48160 Derio, Spain & Dept. Electricity & Electronics, Univ. Basque Country (UPV/EHU) E-48080 Bilbao, Spain, DANIEL SALAZAR, BCMaterials, Technology Park of Biscay E-48160 Derio, Spain, GEORGE C. HADJIPANAYIS, Department of Physics and Astronomy, University of Delaware, Newark, DE, USA, UNIV. OF DELAWARE TEAM, UNIV. BASQUE COUNTRY TEAM — In this work, we have synthesized submicron R<sub>2</sub>Fe<sub>14</sub>B particles by the mechanochemical process. Mechanical activation of oxides of rare earth, iron and boron was done by high energy ball milling in a CaO with a reduction agent (Ca). After a heat treatment at 900 C the powder was washed with water and glycerol solution to remove the dispersant and other non-magnetic phases. Magnetic measurements showed that the as-synthesized unwashed powders had coercivity values of 10.3 kOe, 12.8 kOe, and 24.6 kOe for R=Nd, Pr, and Dy, respectively. During washing, H<sub>2</sub> is released and absorbed by the 2:14:1 structure. After removing the H<sub>2</sub>, the submicron particles have coercivities of 3.3 kOe (Nd), 4.4 kOe (Pr) and 21.0 kOe (Dy) with average sizes 160 nm, 242 nm, and 107 nm, respectively. Fitting of high field M(H) measurements to the law of approach to saturation showed that the anisotropy constant of the Nd<sub>2</sub>Fe<sub>14</sub>B particles are 3.73x10<sup>7</sup> erg/cm<sup>3</sup> which is comparable to bulk. Work supported by DOE DE-FG02-04ERU4612 and Bizkaia Talent AYD-000-195.

<sup>1</sup>DOE DE-FG02-04ERU4612

**10:36AM R19.00014 First-principles study of intrinsic magnetic properties of hexagonal and orthorhombic  $(\text{Fe}_{1-x}\text{Co}_x)_2\text{P}$  alloys<sup>1</sup>**, IVAN ZHURAVLEV, University of Nebraska-Lincoln, V. P. ANTROPOV, Ames Laboratory, K. D. BELASHCHENKO, University of Nebraska-Lincoln —  $(\text{Fe}_{1-x}\text{Co}_x)_2\text{P}$  is a candidate rare-earth-free alloy for permanent-magnet applications, which is hexagonal (*h*) up to  $x \approx 0.12$  and orthorhombic (*o*) at larger  $x$ . The Curie temperature  $T_C$ , which is only 270 K in  $\text{Fe}_2\text{P}$ , raises sharply with  $x$ , peaking above 450 K in the *o*-phase [1]. The measurement [2] of magnetocrystalline anisotropy (MCA) in the *o*-phase is inconsistent with Mössbauer data suggesting a spin reorientation transition (SRT) at  $x \approx 0.3$  [1]. Here we report the results of *ab initio* calculations of the magnetization, mean-field  $T_C$ , and MCA in *h*- and *o*-phases as a function of  $x$ , addressing the role of unequal site occupation, which is confirmed by total-energy calculations. The trends in the magnetization are reproduced, as well as MCA in the *h*-phase, and so is the SRT near  $x \approx 0.3$  (at odds with the results of Ref. 2). The trends in the mean-field  $T_C$ , obtained using the disordered-local-moment method, agree with experimental data. [1] R. Fruchart *et al.*, J. Appl. Phys. 40, 1250 (1969). [2] T. Hokabe *et al.*, J. Phys. Soc. Japan 36, 1704 (1974).

**10:48AM R19.00015 Magnetic effects of H in Metals, the case of Iron<sup>1</sup>**, PATRICIO VARGAS, ANDREA LEN, JUAN MANUEL FLOREZ, Physics Department, USM, Valparaiso, Chile — A growing consensus on the possible role of hydrogen in future energy technology has incited worldwide efforts for the development of new hydrogen-storage materials and their application to rechargeable batteries and fuel cells. Meanwhile, research in the basic properties of metal-hydrogen systems has also been advanced. High-pressure experiments have unraveled new features of elemental hydrogen (phases of solid H<sub>2</sub> and metallization of liquid H<sub>2</sub> and superconductivity) as well as of many metal-hydrogen systems (superabundant vacancy formation, phase diagrams over wide  $p$ - $x$ - $T$  ranges). In this work we address the magnetic changes induced by interstitial hydrogen in Fe. From the point of view of the Slater Pauli Curve, Fe alloys  $(\text{Fe}(1-x)\text{M}_x)$  show an increase of the magnetization (but always less than pure Fe) due substitutional non magnetic impurities like  $\text{M} = \text{V}, \text{Cr}, \text{Ti}$ . For the magnetic impurity Cobalt, the Slater Pauli Curve reaches its maximum of about 2.5 Bohr magnetons per atom when  $x=0.4$ . For an interstitial impurity H, which adds one electron to the system, we observe an increasing of the magnetization too but less than the effect induced by the volume expansion. Therefore like the case of  $\text{NiH}_x$ , one of the effects of interstitial hydrogen on a ferromagnetic material is to fill the minority spin states.

**8:00AM R21.00001 Ultrafast X-ray Studies on the Dynamics of Structural Transitions**, ARIANNA GLEASON, LANL — Understanding the processes which dictate physical properties such as strength, elasticity, plasticity, and the kinetics of phase transformation/crystallization requires studies at the relevant length-scales (e.g., interatomic spacing and grain size) and time-scales (e.g., phonon period). Experiments performed at the Matter in Extreme Conditions end-station at the Linac Coherent Light Source, SLAC combine a laser-driven dynamic compression pump and X-ray free electron laser probe. To showcase some of the capabilities of this end-station, we present time-resolved structural and/or electronic transformations in a suite of materials over a pressure range of a few to tens of GPa, including: 1) quartz/fused silica, 2) water, 3) Fe-bearing pyroxene, 4) iron and 5) titanium.

**8:36AM R21.00002 Nanosecond homogeneous nucleation and crystal growth in shock-compressed  $\text{SiO}_2$** , YUAN SHEN, Stanford Univ, SHAI JESTER, TINGTING QI, EVAN REED, Stanford University — Understanding the kinetics of shock-compressed  $\text{SiO}_2$  is of great importance for mitigating optical damage for high-intensity lasers and for understanding meteoroid impacts. Experimental work has placed some thermodynamic bounds on the formation of high-pressure phases of this material, but the formation kinetics and underlying microscopic mechanisms are yet to be elucidated. Here, by employing multiscale molecular dynamics studies of shock-compressed fused silica and quartz, we find that silica transforms into a poor glass former that subsequently exhibits ultrafast crystallization within a few nanoseconds. We also find that, as a result of the formation of such an intermediate disordered phase, the transition between silica polymorphs obeys a homogeneous reconstructive nucleation and grain growth model. Moreover, we construct a quantitative model of nucleation and grain growth, and compare its predictions with stishovite grain sizes observed in laser-induced damage and meteoroid impact events.

**8:48AM R21.00003 Order parameter aided phase space exploration under extreme conditions<sup>1</sup>**, AMIT SAMANTA, SEBASTIAN HAMEL, ERIC SCHWEGLER, Lawrence Livermore National Laboratory — Efficient exploration of configuration space and identification of metastable structures in condensed phase systems are challenging from both computational as well as algorithmic perspectives. In this talk I will illustrate how we can extend the recently proposed order-parameter aided temperature accelerated sampling schemes to efficiently and systematically explore free energy surfaces, and search for metastable states and reaction pathways within the framework of density functional theory based molecular dynamics. I will illustrate how this sampling scheme can be used to explore the relevant parts of configuration space in prototypical materials, like  $\text{SiO}_2$  and identify the different metastable structures, transition pathways and phase boundaries.

**9:00AM R21.00004 Multi-frame X-ray Phase Contrast Imaging of Impact Experiments at the Advanced Photon Source** , BRIAN JENSEN, Los Alamos National Laboratory, ADAM IVERSON, CARL CARLSON, MATTHEW TEEL, NATIONAL SECURITY TECHNOLOGIES, BENJAMIN MORROW, DAVID FREDENBURG, Los Alamos National Laboratory — Recent advances in coupling synchrotron X-ray diagnostics to dynamic compression experiments are providing new information about the response of materials at extremes conditions. For example, propagation based X-ray Phase Contrast Imaging (PCI) which is sensitive to differences in density (or index of refraction) has been successfully used to study a wide range of phenomena including jet-formation in metals, crack nucleation and propagation, and detonator dynamics. These experimental results have relied, in part, on the development of a robust, optically multiplexed detector system that captures single X-ray bunch images with micrometer spatial resolution on the nanosecond time scale. In this work, the multi-frame PCI (MPCI) system is described along with experiment highlights that include the compression of an idealized system of spheres subjected to impact loading. Additional advances to the detector system will be presented that are designed to increase the efficiency of the detector system and to retrieve phase information from the X-ray images which is required for determining the density during dynamic loading. Experimental results, implications, and future work will be discussed.

**9:12AM R21.00005 The Challenge of Time-Dependent Control of Both Processing and Performance of Materials at the Mesoscale, and the MaRIE Project** , CRIS W. BARNES, Los Alamos National Laboratory — DOE and NNSA are recognizing a mission need for flexible and reduced-cost product-based solutions to materials through accelerated qualification, certification, and assessment. The science challenge lies between the nanoscale of materials and the integral device scale, at the middle or "mesoscale" where interfaces, defects, and microstructure determine the performance of the materials over the lifecycle of the intended use. Time-dependent control of the processing, structure and properties of materials at this scale lies at the heart of qualifying and certifying additive manufactured parts; experimental data of high fidelity and high resolution are necessary to discover the right physical mechanisms to model and to validate and calibrate those reduced-order models in codes on Exascale computers. The scientific requirements to do this are aided by a revolution in coherent imaging of non-periodic features that can be combined with scattering off periodic structures. This drives the need to require a coherent x-ray source, brilliant and high repetition rate, of sufficiently high energy to see into and through the mesoscale. The Matter-Radiation Interactions in Extremes (MaRIE) Project is a proposal to build such a very-high-energy X-ray Free Electron Laser.

**9:24AM R21.00006 The behavior of single-crystal silicon to dynamic loading using in-situ X-ray diffraction and phase contrast imaging<sup>1</sup>** , HAE JA LEE, ZHOU XING, ERIC GALTIER, BRICE ARNOLD, EDUARDO GRANADOS, SHAUGHNESSY B. BROWN, FRANZ TAVELLA, EMMA MCBRIDE, ALAN FRY, BOB NAGLER, SLAC National Accelerator Laboratory, ANDREAS SCHROPP, FRANK SEIBOTH, DIRK SAMBERG, CHRISTIAN SCHROER, DESY, ARIANNA E. GLEASON, Los Alamos National Laboratory, ANDREW HIGGINBOTHAM, University of York — Hydrostatic and uniaxial compression studies have revealed that crystalline silicon undergoes phase transitions from a cubic diamond structure to a variety of phases including orthorhombic Imma phase, body-centered tetragonal phase, and a hexagonal primitive phase [1, 2]. The dynamic response of silicon at high pressure, however, is not well understood. Phase contrast imaging has proven to be a powerful tool for probing density changes caused by the shock propagation into a material [3]. In order to characterize the elastic and phase transitions, we image shock waves in Si with high spatial resolution using the LCLS X-ray free electron laser and Matter in Extreme Conditions instrument. In this study, the long pulse optical laser with pseudo-flat top shape creates high pressures up to 60 GPa. We measure the crystal structure by observing X-ray diffraction orthogonal to the shock propagation direction over a range of pressures. We describe the capability of simultaneously performing phase contrast imaging and in situ X-ray diffraction during shock loading and discuss the dynamic response of Si in high-pressure phases. **9:36AM R21.00007 Calculation of Si L<sub>2,3</sub>-edge Non-Resonant Inelastic X-ray Scattering Spectra of Compressed Silica Glass** , KEITH GILMORE, European Synchrotron Radiation Facility, JOHN TSE, University of Saskatchewan — Despite the abundance of silica in Earth's crust and its corresponding importance to geological processes, debate continues as to the local coordination of Si in silica at geological pressures. Recent *ab initio* molecular dynamics simulations [M. Wu et al., Sci. Rep. 2, 398 (2012)] predicted a change from 4-fold coordinated Si at ambient pressure to 6-fold coordination by 22 GPa. This was consistent with experimental non-resonant inelastic x-ray scattering (NRIXS) measurements at the O K-edge that also suggested a conversion to 6-fold coordination by 22 GPa [J. Lin et al., Phys. Rev. B 75, 012201 (2007)]. However, NRIXS measured at the Si L-edge found the spectra to be largely independent of pressure up to 74 GPa [H. Fukui et al., Phys. Rev. B 78, 12203 (2008)] indicating that 4-fold coordination is maintained. The discrepancy may potentially be due to low instrument resolution of the Si L-edge measurements. We present calculated Si L-edge NRIXS spectra at multiple pressures between ambient and 150 GPa and for several momentum transfer values. This allows us to identify spectral features that may be used to better distinguish 4-fold and 6-fold coordinated environments as experimental resolutions improve.

**9:48AM R21.00008 Probing off-Hugoniot states in Ta, Cu, and Al to 10 Mbar compression with magnetically driven liner implosions** , T.R. MATTSSON, R.W. LEMKE, D.H. DOLAN, D.G. DALTON, J.L. BROWN, G.R. ROBERTSON, M.D. KNUDSON, E. HARDING, A.E. MATTSSON, J.H. CARPENTER, R.R. DRAKE, K. COCHRANE, A.C. ROBINSON, Sandia National Laboratories, K. TOMLINSON, General Atomics, B.E. BLUE, Lawrence Livermore National Laboratory — We report on a technique for obtaining off-Hugoniot equation of state data on solid metals by a magnetically driven cylindrical liner implosion on Sandia's Z-machine (Z). The sample material is in an inner tube with an outer tube composed of Al that serves as the current carrying cathode. A shaped current pulse quasi-isentropically compresses the sample as it implodes. Photonic Doppler velocimetry measures the implosion velocity of the free inner surface of the sample material, and the explosion velocity of the return current anode free outer surface. The velocimetry measurements are used in conjunction with magnetohydrodynamic simulations and optimization to infer pressure and density in the sample. Results are presented for experiments on the Z-machine in which Ta, Cu, and Al samples were compressed to peak pressure 10 Mbar. Sandia National Laboratories is a multi-program laboratory managed and operated by Sandia Corporation, a wholly owned subsidiary of Lockheed Martin Corporation, for the U.S. Department of Energys National Nuclear Security Administration under contract DE-AC04-94AL85000.

**10:00AM R21.00009 Spall Response of Tantalum at Extreme Strain-Rates** , ERIC HAHN, Univ of California - San Diego, TIM GERMANN, Los Alamos National Laboratory, MARC MEYERS, Univ of California - San Diego — Strain-rate and microstructure play a significant role in the ultimate mechanical response of materials. Using non-equilibrium molecular dynamics simulations, we characterize the ductile tensile failure of single and nanocrystalline tantalum over multiple orders of magnitude of strain-rate. This comparison is extended to over nine orders of magnitude including experimental results from recent laser shock campaigns. Spall strength primarily follows a power law dependence with strain-rate over this extensive range. In all cases, voids nucleate heterogeneously at pre-existing defects. Predictions based on traditional theory suggest that, as strain-rate increases, tensile strength should increase. Alternatively, as grain size decreases, tensile strength may decrease due to an increased propensity to fail at a growing volume fraction of grain boundaries. Strain-rate and grain size dictate void nucleation sites by changing the type and density of available defects: vacancies, dislocations, twins, and grain boundaries.

**10:12AM R21.00010 Sound velocity in shock compressed molybdenum obtained by ab initio molecular dynamics**, TYMOFIY LUKINOV, ANATOLY BELONOSHKO, Royal Inst of Tech, SERGEY SIMAK, Linkping University — The sound velocity of Mo along the Hugoniot adiabat is calculated from first principles using density-functional theory based molecular dynamics. These data are compared to the sound velocity as measured in recent experiments. The theoretical and experimental Hugoniot and sound velocities are in very good agreement up to pressures of 210 GPa and temperatures of 3700 K on the Hugoniot. However, above that point the experiment and theory diverge. This implies that Mo undergoes a phase transition at about the same point. Considering that the melting point of Mo is likely much higher at that pressure, the related change in the sound velocity in experiment can be ascribed to a solid-solid transition.

**10:24AM R21.00011 Atomistic Simulation of shock induced dislocation dynamics and evolution of different plasticity mechanisms in Single Crystal Copper**, ANUPAM NEOGI, NILANJAN MITRA, Indian Institute of Technology Kharagpur — Deformation and observation of different types of plasticity mechanisms of FCC metals (e.g. Copper) under shock loading of various intensities has been investigated by several groups of researchers around the globe through different types of experiments and/or atomistic simulations. However, there still exists lacuna in this well researched area. In this study the temporal details of dislocation dynamics are provided. Simulations also demonstrate different types of temporal evolution of different loops observed for single crystal Cu under different intensities of shock loading. Observance of formation of twins and their temporal evolution at higher intensities of shock loading are also demonstrated as part of this study. Comparisons of these NEMD simulations using EAM potential are discussed with regards to different experimental and simulation studies in literature.

**10:36AM R21.00012 Effects of porosity on shock-induced melting of honeycomb-shaped Cu nanofoams.**, FENG PENG ZHAO, Institute of Systems Engineering, CAEP — Metallic foams are of fundamental and applied interests in various areas, including structure engineering (e.g., lightweight structural members and energy absorbers), and shock physics (e.g., as laser ablaters involving shock-induced melting and vaporization). Honeycomb-shaped metallic foams consist of regular array of hexagonal cells in two dimensions and have extensive applications and represent a unique, simple yet useful model structure for exploring mechanisms and making quantitative assessment. We investigate shock-induced melting in honeycomb-shaped Cu nanofoams with extensive molecular dynamics simulations. A total of ten porosities ( $\phi$ ) are explored, ranging from 0 to 0.9 at an increment of 0.1. Upon shock compression, void collapse induces local melting followed by supercooling for sufficiently high porosity at low shock strengths. While superheating of solid remnants occurs for sufficiently strong shocks at  $\phi < 0.1$ . Both supercooling of melts and superheating of solid remnants are transient, and the equilibrated shock states eventually fall on the equilibrium melting curve for partial melting. However, phase equilibrium has not been achieved on the time scale of simulations in supercooled Cu liquid (from completely melted nanofoams). The temperatures for incipient and complete melting are related to porosity via a power law and approach the melting temperature at zero pressure as  $\phi$  tends to 1.

**10:48AM R21.00013 Dynamic Behaviors of Materials under Ramp Wave Loading on Compact Pulsed Power Generators**, JIANHENG ZHAO, BINQIANG LUO, GUIJI WANG, TAO CHONG, FULI TAN, CANG LIU, CHENGWEI SUN, Institute of fluid physics, CAEP — The technique using intense current to produce magnetic pressure provides a unique way to compress matter near isentropically to high density without obvious temperature increment, which is characterized as ramp wave loading, and firstly developed by Sandia in 1998. Firstly recent advances on compact pulsed power generators developed in our laboratory, such as CQ-4, CQ-3-MMAF and CQ-7 devices, are simply introduced here, which devoted to ramp wave loading from 50 GPa to 200 GPa, and to ultrahigh-velocity flyer launching up to 30 km/s. And then, we show our progress in data processing methods and experiments of isentropic compression conducted on these devices mentioned above. The suitability of Gruneisen EOS and Vinet EOS are validated by isentropic experiments of tantalum, and the parameters of SCG constitutive equation of aluminum and copper are modified to give better prediction under isentropic compression. Phase transition of bismuth and tin are investigated under different initial temperatures, parameters of Helmholtz free energy and characteristic relaxation time in kinetic phase transition equation are calibrated. Supported by NNSF of China under contract No.11327803 and 11176002

**Session R22 DCMP: URu<sub>2</sub>Si<sub>2</sub> and Other Related Heavy Fermions** 321 - Adam Dioguardi, Los Alamos National Laboratory

**8:00AM R22.00001 Metamagnetism and Quantum Acoustic Oscillations in UPt<sub>3</sub>:**<sup>1</sup>, V. ULRICH, B SHIVARAM, Univ of Virginia — We present results of high resolution sound velocity measurements performed at the NHMFL, Tallahassee, in magnetic fields upto 33 T in a dilution refrigerator at temperatures down to 35 mK. For magnetic field parallel to the basal plane the observed quantum acoustic oscillations show a change in frequency as expected at the metamagnetic transition of 20 T. However, we find a similar abrupt change in frequency at 25 T for magnetic field parallel to the c-axis. The implications of this Fermi surface instability even though there is no metamagnetic transition in this orientation will be discussed.

<sup>1</sup>Work at the University of Virginia was supported through NSF DMR-0073456 and the NHMFL is supported by NSF and the State of Florida.

**8:12AM R22.00002 Antiferromagnetism and Hidden Order in Isoelectronic Doping of URu<sub>2</sub>Si<sub>2</sub>**, MURRAY WILSON, McMaster University, TRAVIS WILLIAMS, Oak Ridge National Laboratory, YIPENG CAI, ALANNAH HALLAS, TERESA MEDINA, TIMOTHY MUNSIE, McMaster University, SKY CHEUNG, LIAN LIU, BENJAMEN FRANDSEN, YASUTOMO UEMURA, Columbia University, GRAEME LUKE, McMaster University — URu<sub>2</sub>Si<sub>2</sub> has been studied for three decades to understand its unusual hidden order state. Doping of this compound on the Ru site usually causes the transition temperature to decrease and hidden order to transition to magnetic order. In contrast, the isoelectronic dopings Fe and Os cause a substantial increase in the transition temperature over a wide range of dopings, with Fe in particular mimicking applied hydrostatic pressure. However, until recently, the magnetic states of these dopings have not been well characterized. In the past year, neutron scattering results have been reported on Fe doping that show antiferromagnetism with moments that are twice as large as those measured for pure URu<sub>2</sub>Si<sub>2</sub> under pressure. In this talk we present an investigation of the magnetic properties of single crystal samples of URu<sub>2-x</sub>Fe<sub>x</sub>Si<sub>2</sub> and URu<sub>2-x</sub>Os<sub>x</sub>Si<sub>2</sub> by muon spin rotation ( $\mu$ SR) and susceptibility. Our  $\mu$ SR results demonstrate that both of these dopings show an antiferromagnetic ground state with internal fields comparable to pure URu<sub>2</sub>Si<sub>2</sub> under pressure. Interpretation of our data indicates that the evolution of magnetism with doping for both Fe and Os is driven by changes in hybridization.

**8:24AM R22.00003 Kondo bahavior in antiferromagnetic NpPdSn<sup>1</sup>**, K. SHRESTHA, Idaho National laboratory, K. PROKES, Helmholtz-Zentrum Berlin fr Materialien und Energie, Germany, J.-C. GRIVEAU, R. JARDIN, E. COLINEAU, R. CACIUFFO, R. ELOIRDI, European Commission, Institute for Transuranium Elements, Germany, K. GOFTRYK, Idaho National laboratory — Actinide-based intermetallics show a large variety of exotic physical phenomena mainly coming from 5f hybridization with both on-site and neighboring ligand states. Depending on the strength of these process unusual behaviors such as long-range magnetic order, Kondo effect, heavy-fermion ground state, valence fluctuations, and/or superconductivity have been observed. Here we report results of our extensive studies on NpPdSn. The compound crystalizes in hexagonal ZrNiAl-type of crystal structure and is studied by means of x-ray and neutron diffraction, magnetization, heat capacity, electrical resistivity, and thermoelectric power measurements, performed over a wide range of temperatures and applied magnetic fields. All the results revealed Kondo lattice behavior and antiferromagnetic ordering below 19 K. NpPdSn can be classified as a moderately enhanced heavy-fermion system, one of very few known amidst Np-based intermetallics.

**8:36AM R22.00004 A Model for the Polar Kerr Effect in the Hidden-Order Phase of URu<sub>2</sub>Si<sub>2</sub>**, LANCE BOYER, VICTOR YAKOVENKO, Univ of Maryland-College Park — We propose an explanation for the recent experiment [1], where an optical polar Kerr effect (PKE) was observed in the otherwise non-magnetic hidden-order phase of URu<sub>2</sub>Si<sub>2</sub>. In this experiment, a sample was cooled through the hidden-order transition in a strong magnetic field, which was then turned off at low temperature, and the PKE was then observed and measured on warm-up in the absence of magnetic field. We propose an explanation within the framework of a previously developed Ginzburg-Landau theory [2] for a complex order parameter, whose real and imaginary parts correspond to the hidden-order and magnetic states. The former corresponds to the hexadecapole operator as seen in experiment [3], while the latter has ferromagnetic and antiferromagnetic components of z-axis magnetization in a bilayer of URu<sub>2</sub>Si<sub>2</sub>. Exploring the energy landscape for the three competing states, we find to a metastable ferromagnetic local minimum induced by an external magnetic field and preserved after the field has been turned off, which can explain the observed PKE.

**8:48AM R22.00005 <sup>31</sup>P NMR Study of of URu<sub>2</sub>Si<sub>2-x</sub>P<sub>x</sub>**, KENT SHIRER, Univ of California - Davis, ANDREW GALLAGHER, RYAN BAUMBACH, National High Magnetic Field Laboratory, NICHOLAS CURRO, Univ of California - Davis — We report initial <sup>31</sup>P nuclear magnetic resonance measurements in single crystals of URu<sub>2</sub>Si<sub>2-x</sub>P<sub>x</sub> in the antiferromagnetic and paramagnetic phases. We compare these results with the undoped compound both at ambient pressure and under pressure.

**9:00AM R22.00006 Lifshitz transition in high magnetic fields in UPt<sub>2</sub>Si<sub>2</sub>: Magnetoresistivity, Hall effect, magnetostriction and Fermi surface**, S. SULLOW, D. SCHULZE GRACHTRUP, N. STEINKI, Institute of Physics of Condensed Matter, TU Braunschweig, D-38106 Braunschweig, Germany, Z. CAKIR, G. ZWICKNAGL, Institute of Mathematical Physics, TU Braunschweig, D-38106 Braunschweig, Germany, I. SHEIKIN, Laboratoire National des Champs Magnetiques Intenses, F-38042 Grenoble, France, M. JAIME, National High Magnetic Field Laboratory, Los Alamos National Lab., Los Alamos, NM, USA, J. A. MYDOSH, Kamerlingh Onnes Laboratory, Leiden University, 2300RA Leiden, The Netherlands — We have measured the magnetoresistivity and Hall effect of single crystalline UPt<sub>2</sub>Si<sub>2</sub> in DC magnetic fields up to 35 T at temperatures down to 50 mK. Moreover, we have carried out magnetostriction measurements in pulsed magnetic fields up to 55 T for temperatures down to 1.5 K. For the magnetic field applied along the *c* axis we observe strong changes in the Hall effect at the previously established field induced phase boundaries AFM I ↔ III and III ↔ V (see Ref. [1]). From a detailed analysis of the Hall effect, we find evidence for topological changes of the Fermi surface due to at least one Lifshitz transition. Furthermore, in the magnetoresistivity and magnetostriction data we find a distinct history dependent anomaly within phase III, indicative of a first order phase transition. We relate our findings to band structure calculations carried out under consideration of the concept of a dual nature of the uranium 5f electrons with different degrees of localization.

**9:12AM R22.00007 Raman scattering study on the hidden order and antiferromagnetic phases in URu<sub>2-x</sub>Fe<sub>x</sub>Si<sub>2</sub><sup>1</sup>**, HSIANG-HSI KUNG, Rutgers University, SHENG RAN, NORAVEE KANCHANAVATEE, University of California San Diego, ALEXANDER LEE, VIKTOR KRAPIVIN, KRISTJAN HAULE, Rutgers University, M. BRIAN MAPLE, University of California San Diego, GIRSH BLUMBERG, Rutgers University — The heavy fermion compound URu<sub>2</sub>Si<sub>2</sub> possesses an unusual ground state known as the “hidden order” (HO) phase below *T* = 17.5 K, which evolves into an large moment antiferromagnetic (LMAFM) phase under pressure. A recent Raman scattering study shows that an *A*<sub>2g</sub> symmetry (*D*<sub>4h</sub>) in-gap mode emerges in the HO phase, characterizing the excitation from a chirality density wave<sup>2</sup>. Here, we report Raman scattering results for single crystal URu<sub>2-x</sub>Fe<sub>x</sub>Si<sub>2</sub> with *x* ≤ 0.2, where the Fe substitution acts as chemical pressure, shifting the system’s ground state from HO to LMAFM. We found that the *A*<sub>2g</sub> mode softens with doping, vanishes at the HO and LMAFM phase boundary, then re-emerges and hardens with doping in the LMAFM phase. The relations between the *A*<sub>2g</sub> mode energy and the strength of the HO/LMAFM order parameters will be discussed in this talk.

<sup>2</sup>H. Kung, R.E. Baumbach, E.D. Bauer, V.K. Thorsmolle, W. Zhang, K. Haule, J.A. Mydosh and G. Blumberg *Science* **347**, 1339 (2015)

**9:24AM R22.00008 Hidden order to antiferromagnetic transition in URu<sub>2</sub>Si<sub>2</sub>**, JESSE HALL, MAHSA RAHIMI MOVASSAGH, MURRAY WILSON, GRAEME LUKE<sup>1</sup>, McMaster University, NORAVEE KANCHANAVATEE, KEVIN HUANG<sup>2</sup>, MARC JANOSCHEK<sup>3</sup>, M. BRIAN MAPLE, University of California San Diego, TOM TIMUSK<sup>4</sup>, McMaster University — The second-order phase transition in the heavy fermion compound URu<sub>2</sub>Si<sub>2</sub> continues to confound efforts to reveal its true nature, and bears the moniker “hidden order” with good reason. While the order parameter remains mysterious, antiferromagnetism is easily induced with modest chemical substitution. The proximity of these two phases offers tantalizing clues about the nature of the hidden order phase. We present data on the antiferromagnetic phase, revealing the similarities and the differences between the two phases, including evidence for effects above the transition temperature. The implications of these findings for the hidden order parameter will be discussed.

**9:36AM R22.00009 Electronic tuning of URu<sub>2</sub>Si<sub>2</sub> through ligand site substitution (Si → Ga and P)**, R. E. BAUMBACH, A. GALLAGHER, K. W. CHEN, NHMFL-FSU, S. CARY, FSU - Dept Chem. And Biochem., F. KAMETANI, ASC-NHMFL-FSU, D. GRAF, NHMFL-FSU, T. ALBRECHT-SCHMITT, FSU - Dept Chem. And Biochem., S. C. RIGGS, A. SHEKHTER, NHMFL-FSU — Materials that straddle the boundary between itinerant and local electronic behavior are exemplary hosts for novel phenomena, including unconventional superconductivity, anomalous magnetism, non-Fermi liquid behavior, and exotic electronic phases. The 5f-electron intermetallic URu<sub>2</sub>Si<sub>2</sub> is a well-known example, exhibiting an exotic ordered state (“hidden order”) and unconventional superconductivity. In spite of intense experimental and theoretical interest, understanding of the origin of these phenomena remains elusive. We report a study of URu<sub>2</sub>Si<sub>2</sub> using the new tuning parameter, ligand site substitution Si → L (L = Ga and P). While phosphorous substitution quickly suppresses both hidden order and superconductivity, gallium substitution has a mild effect, illustrating the marked difference between electron- and hole-doping on the ligand site for the physics of this compound. In an effort to disentangle these phenomena, we performed electrical transport and thermodynamic measurements. Electrical transport measurements in high magnetic fields are particularly illuminating, and provide insight into the evolution of the anomalous magnetoresistance, Fermi surface topology, electronic effective masses, and *g*-factor anisotropy. We discuss trends in these quantities for electron- and hole-doping and their implications for unraveling the behavior of URu<sub>2</sub>Si<sub>2</sub>.

**9:48AM R22.00010 Thermal expansion measurements on Fe substituted URu<sub>2</sub>Si<sub>2</sub><sup>1</sup>**, SHENG RAN, CHRISTIAN WOLOWIEC, INHO JEON, NAVEEN POUSE, NORAVEE KANCHANAVATEE, KEVIN HUANG, M. BRIAN MAPLE, Department of Physics and Center for Advanced Nanoscience, University of California, San Diego, USA, TYLER DAPRON, MARK WILLIAMSEN, DAVID SNOW, DINESH MARTIEN, STEFANO SPAGNA, Quantum Design, Inc., San Diego, USA — The search for the order parameter of the hidden order (HO) phase in URu<sub>2</sub>Si<sub>2</sub> has attracted an enormous amount of attention for the past three decades. The small antiferromagnetic moment of only ~0.03  $\mu_B$ /U found in the HO phase is too small to account for the entropy of ~0.2Rln(2) derived from the second order mean field BCS-like specific heat anomaly associated with the HO transition that occurs below T<sub>0</sub> = 17.5 K. A first order transition from the HO phase to a large moment antiferromagnetic (LMAFM) phase occurs under pressure. We have recently demonstrated that tuning URu<sub>2</sub>Si<sub>2</sub> by substitution of Fe for Ru reproduces the temperature vs applied pressure phase diagram and offers an opportunity to study the HO and LMAFM phases at atmospheric pressure. Motivated by this observation, we performed thermal expansion measurements on URu<sub>2-x</sub>Fe<sub>x</sub>Si<sub>2</sub> single crystals for various values of x in both the HO and LMAFM regions of the phase diagram. Interesting preliminary results have emerged from these studies that shed light on the LMAFM phase and its relationship with the elusive HO phase.

<sup>1</sup>Research in UCSD is supported by US DOE BES under Grant No.DE-FG02-04-ER46105(materials synthesis and characterization) and US NSF under Grant No.DMR-1206553(low temperature measurements).

**10:00AM R22.00011 Magnetic excitations in URu<sub>2</sub>Si<sub>2</sub> paramagnetic and Hidden Order phases**, NICHOLAS BUTCH, NIST - Natl Inst of Stds & Tech, MICHAEL MANLEY, Oak Ridge National Laboratory, JASON JEFFRIES, Lawrence Livermore National Laboratory, MARC JANOSCHEK, Los Alamos National Laboratory, KEVIN HUANG, M. BRIAN MAPLE, UC San Diego, AYMAN SAID, BOGDAN LEU, Argonne National Laboratory, JEFFREY LYNN, NIST - Natl Inst of Stds & Tech — We have mapped the lattice and magnetic excitations in heavy fermion URu<sub>2</sub>Si<sub>2</sub> via inelastic neutron and x-ray scattering measurements in the Hidden Order and paramagnetic phases. The magnetic excitations and phonons always respect the zone edges of the paramagnetic phase, showing no signs of reduced spatial symmetry. Features of the magnetic and lattice excitation spectra are associated with effects due to electronic interactions. Our results are inconsistent with simple local order parameters and density waves, and place constraints on models invoking Brillouin zone folding of the magnetic excitations. Phys. Rev. B 91, 035128 (2015)

**10:12AM R22.00012 Spin fluctuations and hidden-order phases in Ce-based Kondo systems<sup>1</sup>**, D. S. INOSOV, P. Y. PORTNICHENKO, A. S. CAMERON, TU Dresden, Germany, S. PASCHEN, A. PROKOFIEV, Vienna Univ. of Technology, Austria, G. FRIEMEL, H. JANG, B. KEIMER, MPI for Solid State Research, Germany, V. B. FILIPOV, N. Y. SHITSEVALOVA, Institute for Problems of Materials Science, Ukraine, A. SCHNEIDEWIND, Juelich Center for Neutron Science, Germany, A. IVANOV, J. OLLIVIER, Institut Laue-Langevin, France, P. P. DEEN, European Spallation Source, Sweden, A. M. STRYDOM, University of Johannesburg, South Africa — Among heavy-fermion metals, both CeB<sub>6</sub> and Ce<sub>3</sub>Pd<sub>20</sub>Si<sub>6</sub> compounds exhibit a magnetically hidden ordered phase in their low-temperature phase diagram, which is attributed to the ordering of magnetic quadrupolar moments, known as the antiferroquadrupolar (AFQ) ordering. Using inelastic neutron scattering, we have investigated the spectrum of spin excitations in both systems. In the structurally simplest CeB<sub>6</sub>, it consists of several contributions including conventional spin waves that coexist with both ferro- and antiferromagnetic excitonic resonance-like modes. However, the structurally more complex Ce<sub>3</sub>Pd<sub>20</sub>Si<sub>6</sub> possesses a much simpler magnetic excitation spectrum with only a single contribution peaked around the AFQ wave vector. It remains quasielastic in the absence of an external magnetic field, but then develops into dispersive magnon modes whose band width scales linearly with the applied field. Furthermore, neutron diffraction measurements on the same sample at sub-Kelvin temperatures revealed diffuse magnetic scattering that can be associated with the hidden order parameter.

**10:24AM R22.00013 Evidence for ferroquadrupole order in YbRu<sub>2</sub>Ge<sub>2</sub> from x-ray diffraction and elastoresistivity measurements**, ELLIOTT ROSENBERG, JIUN-HAW CHU, IAN FISHER, Stanford University, JACOB RUFF, CHESS — YbRu<sub>2</sub>Ge<sub>2</sub> undergoes a non-magnetic phase transition at 10K, several Kelvin above a phase transition to a magnetically ordered state that is characterized by a unidirectional incommensurate spin density wave. Here, we show via high-resolution x-ray diffraction that the non-magnetic phase transition corresponds to a continuous tetragonal-to-orthorhombic structural phase transition. Elastoresistance measurements in the tetragonal state indicate a divergence of the quadrupolar strain susceptibility in the B<sub>1g</sub> symmetry channel, implying that the structural phase transition is driven by quadrupolar order.

**10:36AM R22.00014 Evolution of superconductivity and magnetism in La<sub>1-x</sub>Yb<sub>x</sub>Ru<sub>2</sub>P<sub>2</sub>**, CONNOR RONCAIOLI, HALYNA HODOVANETS, SHANTA SAHA, JOHNPIERRE PAGLIONE, University of Maryland — LaRu<sub>2</sub>P<sub>2</sub>, with a 4.1 K transition, is the first known pnictide-based superconductor. Sharing structural and electronic elements similar to those of the unconventional Fe-pnictide superconductors, it is of interest to investigate the parameter space in which a superconducting ground state survives. We present preliminary indications of more interesting magnetic behavior and structural tuning behavior when paramagnetic Yb is substituted for La in La<sub>1-x</sub>Yb<sub>x</sub>Ru<sub>2</sub>P<sub>2</sub>, and investigate potential heavy fermion behavior in the Yb end-member of this series.

**Session R23 DMP GERA DCMP: Thermoelectrics-Nanostructures** 322 - Matthew Grayson, Northwestern University

**8:00AM R23.00001 Thermoelectric properties of  $\text{Mg}_2(\text{Ge}, \text{Sn})$  solid solutions<sup>1</sup>**, JIFENG SUN, DAVID J. SINGH, University of Missouri — Intermetallic compounds  $\text{Mg}_2\text{X}$  ( $\text{X} = \text{Si}, \text{Ge}, \text{Sn}$ ) and their solid solutions have attracted much attention as they are composed of environmental friendly and naturally abundant constituent elements and can be promising thermoelectric materials at intermediate temperature range (500 K - 1000 K). The figure of merit (ZT) of n-type  $\text{Mg}_2\text{X}$  solid solutions can reach up to 1.5. However, the p-type materials have much lower ZT values up to 0.38. In this talk, we will present the evolution of the thermoelectric properties of  $\text{Mg}_2(\text{Ge}, \text{Sn})$  solid solutions with a typical composition of  $\text{Mg}_2\text{Ge}_{0.5}\text{Sn}_{0.5}$  using first principles calculations combining with the experimental data. The ZT was optimized with respect to both doping concentrations and operating temperatures. Importantly, at 500 K - 1000 K temperature range we find ZT values up to 2 are possible for optimized n-type material within  $10^{19} \text{ cm}^{-3}$  to  $10^{20} \text{ cm}^{-3}$  carrier concentrations. But the p-type counterparts show inferior performance with ZT values ranging from 0.2 to 0.7.

**8:12AM R23.00002 Ab initio calculations of the vibrational and dielectric properties of  $\text{PbSnTe}$  alloys**, LUISA SCOLFARO, Texas State University, USA, A.R. REZENDE NETO, H.W. LEITE ALVES, Universidade Federal de Sao Joao del Rei, Brazil, J.E. PETERSEN, T.H. MYERS, Texas State University, USA, P.D. BORGES, Universidade Federal de Viosa, Brazil — Thermoelectric devices have promise in dealing with the challenges of the growing demand for alternative clean energy and Te-based materials well-known candidates for them. Recently [1], we have shown that the high values for the dielectric constant, together with anharmonic LA-TO coupling, reduces the lattice thermal conductivity and enhances the electronic conductivity in  $\text{PbTe}$ . Also, it was shown that by alloying this material with Se, the electronic conductivity of the alloys is also enhanced [2]. But, it is not clear if the same occurs when alloying with Sn. We show, in this work, our ab initio results for the vibrational and dielectric properties of  $\text{Pb}_{1-x}\text{Sn}_x\text{Te}$  alloys. The calculations were carried out by using the Density Functional Theory, and the alloys were described by both the Virtual Crystal Approximation and Cluster Expansion Method. Our results show that the anharmonic LA-TO coupling enhances and reach its maximum for Sn concentration values of 0.75, corresponding to the maximum value for the dielectric constant, which is higher than that obtained for  $\text{PbTe}$ . [1] H. W. Leite Alves, et al., Phys. Rev. B87, 115204 (2013). [2] Y. Pei, et al., Nature 473, 66 (2011).

**8:24AM R23.00003 Band Degeneracy, Low Thermal Conductivity, and High Thermoelectric Figure of Merit in  $\text{SnTe-CaTe}$  Alloys**, R. AL RAHAL AL ORABI, Department of Environmental Science and Engineering, Ewha Womans University, N. MECHOLSKY, Department of Physics and Vitreous State Laboratory, The Catholic University of America, J. P. HWANG, W. KIM, School of Mechanical Engineering, Yonsei University, J. S. RHYEE, Department of Applied Physics, College of Applied Science, Kyung Hee University, D. WEE, Department of Environmental Science and Engineering, Ewha Womans University, M. FORNARI, 5Department of Physics, Central Michigan University and Science of Advanced Materials Program — Pure lead-free  $\text{SnTe}$  has limited thermoelectric potentials because of the low Seebeck coefficients and the relatively large thermal conductivity. In this study, we provide experimental evidence and theoretical understanding that alloying  $\text{SnTe}$  with  $\text{Ca}$  greatly improves the transport properties leading to ZT of 1.35 at 873 K, the highest ZT value so far reported for singly doped  $\text{SnTe}$  materials. The introduction of  $\text{Ca}$  (0-9%) in  $\text{SnTe}$  induces multiple effects: (1)  $\text{Ca}$  replaces  $\text{Sn}$  and reduces the hole concentration due to  $\text{Sn}$  vacancies, (2) the energy gap increases limiting the bipolar transport, (3) several bands with larger effective masses become active in transport, and (4) the lattice thermal conductivity is reduced of about 70% due to the contribution of concomitant scattering terms associated with the alloy disorder and the presence of nanoscale precipitates. An efficiency of 10% (for  $\Delta T = 400 \text{ K}$ ) was predicted for high temperature thermoelectric power generation using  $\text{SnTe}$ -based n- and p-type materials.

**8:36AM R23.00004 Mode resolved modeling of phonon-structure interactions in semiconductor nanocomposites**, JOSEPH FESER, University of Delaware — Introducing nanoscale inhomogeneities into semiconductor alloys is a known route to enhance the scattering of long wavelength phonons and to subsequently reduce thermal conductivity. For key applications such as thermoelectric energy conversion materials, this must be done efficiently to avoid harming electronic functionality. Thus, key questions arise such as what type (i.e. contrast mechanisms), shape, size, and number density of particles should be used. This talk presents two new theoretical developments in this area from our group: (1) The use of continuum mechanics to analytically calculate exact phonon scattering cross sections of cylindrical and spherical shaped elastic discontinuities across the Mie regime, and their subsequent use in Boltzmann transport models of thermal transport and (2) the development of a new frequency-domain atomistic approach to simulate the scattering cross section of nanoparticles of arbitrary complexity for wavevectors spanning the entire Brillouin zone, and which can accommodate very large atomistic systems. Its advantages compared to Atomistic Green's functions and molecular dynamics will be discussed.

**9:12AM R23.00005 Thermal Conductivity of Nanocrystalline Silicon Prepared by Plasma-Enhanced Chemical-Vapor Deposition<sup>1</sup>**, BATTOGTOKH JUGDERSUREN, Sotera Defense Solutions, XIAO LIU, Naval Research Laboratory, BRIAN KEARNEY, DANIEL QUEEN, Natl Research Council, THOMAS METCALF, JAMES CULBERTSON, CHRISTOPHER CHERVIN, Naval Research Laboratory, MICHAEL KATZ, Natl Research Council, RHONDA STROUD, Naval Research Laboratory — Nanocrystallization by ball milling has been used successfully to reduce the thermal conductivity of silicon-germanium alloys ( $\text{SiGe}$ ) and turn them into useful thermoelectric materials at a temperature of a few hundred degrees C. Currently the smallest grain sizes in nanocrystalline  $\text{SiGe}$  are in the 10 nm range. Germanium is added to scatter short wavelength phonons by impurity scattering. In this work, we report a record low thermal conductivity in nanocrystalline silicon prepared by plasma-enhanced chemical-vapor deposition. By varying hydrogen to silane ratio, we can vary the average grain sizes from greater than 10 nm down to 3 nm, as determined by both the high resolution transmission electron microscopy and X-ray diffraction. The values of thermal conductivity, as measured by the  $3\omega$  technique, can be correspondingly modulated from that of ball-milled nanocrystalline  $\text{SiGe}$  to a record low level of 0.3 W/mK at room temperature. This low thermal conductivity is only about 1/3 of the minimum thermal conductivity limit of silicon. Possible causes of such a large reduction are discussed.

**9:24AM R23.00006 Thermal Investigations of Periodically Nanoporous Si Films — The Impact of Structure Sizes and Pore-Edge Amorphization**, DONGCHAO XU, HONGBO ZHAO, QING HAO, Department of Aerospace and Mechanical Engineering, University of Arizona — In recent years, nanoporous Si films have been intensively studied as promising thermoelectric materials, which mainly benefits from their dramatically reduced lattice thermal conductivity  $k_L$  and bulk-like electrical properties.<sup>1,2</sup> Despite many encouraging results, challenges still exist in the theoretical explanation of the observed low  $k_L$ .<sup>3</sup> Existing studies mainly attribute the low  $k_L$  to 1) phonon bandstructure modification by coherent phonon processes in a periodic structure (phononic effects), and/or 2) pore-edge defects. In this work, temperature-dependent  $k_L$  is measured for nanoporous Si films with different pore sizes and spacing to compare with model predictions. For systematic studies, two fabrication techniques are used to drill the nanopores: 1) reactive ion etching, and 2) a focus ion beam to introduce more pore-edge defects. The results from this work will provide guidance for phonon engineering in general materials with periodic interfaces or boundaries. References: 1. Tang et al., *Nano Letters* **10**, 4279-4283 (2010). 2. Yu et al., *Nature Nanotechnology* **5**, 718-721 (2010). 3. **9:36AM R23.00007 Thermoelectric Power of Nanocrystalline Silicon Prepared by Hot-Wire Chemical-Vapor Deposition<sup>1</sup>**, BRIAN KEARNEY, Natl Research Council, XIAO LIU, Naval Research Laboratory, BATTOGTOKH JUGDER-SUREN, Sotera Defense Solutions Inc., DANIEL QUEEN, Natl Research Council, THOMAS METCALF, JAMES CULBERTSON, CHRISTOPHER CHERVIN, RHONDA STROUD, Naval Research Laboratory, WILLIAM NEMETH, QI WANG, National Renewable Energy Laboratory — Although doped bulk silicon possesses a favorable Seebeck coefficient and electrical conductivity, its thermal conductivity is too large for practical thermoelectric applications. Thin film nanocrystalline silicon prepared by hot-wire chemical-vapor deposition (HWCVD) is an established material used in multijunction amorphous silicon solar cells. Its potential in low cost and scalable thermoelectric applications depends on achieving a low thermal conductivity without sacrificing thermoelectric power and electrical conductivity. We examine the thermoelectric power of boron-doped HWCVD nanocrystalline silicon and find that it is comparable to doped nanostructured silicon alloys prepared by other methods. Given the low thermal conductivity and high electrical conductivity of these materials, they can achieve a high thermoelectric figure of merit, ZT.

<sup>1</sup>Work supported by the Office of Naval Research

**9:48AM R23.00008 Anharmonicity Rise the Thermal Conductivity in Amorphous Silicon<sup>1</sup>**, WEI LV, ASEGUN HENRY, Georgia Institute of Technology — We recently proposed a new method called Direct Green-Kubo Modal Analysis (GKMA) method, which has been shown to calculate the thermal conductivity (TC) of several amorphous materials accurately. A-F method has been widely used for amorphous materials. However, researchers have found out that it failed on several different materials. The missing component of A-F method is the harmonic approximation and considering only the interactions of modes with similar frequencies, which neglect interactions of modes with large frequency difference. On the contrary, GKMA method, which is based on molecular dynamics, intrinsically includes all types of phonon interactions. In GKMA method, each mode's TC comes from both mode self-correlations (autocorrelations) and mode-mode correlations (crosscorrelations). We have demonstrated that the GKMA predicted TC of a-Si from Tersoff potential is in excellent agreement with one of experimental results. In this work, we will present the GKMA applications on a-Si using multiple potentials and gives us more insight of the effect of anharmonicity on the TC of amorphous silicon.

**10:00AM R23.00009 Designing SiGe superlattices and alloys for minimum thermal conductivity**, JIHUI NIE, PAWEL KEBLINSKI, Rensselaer Polytech Inst — We use equilibrium molecular dynamics simulations to study the thermal conductivity of SiGe alloys to design the structures for minimum thermal conductivity, which is desired, e.g., for better thermoelectric properties or thermal barriers coatings. We explore how a combination of layered/superlattice structures with a degree of random alloying is capable of effective scattering of both low frequency (long wavelength) and high frequency (short wavelength) phonons thus greatly reducing thermal conductivity. We will discuss strategies towards guided search for arrangements of alloy constituents that minimizes thermal conductivity.

**10:12AM R23.00010 Thermal Conductivity of Quantum Wires with Surface Roughness**, SELMAN HERSHFELD, KHANDKER MUTTALIB, Dept. of Physics, University of Florida — Quantum wires have been shown to have greatly reduced thermal conductivity compared to bulk systems because of the increased role of surface scattering. The lattice thermal conductance and conductivity is calculated in the harmonic approximation for a long quantum wire placed between two heat baths using the Landauer formula for phonons and a recursive Green function technique to compute the transmission probabilities. The width of the wires is varied in the transverse direction so as to have a root mean square value  $\sigma$  and correlation length  $L$ . As observed experimentally, we find that the thermal conductance is decreased with increasing  $\sigma$  and increased as  $L$  increases. The full scaling of the thermal conductance as a function of  $\sigma$ ,  $L$ , the width and the length of the sample is discussed. The simulations are also compared to approximate techniques such as modeling the surfaces as having diffusive scattering.

**10:24AM R23.00011 Probing the low thermal conductivity of single-crystalline porous Si nanowires**, YUNSHAN ZHAO, Natl Univ of Singapore, LINA YANG COLLABORATION, LINGYU KONG COLLABORATION, BAOWEN LI COLLABORATION, JOHN T L THONG COLLABORATION, KEDAR HIPPALGAONKAR COLLABORATION — Pore-like structures provide a novel way to reduce the thermal conductivity of silicon nanowires, compared to both smooth-surface VLS nanowires and rough EE nanowires. Because of enhanced phonon scattering with interface and decrease in phonon transport path, the porous nanostructures show reduction in thermal conductance by few orders of magnitude. It proves to be extremely challenging to evaluate porosity accurately in an experimental manner and further understand its effect on thermal transport. In this study, we use the newly developed electron-beam based micro-electrothermal device technique to study the porosity dependent thermal conductivity of mesoporous silicon nanowires that have single-crystalline scaffolding. Based on the Casino simulation, the power absorbed by the nanowire, coming from the loss of travelling electron energy, has a linear relationship with its cross section. The relationship has been verified experimentally as well. Monte Carlo simulation is carried out to theoretically predict the thermal conductivity of silicon nanowires with a specific value of porosity. These single-crystalline porous silicon nanowires show extremely low thermal conductivity, even below the amorphous limit. These structures together with our experimental techniques provide a particularly intriguing platform to understand the phonon transport in nanoscale and aid the performance improvement in future nanowires-based devices.

**10:36AM R23.00012 Effects of Ordered Stacking Faults on Electrical Transport Properties in Silicon Nanowires**, MARC COLLETTE, Concordia University, Montreal, OUSSAMA MOUTANABBIR, Ecole Polytechnique, Montreal, ALEXANDRE CHAMPAGNE, Concordia University, Montreal — Lattice defects in silicon nanowires (SiNWs) allow the exploration of the fundamental physics governing transport mechanisms. We study charge transport in SiNW transistors with stacking faults in the 3C sequence, producing local hexagonal ordering. This structure leads to polytype SiNWs with distinct properties for novel applications in thermoelectronics. Since charge carrier and phonon behavior depend on crystal structure, these planar defects affect the transport properties of the nanowire. We grow our SiNWs using a VLS method, with stacking faults induced during growth. Structural characterization of each SiNW is done with Raman spectroscopy to quantify hexagonality. Individual nanowires are located and contacted using different metals to understand the Schottky barrier of the contacts at the SiNWs. We suspend 2  $\mu\text{m}$ -long SiNW devices using a wet oxide etch to uncouple the SiNW from the substrate. We study the electrical properties by  $I$ - $V$  measurements across the FET device while modulating the applied back gate voltage. Our initial data show that the presence of stacking faults causes an increase in resistivity by two orders of magnitude, thus greatly hindering charge transport through the SiNW.

**10:48AM R23.00013 Electronic structures and related thermoelectric properties of  $\text{Pb}_7\text{Bi}_4\text{Se}_{13}$  using first principle calculations and Boltzmann transport theory**, MOHAMMED BENALI KANOUN, Al Faisal University, college of science — The electronic structure, optical and thermoelectric properties of  $\text{Pb}_7\text{Bi}_4\text{Se}_{13}$  have been investigated using a combination of Density functional theory and Boltzmann transport theory. We applied the generalized gradient approximation as exchange-correlation energy functional added to the Coulomb energy (U Hubbard term). The existence of Bi and Pb has required the spin-orbit coupling. The intensity data for  $\text{Pb}_7\text{Bi}_4\text{Se}_{13}$  were measured at 100 K and 300 K leading to consider  $\text{Pb}_7\text{Bi}_4\text{Se}_{13}$  in two phases. The valence band maximum emerges predominantly from Se- $p$  state with admixture of Bi- $p$  and Pb- $p$  states, while the conduction band minimum comes from Se- $d$  states. The optical absorption shows the possibility of smaller multiple direct and indirect inter-band transitions in the visible region. We computed Seebeck coefficient, electrical and thermal conductivities, figure of merit and power factor, as function of temperature using the Boltzmann transport theory.  $\text{Pb}_7\text{Bi}_4\text{Se}_{13}$  is a potential shielding material that can be used at visible and UV region for thermoelectric devices. The present results were validated by comparison with the available experimental measurements.

## Session R24 DCMF: Superfluid Helium 323 - Wei Guo, Maglab, Florida State University

### 8:00AM R24.00001 Textural domain walls in superfluid $^3\text{He-B}$ , TAKESHI MIZUSHIMA, Osaka University —

Owing to the richness of symmetry, the superfluid  $^3\text{He}$  serves as a rich repository of topological quantum phenomena. This includes the emergence of surface Majorana fermions and their quantum mass acquisition at the topological critical point.<sup>1</sup> Furthermore, the marriage of the prototype topological superfluid with nanofabrication techniques brings about a rich variety of spontaneous symmetry breaking, such as the formation of the stripe order and nontrivial domain walls. In this work, we examine the possible formation of textural domain walls in the superfluid  $^3\text{He-B}$  confined to a thin slab with a sub-micron thickness. When an applied magnetic field is much higher than the dipolar field, two nearly degenerate ground states appear, which are characterized by the Ising order associated with the spontaneous breaking of a magnetic order-two symmetry,  $\hat{\ell}_z = +1$  and  $-1$ . We here discuss the structure of the textural domain wall formed by the spatial modulation of the Ising order, such as low-lying quasiparticle excitations and spontaneous spin current. We also report bosonic modes bound to the textural domain wall.

### 8:12AM R24.00002 Chiral pair density wave phase of confined $^3\text{He-A}$ film, HAO WU, Dept. Physics, Northwestern University, JAMES A SAULS, Dept. Physics & Astronomy, Northwestern University —

The edge states of a  $^3\text{He-A}$  film are Weyl Fermions propagating in a direction determined by the chirality of the bulk phase, which leads to a non-vanishing spontaneous mass current on the edge. We report calculations of the reduction in the edge mass currents due to hybridization as a function of lateral confinement,  $D$ . Strong lateral confinement leads to a sequence of quantum phase transitions. The A phase undergoes a transition to a pair density wave (PDW) phase with broken translational symmetry at  $D_{c2} \sim 13\xi_0$ , and a transition to a polar state at  $D_{c1} \sim 9\xi_0$ . The order parameter for  $D_{c1} < D$  is calculated self-consistently. The resulting phase is a periodic array of chiral domains with opposite chirality separated by domain walls. The mass currents on the domain walls contradict the direction of current on the edges, which leads to separation into multiple regions of circulating current in each domain. The periodicity of PDW phase increases as confinement length  $D$  increases and eventually only one domain is left in the lateral confined film when  $D$  approaches  $D_{c2}$ . We calculated and compared the free energy of the confined single domain wall and the homogeneous A phase, and determined the phase boundary  $D_{c2} - T$ .

### 8:24AM R24.00003 Equilibrium helical order in radially confined superfluid $^3\text{He}^1$ , JOSHUA WIMAN, J A SAULS, Northwestern University —

An exciting prediction of confined superfluid  $^3\text{He}$  is the presence of spontaneously broken translational symmetry, resulting in a superfluid phase that has a different translational symmetry than that of the confining geometry. Such phases have been described theoretically in films, cylinders, and ribbons. We predict an inhomogeneous superfluid phase with helical order that is energetically stable within cylindrical channels of radius comparable to the Cooper pair coherence length. By incorporating extensions to standard Ginzburg-Landau (GL) strong-coupling theory that accurately reproduce the bulk phase diagram at high pressures and allow tuneable boundary conditions<sup>2</sup>, we find this new phase to be stable at both high and low pressures and favored by boundary conditions with strong pairbreaking. We present superfluid phase diagrams as functions of pressure, temperature, and channel radius showing the regions of stability for this “spiral” phase relative to those phases previously predicted for the channel. Transverse NMR frequency shifts are a possible experimental signature of this phase, and we present calculations of these shifts as functions of rf pulse tipping angle, field orientation, and temperature.

### 8:36AM R24.00004 Order parameter texture transition in superfluid $^3\text{He-B}$ in strained aerogel<sup>1</sup>, A.M. ZIMMERMAN, Northwestern University, J.I.A. LI, Columbia University, W.P. HALPERIN, Northwestern University —

The introduction of anisotropic impurity scattering into superfluid  $^3\text{He}$  using high porosity silica aerogel has proven to be a fruitful method of engineering both the phase and the order parameter texture of the superfluid<sup>2,3</sup>. We have observed an abrupt transition between two orthogonal order parameter textures at a temperature  $T_x \approx 1.9$  mK, in  $^3\text{He-B}$  confined in aerogel samples with anisotropy induced by mechanical compression along an axis  $\vec{\epsilon}$ . At this transition the order parameter, characterized by the quantization axis of the orbital angular momentum  $\hat{l}$ , changes from a configuration with  $\hat{l} \parallel \vec{\epsilon}$  below  $T_x$  to  $\hat{l} \perp \vec{\epsilon}$  above  $T_x$ . This transition is independent of the orientation of  $\vec{\epsilon}$  relative to the external magnetic field, as well as the magnitude of the applied field. This indicates that the textural transition is due to strain alone, with the anisotropic scattering from the aerogel favoring different orientations of  $\hat{l}$  above and below  $T_x$ .

### 8:48AM R24.00005 Phase diagram of a thin film of $^3\text{He}$ confined within a $1.08 \mu\text{m}$ deep cavity<sup>1</sup>, NIKOLAY ZHELEV, ABHILASH SEBASTIAN, ERIC SMITH, JEEVAK PARPIA, Cornell University —

We describe measurements of superfluid  $^3\text{He}$  confined to a high-aspect ratio cavity within the head of a high quality factor torsion pendulum. Superfluid phase diagram for the confined thin film of fluid is predicted to be radically different compared to that of the bulk. In particular, at low pressures at the onset of the A-B transition, a “stripe phase” of alternating degenerate domains of B phase is predicted to occur [1]. By tracking the torsion pendulum frequency and quality factor, we identify a well-defined superfluid transition for the fluid within the pendulum head. At lower temperatures, sharp transitions from the A phase to the B phase on cooling and a gradual transition from the B phase to the A phase on warming are observed. The values for the ratio of the cavity depth and the coherence length ( $D/\xi(T, P)$ ) at the transitions match well the values of the transitions seen in the NMR measurements of  $^3\text{He}$  confined to a 700 nm deep cavity [2]. At present, we do not see any evidence in our measurements that the “stripe phase” is realized at the A-B phase boundary.

## 9:00AM R24.00006 Dislocation motion in solid hcp $^3\text{He}$ <sup>1</sup>, JOHN BEAMISH, ZHI GANG CHENG, University of Alberta

— At temperatures above about 100 mK, dislocations reduce the shear modulus of hcp  $^4\text{He}$  by as much as 90%. This occurs when dislocations thermally unbind from the  $^3\text{He}$  impurities that pin them, becoming extraordinarily mobile. The elastic softening is accompanied by a thermally activated dissipation peak due to the  $^3\text{He}$  impurities. At higher temperatures the dissipation has an  $\omega T^4$  dependence caused by scattering of thermal phonons from moving dislocations. Previous measurements on the fermi solid, hcp  $^3\text{He}$ , showed a similar dislocation softening, but the corresponding dissipation was not measured. We have extended these measurements by measuring the temperature, amplitude and frequency dependence of both the shear modulus and the dissipation in hcp  $^3\text{He}$ . The dissipation behavior is very different from that of hcp  $^4\text{He}$ . Neither the impurity unbinding peak associated with the elastic softening, nor the high temperature phonon scattering dissipation, were observed. Instead, there is a large and non-thermally activated dissipation which is largest at low frequencies. We believe that this unexpected dissipation is associated with a new dislocation damping mechanism in  $^3\text{He}$ , perhaps associated with spin rearrangements caused by moving dislocations.

## 9:12AM R24.00007 Symmetry breaking field in $\text{UPt}_3$ and connection to superfluid $^3\text{He}$ <sup>1</sup>, WILLIAM HALPERIN, northwestern university

— The multiple superconducting phases of  $\text{UPt}_3$  in its temperature-field phase diagram are a strong indication of its unconventional order parameter. It is generally accepted that such a complex phase diagram with 3 different vortex phases are nearly degenerate, and would be so, except for the presence of a symmetry breaking field attributed to antiferromagnetism which appears at a temperature an order of magnitude higher than the superconducting transition.[1] I propose an alternative mechanism where the symmetry breaking field can be, in large part, ascribed to anisotropic electronic scattering from stacking faults. The success of the theory[2] in accounting for stabilization of anisotropic phases of superfluid  $^3\text{He}$  in globally anisotropic aerogel[3] suggests a similar consequence from anisotropic quasiparticle scattering in  $\text{UPt}_3$ . Specific heat measurements indicate that the temperature window of the more anisotropic A-phase, a direct measure of the strength of the symmetry breaking field, decreases systematically with fewer stacking faults. ## 9:24AM R24.00008 The Momentum Distribution of Liquid $^3\text{He}$ , Revisited<sup>1</sup>, PAUL SOKOL, MATTHEW BRYAN, Indiana Univ - Bloomington, TIMOTHY PRISK, Oak Ridge National Lab

— Liquid  $^3\text{He}$  is a system of fundamental importance to condensed matter physics because it is a prototypical example of a strongly interacting fermion system whose interactions are well known. Quantum Monte Carlo calculations predict that the atomic momentum distribution of liquid  $^3\text{He}$  contains a Fermi surface discontinuity and an average atomic kinetic energy in the range 12-13 K at saturated vapor pressure. A number of high-resolution neutron Compton scattering studies of liquid  $^3\text{He}$  have been described in the literature, with experimenters observing no Fermi surface discontinuity and obtaining kinetic energies in the range of 8-10 K. In this presentation, we reconsider measurements of the momentum distribution of liquid  $^3\text{He}$  taken at 500 mK under 0, 10, 15 bar of pressure [R.M. Dimeo *et al* Physica B 241-243, 952 (1998)]. We demonstrate that there is complete agreement between the experimental data and quantum Monte Carlo calculations when instrumental resolution and final state effect corrections are taken into account. We also consider the prospects for a direct observation of the Fermi surface discontinuity in liquid  $^3\text{He}$  using neutron Compton scattering.

## 9:36AM R24.00009 X-ray coherent diffractive imaging of quantum vortices in single helium droplets

, RICO MAYRO TANYAG, CHARLES BERNANDO, CURTIS JONES, LUIS GOMEZ, ANDREY VILESOV, University of Southern California, CAMILA BACELLAR, JAMES CRYAN, KATRIN SIEFERMANN, FELIX STURM, OLIVER GESSNER, Chemical Sciences Division, Lawrence Berkeley National Laboratory, KEN FERGUSON, SEBASTIAN CARRON, SEBASTIAN SCHORB, SLAC National Accelerator Laboratory, CHRISTOPH BOSTEDT, Argonne National Laboratory, LARS ENGLERT, Carl von Ossietzky University of Oldenburg, DENIS ANIELSKI, LUTZ FOUCAR, Max Planck Advanced Study Group at CFEL, JOACHIM ULLRICH, Physikalisch-Technische Bundesanstalt, DANIEL ROLLES, ARTEM RUDENKO, Kansas State University — Free, single, rotating superfluid  $^4\text{He}$  nanodroplets (diameter  $D = 200 - 2000$  nm, temperature  $T = 0.4$  K) containing a number of quantum vortices have been studied via ultrafast X-ray coherent diffraction imaging using a free electron laser. The droplets were doped with Xe atoms, which collect on the vortex cores and serve as a contrast agent. In order to obtain the instantaneous positions and shapes of the vortices from the diffraction images, a phase retrieval technique has been developed, which utilizes the droplet boundary as a physical support. The algorithm also uses the droplet's scattering phase as an input for the iterative phase reconstruction. The obtained reconstructions reveal a plethora of transient vortex configurations within the droplet. The details of the algorithm and the possible origin of the observed vortex configuration will be discussed.

## 9:48AM R24.00010 Investigation of Grid Turbulence in Superfluid $^4\text{He}$ with Improved Measurement Technique<sup>1</sup>, JIHEE YANG, GARY G. IHAS, University of Florida - Gainesville

— Quantum turbulence (QT), a tangle of quantized vorticity in a macroscopically correlated quantum fluid, can have many analogous aspects to classical turbulence. Understanding QT can give us insights into classical turbulence as well as fluids in general. We generate QT by pulling a grid through a  $4.6 \text{ cm} \times 4.6 \text{ cm}$  cross-section channel in superfluid  $^4\text{He}$ . Second sound, a temperature/entropy wave, is used to monitor vorticity,  $\omega$ . A resonant technique with high (3000) Q increases greatly the sensitivity of the measurement, but it requires a phase and amplitude locked tracking system which adheres to the resonant peak independent of frequency shifts. According to theories, the vorticity decays as  $\omega \sim t^{-11/10}$  or  $\omega \sim t^{-17/14}$  when the energy containing eddies are growing. When they saturate at the channel size, the vorticity begins decaying as  $\omega \sim t^{3/2}$ . These different decaying regions are examined in this large channel and compared to previous experiments that have been performed in  $1 \text{ cm}^2$  square channels<sup>2</sup>.

**10:00AM R24.00011 Anomalous Elasticity of  $^4\text{He}$  Films at the Quantum Phase Transition**, KEIYA SHIRAHAMA, Keio University, DAISUKE TAKAHASHI, Ashikaga Institute of Technology, TAKAYUKI KOGURE, HITOMI YOSHIMURA, RAMA HIGASHINO, Keio University —  $^4\text{He}$  films on solid substrates exhibit a quantum phase transition between localized (nonsuperfluid) and superfluid states by changing coverage  $n$ . We have made torsional oscillator (TO) studies for  $^4\text{He}$  films adsorbed on nanoporous glasses. A TO with localized films showed an apparent "supersolid" behavior, an increase in TO frequency  $f$  with broad peak in  $Q^{-1}$ . Combining with FEM analyses for TO's with different designs, we conclude that the behavior results from the softening of adsorbed  $^4\text{He}$  films at high temperatures. The features in  $f$  and  $Q^{-1}$  are fitted well to a Debye-like activation with a distributed energy gap  $\Delta$ , so the elasticity is accounted by thermal excitation of localized atoms to an "extended" state. As the critical coverage  $n_c$  approaches the gap decreases to zero with a powerlaw  $\Delta \propto (n - n_c)^{1.2}$ . Assuming that the  $^4\text{He}$  chemical potential  $\mu(n)$  is located in the middle of the gap, we can estimate the elastic constant  $\kappa^{-1} = n^2 \partial \mu / \partial n$ . The elasticity agrees with shear moduli of  $^4\text{He}$  films obtained from the FEM analysis within factor of three. The energetics proposed from the elastic behavior naturally explains other properties of He films adsorbed on disordered substrates.

**10:12AM R24.00012 Superfluidity, Bose-Einstein condensation and dimensions of liquid  $^4\text{He}$  in nanopores**<sup>1</sup>, LEANDRA VRANJEŠ MARKIĆ, Faculty of Science, University of Split, HR-21000 Split, Croatia, EU, HENRY GLYDE, Department of Physics and Astronomy, University of Delaware, Newark, Delaware 19716-2593, USA — Path integral Monte Carlo (PIMC) calculations of the superfluid fraction,  $\rho_S/\rho$ , and the one-body density matrix (OBDM) (Bose-Einstein condensation (BEC)) of liquid  $^4\text{He}$  confined in nanopores are presented. The goal is to determine the effective dimensions of the liquid in the nanopore. We simulate a cylinder of liquid of diameter  $d_L$  surrounded by 5 Å of inert solid  $^4\text{He}$  in a nanopore of diameter  $d$ ;  $d = d_L + 10$  Å [1]. The PIMC  $\rho_S(T)/\rho$  and OBDM scales as a 1D Luttinger Liquid at extremely small liquid pore diameters only,  $d_L = 6$  Å where the liquid atoms form a 1D line at the center of the pore. In the range  $8 \leq d_L \leq 22$  Å the PIMC  $\rho_S(T)/\rho$  scales as a 2D liquid. In this  $d_L$  range the liquid fills the pores in cylindrical layers. There is a cross over from 2D to 3D scaling at larger  $d_L \simeq 22$  Å. In the range  $8 \leq d_L \leq 22$  Å, the  $T_C$  predicted using the Kosterlitz-Thouless 2D scaling criterion of the OBDM agrees well with the  $T_C$  obtained from  $\rho_S(T)/\rho$ . Superflow observed in pores of diameter (18 <  $d$  < 32 Å) is apparently standard static superflow with the low  $T_C$  arising from its 2D character.

**10:24AM R24.00013 Dissipation in Nanoscale Superfluids**, ADRIAN DEL MAESTRO, University of Vermont, BERND ROSENOW, University of Leipzig — Pressure driven flow of a superfluid inside a narrow channel can be maintained by the nucleation of vortices and their resulting motion across the flow lines. The maximum velocity of the superfluid is set by a nucleation rate which crucially depends on the microscopic details of the vortices and flow profile. Within the kinetic vortex theory, we have determined the critical superfluid velocity inside a nanoscale constriction and obtain agreement with experimental results for superfluid helium-4 in nanopores. In the small pore limit, when the ratio of pore radius to correlation length is of order unity, we find a drastic suppression of the superfluid velocity that can be understood within the Langer-Ambegaokar-McCumber-Halperin theory of resistive fluctuations in thin superconducting wires.

**10:36AM R24.00014 High-Resolution Measurements of the Roton Lifetime in Nano-Confinement**<sup>1</sup>, MATTHEW BRYAN, Indiana University - Bloomington, TIMOTHY PRISK, SOULEYMANE DIALLO, EUGENE MAMONTOV, Oak Ridge National Lab, PAUL SOKOL, Indiana University - Bloomington — At very low temperatures, the phonon-roton spectrum of bulk superfluid helium is sharp and well-defined in energy. As the temperature is increased, the roton energy gap becomes smaller and the roton peak acquires a finite linewidth. The conventional understanding of this effect is that roton-roton scattering drives the softening and broadening of the roton mode where the mean free path is governed by the thermal population of rotons. It is an open question whether the roton mode follows the same behavior when the liquid is confined within sufficiently small mesopores. It is possible that the restricted geometry introduces a new length scale which controls the roton mean free path at low temperatures. We report high-resolution (4  $\mu\text{eV}$ ) measurements of the roton energy and linewidth within tubular, silica nanopores 2.8 nm in diameter. The new results provide a critical test of the idea that tight, nanoscale confinement modifies the energy and linewidth of the roton excitation.

**10:48AM R24.00015 Pressure driven flow studies of superfluid helium-4 through single, high aspect ratio nanopipes**, JEFFREY BOTIMER, PETER TABOREK, Univ of California - Irvine — We have measured flow rates of helium-4 through high aspect ratio (>10,000) single glass nanopipes and etched nanopores under the influence of a pressure drop. The initial diameter of the glass pipes is 200nm while the initial diameter of the nanopores is approximately 80nm; the diameter of both types of nanopipe were reduced using atomic layer deposition(ALD) of Al<sub>2</sub>O<sub>3</sub>. Flow rates were measured for a wide range of temperatures (0.8K to 3.0K), pressures (up to 40 atm), and pipe lengths (0.8 mm to 30 mm). We observed flow velocities in the range of 1-6 m/s which has a power law dependence on pressure. Flow appears to be governed by turbulence at low temperatures. We have found evidence for a critical pressure above which turbulent flow is eliminated. This critical pressure appears to depend on temperature.

**Session R25 DCMP: Superconductivity: Less Common Materials I** 324 - Harald Jeschke, Goethe-Universitt Frankfurt

**8:00AM R25.00001 Spin triplet superconductivity in a weak-coupling Hubbard model for the quasi-one-dimensional compound Li<sub>0.9</sub>Mo<sub>6</sub>O<sub>17</sub>**, CHRISTIAN PLATT, WEEJEE CHO, Department of Physics, Stanford University, ROSS H. MCKENZIE, School of Mathematics and Physics, University of Queensland, SRI RAGHU, Department of Physics, Stanford University — The purple bronze Li<sub>0.9</sub>Mo<sub>6</sub>O<sub>17</sub> is of interest due to its quasi-one-dimensional electronic structure and the possible Luttinger liquid behavior resulting from it. For sufficiently low temperatures, it is a superconductor with a pairing symmetry that is still to be determined. To shed light on this issue, we analyze a minimal Hubbard model for this material involving four Molybdenum orbitals per unit cell near quarter filling, using asymptotically exact perturbative renormalization group methods. We find that spin triplet odd-parity superconductivity is the dominant instability. Approximate nesting properties of the two quasi-one-dimensional Fermi surfaces enhance certain second-order processes, which play crucial roles in determining the structure of the pairing gap. Notably, we find that the gap has accidental nodes, i.e. it has more sign changes than required by the point-group symmetry.

**8:12AM R25.00002 Geometrical structures and electronic properties of Sm, K-doped chrysene**, XIAOHUI WANG, Beijing CSRC, SIMULATIONS OF PHYSICAL SYSTEM DIVISION TEAM — The discovery of superconductivity in potassium-doped picene (KxC<sub>22</sub>H<sub>14</sub>) has revitalized the research interest in polycyclic aromatic hydrocarbons (PAHs), and a large variety of PAHs superconductors have been reported afterwards, such as phenanthrene, coronene and 1,2,8, 9-dibenzopentacene. Recently a new PAHs superconductor, Sm-doped chrysene, with T<sub>c</sub> = 5 K was reported experimentally whose precise nature is still unknown. In this work, crystal structure search and electronic structure of A-doped chrysene, Ax-C<sub>18</sub>H<sub>12</sub> (A=Sm, K), have been studied by the first-principles density-functional theory using the projector augmented wave method based on the generalized gradient approximation implemented in the VASP package. We also include with van der Waals (vdW) corrections in the calculations, thus clarifying the dopant atoms positions and optimized crystal structures of doped superconducting chrysene. Our findings represent a significant step toward the understanding of superconductivity of PAHs.

**8:24AM R25.00003 Coulomb-induced pairing in a quarter-filled band model for  $\kappa$ -(BEDT-TTF)<sub>2</sub>X<sup>1</sup>**, W. WASANTHI DE SILVA, Mississippi State Univ, NILADRI GOMES, SUMIT MAZUMDAR, Univ of Arizona, R. TORSTEN CLAY, Mississippi State Univ —  $\kappa$ -(BEDT-TTF)<sub>2</sub>X is a two dimensional organic charge transfer solid superconductor with a hole density of one half per (BEDT-TTF) molecule. With one hole per dimer of molecules, the material is frequently described using an effective 1/2-filled band Hubbard model on an anisotropic triangular lattice. Within this effective model a metal to antiferromagnetic (AFM) semiconductor phase transition is found. Calculations beyond the mean field level, however, have shown absence of superconductivity within the model. We present the results of correlated-electron calculations on the  $\kappa$ -lattice for up to 64 BEDT-TTF molecules using the Constrained Path Monte Carlo (CPMC) and Path Integral Renormalization Group (PIRG) methods over a wide range of carrier density. We show that superconducting pair-pair correlations in this model are enhanced by electron-electron (e-e) interactions for d-wave pairing symmetry uniquely for hole density close to quarter-filling. Our results indicate that this enhancement of superconductivity is not related to the presence of AFM order, but to the strong tendency to spin-singlet formation in the quarter-filled band.

<sup>1</sup>Supported by DOE Grant DE-FG02-06ER46315 and NSF-CHE-151475

**8:36AM R25.00004 Quarter-filled systems with frustration: Candidate for correlated electron superconductivity<sup>1</sup>**, NILADRI GOMES, Univ of Arizona, W. WASANTHI DE SILVA, Mississippi State Univ, TIRTHANKAR DUTTA, Univ of Arizona, R. TORSTEN CLAY, Mississippi State Univ, SUMIT MAZUMDAR, Univ of Arizona — A necessary condition for superconductivity (SC) driven by electron correlation is that electron electron (e-e) interactions enhance superconducting pair-pair correlations, relative to the non-interacting limit. We present the results of high-precision calculations of superconducting pair-pair correlations on four different frustrated lattices over the complete range of carrier density  $0 < \rho < 1$  in each case. We find that pair correlations are enhanced relative to the noninteracting limit only for density  $\rho$  equal to or close to 0.5 (1/4 filling). At all other  $\rho$  pair correlations are suppressed by interactions. This enhancement is due to the proximity to a spin-gapped paired-electron crystal (PEC) state that occurs at  $\rho = 0.5$ . Our theory explains the pseudogap observed at high temperatures in many organic superconductors. The remarkable bandfilling specificity is an essential ingredient to understanding the mechanism of superconductivity in the two-dimensional organic charge-transfer solids as well as the many different families of other unconventional superconductors that share this bandfilling.

**8:48AM R25.00005 Quantum critical origin of the superconducting dome and the isotope effect in SrTiO<sub>3</sub><sup>1</sup>**, YARON KEDEM, JONATHAN EDGE, NORDITA, ULRICH ASCHAUER, NICOLA SPALDIN, ETH Zurich, ALEXANDER BALATSKY, NORDITA, Los Alamos National Laboratory — We expand the notion that quantum criticality can induce superconductivity, by proposing a concrete mechanism for superconductivity due to quantum ferroelectric fluctuations. To this end, we investigate the origin of superconductivity in doped SrTiO<sub>3</sub> (STO) using a combination of density functional and strong coupling theories within the framework of quantum criticality. Our density functional calculations of the ferroelectric soft mode frequency as a function of doping reveal a crossover related to quantum paraelectricity at a doping level coincident with the experimentally observed top of the superconducting dome. Thus, we suggest a model in which the soft mode fluctuations provide the pairing interaction for superconductivity carriers. Within our model, the low doping limit of the superconducting dome is explained by the emergence of the Fermi surface, and the high doping limit by departure from the quantum critical regime. This results in a prediction that the highest critical temperature will increase and shift to lower carrier doping with increasing <sup>18</sup>O isotope substitution, a scenario that is experimentally verifiable. In addition we show a connection between the isotope exponent of superconductivity and the critical exponent pertaining to quantum phase transition.

**9:00AM R25.00006 Structure and magnetism of oxygen-deficient SrTiO<sub>3</sub> surface**, SOHAM GHOSH, EFSTRATIOS MANOUSAKIS, Florida State Univ — Using density functional theory within a fully relaxed spin generalized gradient approximation we have investigated the structural, electronic and magnetic properties of the oxygen-deficient STO surface. We also study the role of the Rashba interaction to explain the observed momentum-spin correlations by spin and angle resolved photoemission spectroscopy.

**9:12AM R25.00007 Screening of the electron-phonon interaction in STO**, ALEXANDER EDELMAN, PETER LITTLEWOOD, Univ of Chicago — Strontium titanate is a bulk insulator that becomes superconducting at remarkably low carrier densities. Even more enigmatic properties become apparent at the strontium titanate/lanthanum aluminate (STO/LAO) interface and it is important to disentangle the effects of reduced dimensionality from the poorly-understood pairing mechanism. Recent experiments<sup>1</sup> measuring the electronic structure of the analogous strontium titanate surface have found a cross-over as a function of carrier density from a series well-resolved phonon replica bands to a single quasiparticle dispersion, with the crossover occurring at densities that correspond to the disappearance of superconductivity in the STO/LAO system. We interpret these results in a simple analytical model that extends an Engelsberg-Schrieffer theory of electrons coupled to a single longitudinal optic phonon mode to include the effects of electronic screening. As the carrier density increases, the effective dielectric function cuts off the long-range phonon interaction beyond the Thomas-Fermi screening length, eventually leaving only a uniform short-range coupling to the phonon bath. We additionally incorporate the effects of carrier density on the static dielectric properties of the interface.

**9:24AM R25.00008 A DFT study of electron-phonon mediated superconductivity in doped Mott-Hubbard proxy cubic-tetragonal copper monoxide**, PAUL GRANT, W2AGZ Technologies — We report our preliminary study of electron-phonon mediated Cooper pairing as a component underlying high temperature superconductivity, in the presence of a Hubbard U driven antiferromagnetic ground state, subject to itinerant carrier doping, in the copper oxide perovskites. Our model is based on a proxy CuO fcc cubic-tetragonal structure that contains the basic physics of the electronic structure of copper oxide perovskites readily amenable to numerical analysis. We explore its phase diagram as a function of carrier concentration and coulomb repulsion ranging from the pure Mott-Hubbard AF insulating state to that of a metallic Fermi liquid, focusing on those conditions which might manifest high temperature superconducting behavior. In the Fermi liquid state, we find clear evidence that superconductivity arises from Jahn-Teller instabilities in the CuO bond which guided Bednorz and Mueller on the path to their 1986 discovery.

**9:36AM R25.00009 The effect of pressure and doping on SrPt<sub>3</sub>P superconductor: First-principles calculations.**, ARMINDO S. CUAMBA, HONG-YAN LU, CHIN S. TING, Univ of Houston, ARMINDO S. CUAMBA, HONG-YAN LU, C.S. TING TEAM — Recently, experiments of resistivity and magnetization on SrPt<sub>3</sub>P under pressure and doping have been conducted by B. Jawdat et al., (Phys.RevB.91,094514(2015)), it was found that with the increase of pressure, the superconducting transition temperature T<sub>c</sub> first increases with the maximal at 0.99 Gpa and then decreases, while the Si doping suppress T<sub>c</sub>. In this work, we investigate the electronic and phonon properties of SrPt<sub>3</sub>P under pressure and partial replacement of P by Si, using first-principles method. When pressure increases from 0 to 0.7 Gpa the electron phonon coupling and T<sub>c</sub> increases, the calculated T<sub>c</sub> agrees with the experiments. For the doped case, SrPt<sub>3</sub>P<sub>0.5</sub>Si<sub>0.5</sub>, an additional hole pocket around M point in Brillouin zone is formed, almost all the phonon modes shifts into lower energy, and the density of states at the Fermi level decreases, which may explains the drop in T<sub>c</sub> observed experimentally.

**9:48AM R25.00010 Real-time study of light-enhanced superconductivity**, MICHAEL SENTEF, Max Planck Institute for the Structure and Dynamics of Matter, Hamburg, ALEXANDER KEMPER, North Carolina State University, ANTOINE GEORGES, Ecole Polytechnique and College de France, Paris, CORINNA KOLLATH, HISKP, University of Bonn — Resonant pumping of IR-active phonons with lasers enables the ultrafast control of the crystal lattice in solids [1]. It has been shown that transient states with significantly modified electronic properties can be created on picosecond time scales, such as a light-induced state at elevated temperatures with optical properties in close resemblance to those of a superconductor [2]. In our work, we investigate theoretically a situation in which a change of the electronic hopping leads to a modified density of states in real time [3]. This modification, together with electron-phonon coupling, enhances superconductivity if the system is at thermal equilibrium. Our study monitors the out-of-equilibrium time evolution of the electronic momentum distribution and the superconducting order parameter. We show that the condensate dynamics dominates the initial enhancement of superconducting order, and that energy dissipation through electron-phonon scattering helps this enhancement. [1] M. Frst et al., Nature Phys. 7, 854 (2011) [2] M. Mitrano et al., arXiv:1505.04529 [3] M. A. Sentef et al., arXiv:1505.07575

**10:00AM R25.00011 Ising Superconductivity and Majorana Fermions in Transition Metal Dichalcogenides**, TONG ZHOU, HONG-LIANG JIANG, NOAH, FANQI YUAN, KAM TUEN LAW, Physics Department, the Hong Kong University of Science and Technology — In monolayer transition metal dichalcogenides (TMDs), electrons in opposite K valleys are subject to opposite effective Zeeman fields, which are referred to as Ising spin-orbit coupling (SOC) fields. The Ising SOC, originated from in-plane mirror symmetry breaking, pins the electron spins in out-of-plane directions, and results in the newly discovered Ising superconducting states with strongly enhanced upper critical fields. In this work, we show that the Ising SOC generates equal-spin triplet Cooper pairs with spin polarization in the in-plane directions. Importantly, the spin-triplet Cooper pairs can induce superconducting pairings in a half-metal wire placed on top of the TMD and result in a topological superconductor with Majorana end states. Direct ways to detect equal-spin triplet Cooper pairs and the differences between Ising superconductors and Rashba superconductors are discussed.

**10:12AM R25.00012 A DMRG Study of MoS<sub>2</sub>**, JORDAN VENDERLEY, Cornell University — In a recent work, Hsu, Vaezi, and Kim predicted spatially modulated, topological superconductivity in a class of materials known as transition metal dichalcogenides (TMDs) by studying RG flow.<sup>1</sup> Since electrons can readily develop topological superconductivity at low temperatures when spin-degeneracy is lifted, their insight was to exploit the spin-splitting of the TMD valance band in k-space in order to induce p-wave pairing. With experimental efforts currently underway to realize this phenomenon, particularly in monolayer, hole-doped MoS<sub>2</sub>, it is important to have a non-perturbative check on this result. To this end, we employ a density matrix renormalization group (DMRG) approach to study MoS<sub>2</sub>. We probe the superconducting susceptibility of the system and explore the properties of its order parameter in order to confirm the predicted FF (Fulde-Ferrell) p<sub>x</sub>+ip<sub>y</sub> phase. A quantitative understanding of the Hamiltonian parameters will provide guidance in experimental efforts to realize this topological superconductor and help ensure that the proposed material will indeed exhibit the expected order. 1.) Y.-T. Hsu, A. Vaezi, E.-A. Kim. Topological modulated superconductivity in monolayer transition metal dichalcogenides, in preparation (2015).

**10:24AM R25.00013 Superconductivity in quasi-2d organic doped Mott insulators: a superconducting dome without an antiferromagnetic quantum critical point<sup>1</sup>**, A. -M. S. TREMBLAY, CHARLES-DAVID HÉBERT, Université de Sherbrooke, PATRICK SÉMON, Université de Sherbrooke and Rutgers University — Layered organic superconductors of the BEDT family are model systems for understanding the interplay of the Mott transition with superconductivity, magnetic order and frustration. Recent experimental studies on a hole-doped compound reveal an enhancement of superconductivity and a rapid crossover between two different conducting phases above the superconducting dome. Using plaquette cellular dynamical mean field theory with state of the art continuous-time quantum Monte Carlo calculations, we study this problem with the two-dimensional Hubbard model on the anisotropic triangular lattice. Phase diagrams are in broad agreement with experiment. As in the case of the cuprates, we find, at finite doping in the unstable normal state, a first-order transition between a pseudogap and a correlated metal. We make several experimental predictions. This work also clearly shows that the superconducting dome in organic superconductors is tied to the Mott transition and its continuation as a transition separating pseudogap phase from correlated metal in doped compounds, as in the cuprates. Contrary to heavy fermions for example, the maximum T<sub>c</sub> is definitely not attached to an antiferromagnetic quantum critical point. That can also be verified experimentally.

**10:36AM R25.00014 On the equilibrium of a extremely extended and diluted magneto-matter state subject to its weight.**, DANIEL BERDICHEVSKY, Independent Scholar — Solutions to the force relationship between the magnetic stresses and the self-gravitational force are discussed for a simple homogeneous distribution of matter coalescent to a magnetic field in a cylindrical geometry. Consideration are given to the needed permeability of the medium to make it capable of supporting many times the mass of the Sun, on an extension of several parsecs to kiloparsec. This state of self organization of matter and magnetic field (magneto-matter state) has proven useful interpretation for the explanation of anomalous thermodynamic of the gas of electrons contained in flux-tubes with a twist, low-beta, often observed at 1 AU in the interplanetary medium, Berdichevsky and Shefers, 2015. This state of matter, which most basic property, the freezing in the magnetic field, see e.g., Chew et al, 1956, has proved to exist in the regions where robotic observations in the near and far space perform detailed observations of magnetic fields, and extreme dilute plasma (commonly about 1000 to 0.1 or less ionized particles per cubic cm). This work is in many ways an extension of Alfven work on magnetized space plasmas, Alven, 1942. Berdichevsky, D.B., and K., Schefers, ApJ, 803, 70, 2015, doi: 10.1088/0004-637X/805/1/70 Chew, G.F., M.L., Goldberger, and F.E. Low, 1956, the Royal Soc. **8:00AM R26.00001 Topological Phonon-Plasmon Modes in Two-Dimensional Ferromagnetic Wigner Crystal of Electrons**, WENCHENG JI, JUNREN SHI, Peking Univ — We show that a two-dimensional ferromagnetic Wigner crystal of electrons confined in a semiconductor quantum well/heterostructure with spin-orbit coupling and an appropriate sign of  $g$ -factor could be transformed to a topological phonon-plasmon system by applying a weak perpendicular magnetic field. The competition between the magnetic field and the spin-orbit coupling will drive a topological phase transition, resulting in a topologically trivial phonon-plasmon system in the high magnetic field. We demonstrate the existence of chiral edge phonon-plasmon modes in finite size samples for both phases, and the robustness of the chiral edge modes in the topological phase. We estimate parameters for a few commonly used semiconductors, such as GaAs, GaAl, InAs and InSb. Moreover, we rule out the possibility of Wigner crystal of holes as a topological phonon-plasmon system, due to the unfavorable form of spin-orbit coupling in hole bands dictated by symmetry.

**8:12AM R26.00002 Electron transport calculations with Wannier functions in van der Waals heterostructures**, WUSHI DONG, ALEJANDRO LOPEZ-BEZANILLA, PETER LITTLEWOOD, University of Chicago, Argonne National Laboratory, ANDREAS ROELOFS' GROUP AT ARGONNE NATIONAL LAB COLLABORATION — The vertical stacking of 2D materials forming van der Waals heterostructures (vdWHs) exhibits a wide range of interesting properties. A combined approach based on the Green's function formalism and a mean-field description of the electronic structure is used to calculate vertical electron transport in vdWHs. Tight-binding parameters obtained from Maximally Localized Wannier Functions enable us to model quantum electron transport at low computational costs. Our analysis of electron transport efficiencies provides the foundation and motivation for experimental works.

**8:24AM R26.00003 Interlayer coupling in few-layers transition metal dichalcogenides**, BOXIAO CAO, TIANSHU LI, George Washington Univ — The vertically heterostructured transition metal dichalcogenides (TMD) few-layers may display a wide range of lattice registry. By density functional theory and numerical structural analysis, we examined both the atomic and electronic structures of arbitrarily stacked TMD few-layers. It is shown [1] that the variation of indirect band gap in MoS<sub>2</sub> bilayers is mainly attributed to the interlayer sulfur-sulfur (S-S) interaction. We developed a structural model that allows understanding such interaction under an arbitrary stacking sequence. It is shown the arbitrarily stacked MoS<sub>2</sub> bilayers should exhibit a weak twist angle dependence on the magnitude of its indirect band gap, except for those special twist angles that recover high symmetry stacking sequences. Our analysis provides a thorough theoretical explanation to the recently measured photoluminescence spectroscopy and can form the basis for understanding the coupling in other vertically heterostructured TMD few-layers. For example, through a close experimental collaboration, we have recently identified the electronic origin for the metallization of WS<sub>2</sub> under high hydrostatic pressure (up to 35 GPa) [2].

**8:36AM R26.00004 First-principles study of electric and magnetic properties of an F4TCNQ ribbon on graphene**, HYUNGJU OH, SINISA COH, Univ of California - Berkeley, YOUNG-WOO SON, Korea Institute for Advanced Study, MARVIN COHEN, Univ of California - Berkeley — We present density functional calculations on the electrical and magnetic properties of a ribbon of tetrafluoro-tetracyanoquinodimethan (F4TCNQ) molecules deposited on a graphene sheet. We find that doping the system with electrons results in a spatial variation of the Dirac point energy along the direction perpendicular to the ribbon, which makes a p-n junction configuration in the graphene sheet. In addition, ferromagnetism appears in the ribbon and the ferromagnetic moments can be controlled by the electron doping. This work was supported by NSF Grant No. DMR10-1006184 and the U.S. Department of Energy under Contract No. DE-AC02-05CH11231. Computational resources have been provided by the DOE at Lawrence Berkeley National Laboratory's NERSC facility.

**8:48AM R26.00005 RKKY interaction in triangular MoS<sub>2</sub> nanoflakes<sup>1</sup>**, DIEGO MASTROGIUSEPPE, Instituto de Fisica Rosario, OSCAR AVALOS-OVANDO, SERGIO ULLOA, Ohio University — Transition-metal dichalcogenides (TMDs), such as MoS<sub>2</sub>, possess unique electronic and optical properties, making them promising for optospintronics. Exfoliation and CVD growth processes produce nanoflakes of different shapes, often triangular with zigzag edges [1]. Magnetic impurities in this material interact indirectly through the TMD conduction electrons/holes. Using an effective 3-orbital tight-binding model [2], we study the Ruderman-Kittel-Kasuya-Yosida interaction between magnetic impurities in p-doped triangular flakes with zigzag termination. We analyze the interaction as function of impurity separation along high symmetry directions in the nanoflake, considering hybridization to different Mo orbitals, and different fillings. The interaction is anisotropic for impurities in the interior of the flake. However, when impurities lie on the edges of the crystallite, the effective exchange is Ising-like, reflecting the presence of z<sup>2</sup>-orbitals associated with edge states. Other interactions are possible by selecting impurity positions and orbital character of the states in their neighborhood. Our results can be tested with local probes, such as spin-polarized STM. **9:00AM R26.00006 Symmetry origins of the 'caldera' valence band distortion in 2D semiconductors**, PENGKE LI, IAN APPELBAUM, Univ of Maryland-College Park, PHYSICS DEPARTMENT TEAM — The electronic structures of many two-dimensional van der Waals semiconductors exhibit various fascinating properties distinct from their three-dimensional bulk counterparts. Through an examination of their lattice symmetries, we identify several universal factors dictating their band dispersion in the monolayer limit, where in-plane mirror symmetry and quantum confinement play critical roles. Taking group-III metal monochalcogenides (such as GaSe) as an example, we reveal the origin of the unusual 'caldera' shape of the valence band edge (otherwise inelegantly dubbed an 'upside down Mexican hat'), which we show is surprisingly common among other 2D semiconductors (such as in phosphorene for  $\text{S}_k\text{S}_k$  along its zigzag direction). Reference: arXiv:1508.06963

**9:12AM R26.00007 First-principles simulations of Graphene/Transition-metal-Dichalcogenides/Graphene Field-Effect Transistor<sup>1</sup>**, XIANGGUO LI, YUN-PENG WANG, X. -G ZHANG, HAI-PING CHENG, Univ of Florida - Gainesville — A prototype field-effect transistor (FET) with fascinating properties can be made by assembling graphene and two-dimensional insulating crystals into three-dimensional stacks with atomic layer precision. Transition metal dichalcogenides (TMDCs) such as WS<sub>2</sub>, MoS<sub>2</sub> are good candidates for the atomically thin barrier between two layers of graphene in the vertical FET due to their sizable bandgaps. We investigate the electronic properties of the Graphene/TMDCs/Graphene sandwich structure using first-principles method. We find that the effective tunnel barrier height of the TMDC layers in contact with the graphene electrodes has a layer dependence and can be modulated by a gate voltage. Consequently a very high ON/OFF ratio can be achieved with appropriate number of TMDC layers and a suitable range of the gate voltage. The spin-orbit coupling in TMDC layers is also layer dependent but unaffected by the gate voltage. These properties can be important in future nanoelectronic device designs.

**9:36AM R26.00009 Optical Properties of the  $\alpha$ -T<sub>3</sub> Model**, EMILIA ILLES, University of Guelph, JULES CARBOTTE, McMaster University, ELISABETH NICOL, University of Guelph — The  $\alpha$ -T<sub>3</sub> model, recently introduced by Raoux et. al [1], provides a continuous evolution between the honeycomb lattice of graphene and the T<sub>3</sub> or dice lattice. It is characterized by a variable Berry phase that changes continuously from  $\pi$  to 0. We present our calculations of optical properties of the  $\alpha$ -T<sub>3</sub> model, including the Hall quantization and optical conductivity, with an emphasis on the effect of the variable Berrys phase of the model. In particular, we describe the continuous evolution of the Hall quantization from a relativistic to a non-relativistic regime. [1] A. Raoux, M. Morigi, J.-N. Fuchs, F. Piechon, and G. Montambaux, Phys. Rev. Lett. 112, 026402 (2014)

**9:48AM R26.00010 Microscopic modeling of nitride intersubband absorbance<sup>1</sup>**, INES MONTANO, A.A. ALLERMAN, Sandia Natl Labs, J.J. WIERER, Lehigh University, M. MOSELEY, E.J. SKOGEN, A. TAUKE-PEDRETTI, G.A. VAWTER, Sandia Natl Labs — III-nitride intersubband structures have recently attracted much interest because of their potential for a wide variety of applications ranging from electro-optical modulators to terahertz quantum cascade lasers. To overcome present simulation limitations we have developed a microscopic absorbance simulator for nitride intersubband devices. Our simulator calculates the band structure of nitride intersubband systems using a fully coupled 8x8 k.p Hamiltonian and determines the material response of a single period in a density-matrix-formalism by solving the Heisenberg equation including many-body and dephasing contributions. After calculating the polarization due to intersubband transitions in a single period, the resulting absorbance of a superlattice structure including radiative coupling between the different periods is determined using a non-local Green's-function formalism. As a result our simulator allows us to predict intersubband absorbance of superlattice structures with microscopically determined lineshapes and linewidths accounting for both many-body and correlation contributions.

**10:00AM R26.00011 Enhancement of bulk photovoltaic effect in band inversion topological phase transitions**, LIANG TAN, ANDREW RAPPE, Univ of Pennsylvania — The bulk photovoltaic effect (BPVE) is the generation of photocurrents in the bulk of a single-phase material. The dominant mechanism for the BPVE is the shift current, a non-linear optical effect which involves the excitation of carriers into current-carrying coherent superpositions. This mechanism has a number of advantages over traditional photovoltaics, such as above-band gap photovoltages, and current generation in the bulk. In this work, we show that the shift current BPVE can be enhanced in materials with band inversion topological phase transitions. Using first-principles calculations, we show that the magnitude of the shift current is sharply increased in the vicinity of the band inversion transition, and that the direction of the shift current changes abruptly at the band inversion transition. Taking as examples layered BiTeI and perovskite CsPbI<sub>3</sub>, we demonstrate that this effect is robust across different materials systems. To understand these results, we analyze our results using a low-energy effective Hamiltonian and derive the functional form of the shift current lineshape near the band gap energy.

**8:00AM R27.00001 New phases from interacting Majorana fermions in one dimension**, MARCEL FRANZ, ARMIN RAHMANI, XIAOYU ZHU, IAN AFFLECK, University of British Columbia — Vortices in the Fu-Kane model (describing a superconducting surface of a 3D topological insulator) are known to host Majorana zero modes. By adjusting a single system parameter – the global chemical potential – the zero modes can be tuned to the regime of strong interactions. The simplest interacting system that can be built from these ingredients is a 1D Majorana chain with nearest neighbor hopping and the most local 4-fermion interaction. The system exhibits a complex phase diagram with interesting phases and phase transitions between them. For repulsive interactions we find an interesting gapless phase with coexisting Luttinger liquid and Ising degrees of freedom. The latter is separated from a 4-fold degenerate gapped phase at strong coupling by a novel generalization of the commensurate-incommensurate transition.

**8:12AM R27.00002 Supersymmetry from Strongly Interacting Majoranas<sup>1</sup>**, ARMIN RAHMANI, XIAOYU ZHU, MARCEL FRANZ, IAN AFFLECK, UBC — We show that a strongly interacting chain of Majorana zero modes exhibits a supersymmetric quantum critical point corresponding to the tricritical Ising model, separating the Ising critical phase from a doubly degenerate gapped phase. The supersymmetry extends into a gapped phase. We identify the signatures of our predictions in tunneling experiments.

**8:24AM R27.00003 Quantum phase transition in a strongly interacting 2D model of Majorana fermions**, BO-HAI LI, SHAO-KAI JIAN, HONG YAO, Institute for Advanced Study, Tsinghua Univ — Abstract: We study a 2D strongly-interacting time-reversal-invariant system consisting of Majorana fermions on the square lattice. This model may be realized as an Abrikosov vortex lattice in the superconducting surface state of a strong topological insulator. From the mean-field calculations, we show that for strong interactions a time-reversal-symmetry breaking phase occurs with chiral edge states. We further investigate the quantum critical behavior at the phase transition point by renormalization group analysis.

**8:36AM R27.00004 Landau levels of Majorana fermions in a spin liquid**, STEPHAN RACHEL, TU Dresden, LARS FRITZ, Utrecht University, MATTHIAS VOJTA, TU Dresden — Majorana fermions, originally proposed as elementary particles acting as their own antiparticles, can be realized in condensed-matter systems as emergent quasiparticles, a situation often accompanied by topological order. Here we propose a physical system which realizes Landau levels highly degenerate single-particle states usually resulting from an orbital magnetic field acting on charged particles for Majorana fermions. This is achieved in a variant of a quantum spin system due to Kitaev which is distorted by triaxial strain. This strained Kitaev model displays a spin-liquid phase with charge-neutral Majorana-fermion excitations whose spectrum corresponds to that of Landau levels, here arising from a tailored pseudo-magnetic field. We show that measuring the dynamic spin susceptibility reveals the Landau-level structure by a remarkable mechanism of probe-induced bound-state formation.

**8:48AM R27.00005 MOVED TO M1.377 —**

**9:00AM R27.00006 Johnson noise thermometry reveals the Dirac fluid in graphene**, JESSE CROSSNO, JING SHI, KE WANG, XIAOMENG LIU, ACHIM HARZHEIM, ANDREW LUCAS, SUBIR SACHDEV, PHILIP KIM, Harvard University, TAKASHI TANIGUCHI, KENJI WATANABE, National Institute for Material Science, Japan, THOMAS OHKI, KIN CHUNG FONG, Raytheon BBN Technologies — Near the charge neutrality point in graphene, the Fermi surface vanishes leading to the formation of a strongly-interacting quasi-relativistic electron-hole plasma, known as a Dirac fluid. These non-Fermi liquids share many features with quantum critical systems including a fast electron-electron scattering rate which makes them well suited to hydrodynamic descriptions. A number of exotic properties have been predicted including a diverging thermal conductivity resulting in the breakdown of the Wiedemann-Franz (WF) law. I will discuss the experimental technique—based on Johnson noise thermometry—used to measure the electronic thermal conductivity of graphene and probe the unique transport dynamics of the Dirac fluid.

**9:12AM R27.00007 Transport in inhomogeneous quantum critical fluids and in the Dirac fluid in graphene**, ANDREW LUCAS, JESSE CROSSNO, PHILIP KIM, SUBIR SACHDEV, Harvard University, KIN CHUNG FONG, Raytheon BBN — We present a hydrodynamic theory of transport in quantum critical fluids, disordered on long wavelengths due to fluctuations in the chemical potential. We argue that this approach is also well-suited to the Dirac fluid in graphene near the charge-neutrality point. Numerical simulations of this theory are compared to recent experiments on thermal and electric transport in clean samples of charge-neutral graphene. We obtain substantially improved quantitative agreement with data over existing hydrodynamic models. This provides evidence that the Dirac fluid behaves as a strongly interacting electronic fluid with transport governed by essentially classical collective phenomena. This work makes quantitative contact between AdS/CMT-inspired models of transport and an experimentally realized condensed matter system for the first time.

**9:24AM R27.00008 Dimensional Crossover from 2D Fermi liquids to 1D Luttinger liquids<sup>1</sup>**, JIA-HUA GU, KAI SUN, Univ of Michigan - Ann Arbor — We demonstrate an analytic theory for the crossover between Fermi liquids and Luttinger liquids. By deforming the Fermi surface of a 2D Fermi liquid towards perfect nesting, we show that signatures of Luttinger liquids arise. In the crossover regime, bosonic particles emerge from the fermionic theory, whose the spectral weight characterize the crossover towards 1D Luttinger liquids. At perfect nesting, these bosonic modes recover the bosonization formalism for Luttinger liquids. Spin-charge separation and instabilities due to attractive interactions are also studied.

**9:36AM R27.00009 Numerical study on a random 4-fermion interaction model of a strange metal**, WENBO FU, SUBIR SACHDEV, Department of Physics, Harvard University — We use exact diagonalization (ED) method to study the infinite range random 4 fermion model [1] of a strange metal. We examine the Greens function and show that ED result is in agreement with the large N result in the scaling limit [2]. We also examine the thermal entropy; this has an increasing trend as we increase the system size in the low temperature regime, and is consistent with large N high temperature expansion in the high temperature regime. [1] S. Sachdev, arXiv:1506.05111 [2] S. Sachdev and J. Ye, Phys. Rev. Lett. 70, 3339 (1993)

**9:48AM R27.00010 Electronic transport and Luttinger behavior in polymer thin films in the quasi-atomic limit<sup>1</sup>**, AARON SZASZ, RONI ILAN, Univ of California - Berkeley, JOEL MOORE, Univ of California - Berkeley, Lawrence Berkeley National Laboratory — Recent experiments have shown two-dimensional polymer films to be promising materials for thermoelectric devices, but some of the observed properties are not well understood. To better understand these materials, we introduce a new model in which each polymer is a Luttinger liquid and the polymers are weakly coupled to each other. This approximation of strong interactions within each polymer and weak coupling between them is the “quasi-atomic limit.” We find integral expressions for transport coefficients, including the electrical and thermal conductivities and the thermopower, and we extract their power law dependencies on temperature. Luttinger liquid physics is manifested in a violation of the Wiedemann-Franz law.

<sup>1</sup>This research was supported by the AFOSR MURI program.

**10:00AM R27.00011 Fractionalization beyond Luttinger Liquid in the spectroscopy of Lithium Purple Bronze<sup>1</sup>**, LERA NATALIA, CIC nanoGUNE San Sebastian Spain, ALVAREZ JOSE, Universidad Autonoma de Madrid — We offer an interpretation for the departures of ARPES and STS spectroscopies experiments in quasi-one-dimensional Lithium Purple Bronze (LiPB) from single-band Luttinger Liquid (LL) theory. We base our calculation on a phenomenological description of the published data proposed in the original experiments and consider two bands crossing the Fermi level. We discuss the breakdown of the LL scaling relation  $\eta = \alpha - 1$ , the separation of the spinon edge and the holon peak, the phenomenological TL fit to the Energy Distribution Curves (EDC) and the survival of power-like density of states down to 4K. We consider non-critical fluctuations in one of the separated modes in which the electron fractionalize, and discuss under which conditions could be related with the upturn in the resistivity at 20-30K. We discuss the possibility of a gap in such separated mode and its role on the robust one-dimensional behavior. The connection with the proposed triplet superconductivity is at  $T = 1.4K$  is also studied.

<sup>1</sup>We acknowledge financial support from MINECO FIS2012-37549-C05-03.

**10:12AM R27.00012 Universal Symmetry-Protected Resonances in a Spinful Luttinger Liquid**, YICHEN HU, CHARLES KANE, Univ of Pennsylvania — We study the problem of resonant tunneling through a quantum dot in a spinful Luttinger liquid. It provides the simplest example of a  $(0+1)$ d system with symmetry-protected topological phases. Transitions between different symmetry-protected topological phases separated by fixed points are achieved by tuning the system through resonance. For a particular interaction strength (Luttinger parameter  $g_\rho = \frac{1}{3}$ ,  $g_\sigma = 1$ ), we show that the problem is equivalent to a two channel  $SU(3)$  Kondo problem. Both problems can be mapped to a quantum Brownian motion model on a Kagome lattice, which in turn is related to quantum Brownian motion on a honeycomb lattice and the three channel  $SU(2)$  Kondo problem. Utilizing boundary conformal field theory, we find the universal peak conductance  $g^* \frac{e^2}{h}$  as well as dimensions of the leading relevant operators of the problem. This allows us to compute the scaling behavior of the resonance line-shape as a function of temperature. We also established the fact that the fixed point quantum Brownian motion on both generalized honeycomb lattice( $SU(2)_k$  Kondo) and generalized Kagome lattice( $SU(k)_2$  Kondo) flow into are the same (with  $k = 3$  our original resonant tunneling problem).

**10:24AM R27.00013 Structure of Inert Gases Adsorbed in MCM-41<sup>1</sup>**, DYLAN EVANS, PAUL SOKOL, Indiana Univ - Bloomington — One-dimensional quantum liquids of  $^3\text{He}$  or  $^4\text{He}$  have generated recent interest for investigation in the Luttinger liquid model. Unfortunately, current studies lack a clear demonstration of definitively one-dimensional behavior. We propose using the templated, porous material, MCM-41, as a host for an atomic Luttinger liquid. In general, the pores of MCM-41 are too wide to provide a strictly one-dimensional environment, so we investigate preplating these pores with inert gases to effectively reduce their diameter. We present the results of studies of the structure of inert gases in MCM-41. Nitrogen sorption isotherms were used to characterize the sample. Then, using inert gases as adsorbates, we determined the minimum effective pore diameter that can be achieved in our sample before capillary condensation takes over. X-ray powder diffraction (XRD) was performed on the ideally preplated sample to investigate the structure of the adsorbates in the nanopores. The XRD measurements are compared to simulations of core-shell cylinder model scattering, and the validity of the model is assessed. The prospects for creating a definitively one-dimensional channel for the application of studying the structure and dynamics of helium confined in one dimension are discussed.

**10:36AM R27.00014 Fractionally Charged Solitons in the t-J model on a diagonal two-leg ladder**, YIFAN JIANG, Institute for Advanced Study, Tsinghua University, HONGCHEN JIANG, Department of Physics, Stanford University, HONG YAO, Institute for Advanced Study, Tsinghua University, STEVEN KIVELSON, Department of Physics, Stanford University — We define a new class of "diagonal" t-J ladders rotated by  $\pi/4$  relatively to the canonical lattice directions of the square lattice, and study it using density matrix renormalization group (DMRG). We focus on the two-leg ladder with a doped hole concentration near  $x = 1/4$ . At exactly  $x = 1/4$ , the system forms a period 4 CDW and exhibits spin-charge separation. Slightly away from  $1/4$  doping, we observe several topologically distinct types of solitons with well defined fractionalized quantum numbers. Remarkably, given the absence of any small parameters, the effective masses of the various emergent solitons differ by over four orders of magnitude.

**10:48AM R27.00015 Non Fermi Liquid Crossovers in a Quasi-One-Dimensional Conductor in an Inclined Magnetic Field<sup>1</sup>**, ANDREI LEBED<sup>2</sup>, Department of Physics, University of Arizona — We consider a theoretical problem of electron-electron scattering time in a quasi-one-dimensional (Q1D) conductor in a magnetic field, perpendicular to its conducting axis. We show that inverse electron-electron scattering time becomes of the order of characteristic electron energy,  $1/\tau \sim \epsilon \sim T$ , in a high magnetic field, directed far from the main crystallographic axes, which indicates breakdown of the Fermi liquid theory. In a magnetic field, directed close to one of the main crystallographic axis, inverse electron-electron scattering time becomes much smaller than characteristic electron energy and, thus, applicability of Fermi liquid theory restores. We suggest that there exist crossovers between Fermi liquid and some non Fermi liquid states in a strong enough inclined magnetic field. Application of our results to the Q1D conductor  $(\text{Per})_2\text{Au}(\text{mnt})_2$  shows that it has to be possible to observe the above mentioned phenomenon in feasibly high magnetic fields of the order of  $H \geq H^* \simeq 25 T$ .

**Thursday, March 17, 2016 8:00AM - 11:00AM –**  
**Session R28 DCMP: Semiconductor Films, Defects, and Topological Materials** 327 - Kenjiro Gomes, University of Notre Dame

**8:00AM R28.00001 Nanoscopic oxidation of p-type and un-doped Si (100) surfaces using un-externally biased atomic force microscope tips (AFM) in the presence of selected organic solvents**, JEFFREY MCCAUSLAND, SAJEEVI WITHANAGE, ROBERT MALLIK, SERGEI LYUKSYUTOV, University of Akron — A conductive un-biased AFM tip oscillating above p-type or un-doped Si (100) treated with toluene, butan-2-ol, and propan-2-ol creates nanostructures ranging in height from 1-100 nm. The tip was oscillated in ambient conditions (30-70% Rel. Humidity) at frequencies in the  $10^2$  kHz range. It was repeatable with various concentrations of solvent in aqueous solution. It is suggested that mechanical oscillations of the AFM tip polarizes the solvent molecules deposited on the surface resulting in electron transfer from the tip to the surface followed by feature formation. This process effectively creates an electrochemical cell at the microscopic level and the miscibility of the solvents is the key to enabling the process. Species which ionize during the process may be consumed in irreversible reactions whereas the alcohols act as catalysts and are not consumed. The influence of boron defects in the Si substrates is also discussed. It appears that the observed oxidation is different from all other similar reported phenomena including local anodic oxidation, and chemo-mechanical lithographic techniques utilizing AFM.

**8:12AM R28.00002 Interface investigation of solution processed high- $\kappa$   $\text{ZrO}_2/\text{Si}$  MOS structure by DLTS**, ARVIND KUMAR, SANDIP MONDAL, KSR KOTESWARA RAO, Dept of Physics, IISc, India — The interfacial region is dominating due to the continuous downscaling and integration of high- $\kappa$  oxides in CMOS applications. The accurate characterization of high- $\kappa$  oxides/semiconductor interface has the significant importance towards its usage in memory and thin film devices. The interface traps at the high- $\kappa$ /semiconductor interface can be quantified by deep level transient spectroscopy (DLTS) with better accuracy in contrast to capacitance-voltage (CV) and conductance technique. We report the fabrication of high- $\kappa$   $\text{ZrO}_2$  films on p-Si substrate by a simple and inexpensive sol-gel spin-coating technique. Further, the  $\text{ZrO}_2/\text{Si}$  interface is characterized through DLTS. The flat-band voltage ( $V_{\text{FB}}$ ) and the density of slow interface states (oxide trapped charges) extracted from CV characteristics are 0.37 V and  $2 \times 10^{-11} \text{ C/cm}^2$ , respectively. The activation energy, interface state density and capture cross-section quantified by DLTS are  $E_{\text{V}} + 0.42 \text{ eV}$ ,  $3.4 \times 10^{11} \text{ eV}^{-1} \text{ cm}^{-2}$  and  $5.8 \times 10^{-18} \text{ cm}^2$ , respectively. The high quality  $\text{ZrO}_2$  films own high dielectric constant 15 with low leakage current density might be an appropriate insulating layer in future electronic application. The low value of interface state density and capture cross-section are the indication of high quality interface and the defect present at the interface may not affect the device performance to a great extent. The DLTS study provides a broad understanding about the traps present at the interface of spin-coated  $\text{ZrO}_2/\text{Si}$ .

**8:24AM R28.00003 A New Approach for Surface Energy Calculations Applicable to High-throughput Design of New Interfaces<sup>1</sup>**, CHRISTIAN RATSCH, JAKUB KAMINSKI, UCLA — In this talk we will present a new approach for the calculation of surface energies of periodic crystal. For non-polar materials slabs (which are terminated by two identical surfaces) the task of calculating the surface energy is trivial. But it is more problematic for polar systems where both terminating surfaces are different, as there is no single established method allowing for equal treatment of a wide range of surface morphologies and orientations. Our proposed new approach addresses this problem. It relies on carefully chosen capping atoms and the assumptions that their bond energy contributions can be used to approximate the total energy of the surface. The choice of the capping atoms is governed by a set of simple guidelines that are applicable for surfaces with different terminations. We present the results for different semiconductor materials and show that our approach leads to surface energies with errors as low as 2%. We show that hydrogen is not always the best choice for a capping atom if accurate surface energies are the target of the calculations. Our approach is suitable for high-throughput screening of new material interfaces, as accurate calculations of surface energies can be performed in an unsupervised algorithm.

<sup>1</sup>A New Approach for Surface Energy Calculations Applicable to High-throughput Design of New Interfaces

**8:36AM R28.00004 Schottky Barrier Mapping to Nanoscale Dimensions Utilizing Ballistic Electron Emission Microscopy**, VINCENT LABELLA, SUNY Polytechnic Institute, ROBERT BALSANO, CHRIS DURCAN, WES NOLTING, University at Albany - SUNY — The Schottky barrier is the electrostatic barrier between a metal and a semiconductor that results in rectification and is found in many types of devices such as source drain contacts to sub 20-nm-node transistors. Nanoscale fluctuations in the Schottky barrier height can occur due to variations in bonding, compositional fluctuations in the materials, and the presence of defects. Measuring and mapping these electrostatic fluctuations to nanoscale dimensions can be achieved with ballistic electron emission microscopy (BEEM) an STM based technique. This presentation will demonstrate how the Schottky barrier height can be mapped to nanoscale dimensions using BEEM at 77K and under ultra-high vacuum. The STM tip is positioned on a regularly spaced grid and BEEM spectra are acquired from which the barrier height can be extracted. Maps and histograms can be generated by measuring and fitting thousands of these spectra. These maps provide detailed insight into the electrostatic fluctuations occurring at the buried interface with nanoscale resolution that cannot be accomplished with other bulk measurements.

**8:48AM R28.00005 Hot Electron Scattering in Thin Metal Films Utilizing Ballistic Electron Emission Microscopy**, CHRISTOPHER DURCAN, WESTLY NOLTING, ROBERT BALSANO, State Univ of NY - Albany, VINCENT LABELLA, SUNY Polytechnic Institute — Electron scattering in nm-thick metal films has fundamental and technological importance. Ballistic Electron Emission Microscopy (BEEM) an STM based technique can be utilized to measure the scattering rate and understand the scattering mechanisms. By injecting electrons from the STM tip in the energy range of 0.2 eV- 1.5 eV into the metal base of a metal semiconductor diode and measuring the amount of current collected in the semiconductor a Schottky barrier height can be measured. In addition, by measuring the decay in the collector or BEEM current vs. metal film thickness, an electron attenuation length can be measured. One question has always been; what are these BEEM attenuation lengths sensitive to? Intrinsic properties of the metal, or extrinsic effects such as the structure of the film? By measuring the attenuation length of W and Cr and comparing to prior measurements of Cu, Ag, Au a comparison between the BEEM attenuation length and resistivity can be achieved over an order of magnitude in resistivity. The results show an inverse relationship that one expects for mean free path and resistivity, indicating that BEEM measurements are sensitive to the intrinsic properties of the metal and not solely the structure of the films.

**9:00AM R28.00006 Surface phase stability and surfactant behavior of InAsSb alloy surfaces.<sup>1</sup>**, EVAN M ANDERSON, ADAM M LUNDQUIST, Materials Science and Engineering, University of Michigan, CHRIS PEARSON, Computer Science, Engineering, and Physics, University of Michigan-Flint, JOANNA M MILLUNCHICK, Materials Science and Engineering, University of Michigan — InAsSb has the narrowest bandgap of any of the conventional III-V semiconductors: low enough for long wavelength infrared applications. Such devices are sensitive to point defects, which can be detrimental to performance. To control these defects, all aspects of synthesis must be considered, especially the atomic bonding at the surface. We use an *ab initio* statistical mechanics approach that combines density functional theory with a cluster expansion formalism to determine the stable surface reconstructions of Sb (As) on InAs (InSb) substrates. The surface phase diagram of Sb on InAs is dominated by Sb-dimer termination  $\alpha 2(2 \times 4)$  and  $\beta 2(2 \times 4)$  and  $c(4 \times 4)$ . Smaller regions of mixed Sb-As dimers appear for high Sb chemical potentials and intermediate As chemical potential. We propose that InAsSb films could be grown on  $(2 \times 4)$ , which maintain bulk-like stoichiometry, to eliminate the formation of typically observed n-type defects. Scanning tunneling microscopy and reflection high energy electron diffraction confirm the calculated phase diagram. Based on these calculations, we propose a new mechanism for the surfactant behavior of Sb in these materials.

**9:12AM R28.00007 Formation, properties, and function of vacancies in Si/Ge Clathrates: The importance of broken symmetries**, AMRITA BHATTACHARYA, CHRISTIAN CARBOGNO, MATTHIAS SCHEFFLER, Fritz Haber Institute of the Max Planck Society — Inclusion compounds, such as clathrates, are cage-like crystal structures that can encapsulate guest atoms. Since this allows to tune their electronic and vibrational properties, they are regarded as interesting materials for thermoelectric applications. Progress in this field is, however, hindered by the fact that filling of group-IV clathrates often results in complex and unexpected structural changes, e.g., the spontaneous formation of vacancies in certain hosts: In Ge<sub>46</sub> clathrates filled with K or Ba, the most favourable phases K<sub>8</sub>Ge<sub>44</sub>/Ba<sub>8</sub>Ge<sub>43</sub> feature two/three vacancies. Conversely, the framework of the isoelectronic Si<sub>46</sub> clathrate remains intact (K<sub>8</sub>Si<sub>46</sub>/Ba<sub>8</sub>Si<sub>46</sub>) upon filling with the exact same guests. Our first-principles calculations of the formation energies and of the thermodynamic phase stabilities confirm this experimental scenario and shed light on the underlying mechanisms. Due to the spatially more delocalized 4sp<sup>3</sup> orbitals in Ge compared to the more localized 3sp<sup>3</sup> orbitals in Si, fundamentally different symmetry breaking distortions become possible to stabilize the vacancies. Eventually, we discuss the implications of these findings for the thermoelectric properties of clathrates.

**9:24AM R28.00008 Symmetry of Highly Strained ZnSnN<sub>2</sub> Thin Films<sup>1</sup>**, NANCY SENABULYA, Univ of Michigan - Ann Arbor, YONGSOO YANG, Univ of California, Los Angeles, CHRISTIAN SCHLEPUTZ, Swiss Light Source, Paul Scherrer Institut, NATHANIEL FELDBERG, Univ of Buffalo, ROBERT MAKIN, Western Michigan Univ, CHRISTINA JONES, Univ of Michigan - Ann Arbor, STEVEN DURBIN, Western Michigan Univ, ROY CLARKE, Univ of Michigan - Ann Arbor — Zinc Tin Nitride (ZnSnN<sub>2</sub>) is a member of the ternary class of II-IV-V<sub>2</sub> semiconducting materials that have gained significant research interest in the recent past as a cheaper, earth abundant and environmentally friendly alternative to Indium-based materials used in photovoltaic and solid state lighting applications. Surface x-ray diffraction measurements performed at Argonne National Laboratory on single crystal thin films of ZnSnN<sub>2</sub> grown on (111)yttria stabilized zirconia(YSZ) substrates show a structural change from the wurtzite to the orthorhombic phase in films grown under low values of nitrogen flux and high substrate temperatures. This orthorhombic phase is characterized by in plane contraction and out of plane elongation of the unit cell lattice parameters, a phenomenon that theoretically results from the doubling of the wurtzite unit cell in the basal plane and ordering on the cation sub lattice [APL 103,042109(2013)]. We are currently studying the crystal structure of ZnSnN<sub>2</sub> thin films using 3-dimensional reciprocal space maps and pole figure measurements in order to characterize the high symmetry orthorhombic phase achieved using epitaxy.

**9:36AM R28.00009 Surface charge transport in Silicon (111) nanomembranes<sup>1</sup>**, WEIWEI HU, SHELLEY SCOTT, RB JACOBSON, DONALD SAVAGE, MAX LAGALLY, University of Wisconsin-Madison, THE LAGALLY GROUP TEAM — Using thin sheets (nanomembranes) of atomically flat crystalline semiconductors [1], we are able to investigate surface electronic properties, using back-gated van der Pauw measurement in UHV. The thinness of the sheet diminishes the bulk contribution, and the back gate tunes the conductivity until the surface dominates, enabling experimental determination of surface conductance [2]. We have previously shown that Si(001) surface states interact with the body of the membrane altering the conductivity of the system. Here, we extended our prior measurements to Si(111) in order to probe the electronic transport properties of the Si(111)  $7\times 7$  reconstruction. Sharp ( $7\times 7$ ) LEED images attest to the cleanliness of the Si(111) surface. Preliminary results reveal a highly conductive Si(111)  $7\times 7$  surface with a sheet conductance  $R_s$  of order of  $\mu S/\square$ , for 110nm thick membrane, and  $R_s$  is a very slowly varying function of the back gate voltage. This is in strong contrast to Si(001) nanomembranes which have a minimum conductance several orders of magnitude lower, and hints to the metallic nature of the Si(111) surface. 1. Zhang, P. P. *et al.*, Nature 439, 703-706 (2006); 2. W. Peng, *et al.*, Nature Commun. 4, 1339 (2013).

**9:48AM R28.00010 Detection of a History Dependent Topological Hall Effect Due to Skyrmion Formation in FeGe Thin Films**, JAMES GALLAGHER, MICHAEL PAGE, VIDYA BHALLAMUDI, JACK BRANGHAM, KENG YUAN MENG, BRYAN ESSER, HAILONG WANG, DAVE MCCOMB, CHRIS HAMMEL, FENGYUAN YANG, Ohio State Univ - Columbus — B20 phase crystal structures, such as FeGe and MnSi, have been of interest because they enable magnetic skyrmion phases, which can potentially lead to low energy cost spintronic device applications. We report the synthesis of pure phase FeGe epitaxial thin films grown on Si (111) substrates by ultra-high vacuum off-axis magnetron sputtering. The FeGe films were characterized by x-ray diffraction, scanning transmission electron microscopy (STEM) and Hall effect measurements. The topological Hall effect (THE) signals were extracted by subtracting out the anomalous Hall effect and ordinary Hall effect, demonstrating the existence of the skyrmion phase in FeGe films between 5 and 275 K. Topological hall effect was observed at zero field at all temperatures below the Curie temperature, showing the possibility of metastable skyrmion particles at zero field and high temperatures. We will also discuss the study of dynamics of the ferromagnetic phases using ferromagnetic resonance.

**10:00AM R28.00011 Topological Imbert-Fedorov Shift in Weyl Semimetals<sup>1</sup>**, QING-DONG JIANG, Peking Univ, HUA JIANG, Soochow Univ, HAIWEN LIU, QING-FENG SUN, XIN-CHENG XIE, Peking Univ — The Goos-Hnchen (GH) shift and the Imbert-Fedorov (IF) shift are optical phenomena which describe the longitudinal and transverse lateral shifts at the reflection interface, respectively. Here, we predict the GHIF shifts in Weyl semimetals (WSMs) a promising material harboring low energy Weyl fermions, afemionic cousin of photons. Our results show that the GH shift in WSMs is valley independent, is analogous to that discovered in a 2D relativistic material graphene. However, the IF shift has been explored in nonoptical systems, and here we show that it is valley dependent. Furthermore, we show that the IF shift actually originates from the topological effect of the system. Experimentally, the IF shift can be utilized to characterize the Weyl semimetals, design valleytronic devices of high, and measure the Berry curvature. Moreover, we investigate the transport properties of topological semimetal using the wave-packet dynamics, which give some interesting results.

**10:12AM R28.00012 Hybridization-induced interface states in a topological insulator - ferromagnetic metal bilayer<sup>1</sup>**, YI-TING HSU, PRIYAMVADA JADAUN, CRAIG FENNIE, EUN-AH KIM, Cornell University — Recent experiments demonstrating large spin-torque in topological insulator (TI)/ferromagnetic metal (FM) bilayer, revealing their potential for spintronic applications raised much excitement. However, there is little understanding on the impact of the bilayer formation on the TI surface state and whether it is possible to represent such bilayer using a simple model. Moreover, due to the large charge-transfer from the FM layer, these Dirac surface states are unlikely to be anywhere near the Fermi level to contribute to the observed spin-torque. In order to establish a theoretical starting point, we calculated the band structure of a TI-FM bilayer using density functional theory (DFT) and built a simple effective model that captures the essence of the DFT results. Through this double-pronged approach, we find new surface states we dubbed reflection states to form close to chemical potential due to level-repulsion between the original Dirac surface states and the energetically close-by FM states with the same momentum. Depending on the coupling strength, the reflection states can carry a large weight of the original surface states and thus inherit not only the spatial localization but also the spin-winding of the original Dirac surface state.

**10:24AM R28.00013 Local electronic structures and 2D topological phase transition of ultra-thin Sb films<sup>1</sup>**, SUNGHWAN KIM, Center for Artificial Low Dimensional Electronic Systems, Institute for Basic Science, Korea, KYUNG-HWAN JIN, JOONBUM PARK, JUN SUNG KIM, SEUNG-HOON JHI, Department of Physics, Pohang University of Science and Technology, Korea, HAN WOONG YEOM, Center for Artificial Low Dimensional Electronic Systems, Institute for Basic Science, Korea — We investigate local electronic structures of ultrathin Sb islands and their edges grown on Bi<sub>2</sub>Te<sub>2</sub>Se by scanning tunneling microscopy/spectroscopy (STM/STS) and density functional theory (DFT) calculations. The Sb islands of various thickness are grown with atomically well ordered edge structure over the 3 bilayers (BL). On the surfaces and edges of these islands, we clearly resolve edge-localized electronic states by STS measurements, which depend on the thickness. The DFT calculations identify that the strongly localized edge states of 4 and 5 BL films correspond to a quantum spin Hall (QSH) states while the edge states of 3 BL are trivial. Our experimental and theoretical results confirm the 2D topological phase transition of the ultrathin Sb films from trivial to QSH phase.

**10:36AM R28.00014 The novel properties of epitaxial bismuth ultra-thin films on superconducting substrate NbSe<sub>2</sub>**, DANDAN GUAN, HAOHUA SUN, MEIXIAO WANG, GUANYONG WANG, DAN XU, Shanghai Jiao Tong Univ, XIAOJUN YANG, ZHU-AN XU, Zhejiang University, YAOYI LI, CANHUA LIU, DONG QIAN, JIN-FENG JIA, Shanghai Jiao Tong Univ, SHANGHAI JIAO TONG UNIVERSITY TEAM, ZHEJIANG UNIVERSITY COLLABORATION, COLLABORATIVE INNOVATION CENTER OF ADVANCED MICROSTRUCTURE COLLABORATION — Bismuth is theoretically predicted to be a quantum spin Hall (QSH) system. Such a QSH system, interesting itself with the genuine spin degenerated backscattering forbidden transport property, is also a potential platform to study the 2D topological superconductor with superconductivity induced by proximity effect. The epitaxial growth of ultra-thin Bi(111) film on superconductor NbSe<sub>2</sub> was investigated by scanning tunneling microscopy (STM) and scanning tunneling spectroscopy (STS). The orientation transition from Bi(110) phase to Bi(111) phase has been observed. One-dimensional topological edge states on the zig-zag edge of Bi(111) bilayers and proximity effect-induced superconductivity were also revealed by STS analysis.

**10:48AM R28.00015 Vertical electrical field induced island growth in layered TiSe<sub>2</sub>.**<sup>1</sup>, HUSONG ZHENG, Virginia Tech, SALVADOR VALTIERRA, NANA OPOKU, McGill University, CHUANHUI CHEN, Virginia Tech, LIYING JIAO, Tsinghua University, KIRK BEVAN, McGill University, CHENGGANG TAO, Virginia Tech — For practical applications of atomically thin transition metal dichalcogenides, it is essential to characterize the structural stability under external stimuli such as electrical fields. Using vacancy monolayer islands on TiSe<sub>2</sub> surfaces as a model system, we experimentally and theoretically investigated the shape evolution and growth rate by using scanning tunneling microscopy. The growth rate that depends on the tunneling current is experimentally determined. Our simulations of monolayer island evolution using a phase-field model are consistent with the experimental observations. The results could be potentially important for electronic device applications of ultrathin transition metal dichalcogenides and other 2D materials.

**Thursday, March 17, 2016 8:00AM - 11:00AM –**  
**Session R29 DCMP: Disordered and Floquet Topological Phases** 328 - Andrew Potter, University of California, Berkeley

**8:00AM R29.00001 Spin susceptibility function of helical metal and RKKY interaction**<sup>1</sup>, CHUNXIAO LIU, BITAN ROY, JAY SAU, university of maryland, CMTc AND JQI TEAM — Topological insulator is a peculiar material, which is insulating in the bulk, while conducting on the surface due to the topology in momentum space. Here, we study the surface of 3D topological insulator, which is also called helical metal. The Hamiltonian of the surface electrons is  $H = k \times \sigma$ , which has spin-momentum locking and Dirac dispersion. The property that we are interested in is the spin susceptibility function of the helical metal. It describes how the system responds to the external magnetic field in the linear response regime. However, because the dispersion of helical metal is linear in momentum  $k$ , the spin susceptibility is easily divergent in terms of UV momentum cutoff. The talk we will present is focusing on how we renormalize the spin susceptibility function in the particular renormalization scheme we choose. In the second part of the talk, we will make use of the renormalized spin susceptibility to show how external magnetic impurities on the surface would interact with each other, with the interaction mediated by electrons of helical metal. This interaction is also called RKKY interaction. Treating impurities as classical spins, we show the pattern of ground state with numerical simulations.

**8:12AM R29.00002 NonSymmorphic Symmetry Protected Topological Order in Many-body Localized Systems**, KHALID ASHRAF, UC Berkeley — Many-body localized systems have many interesting physical properties such as localization protected quantum order, symmetry protected topological order, area law in entanglement spectrum etc. [1]. Specifically, it has been shown that closed quantum system in 1D i.e. p-wave superconducting wires host localization protected topological order [2]. In this work, we explore the interplay between non-symmorphic symmetry which protects topological order and localization due to disorder. Using a Bogoliubov-de Gennes (BdG) description of p-wave superconductors, we study the topological edge states on a 2D non-symmorphic crystal. We show that a localization protected topological order can exist at high energy in a 2D non-symmorphic crystal. The system goes between topologically trivial and non-trivial phases based on the degree of disorder and shift between the adjacent atoms in the bipartite lattice. We further explore the nature of this phase transition by calculating the entanglement spectrum of the two phases. Finally, the effect of dimensionality on the realization of these phases are discussed. Nandkishore et al. Annual Rev. Cond. Matt. Phys., vol 6 (2015). 2. Huse et al., Phys. Rev. B 88, 014206 (2013).

**8:24AM R29.00003 Effect of disorder on the decreasing the critical value of magnetic field in proximity induced topological superconductors**<sup>1</sup>, YAHYA ALAVIRAD, CHING-KAI CHIU, JAY SAU, Univ of Maryland-College Park — Here we investigate how adding disorder changes the critical value of magnetic field  $B_c$  required to observe the topological phase transition in proximity induced topological superconductors. We consider disordered topological superconductors in  $D = 1, 2$  spatial dimensions and use numerical analysis to directly calculate the topological invariant. Qualitatively different behavior are found depending on the dimensionality of the system. In contrast to  $D = 2$  for  $D = 1$  we show that adding disorder gradually decreases  $B_c$  from the clean case limit of  $B_c = \sqrt{\mu^2 + \Delta^2}$  to  $B_c = \Delta$ . A discussion of why these results are expected is provided. These findings, specially in  $D = 1$  dimension are of experimental interest since they show that the topological phase transition might be observable at values of magnetic field  $B_c$  much smaller than previously expected.

**8:36AM R29.00004 Anderson Chern Insulators**, JAMES JUN HE, TONG ZHOU, Hong Kong Univ of Sci & Tech, Z. C. GU, Perimeter Institute, K. T. LAW, Hong Kong Univ of Sci & Tech — When a magnetic field is applied to a quantum spin Hall insulator (QSHI) without inversion symmetry, the edge states become gapful due to the breaking of time reversal symmetry (TRS) and the QSHI becomes a trivial spin Hall insulator (SHI) whose Chern number is  $N = 0$ . In this work we show that disorder can drive such a SHI to a Chern insulator (CI) with  $N = 1$  which supports a gapless chiral edge state. This CI exists in a finite range of disorder strength. Interestingly, the edge state is protected by the bulk mobility gap instead of an energy gap. For this reason, the new phase is called an Anderson Chern insulator (ACI).

**8:48AM R29.00005 Disorder-driven breakdown of topological protection in Bi<sub>2</sub>Se<sub>3</sub> films.**, JISOO MOON, Rutgers University, MATTHEW BRAHLEK, Pennsylvania State University, NIKESH KOIRALA, MARYAM SALEHI, Rutgers University, LIANG WU, N. PETER ARMITAGE, The Johns Hopkins University, SEONGSHIK OH, Rutgers University — In topological insulators (TI), there are unusual metallic states on their surfaces, so-called topological surface states (TSS). They are protected by time reversal symmetry through strong spin-orbit coupling, making them immune to disorder-related localization effects. However, in highly-disordered TIs the crystal momentum becomes ill-defined because translational invariance is broken. In those materials, it is doubtful that topological protection is still valid. In this presentation, we show that high level of disorder drives breakdown of topological protection in Bi<sub>2</sub>Se<sub>3</sub> films. TSS in the films are not protected above a critical level of disorder, and the films become trivial insulators. The films are grown by Molecular Beam Epitaxy (MBE), and the level of disorder in the films is controlled by annealing after the films are grown at room temperature.

**9:00AM R29.00006 Disordered topological crystalline phases**, IAN MONDRAGON-SHEM, TAYLOR L. HUGHES, University of Illinois at Urbana-Champaign — We study topological crystalline phases in the presence of disorder potentials that are invariant under the point group symmetries that protect the corresponding nontrivial phase. Topological states protected by spatial symmetries have so far only been clearly defined for translationally invariant systems. It has been proposed that the stability of such phases against disorder can be inferred from the existence of robust delocalized states at the boundary. However, a bulk characterization is still lacking that can provide a more complete and fundamental understanding of how these phases remain topological in the presence of disorder. We study this problem by focusing on models for which the disorder potential preserves exactly mirror and rotational symmetries. We generalize the expressions of the corresponding topological invariants to the case of broken translational invariance, and analyze their spatial distribution in the bulk of the system. We further study critical behavior in the bulk and at the boundary to determine how these states of matter undergo disorder-induced topological phase transitions. Finally, we discuss how our results could offer a bulk understanding of topological crystalline phases protected by average spatial symmetries.

**9:12AM R29.00007 Disorder-induced WAL-WL transition and anomalous Hall effect in undoped thin  $\text{Sb}_2\text{Te}_3$  films**<sup>1</sup>, INNA KORZHOVSKA, CUNY-Graduate Ctr, The City College of New York, YURY DESHKO, LUKAS ZHAO, ZHIYI CHEN, LIA KRUSIN-EBAUM, The City College of New York, SIMONE RAOUX, Helmholtz-Zentrum, Berlin, Germany — We examine the effects of disorder on charge transport in thin (20-50 nm) films of topological insulator (TI)  $\text{Sb}_2\text{Te}_3$ , where, uniquely, structural disorder can be controllably tuned over a huge range - from amorphous to crystalline - by a suitable annealing schedule. We report on the observation of disorder-induced transition from weak localization-like state (WL-like) to weak anti-localization (WAL), at which conductance changes its character from 3D in the WL-like state to 2D in the WAL (crystalline) state. Near the transition, the conductance is  $G \approx e^2/h$ , suggestive of the transport through a surface channel that is decoupled from the bulk by disorder. Quite remarkably, the onset of the WL state (where bulk transport is of variable range hopping type) is found to be concurrent with the appearance of anomalous Hall signal (AHE) which grows with increased disorder, with Hall resistivity  $\rho_{xy}$  scaling as the longitudinal resistivity squared,  $\rho_{xy} \propto \rho_{xx}^2$ . The nature of spin correlations (probed directly by the arrays of micro Hall sensors) responsible for AHE in disordered TI films in the absence of magnetic dopants will be discussed.

**9:24AM R29.00008 Anderson localization at the edge of a 2D topological insulator**, ESLAM KHALAF, PAVEL OSTROVSKY, Max Planck Institute for Solid State Research, Stuttgart — We study transport via edge modes in a disordered 2D topological insulator allowing for the presence of non-protected diffusive channels in addition to the topologically protected edge channels. This scenario can be realized at the interface between two quantum Hall system, in a Weyl semimetal in a magnetic field or at the edge of a quantum spin Hall system. The edge transport is described by a one-dimensional field theory in the form of a supersymmetric non-linear sigma model with a topological term. The transfer-matrix formalism is employed to map the problem to the problem of finding the eigenfunctions of a certain operator on a symmetric superspace. The latter problem is solved exactly for all symmetry classes, enabling us to obtain the full counting statistics and mesoscopic conductance fluctuations in the system. Our main finding is that disorder is much more effective in localizing the diffusive (non-protected) channels in the presence of topologically protected ones. This manifests itself as a suppression of the shot noise and conductance fluctuations at scales much shorter than the localization length.

**9:36AM R29.00009 Superconductivity and disorder in the potential topological superconductor  $(\text{Sn,In})\text{Te}^1$** , MATTHEW SMYLIE, Univ of Notre Dame, BING SHEN, HELMUT CLAUS, ALEXEY SNEZHKO, ULRICH WELP, WAI-KWONG KWOK, Argonne National Lab, MORTEN ESKILDSEN, ELIZABETH DE WAARD, Univ of Notre Dame, MICHAEL SUSNER, ATHENA SEFAT, Oak Ridge National Lab — In-doped SnTe has been proposed as a candidate topological superconductor. It has been suggested that the superconducting critical temperature ( $T_c$ ) is strongly enhanced with impurity scattering in this material, with the pairing mechanism perhaps changing with doping. To access information on the pairing symmetry of the superconducting order parameter, ultra-sensitive magnetic field penetration measurements have been conducted by means of a Tunnel-Diode-Oscillator (TDO) technique. Particle irradiation with low MeV protons was used as a controllable source of disorder, but no enhancement of  $T_c$  was observed in cubic-phase material as scattering increased. Detailed characterization measurements and analysis were performed before and after irradiation of the samples.

<sup>1</sup>Tunnel diode oscillator and magnetization measurements were supported by the U.S. Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division.

**9:48AM R29.00010 Characterization & Transport Signatures of Periodically Driven Topological Phases**, MICHEL FRUCHART, PIERRE DELPLACE, KRZYSZTOF GAWEDZKI, DAVID CARPENTIER, Laboratoire de Physique, ENS de Lyon — The discovery of the Quantum Hall Effect in the 80's opened the field of topological phases of matter, which has been renewed by the discovery of a new kind of topological insulator in 2005, this time in a time-reversal invariant system. In order to obtain a material with tunable topological properties, research were carried out on out-of-equilibrium systems subject to a periodic drive. Such periodically driven topological phases turn out to be richer than their equilibrium counterparts. We consider a 2D crystal subject to a drive periodic in time, constrained so that it is time-reversal invariant and show that such a system is characterized by  $\mathbb{Z}_2$  indices attached to a gap (and not to a band), which we explicitly construct. To probe these out-of-equilibrium phases in a phase coherent regime, we use standard transport measurements. With the help of numerical simulations, we show that the running time-averaged differential conductances are quantized in a topological gap, and that multi-terminal setups enable to probe the chirality of the out-of-equilibrium topological states.

**10:00AM R29.00011 Floquet topological phases coupled to environments**, SZABOLCS VAJNA, Department of Physics, Boston University and Budapest University of Technology and Economics, BARUCH HOROVITZ, Department of Physics, Ben-Gurion University of the Negev — We consider the fate of a helical edge state of a spin Hall insulator and its topological transition in presence of a circularly polarized light when coupled to various forms of environments. A Lindblad type equation is developed to determine the fermion occupation of the Floquet bands. We find that non-secular terms, corresponding to 2-photon transitions lead to a mixing of the band occupations, hence the light induced photocurrent is in general not perfectly quantized, although deviations are small in the adiabatic limit. Sharp crossovers are identified at frequencies  $\Omega$  and  $1/2 \Omega$  ( $\Omega$  is the strength of light-matter coupling) with the former corresponding to a phase transition on the level of the 2nd order theory.

**10:12AM R29.00012 Time periodic perturbations and transport signatures in Floquet topological insulators**, AARON FARRELL, T. PEREG-BARNEA, McGill Univ — A Floquet topological insulator represents an out-of-equilibrium topological state. The topology of these systems emerges only when a time periodic perturbation is carefully applied. In time-periodic systems one can define quasi-energy states, which replace equilibrium stationary states (i.e. energy eigenstates). For appropriate time periodic potential strengths, a Floquet topological insulator exhibits edge localized quasi-energy states which lie in a gap of its quasi-energy spectrum. These edge states are a non-equilibrium analogue of the topologically protected edge-states in equilibrium topological insulators. In an equilibrium system such edge states lead to robust signature transport properties, e.g. a two-terminal conductivity of  $2e^2/h$ . This talk will explore how these transport signatures translate to Floquet topological insulators. We will do this by developing and generalizing intuition borrowed from the field of photon-assisted tunneling. We show that ultimately the signature transport properties of an equilibrium topological insulator do not directly hold in the out-of-equilibrium setting. This fact notwithstanding, we will provide an indirect way of retaining these transport signatures by using a so-called Floquet sum rule.

**10:24AM R29.00013 Selective scattering between Floquet-Bloch and Volkov states in a topological insulator**, FAHAD MAHMOOD, CHING-KIT CHAN, ZHANYBEK ALPICHSEV, DILLON GARDNER, YOUNG LEE, PATRICK LEE, NUH GEDIK, Massachusetts Inst of Tech-MIT — The coherent optical manipulation of solids is emerging as a promising way to engineer novel quantum states of matter. The strong time periodic potential of intense laser light can be used to generate hybrid photon-electron states. Interaction of light with Bloch states leads to Floquet-Bloch states which are essential in realizing new photo-induced quantum phases. Similarly, dressing of free electron states near the surface of a solid generates Volkov states which are used to study non-linear optics in atoms and semiconductors. The interaction of these two dynamic states with each other remains an open experimental problem. Here we use Time and Angle Resolved Photoemission Spectroscopy (TR-ARPES) to selectively study the transition between these two states on the surface of the topological insulator  $\text{Bi}_2\text{Se}_3$ . We find that the coupling between the two strongly depends on the electron momentum, providing a route to enhance or inhibit it. Moreover, by controlling the light polarization we can negate Volkov states in order to generate pure Floquet-Bloch states. This work establishes a systematic path for the coherent manipulation of solids via light-matter interaction.

**10:36AM R29.00014 Anisotropic ultrafast dynamics in  $\text{BiSbTe}_2\text{S}$  topological insulator investigated by time-resolved photoemission spectroscopy**, F. BOSCHINI, M. ZONNO, E. DA SILVA NETO, S. ZHDANOVICH, M. SCHNEIDER, B. ZWARTSENBURG, G. LEVY, A. MILLS, D. JONES, A. DAMASCELLI, University of British Columbia, S. KUSHWAHA, R. J. CAVA, Department of Chemistry, Princeton University — Topological insulating phases in 3-dimensional bulk materials are characterized by the presence of a Dirac-like dispersive surface state – with a specific momentum-locked spin structure – localized within the bulk insulating band gap [1,2] Here we will present time-resolved photoemission (TR-ARPES) experimental results from a new topological insulator,  $\text{BiSbTe}_2\text{S}$ .  $\text{BiSbTe}_2\text{S}$  exhibits superior chemical stability, as evidenced by the lack of any measurable energy shift of the Dirac point over time. The TR-ARPES signal (1.55-eV pump and 6.2-eV probe) reveals a direct optical population/depopulation of the Dirac states followed by slow recombination processes on a ps-timescale with a marked dependence of the relaxation time on crystallographic orientation. In addition, we also observe an ultrafast pump-induced modification of the equilibrium Dirac state energy dispersion. These effects can be ascribed to an anisotropic pump-induced modification of the phonon population, which in turn leads to an anisotropic electron-phonon assisted scattering of the hot electrons populating the unoccupied Dirac states. [1] Y. Xia et al. Nat. Phys. **5**, 398 (2009) [2] Z.-H. Zhu et al. Phys. Rev. Lett. **112**, 076802 (2014)

**10:48AM R29.00015 Using Non-Equilibrium Dynamics to Probe Competing Orders in a Mott-Peierls System**, YAO WANG, Stanford University, BRIAN MORITZ, SIMES SLAC National Accelerator Laboratory, CHENG-CHIEN CHEN, Argonne National Laboratory, CHUNJING JIA, SIMES SLAC National Accelerator Laboratory, MICHEL VAN VEENENDAAL, Argonne National Laboratory/Northern Illinois University, THOMAS DEVEREAUX, SIMES SLAC National Accelerator Laboratory — The competition between ordered phases and the associated quantum criticality are significant in the study of strongly correlated systems. Here we examine one aspect, the non-equilibrium dynamics of a photoexcited Mott-Peierls system, using an effective Hubbard-bond-phonon model and exact diagonalization. Near the quantum phase transition where spin and charge become intertwined, we observe anti-phase dynamics and coupling-strength-dependent suppression or enhancement in the static structure factors. The renormalized bosonic excitations coupled to a photoemitted electron can be extracted from the spin and charge dynamics, providing an approach for characterizing the underlying bosonic modes. The results from this analysis for different electron momenta show uneven softening of bosonic modes due to a stronger coupling near  $k_F$ . This behavior reflects the strong link between the fermionic momenta, the coupling vertices, and ultimately the bosonic susceptibilities near a quantum phase transition.

**Session R30 DMP DCMP: Properties of Multiferroic Materials** 329 - Sergey Artyukhin, Rutgers University

**8:00AM R30.00001 Large-amplitude spin dynamics driven by a THz pulse in resonance with an electromagnon**, STEVEN JOHNSON, ETH Zurich — With femtosecond time resolution, x-ray diffraction offers unique capabilities to observe directly the dynamics of long range order. When the x-ray energy is tuned near a core-level transition it is possible in many systems to selectively study the dynamics of long-range order of valence properties such as orbital ordering or magnetic spin. Here I discuss how resonantly enhanced magnetic scattering can be used to quantitatively measure the character and magnitude of spin motion in a coherent electromagnon in  $\text{TbMnO}_3$  driven by a THz frequency electromagnetic field. We observe a  $4^\circ$  rotation of the antiferromagnetically ordered spin spiral plane, a result consistent with a previously published model that suggests this may be a viable route for ultrafast domain switching in multiferroics.

**8:36AM R30.00002 Terahertz excitations of spin-orbital ground state in multiferroic  $\text{Sr}_2\text{FeSi}_2\text{O}_7$** , THUC MAI, C. SVOBODA, E.V. JASPER, M.T. WARREN, J. BRANGHAM, Department of Physics, The Ohio State University, Columbus OH 43210, S-W. CHEONG, Rutgers Center for Emergent Materials, Rutgers University, T-H. HWAN, POSTECH, South Korea, R. VALDÉS AGUILAR, Department of Physics, The Ohio State University, Columbus OH 43210 — We studied the elementary excitations in  $\text{Sr}_2\text{FeSi}_2\text{O}_7$ , a novel multiferroic material, using time domain terahertz spectroscopy. We found 3 absorption modes above the Néel temperature. These modes can be described as optical transitions between the  $\text{Fe}^{2+} 3d^6$  energy levels, that are split by the compressive tetrahedral crystal field and spin orbit coupling. The excitations from the singlet spin-orbital ground state to the upper doublets are both magnetic and electric dipole active. We explored the behavior of these transitions at temperatures below  $T_{N\acute{e}el}$ , and as a function of external magnetic field, applied along different crystalline axes.

**8:48AM R30.00003 Non-reciprocal directional dichroism in the AFM phase of  $\text{BiFeO}_3$  at THz frequencies<sup>1</sup>**, URMAS NAGEL, T. RÖÖM, Natl Inst of Chem Phys & Biophys, Tallinn, D. FARKAS, D. SZALLER, S. BORDÁCS, I. KÉZSMÁRKI, Budapest University of Technology and Economics, Hungary, H. ENGELKAMP, HFML, Radboud University Nijmegen, The Netherlands, Y. OZAKI, Y. TOMIAKI, T. ITO, Electronics and Photonics Research Institute, National Institute of Advanced Industrial Science and Technology (AIST), Tsukuba, Japan, RANDY S. FISHMAN, Oak Ridge National Laboratory, Tennessee, USA — We did THz absorption spectroscopy of  $\text{BiFeO}_3$  single crystals in the AFM phase, where the spin cycloid is destroyed in magnetic fields between 18 T and 32 T in Voigt geometry at 1.6 K. If  $\mathbf{B}_0 \parallel [1\bar{1}0]$ , we see strong directional dichroism (DD) of absorption of the magnon mode with light propagating along the direction of the ferroelectric polarization  $\mathbf{k} \parallel \mathbf{P} \parallel [111]$  and  $\mathbf{e}^\omega \parallel [1\bar{1}0]$ ,  $\mathbf{b}^\omega \parallel [\bar{1}12]$ . The sign of DD can be reversed (i) by reversing the direction of  $\mathbf{B}_0$  or (ii) by flipping the sample, thus reversing the propagation direction of light. The observed effect is caused by the strong magneto-electric coupling in the collinear AFM phase.

<sup>1</sup>Research sponsored by the Estonian Ministry of Education and Research (IUT23-3).

**9:00AM R30.00004 Ultrafast Anisotropic Optical Response and Coherent Acoustic Phonon Generation in Polycrystalline BaTiO<sub>3</sub>-BiFeO<sub>3</sub><sup>1</sup>**, B. A. MAGILL, G. A. KHODAPARAST, M. GYU KANG, Y. ZHOU, H-C SONG, S. PRIYA, Virginia Tech — Ultrafast optical spectroscopy can provide insight into fundamental microscopic interactions, dynamics and the coupling of several degrees of freedom. Pump/ probe studies can reveal the answer to questions like What are the achievable switching speeds in multiferroics?, What is the influence of the crystallographic orientation and domain states on the available switching states?, and What is the effect of the hetrostructure on promoting the coupling between the varying field excitations?. In this presentation, we report on two color (400/800nm) ultrafast pump-probe differential reflectance spectroscopy of *BiFeO<sub>3</sub> – BaTiO<sub>3</sub>* structures. The (001) – *BiFeO<sub>3</sub> – BaTiO<sub>3</sub>* thin films were prepared using pulsed laser deposition on vicinal *SrTiO<sub>3</sub>* substrates using LSMO bottom electrodes. Crystal orientation and topography were analyzed by x-ray diffraction and atomic force microscopy. The films were found to exhibit perovskite phase and in our study, we introduce the first observation of photoexcited strain waves, with the frequencies in the GHz range.

**9:12AM R30.00005 Optical diode effect at THz frequencies of spin-wave excitations in the room-temperature multiferroic BiFeO<sub>3</sub><sup>1</sup>**, TOOMAS RÕÖM, U. NAGEL, National Institute of Chemical Physics and Biophysics, Tallinn, Estonia, S. BORDÁCS, I. KÉZSMÁRKI, Budapest University of Technology and Economics, Budapest, Hungary, H.T. YI, S.-W. CHEONG, Rutgers Univ., New Jersey, J. H. LEE, R.S. FISHMAN, Oak Ridge National Laboratory, Tennessee — We studied the unidirectional transmission of THz radiation in BiFeO<sub>3</sub> crystals, the unique multiferroic compound offering a real potential for room-temperature applications. We found that the optical magnetoelectric effect generated by spin waves in BiFeO<sub>3</sub> is robust enough to cause considerable nonreciprocal directional dichroism in the GHz-THz range even at room temperature. The optical magnetoelectric effect in BiFeO<sub>3</sub> is dominated by two types of spin-current induced polarizations, while the exchange-striction and single-ion polarization terms do not significantly contribute to it. Our work demonstrates that the nonreciprocal directional dichroism spectra and their theoretical analysis provide microscopic model of the magnetoelectric couplings in multiferroic materials.

**9:24AM R30.00006 Magnetoelectric coupling in hexagonal LuFeO<sub>3</sub> thin films**, HAO LIU, Fudan University — The magnetic and polar properties of single-crystalline hexagonal LuFeO<sub>3</sub> films have been studied. Both theoretical and experimental approaches indicated the coexisting of multiple ferroic orders. The spontaneous electric polarization is associated with a structural change, which also influences the magnetic properties, predicting a strong magnetoelectric coupling in these films. To investigate the magnetoelectric coupling, the micro capacitance structures were fabricated by photolithography combined with Ar ion beam etching method. The capacitance vs voltage curves show significant magnetic field effect, indicating strong magnetoelectric coupling in this system.

**9:36AM R30.00007 Temperature Dependent Atomic and Electronic Structure of LuFe<sub>2</sub>O<sub>4</sub>**, SIZHAN LIU, HAN ZHANG, New Jersey Institute of Technology, SANJIT GHOSE, Brookhaven National Laboratory, THOMAS EMGE, Rutgers University, DANIEL KAPLAN, U.S Army RDECOM-ARDEC, CHERNO JAYE, DANIEL FISHER, NIST, SANG-WOOK CHEONG, Rutgers University, TREVOR TYSON, New Jersey Institute of Technology — Structural measurements on multiple length scales have been conducted over a broad range of temperatures. These measurements have been complemented by optical and thermal measurements. The nature of the observed local atomic and electronic structural changes will be discussed and compared with previous work. This work is supported by DOE Grant DE-FG02-07ER46402.

**9:48AM R30.00008 Structure of Multiferroic RAl<sub>3</sub>(BO<sub>3</sub>)<sub>4</sub> and RFe<sub>3</sub>(BO<sub>3</sub>)<sub>4</sub> in the Region of High Electric Polarization**, HAN ZHANG, TIAN YU, New Jersey Institute of Technology, ZHIQIANG CHEN, Center for High Pressure Science and Technology Advanced Research, China, CHRISTIE NELSON, Brookhaven National Laboratory, LEONARD BEZMATERNYKH, L.V. Kirensky Institute of Physics, YU-SHENG CHEN, Advanced Photon Source, Argonne National Laboratory, MILINDA ABEYKOON, Brookhaven National Laboratory, TREVOR TYSON, New Jersey Institute of Technology — The multiferroic system RAl<sub>3</sub>(BO<sub>3</sub>)<sub>4</sub> is known to exhibit a strong coupling of magnetic field to the electrical polarization at low temperature (below ~100 K). A giant magnetoelectric effect was found in this system. Recent work by us (PRB B 92 104108) reveals evidence for changes in the local structure at low temperature. In this work we explore the structural changes using single crystal diffraction and other structural probes. Comparisons between the Fe and Al based systems will be made. This work is supported by DOE Grant DE-FG02-07ER46402.

**10:00AM R30.00009 Optical and Electro-Optical Properties of RFe<sub>2</sub>O<sub>4</sub> (R = Y and Yb) Thin Films<sup>1</sup>**, RAM RAI, MICHELLE PASCOLINI, JOSHUA HINZ, SUNY Buffalo State — We present optical, and electro-optical properties of RFe<sub>2</sub>O<sub>4</sub> (R = Y and Yb) thin films deposited on sapphire and YSZ substrates by reactive electron-beam deposition. In order to investigate the electronic transitions and optical properties, we measured transmittance and reflectance of the RFe<sub>2</sub>O<sub>4</sub> thin films in the 1 – 6 eV photon energy range and at temperatures from 10 to 400 K. The optical spectra of RFe<sub>2</sub>O<sub>4</sub> show several electronic peaks arising from Fe 2p<sup>+</sup> to d<sub>on</sub>-site and O 2p to Fe 3d, Y 4d and Y 5s (Yb 5d and 6s) charge-transfer transitions. Interestingly, the electronic excitations display strong temperature dependence with an anomaly between 170 K and 190 K, indicating a structural distortion. Moreover, the electro-optical effects up to 10 % have been observed in the RFe<sub>2</sub>O<sub>4</sub> thin films at 10 K for applied electric fields below 1 kV/cm. These electro-optical effects mostly occur between the photon energy of 1 and 3 eV, vary almost linearly with applied fields, and the effects disappear above 150 K. We will discuss the driving mechanism for the observed electro-optical effects of these compounds.

**10:12AM R30.00010 Magnetically induced ferroelectricity in single crystalline ferrimagnet, Mn<sub>2</sub>Mo<sub>3</sub>O<sub>8</sub><sup>1</sup>**, SHALINEE CHIKARA, JOHN SINGLETON, National High Magnetic Field Lab, Los Alamos National Laboratory, Los Alamos, NM 87544, USA, BIN GAO, YAZHONG WANG, SANG-WOOK CHEONG, Rutgers Center for Emergent Materials and Department of Physics and Astronomy, Rutgers University, Piscataway, New Jersey 08854, USA, VIVIEN ZAPF, National High Magnetic Field Lab, Los Alamos National Laboratory, Los Alamos, NM 87544, USA — We present magnetization and electric polarization results on multiferroic ferrimagnet molybdate system, Mn<sub>2</sub>Mo<sub>3</sub>O<sub>8</sub> in pulsed magnetic fields. Mn<sub>2</sub>Mo<sub>3</sub>O<sub>8</sub>, also known as the mineral isiemite crystallizes in a hexagonal P6<sub>3</sub>mc space group. The magnetism is attributed to the Mn ions whereas the Mo is diamagnetic. The Mo and Mn atoms are stacked alternately along c-axis. The Mn ions form a hexagonal lattice and occur in octahedral and tetragonal coordination. The spins on two different Mn sites give rise to ferrimagnetism. The system orders at about 42 K accompanied by a lambda like anomaly in heat capacity. Mn<sub>2</sub>Mo<sub>3</sub>O<sub>8</sub> shows anisotropic magnetization with a change in slope at 40 K signaling possibly an AFM to ferrimagnet ordering. We observe magnetic field induced electric polarization in our preliminary results and an anomaly at 40 K corresponding to T<sub>N</sub>.

**10:24AM R30.00011 Temperature Dependent Structure of BiFeO<sub>3</sub>: Probing For Spin Lattice Correlations**, TREVOR TYSON, TIAN YU, HAN ZHANG, NJIT, MILINDA ABEYKOON, Photon Sciences, Brookhaven National Laboratory — The local structure of BiFeO<sub>3</sub> has been measured over a broad range of temperatures and in magnetic fields. This detailed study explores the nature of the coupling of magnetism and with the lattice on crossing magnetic transitions. Estimates on the structural changes are given. This work is supported by DOE Grant DE-FG02-07ER46402.

**10:36AM R30.00012 Lattice and magnetic excitations in NdFe<sub>3</sub>(BO<sub>3</sub>)<sub>4</sub>**, RICARDO LOBO, ESPCI PSL, CNRS, UPMC — We measured the temperature dependent polarized infrared spectra of multiferroic NdFe<sub>3</sub>(BO<sub>3</sub>)<sub>4</sub>. The spectra is mostly temperature independent except for the lowest energy phonon in the hexagonal plane. This phonon splits into two at around 60 K, a temperature sensibly larger than the system Néel temperature of 31 K. X-ray scattering indicates that the lattice parameters have an anomaly at the same temperature that the phonon splits. Using inelastic neutron scattering we looked for magnetic excitations that could explain be coupled to phonons. Momentum and energy dispersion curves around the magnetic Bragg peaks show magnetic excitations at energies comparable to the split phonon. We will discuss these results in terms of magnetic fluctuations and activation of Brillouin zone boundary modes.

**Thursday, March 17, 2016 8:00AM - 11:00AM —**  
**Session R32 DCP: Plasmonics and Beyond II: Ultrafast Dynamics** 332 - Teri Odom, Northwestern University

**8:00AM R32.00001 Quantum theory for plasmon-assisted local field enhancement**, ILYA GRIG-ORENKO, New York City College of Technology — We applied quantum theory for nonlocal response and plasmon-assisted field enhancement near a small metallic nanoscale antenna in the limit of weak incoming fields. A simple asymmetric bio-inspired design of the nanoantenna for polarization-resolved measurement is proposed. The spatial field intensity distribution was calculated for different field frequencies and polarizations. We have shown that the proposed design the antenna allows us to resolve the polarization of incoming photons.

**8:12AM R32.00002 Propagating and localized surface plasmons in Ag nanostructures**, MACIEJ DABROWSKI, YANAN DAI, HRVOJE PETEK, Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA 15260 — Plasmonic excitations strongly depend on the size, geometry and dielectric environment of nanoscale metals. Here, we study an epitaxially grown Ag nanostructures on Si(001) and Si(111) surfaces by Low Energy Electron Microscopy/Photoemission Electron Microscopy (LEEM/PEEM). Using the combination of LEEM and broadly tunable femtosecond laser excited multiphoton PEEM we image how single crystalline metallic nanostructures form and how plasmon excitations depend on the particle structure and laser excitation parameters. For Ag pyramids with the dimensions of few hundreds nanometers, dipolar and quadrupolar localized surface plasmons are observed. For Ag wires with several micrometer lengths, both localized and propagating surface plasmons can be excited, depending on the polarization, particle orientation and energy of the excitation. Finally, in larger Ag islands, several micrometers in size, the interference patterns are created by plasmon waves excited at the island edges. In addition to plasmonic response, light diffraction patterns around the Ag nanostructures are discussed.

**8:24AM R32.00003 Plasmon-exciton coupling at Ag nanocluster decorated TiO<sub>2</sub>(110) surface studied by time-resolved two-photon photoemission spectroscopy**, SHIJING TAN, ADAM ARGONDISO, HRVOJE PETEK, Department of Physics and Astronomy, University of Pittsburgh — We study the spectroscopy and electron dynamics at Ag nanocluster decorated TiO<sub>2</sub>(110) surface upon photoexcitation of plasmonic modes by two-photon photoemission spectroscopy (2PP). Depositing Ag onto a reduced rutile TiO<sub>2</sub>(110) surface at room temperature forms pancake-like Ag particles with an average diameter of 4 nm and height of 1.5 nm. Measurements of the 2PP yield from Ag/TiO<sub>2</sub> surface with tunable femtosecond laser excitation show enhancement at plasmonic resonances. Exciting with s-polarization ( $\vec{S}$ ) the plasmonic resonance enhancement has a single peak at 3.1 eV, whereas with p-polarization ( $\vec{P}$ ) there is an additional more intense resonance at 3.8 eV. We attribute the 3.1 and 3.8 eV peaks to the in-plane and the surface-normal plasmon modes respectively. Crystal azimuth orientation dependent excitation with ( $\vec{S}$ ) shows an anisotropy in the 2PP spectra for the 3.1 eV in-plane plasmon mode when the laser electric field is aligned in the [001] vs. [110] directions. The existence of two plasmon modes and the in-plane plasmon anisotropy imply that the plasmon modes are perturbed by coherent coupling with excitons in the rutile TiO<sub>2</sub> substrate. We speculate that plasmon-exciton resonant energy transfer could play an important role in the plasmonically enhanced photocatalysis at the Ag/TiO<sub>2</sub> surface.

**8:36AM R32.00004 Plasmonics at the Space-Time Limit**, MARTIN AESCHLIMANN, Department of Physics and Research Center OPTIMAS, University of Kaiserslautern, Germany — The optical response of metallic nanostructures exhibits fascinating properties: local field interference effects that lead to strong variations of the near field distribution on a subwavelength scale, local field enhancement, and long lasting electronic coherences. Coherent control in general exploits the phase properties of light fields to manipulate coherent processes. Originally developed for molecular systems these concepts have recently been adapted also to nano-optical phenomena. Consequently, the combination of ultrafast laser spectroscopy, i.e. illumination with broadband coherent light sources, and near-field optics, opens a new realm for nonlinear optics on the nanoscale. To circumvent the experimental limitation of optical diffraction we use a photoemission electron microscope (PEEM) that has been proved to be a versatile tool for the investigation of near field properties of nanostructures with a spatial resolution of only a few nanometers and that allows for new spectroscopy techniques with ultrafast time resolution [1,2]. We introduce a new spectroscopic method that determines nonlinear quantum-mechanical response functions beyond the optical diffraction limit. While in established coherent two-dimensional (2D) spectroscopy a four-wave-mixing response is measured using three ingoing and one outgoing wave, in 2D nanoscopy we employ four ingoing and no outgoing waves. This allows studying a broad range of phenomena not accessible otherwise such as space-time resolved coupling, transport, and Anderson localized photon modes [3, 4]. [1] M. Aeschlimann et al, Nature **446**, 301 (2007) [2] M. Aeschlimann et al, PNAS **107** (12), 5329 (2010) [3] M. Aeschlimann et al, Science **333**, 1723-1726 (2011) [4] M. Aeschlimann et al, Nature Photonics **9**, 663, (2015)

**9:12AM R32.00005 Imaging of Surface Plasmons by Ultrafast Multi-Photon Photoemission Electron Microscopy**, YANAN DAI, MACIEJ DABROWSKI, HRVOJE PETEK, Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, PA 15260 — Silver nanostructures on silicon substrates are characterized by Low Energy Electron Microscopy (LEEM) and their plasmonic modes are imaged by ultrafast femtosecond laser pulse with Multi-Photon Photoemission Electron Microscopy (mP-PEEM). Simulations of Surface Plasmon Polariton (SPP) and Localized Surface Plasmon (LSP) mP-PEEM images are performed by 3D finite difference time domain (FDTD) method in order to characterize the plasmonic excitations. We imaged and simulated the interference patterns of multiple SPPs launched at the edges of microns scale single-crystal Ag islands with excitation wavelengths covering whole visible range. In addition, we studied the plasmonically enhanced excitation and plasmonic field distributions on single-crystal Ag wires of a few microns in length. Finally, we studied plasmon dynamics by recording plasmon field evolution on Ag structures from FDTD simulation.

**9:24AM R32.00006 EELS study of plasmon excitations in LPNE aluminum nanowires**, RODOLFO LOPEZ JR, JAY SHARPING, ERIK MENKE, Univ of California - Merced — We present our current experimental investigations of plasmonic resonances of aluminum nanowire arrays. Ordered nanowires with well-defined shape and size distributions are fabricated on silicon wafers and TEM apertures using lithographically patterned nanowire electrodeposition (LPNE). The structures, which have sizes down to 40 nm in the z direction, and planar sizes varying up to 200nm, exhibit prominent and tunable plasmon resonances which are visible in EELS spectra. The electron energy loss spectra is correlated to the native oxide layer thickness as well as growth parameters of the nanowire array.

**9:36AM R32.00007 Excited carrier dynamics and transport in plasmonic nanostructures<sup>1</sup>**, RAVIS-HANKAR SUNDARARAMAN, PRINEHA NARANG, ADAM JERMYN, HARRY ATWATER, WILLIAM GODDARD III, Joint Center for Artificial Photosynthesis, California Institute of Technology — Surface plasmon resonances provide a pathway to efficiently capture electromagnetic radiation in sub-wavelength structures for energy conversion and photodetection at the nano scale. The complete mechanism involves several microscopic steps spanning length scales from atomic dimensions to tens or hundreds of nanometers, posing challenges for experimental characterization and for first-principles predictions. To provide the basis for predicting and optimizing the complex interplay of materials and geometric effects in plasmon decay-induced excited carrier phenomena, we combined *ab initio* electronic structure calculations, electromagnetic simulations and Boltzmann transport models. In Au, Ag, Cu and Al nanostructures, we find that initial carrier distributions as well as their subsequent transport, relaxation and thermalization are sensitive to electronic structure, exhibiting strong asymmetries between electrons and holes. We predict energy-dependent spatially-resolved carrier distributions collected in plasmonic nanostructures with strong field inhomogeneities, and explore the possibility of tailoring materials and geometry to collect the carrier distributions needed for such applications as photochemically driven CO<sub>2</sub> reduction and water splitting.

**9:48AM R32.00008 Solar upconversion with plasmonic hot carriers**, JENNIFER A. DIONNE, Stanford University — Upconversion of sub-bandgap photons is a promising approach to exceed the Shockley-Queisser limit in solar technologies. Placed behind a solar cell, upconverting materials convert lower-energy photons transmitted through the cell to higher-energy above-bandgap photons that can then be absorbed by the cell and contribute to photocurrent. Because the upconverter is electrically isolated from the active cell, it need not be current-matched to the cell, nor will it add mid-gap recombination pathways. Calculations have indicated that single-junction cell efficiencies can exceed 44% upon addition of an upconverter – a significant improvement over the maximum cell efficiency of 30% without an upconverter. However, due to the low quantum efficiencies and narrow absorption bandwidths of existing upconverters, such significant cell improvements have yet to be observed experimentally. In this presentation, we will describe an entirely new solar upconverting scheme based on hot-carrier injection from a plasmonic absorber to an adjacent semiconductor. The plasmonic system both induces upconversion based on injection of hot-electrons and hot-holes and also enhances light-matter interactions. Low-energy photons incident on a plasmonic particle generate hot electrons and hot holes, which are injected into a semiconducting quantum well and subsequently radiatively recombine. Importantly, the bandgap of the quantum well can be higher than the energy of the incident photon, enabling emission of a higher-energy photon than that absorbed. First, we present analytic calculations showing that efficiencies as high as 25% are possible, significantly higher than existing solid-state upconverters, which are only 2-5% efficient. We also describe how further improvements in the efficiency are possible by employing materials and geometries that allow for more efficient carrier injection. Then, we describe experiments on InGaN/GaN quantum wells decorated with Au disks. On their own, the InGaN/GaN quantum wells do not upconvert. With the addition of the gold disks, strong upconversion is observed. We show how this new upconversion scheme offers spectral tunability across visible and near-infrared frequencies, does not require coherent illumination, is a linear process, and can be broadband. Contributing authors include Guru Naik and Alex Welch, Stanford University

**10:24AM R32.00009 Detecting antibody-antigen reaction using nano ripple gold LSPR based biosensor**, IRAM SALEEM, DHARSHANA WIJESUNDERA, BUDDHI TILAKARATNE, Department of Physics, University of Houston and Texas center for superconductivity TcSUH, WILLIAM WIDGER, Department of Biology and Biochemistry, University of Houston and Texas center for superconductivity TcSUH, WEI-KAN CHU, Department of Physics, University of Houston and Texas center for superconductivity TcSUH — We introduce a simple and cost-effective scheme for bio-sensing using nano-ripple structures. One-dimension metallic nano-ripple structures formed by gas cluster ion beam irradiation have shown polarization of light as well as the localized surface plasmon resonance. These localized surface plasmon resonance (LSPR) based bio sensors not only are capable of label free real time analytical detection but also show high sensitivity. The nano surface morphology determines the changes in the plasmonic properties of nanostructures hence the plasmonic response is tunable. By immobilizing a stable and sterically accessible monolayer of antibody on the surface of these substrates and loading different concentrations of the specific antigen we identified the shift in the LSPR peaks triggered by the change of dielectric function in the neighborhood of the structures. These plasmonic nano-metallic structures can be utilized to observe the shift in the LSPR resonance frequency due to the cycle of adsorption, re-adsorption and reactions taking place on the surface that can potentially be mapped in to reaction mechanics. The bio-sensor has monolayer molecule-coating sensitivity and specific selectivity.

**10:36AM R32.00010 Unique signature of bivalent analyte surface plasmon resonance model: A model governed by non-linear differential equations<sup>1</sup>**, PURUSHOTTAM TIWARI, Georgetown University, XUEWEN WANG, YESIM DARICI, JIN HE, Florida International University, AYKUT UREN, Georgetown University — Surface plasmon resonance (SPR) is a biophysical technique for the quantitative analysis of bimolecular interactions. Correct identification of the binding model is crucial for the interpretation of SPR data. Bivalent SPR model is governed by non-linear differential equations, which, in general, have no analytical solutions. Therefore, an analytical based approach cannot be employed in order to identify this particular model. There exists a unique signature in the bivalent analyte model, existence of an 'optimal analyte concentration', which can distinguish this model from other biphasic models. The unambiguous identification and related analysis of the bivalent analyte model is demonstrated by using theoretical simulations and experimentally measured SPR sensorgrams.

<sup>1</sup>Experimental SPR sensorgrams were measured by using Biacore T200 instrument available in Biacore Molecular Interaction Shared Resource facility, supported by NIH Grant P30CA51008, at Georgetown University

**10:48AM R32.00011 Selective plasmon enhancement of fluorescence towards point of care disease diagnostics**, BISHWAMBHAR SENGUPTA, JINGYI ZHU, Clemson University, RAMAKRISHNA PODILA, APPARAO RAO, Clemson University — Surface plasmon coupled emission (SPCE) is a novel analytical technique in which the isotropic emission of a fluorophore is combined with the surface plasmon resonance of a metal thin film to yield highly directional emission from the so-called plasmaphore and thus greatly increased sensitivity. The optimal SPCE enhancement is achieved by introducing a spacer layer to mitigate fluorescence-quenching arising from metal-fluorophore interactions. Here we report a >10-fold amplification of rhodamine B (RhB) fluorophore when carbon nanomaterials are used as the spacer layer. By combining experimental and density functional theory studies, we found that the rehybridization between CNMs and RhB results in emission redshift. We present SPCE-based biosensors for smart-phone based sensing of different analytes including biomarkers for diseases such as tuberculosis.

**Thursday, March 17, 2016 8:00AM - 11:00AM –**

**Session R33 DPOLY: Organic Electronics and Photonics - Organic Photovoltaics** 336 - Daniel Sinkovits, University of Wisconsin, Stout

**8:00AM R33.00001 ABSTRACT MOVED TO V4.002 –**

**8:36AM R33.00002 Multiple Charge Transfer States at Ordered and Disordered Donor/Acceptor Interfaces**, MICHAEL FUSELLA, BRETT VERRETT, YUNHUI LIN, Princeton University, ALYSSA BRIGEMAN, The Pennsylvania State University, GEOFFREY PURDUM, YUEH-LIN LOO, Princeton University, NOEL GIEBINK, The Pennsylvania State University, BARRY RAND, Princeton University — The presence of charge transfer (CT) states in organic solar cells is accepted, but their role in photocurrent generation is not well understood. Here we investigate solar cells based on rubrene and C<sub>60</sub> to show that CT state properties are influenced by molecular ordering at the donor/acceptor (D/A) interface. Crystalline rubrene films are produced with domains of 100s of microns adopting the orthorhombic phase, as confirmed by grazing incidence XRD, with the (h00) planes parallel to the substrate. C<sub>60</sub> grown atop these films adopts a highly oriented face-centered cubic phase with the (111) plane parallel to the substrate. For this highly ordered system we have discovered the presence of four CT states. Polarized external quantum efficiency (EQE) measurements assign three of these to crystalline origins with the remaining one well aligned with the disordered CT state. Varying the thickness of a disordered blend of rubrene:C<sub>60</sub> atop the rubrene template modulates the degree of crystallinity at the D/A interface. Strikingly, this process alters the prominence of the four CT states measured via EQE, and results in a transition from single to multiple electroluminescence peaks. These results underscore the impact of molecular structure at the heterojunction on charge photogeneration.

**8:48AM R33.00003 Charge Photogeneration in Organic Photovoltaics: Role of Hot versus Cold Charge Transfer Excitons**, KENAN GUNDOĞDU, BHOJ GAUTAM, ROBERT YOUNTS, NC State University, LIANG YAN, UNC, ROBERT YOUNTS, HARALD ADE, NC State University, WEI YOU, UNC, NC STATE UNIVERSITY TEAM, UNIVERSITY OF NORTH CAROLINA TEAM — The role of excess excitation energy on long-range charge separation in organic donor/acceptor bulk heterojunctions continues to be unclear. While ultrafast spectroscopy results argue for efficient charge separation through high energy CT states within the first picosecond (ps) of excitation, charge collection measurements suggest excess photon energy does not increase the current density in bulk heterojunction (BHJ) devices. Here we studied the population dynamics of charge separated polarons upon excitation of high energy polymer states and low energy interfacial CT states in two polymer/fullerene blends from ps to nanosecond (ns) time scales. We observed that the charge separation dynamics do not show significant dependence on excitation energy. These results confirm that excess exciton energy is not necessary for the effective generation of charges.

**9:00AM R33.00004 Fully conjugated donor-acceptor block copolymers as model systems for studies of charge transfer<sup>1</sup>**, MELISSA APLAN, YOUNGMIN LEE, CHRISTOPHER GRAY, THOMAS MALLOUK, ENRIQUE GOMEZ, Pennsylvania State University — Fully conjugated block copolymers, consisting of an electron donor and an electron acceptor block, can serve as the active layer in organic photovoltaic devices. Incorporating the donor-acceptor interface within the chemical structure enables model studies of charge transfer. We synthesized a series of block copolymers consisting of a P3HT electron donor and a push-pull polymer electron acceptor, yielding: poly(3-hexylthiophene)-block-poly-((9-(9-heptadecanyl)-9H-carbazole)-1,4-diyl-alt-[4,7-bis(3-hexylthiophen-5-yl)-2,1,3-benzothiadiazole]-2',2''-diyl) (P3HT-b-PCT6BT), poly(3-hexylthiophene)-block-poly-((9,9-dioctylfluorene)-2,7-diyl-alt-[4,7-bis(3-hexylthiophen-5-yl)-2,1,3-benzothiadiazole]-2',2''-diyl) (P3HT-b-PFT6BT), and poly(3-hexylthiophene)-block-poly-((2,5-dihexylphenylene)-1,4-diyl-alt-[4,7-bis(3-hexylthiophen-5-yl)-2,1,3-benzothiadiazole]-2',2''-diyl) (P3HT-b-PPT6BT). By altering the electron rich unit of the acceptor, we adjust the energy difference between donor and acceptor HOMOs. Using photoluminescence, we observe no evidence of exciton dissociation to a charge transfer state in P3HT-b-PCT6BT. In P3HT-b-PFT6BT and P3HT-b-PPT6BT we observe varying degrees of intrachain charge transfer. These results measure the critical driving force needed for charge transfer.

<sup>1</sup>Fully conjugated donor-acceptor block copolymers as model systems for studies of charge transfer

**9:12AM R33.00005 Morphology-insensitive Performance Facilitates Transition from Spin-Coating to Roll-to-Roll Coating For High-Performance, Solution-Processed Solar Cells**, DEAN DELONGCHAMP, National Institute of Standards and Technology — Solution processing via roll-to-roll (R2R) coating promises a low cost, low thermal-budget, sustainable revolution for the production of solar cells. Yet virtually all high efficiency solution processed research cells have been demonstrated by spin-coating, a low-volume deposition process. We present detailed device and morphology studies of an organic photovoltaic (OPV) system deposited by a high volume manufacturing technique, blade-coating, that achieves greater than 9.5 % power conversion efficiency (PCE). The average crystal domain orientation and characteristic phase separation length distribution are markedly different when deposited by blade-coating rather than spin-coating. This result allows us to determine which aspects of morphology are not relevant to the PCE of this system. Whether the crystallites are “face on” or “edge on” does not appear to impact the PCE of system, nor does the length scale or “hierarchical” nature of the phase length scale. Persistent morphological qualities that may be associated with high PCE in this system are relatively pure phases and relatively strong diffraction. We posit that OPV systems in which the PCE is less sensitive to morphology may also be less sensitive to film thickness, enabling some to maintain high PCE in active layers thicker than greater than ~200 nm. We confirm that blade-coating is a suitable prototyping technique for R2R coating by demonstrating nominally identical morphologies for both piece blade-coating and continuous-web, slot-die coating.

**9:48AM R33.00006 Contorted hexabenzocoronene derivatives enable fullerene-free, semi-transparent solar cells with record-breaking single-junction photovoltage**, NICHOLAS DAVY, MELDA SEZEN, YUEH-LIN LOO, Department of Chemical and Biological Engineering, Princeton University — Recent work on tuning the chemical structure of contorted hexabenzocoronene (cHBC) in our group has yielded derivatives with a spectrum of energy levels and absorption profiles, greatly improving the utility of these materials as donor and/or acceptor constituents in organic solar cells. Here, we report planar-heterojunction solar cells comprising an extended heterocyclic cHBC donor and a halogenated cHBC acceptor. By harvesting primarily near-UV light, these devices exhibit a record open-circuit voltage of 1.5 V; this value is higher than any previously reported value for a single-junction organic solar cell. Our active layers are molecularly smooth and pinhole-free; these devices should be scalable to large areas without incurring substantial loss to performance. With a transmittance of 79% across the visible, our devices can be vertically integrated to directly drive the switching of electrochromic windows, where existing prototypes depend on tandem solar cells having near-infrared absorbers.

**10:00AM R33.00007 Layer-by-layer fabrication of supramolecular dyes on TiO<sub>2</sub> surfaces for optoelectronic applications**, XIAOQING KONG, SHAWN MAGUIRE, Stevens Institute of Technology, DIANE LYE, MARCUS WECK, New York University, STEPHANIE LEE, Stevens Institute of Technology — We present a modular layer-by-layer approach based on metal coordination chemistry to assemble supramolecular dyes exhibiting increased absorption in the visible range on electrode surfaces. Specifically, palladiated bis-pincer complexes (Pd-BPCs) were employed as linkers between pyridyl-terminated organic molecules via dative bonding. By alternately immersing mesoporous TiO<sub>2</sub>-coated glass substrates in solutions containing dissolved zinc porphyrin (ZnP) and Pd-BPCs, supramolecular dyes were assembled layer-by-layer on the TiO<sub>2</sub> surfaces. UV-visible absorption spectra of these assembled structures revealed a linear increase in the Soret and Q bands of ZnP after each immersion of the substrate in the ZnP solution. Coordination of the ZnP layers with Pd-BPC resulted in a slight red shift (<10 nm) of the absorption bands. The modular nature of the assembly process afforded the incorporation of other pyridyl-terminated organic molecules in specific layers of the supramolecular assemblies. By assembling unique organic dyes that absorb different wavelengths of light, we expect to expand light absorption across the visible region of the solar spectrum for solar cell applications.

**10:12AM R33.00008 Surprising increase in photostability of organic amorphous materials by efficient molecular packing**, YUE QIU, Univ of Wisconsin, Madison, LUCAS ANTONY, JUAN DE PABLO, University of Chicago, MARK EDIGER, Univ of Wisconsin, Madison — Photochemically robust materials are desired for organic electronics. Previous work has demonstrated that crystal packing can strongly influence photochemical reactivity. In amorphous materials, however, similar efforts to tune photostability have not been successful. In this work, we show that organic glasses prepared by physical vapor deposition can be highly stable against photo-isomerization. Disperse orange 37 (DO37), an azobenzene derivative, is studied as a model molecule. The thickness and molecular orientation of DO37 thin films can be altered by the photo-isomerization reaction. We use spectroscopic ellipsometry to measure sample thickness and molecular orientation during light irradiation. By changing the substrate temperature during the deposition, photostability can increase 2 to 3 orders of magnitude relative to the liquid-cooled glass. We find that photostability correlates with density of packing, with density increases of up to 1.3%. Simulations also show that glasses with higher density can be significantly more photo-stable. These results show for the first time that photostability of glasses can be significantly modulated by molecular packing. And they may provide insight in designing organic photovoltaics and light emission devices with longer lifetimes.

**10:24AM R33.00009 Fixed Junction Photovoltaic Devices Based On Polymerizable Ionic Liquids<sup>1</sup>**, AUSTIN LIMANEK, DR. JANELLE LEGER, Western Washington University — Recently, polymer-based photovoltaic devices (PPVs) have received significant attention as a possible affordable, large area and flexible solar energy technology. In particular, research on chemically fixed p-i-n junctions in polymer photovoltaic devices has shown promising results. These devices are composed of ionic monomers in a polymer matrix sandwiched between two electrodes. When a potential is applied, the ionic monomers migrate towards their corresponding electrodes, enabling electrochemical doping of the polymer. This leads to the formation of bonds between the polymer and ionic monomers, resulting in the formation of a chemically fixed p-i-n junction. However, early devices suffered from long charging times and low overall response. This has been attributed to the low phase compatibility between the ionic monomers and the polymer. It has been shown for light-emitting electrochemical cells, replacing the ionic monomers with polymerizable ionic liquids (PILs) mitigates these challenges. We will present the use of PILs as the dopant in fixed junction PPV devices. Preliminary devices demonstrate significantly improved performance, decreased charging times, and high open circuit voltages.

**10:36AM R33.00010 Physical and electrical models for interpreting AC and DC transport measurements in polymer solar cells**, MAX MCINTYRE, MARIAN TZOLOV, RAQUEL COSSEL, SETH PEELER, Lock Haven Univ — We have fabricated and studied bulk heterojunction solar cells using a mixture of the low bandgap material PCPDTBT and PCBM-C60. Our transport studies show that the devices in dark have good rectification and they respond to AC voltage as a simple RC circuit. The illumination causes an additional contribution to the impedance, which varies with the level of illumination. One proposed model is that photo-generated charges can become trapped in potential wells. These charges then follow a Debye relaxation process, which contributes to a varying dielectric constant. Another proposed model is based on a RC circuit model with two capacitors which can describe the varying capacitance behavior. The physical mechanism for this model is that photo-generated charges become accumulated at the interface between PCPDTBT and PCBM-C60 and form an additional layer of charge. We will show that our circuit models and their analogous physical models can predict the AC and DC responses of polymer solar cells.

**10:48AM R33.00011 Dye-Sensitized Carbon Nano-Yarn Based Photovoltaic Cells with Enhanced Electron-Hole Separation and Barrier Characteristics<sup>1</sup>**, H. JUSTIN MOORE, MIGUEL LEAL, GLENN GRIS-SOM, TAREK TRAD, NAZMUL ISLAM, AHMED TOUHAMI, M. JASIM UDDIN, University Texas Rio Grande Valley — Over the last 30 years dye-sensitized solar cells have received considerable interest as an alternative energy source due to their low-cost, environmental sustainability, flexibility, and an abundant number of other practical applications. Flexible carbon nanotube-yarn based photo voltaic cells have shown considerable advantages over metal wire based solar cells or non-flexible substrates like indium-doped tin oxide glass. Carbon nanotubes are superior for photo voltaic cells due to their lower electrical resistance, excellent electrocatalytic activity, and high mechanical integrity. Here, we introduce the use of poly(3-hexylthiophene-2,5-diyl), [6.6] diphenyl C<sub>62</sub> bis(butyric acid methyl ester), cadmium sulfide-cadmium selenide quantum dots, and ruthenium-based dye N719 to locally increase electron generation, decrease electron-hole pair recombination, as well as enhancing barrier characteristics. Our prototype 3-dimensional carbon nano-yarn based photovoltaic cells show an enhancement in photon to energy conversion efficiency (>6.5%). This along with prolonged environmental stability makes for a very promising solar cell.

**Session R34 DPOLY: Polymer Glasses** 337 - Rob Hoy, University of South Florida

**8:00AM R34.00001 Elastic yielding after  $\gamma$ -irradiation of cold-drawn polymer glasses<sup>1</sup>**, PANPAN LIN, Univ of Akron, QUAN XU, China University of Petroleum, ABRAHAM JOY, SHI-QING WANG, Univ of Akron — Elastic yielding shows up when a considerable retractive stress rises from a piece of cold-drawn polymer glass during annealing at temperatures above storage temperature .....[1,2]. This phenomenon indicates significant chain tension built up during cold drawing. To explore the role of chain networking, we applied  $\gamma$ -irradiation to produce chain scission and cause partial breakdown of the chain network in the pre-necked polymer glasses. To demonstrate universality, four different glasses, i.e., polycarbonate (PC), polystyrene (PS), poly(methyl methacrylate) (PMMA), and poly(2,6-dimethyl-1,4-phenylene oxide) (PPE) were first subjected to uniaxial extension at room temperature before the irradiation. Our data shows that the retractive stress significantly decreases in magnitude with increasing dosage of the  $\gamma$ -irradiation. The diminishing elastic yielding effect may be due to the loss of chain tension by chain scission brought about by the irradiation. [1] S. Cheng and S.-Q. Wang, Phys. Rev. Lett. **110**, 065506 (2013). [2] S. Cheng and S.-Q. Wang, Macromolecules **47**, 3661 (2014).

**8:12AM R34.00002 To explore the nature of mechanical stress of polymeric glass by stress relaxation tests<sup>1</sup>**, XIAOXIAO LI, JIANNING LIU, PANPAN LIN, SHI-QING WANG, University of Akron — In a glassy polymer intermolecular interactions glue all segments into one single macroscopic piece thanks to attractive van der Waals bonding. The cohesive strength of such a primary structure is rather weak. If the molecular weight is sufficiently high, the covalent bonding can "magically" take part in the cohesion of the polymer glass through formation of a chain network. This picture of hybrid structure enables us to delineate the nature of mechanical stress [1]. Under either extension or compression, we performed stress relaxation experiments in both pre-yield and post-yield regimes to illustrate how inter-segmental and intra-segmental components of stress emerge in the different regimes. [1] S.-Q. Wang, S. Cheng, P. Lin, and X. Li, J. Chem. Phys. 141, 094905 (2014).

**8:24AM R34.00003 Role of dynamical heterogeneities on the viscoelastic spectrum of polymers: a stochastic continuum mechanics model**, ROBIN MASUREL, CNRS UPMC ESPCI ParisTech PSL Res Univ, Lab SIMM, SABINE CANTOURNET, MINES ParisTech, PSL-Research University, MAT Centre des matériaux, ALAIN DEQUIDT, Univ Clermont Ferrand, Inst Chim Clermont Ferrand, DIDIER LONG, Laboratoire Polymères et Matériaux Avancés, HELNE MONTES, FRANOIS LEQUEUX, CNRS UPMC ESPCI ParisTech PSL Res Univ, Lab SIMM — Amorphous polymers in their glass transition regime can be described as a tiling of nanometric domains. Each domain exhibits its own relaxation time which is distributed over at least 4 decades. These domains are known as dynamical heterogeneities. This article will describe the mechanics of amorphous polymers using a stochastic continuum mechanics model that includes their heterogeneous dynamics. Solving this model both by finite elements and using a self-consistent method, we find a viscoelastic relaxation spectrum quantitatively similar to that of an experimentally measured one in a polymer. We show evidence that elastic couplings between domains control the stress relaxation after a step strain and result in a narrowing of the long-time region of the viscoelastic spectrum (as compared to that of dynamical heterogeneities).

**8:36AM R34.00004 Recovery from nonlinear creep provides a window into physics of polymer glasses**, JAMES CARUTHERS, GRIGORI MEDVEDEV, Purdue University — Creep under constant applied stress is one of the most basic mechanical experiments, where it exhibits extremely rich relaxation behavior for polymer glasses. As many as five distinct stages of nonlinear creep are observed, [1] where the rate of creep dramatically slows down, accelerates and then slows down again. Modeling efforts to-date has primarily focused on predicting the intricacies of the nonlinear creep curve. We argue that as much attention should be paid to the creep recovery response, when the stress is removed. The experimental creep recovery curve is smooth, where the rate of recovery is initially quite rapid and then progressively decreases. In contrast, the majority of the traditional constitutive models predict recovery curves that are much too abrupt. A recently developed stochastic constitutive model that takes into account the dynamic heterogeneity of glasses produces a smooth creep recovery response that is consistent with experiment. 1. G. A. Medvedev and J. M. Caruthers, Polymer 74, 235 (2015)

**8:48AM R34.00005 Multi-step deformations – a stringent test for constitutive models for polymer glasses**, GRIGORI MEDVEDEV, JAMES CARUTHERS, Purdue University — A number of constitutive models have been proposed to describe mechanical behavior of polymer glasses, where the focus has been on the stress-strain curve observed in a constant strain rate deformation. The stress-strain curve possesses several prominent features, including yield, post-yield softening, flow, and hardening, which have proven challenging to predict. As a result, both viscoplastic and nonlinear viscoelastic constitutive models have become quite intricate, where a new mechanism is invoked for each bend of the stress-strain curve. We demonstrate on several examples that when the models are used to describe the multi-step deformations vs. the more common single strain rate deformation, they produce responses that are qualitatively incorrect, revealing the existing models to be parameterizations of a single-step curve. A recently developed stochastic constitutive model has fewer problems than the traditional viscoelastic/viscoplastic models, but it also has difficulties. The implications for the mechanics and physics of glassy polymers will be discussed.

**9:00AM R34.00006 Brittle-ductile transition under compression of glassy polymers<sup>1</sup>**, JIANNING LIU, XIAOXIAO LI, PANPAN LIN, Univ of Akron, SHIWANG CHENG, Oak Ridge National Laboratory, WEIYU WANG, Univ of Tennessee, JIMMY MAYS, Oak Ridge National Laboratory, SHI-QING WANG, Univ of Akron — Polymeric glasses of high molecular weight are always ductile in compression. Even the most brittle (in tensile extension) polystyrene is ordinarily ductile in uniaxial compression. Thus, it seems that theoretical studies only need to develop a description of yielding and post-yield plastic deformation for polymer glasses. But can yielding take place in compression if the molecular weight is sufficiently reduced? In other words, can alpha processes be greatly accelerated during external deformation in absence of chain networking? Must a new paradigm account for the role of chain networking that only takes place in polymers of high molecular weight? To address these questions, we systematically explored the response over a range of temperature to uniaxial compression at different rates of polystyrene with various molecular weights and molecular weight distributions. Our preliminary results [1] show that PS of low molecular weight is brittle in compression and chain networking is necessary (but not sufficient) to ensure a ductile response. [1] Liu, J.; Lin, P.; Cheng, S.; Wang, W.; Mays, J. W.; Wang, S.-Q. Polystyrene glasses under compression: Ductile and brittle responses. *ACS Macro Letters* 2015, 1072-1076.

**9:12AM R34.00007 Incorporating the effect of orientation hardening in an effective temperature nonequilibrium theory for glassy polymers**, JINGKAI GUO, Johns Hopkins Univ, RUI XIAO, Hohai Univ, THAO NGUYEN, Johns Hopkins Univ — Amorphous polymers exhibit a wide range of time and temperature dependent behavior. Recently, Xiao and Nguyen developed an effective temperature theory that can capture a wide variety of nonequilibrium behaviors at moderate strains. At large strains, the stress response of glassy polymers is dominated by strain hardening as a result of chain alignment. The goal of this study was to extend the effective temperature theory to large deformation and make it capable of modeling strain hardening from deformation-induced molecular alignment. We compared two approaches. In the spirit of internal state variable thermodynamics theory, we introduced a series of stretch-like internal state variables to characterize the molecular resistance to plastic flow associated with each inelastic mechanism. The dependence of free energy on the internal state variables naturally gives rise to a deformation dependent back stress. The flow rule and the evolution of effective temperatures were derived in a thermodynamically consistent manner. In the second approach, we introduced a steady-state limit in the evolution of the effective temperature characterizing the nonequilibrium structure of the material. Both approaches can well capture the experimentally measured phenomena of orientation hardening, including the development of deformation-induced anisotropy in the yield strength and hardening modulus, the Bauschinger effect, and differences in the hardening moduli in tension and compression of pre-oriented specimens.

**9:24AM R34.00008 An effective temperature theory coupling structural evolution and viscoplastic deformation of glassy polymers**, THAO NGUYEN, Department of Mechanical Engineering, Johns Hopkins University, RUI XIAO, Department of Engineering Mechanics, Hohai University — Glassy polymers are amorphous polymers that have been driven out of equilibrium below the glass transition temperature. In the nonequilibrium state, the polymer chains continue to slowly rearrange towards a lower entropy state, which causes physical properties to change with time in a process referred to as physical aging. Physical aging can be reversed by plastic deformation, which moves the material further away from equilibrium. Though structural evolution and viscoplasticity are interdependent, they have been treated as separate processes and described by different theoretical approaches. Here, we introduce a new theory that strongly couples viscoplasticity and structural evolution through an effective temperature thermodynamic framework and a constitutive model for the dependence of the relaxation time on the configurational structure. The theory can describe a wide range of nonequilibrium behaviors, including viscoplasticity, physical aging, mechanical rejuvenation, and the glass transition, using a common set of parameters. We will show comparisons of theoretical predictions and experimental measurements of the effect of cold work and aging on the viscoplastic stress response and energy storage as measured by dynamic scanning calorimetry.

**9:36AM R34.00009 Entropy Theory of Polymer Glass-Formation in Variable Spatial Dimension.**, WEN-SHENG XU, Univ of Chicago, JACK DOUGLAS, National Institute of Standards and Technology, KARL FREED, Univ of Chicago — The importance of packing frustration is broadly appreciated to be an important aspect of glass-formation. Recently, great interest has focused on using spatial dimensionality ( $d$ ) as a theoretical tool for exploring this and other aspects of glass-forming liquids. We explore glass-formation in variable based on the generalized entropy theory, a synthesis of the Adam-Gibbs model with direct computation of the configurational entropy of polymer fluids using an established analytical statistical thermodynamic model. We find that structural relaxation in the fluid state asymptotically becomes Arrhenius in the limit and that the fluid transforms upon sufficient cooling above a critical dimension near into a dense amorphous state with a finite positive residual configurational entropy. The GET also predicts the variation with measures of fragility and of the characteristic temperatures of glass-formation demarking the onset, middle, and end, of the broad glass transition. Direct computations of the isothermal compressibility and thermal expansion coefficient, which are physical measures of packing frustration, demonstrate that these fluid properties strongly correlate with the fragility of glass-formation. Back to three dimensions, we deduce apparently universal relationships between  $d$ , a measure of the breadth of the glass-formation and both the isothermal compressibility and thermal expansion coefficient of polymer melts at  $T_g$ .

**9:48AM R34.00010 Free Volume, Energy, and Entropy at the Polymer Glass Transition: New Results and Connections with Widely Used Treatments**<sup>1</sup>, RONALD WHITE, JANE LIPSON, Dartmouth College — Free volume has a storied history in polymer physics. To introduce our own results, we consider how free volume has been defined in the past, e.g. in the works of Fox and Flory, Doolittle, and the equation of Williams, Landel, and Ferry. We contrast these perspectives with our own analysis using our Locally Correlated Lattice (LCL) model where we have found a striking connection between polymer free volume (analyzed using *PVT* data) and the polymer's corresponding glass transition temperature,  $T_g$ . The pattern, covering over 50 different polymers, is robust enough to be reasonably predictive based on melt properties alone; when a melt hits this  $T$ -dependent boundary of critical minimum free volume it becomes glassy. We will present a broad selection of results from our thermodynamic analysis, and make connections with historical treatments. We will discuss patterns that have emerged across the polymers in the energy and entropy when quantified as "per LCL theoretical segment". Finally we will relate the latter trend to the point of view popularized in the theory of Adam and Gibbs.

**10:00AM R34.00011 The Effects of Pressure, Local Packing, and Chain Stiffness on the Polymer Glass Transition.**<sup>1</sup>, JANE LIPSON, RONALD WHITE, Dartmouth Chemistry Department — We have recently shown that thermodynamic properties like free volume, energy, and entropy in the polymer melt state can be connected to the polymer's glass transition temperature,  $T_g$ . One of the strongest correlations we have observed is that relating  $T_g$  to polymer free volume. However, isochoric results on glassifying systems, which can be accessed by taking pressure-dependent measurements, reveal that free volume cannot be the only parameter to control the approach to the glass transition. We therefore turn to the effects of pressure, local packing, and chain stiffness. Up to this point we have focused on ambient pressure; we now apply our LCL model analysis to changes in dynamical behavior with  $T$ , or  $P$ . In addition we will correlate our LCL results with various measures of chain stiffness in the context of glassy behavior.

**10:12AM R34.00012 Design rules for rational control of polymer glass formation behavior and mechanical properties with small molecular additives**<sup>1</sup>, JAYACHANDRA HARI MANGALARA, DAVID SIMMONS, The University of Akron — Small molecule additives have long been employed to tune polymers' glass formation, mechanical and transport properties. For example, plasticizers are commonly employed to suppress polymer  $T_g$  and soften the glassy state, while antiplasticizers, which stiffen the glassy state of a polymer while suppressing its  $T_g$ , are employed to enhance protein and tissue preservation in sugar glasses. Recent literature indicates that additives can have a wide range of possible effects, but all of these have not been clearly understood and well appreciated. Here we employ molecular dynamics simulations to establish design rules for the selection of small molecule additives with size, molecular stiffness, and interaction energy chosen to achieve targeted effects on polymer properties. We furthermore find that a given additive's effect on a polymer's  $T_g$  can be predicted from its Debye-Waller factor  $\langle u^2 \rangle$  via a function previously found to describe nanoconfinement effects on the glass transition. These results emphasize the potential for a new generation of targeted molecular additives to contribute to more targeted rational design of polymers.

<sup>1</sup>We acknowledge the Keck Foundation and the Ohio Supercomputing Center for financial and computational support of this effort, respectively.

**10:24AM R34.00013 Molecular dynamics simulation of a model polystyrene glass**<sup>1</sup>, ZHUONAN LIU, SHIQING WANG, MESFIN TSIGE, Univ of Akron — We have performed all-atom molecular dynamics (MD) simulations of a model polystyrene glass to examine such concepts as load-bearing strands (LBSs) and activation zones (AZs) surrounding the LBSs that were proposed in a recent molecular model for yielding and failure of polymer glasses.<sup>1</sup> In our simulations, two long chains form a pair of hairpins in a matrix of short polystyrene chains. By deforming the system in different ways including pulling on the two long chains in opposite directions, we examine whether AZs emerge around the two long chains that can be taken as LBSs and how such AZs develop during deformation. 1. S. Wang, S. Cheng, P. Lin, and X. Li, J. Chem. Phys., 2014, 141, 094905.

**10:36AM R34.00014 Molecular dynamics as observed with probes of different dimensions in thin polymer films<sup>1</sup>**, JIANG ZHAO, HAO ZHANG, JINGFA YANG, FUYI WANG, Institute of Chemistry, Chinese Academy of Sciences, DILIU, Department of Chemistry, Dalian University of Technology, China — Rotational motion of individual fluorescence molecules doped in thin films of polyvinylacetate (PVAc) was monitored by single molecule fluorescence de-focus microscopy. Perylendiimide and its derivatives of different dimension were chosen as probes for local dynamics. The results demonstrate that the local vibration mode detected by different molecules probe depends on dimension of the probes the larger probes the lower frequency. The population of rotating probes is found to increase with temperature elevation, depending on the molecular dimension as well. The comparison of the results with thermo-dynamic measurements helps to shed new light on the physical picture of glass transition.

**10:48AM R34.00015 Preparation of a series of model poly(*n*-alkyl styrene)s and their viscoelasticity and glass transition temperatures**, SATORU MATSUSHIMA, ATSUSHI TAKANO, Department of applied chemistry, Graduate School of Engineering, Nagoya University, YOSHIKI TAKAHASHI, Institute for Materials Chemistry and Engineering, Kyushu University, YUSHU MATSUSHITA, Department of applied chemistry, Graduate School of Engineering, Nagoya University — Viscoelasticity and glass transition temperatures for linear polymers of many species have been investigated so far, and it is well-known that the melt viscosity for the linear polymers varies with molecular weight in essentially the same manner such as packing length theory. It is important to understand the relationship between the viscosity and the molecular structure of various kinds of linear polymers. To investigate the relationship deeply, viscoelastic measurements using linear polymer analogues which the molecular structure is systematically varied should be useful. For example, poly(*n*-alkyl-substituted polymers) such as poly(*n*-alkyl methacrylate)s are one of the good candidate. In this study, a series of poly(*n*-alkyl styrene)s with the different number of carbon atoms(*n*) in the side alkyl groups (*n*=1, 2, 3, 4, 6, 8, 10 and 12) were carefully synthesized by an anionic polymerization technique, and the viscoelasticity and the glass transition temperatures of the poly(*n*-alkyl styrene)s with high molecular weight ( $M_w \geq 4Me$ ) and narrow molecular weight distribution ( $M_w/M_n \leq 1.1$ ) were discussed.

**8:00AM R35.00001 Phase separation dynamics during *Myxococcus xanthus* fruiting body formation**, GUANNAN LIU, Princeton University, FATMAGUL BAHAR, ADAM PATCH, Syracuse University, SHASHI THUTUPALLI, Princeton University, DAVID YLLANES, M. CRISTINA MARCHETTI, ROY WELCH, Syracuse University, JOSHUA SHAEVITZ, Princeton University — Many living systems take advantage of collective behavior for group survival. We use the soil-dwelling bacterium *Myxococcus xanthus* as a model to study out-of-equilibrium phase separation during fruiting body formation. *M. xanthus* cells have the ability to glide on solid surfaces and reverse their direction periodically. When starved, *M. xanthus* cells aggregate together and form structures called fruiting bodies, inside of which cells sporulate to survive stressful conditions. We show that at high cell density the formation of fruiting bodies is a phase separation process. From experimental data that combines single-cell tracking, population-scale imaging, mutants, and drug applications, we construct the phase diagram of *M. xanthus* in the space of Péclet number and cell density. When wild type cells are starved, we find that they actively increase their Péclet number by modulating gliding speed and reversal frequency which induces a phase separation from a gas-like state to an aggregated fruiting body state.

**8:12AM R35.00002 Active matter model of *Myxococcus xanthus* aggregation**, ADAM PATCH, Department of Physics, Syracuse University, FATMAGUL BAHAR, Department of Biology, Syracuse University, GUANNAN LIU, Department of Physics, Princeton University, SHASHI THUTUPALLI, Department of Physics, Princeton University; Lewis-Sigler Institute for Integrative Genomics, Princeton University, ROY WELCH, Department of Biology, Syracuse University, DAVID YLLANES, Department of Physics, Syracuse University, JOSHUA SHAEVITZ, Department of Physics, Princeton University; Lewis-Sigler Institute for Integrative Genomics, Princeton University, M. CRISTINA MARCHETTI, Department of Physics, Syracuse University; Syracuse Biomaterials Institute, Syracuse University — *Myxococcus xanthus* is a soil-dwelling bacterium that exhibits several fascinating collective behaviors including streaming, swarming, and generation of fruiting bodies. A striking feature of *M. xanthus* is that it periodically reverses its motility direction. The first stage of fruiting body formation is characterized by the aggregation of cells on a surface into round mesoscopic structures. Experiments have shown that this aggregation relies heavily on regulation of the reversal rate and local mechanical interactions, suggesting motility-induced phase separation may play an important role. We have adapted self-propelled particle models to include cell reversal and motility suppression resulting from sporulation observed in aggregates. Using 2D molecular dynamics simulations, we map the phase behavior in the space of Péclet number and local density and examine the kinetics of aggregation for comparison to experiments.

**8:24AM R35.00003 Thermodynamics of the motility-induced phase separation**, ALEXANDRE SOLON, Massachusetts Institute of Technology, USA, JOACHIM STENHAMMAR, Lund University, Sweden, MICHAEL CATES, University of Cambridge, UK, JULIEN TAILLEUR, Université Paris Diderot, France — Self-propelled particles are known to accumulate in regions of space where their velocity is lowered. In addition, if their velocity diminishes when the local density increases (for example due to crowding effects), a positive feedback loop leads to the now well-established motility-induced phase separation (MIPS) between a dense immobile phase and a dilute motile phase. Understanding the phase equilibrium of MIPS is still a matter of debate. Although, depending on the models used to study the transition, a chemical potential or a pressure can be defined, these quantities do not play their usual thermodynamic role. In particular, the usual common tangent or equal-area constructions fail in these systems. Indeed, we will show that describing the phase equilibrium of MIPS necessitates generalized thermodynamics that include non-equilibrium contributions. This approach allows us to predict correctly the phase diagram of MIPS and to gain insight into the thermodynamics of active systems. It also sheds light on the (in)equivalence of statistical ensembles for these systems, paving the way for more efficient computational studies.

**8:36AM R35.00004 Epithelial gap closure governed by forces and geometry.**, BENOIT LADOUX, Mechanobiology Institute (Singapore) and Institut Jacques Monod (CNRS, France) — The closure of gaps within epithelia is crucial to maintain the integrity and the homeostasis of the tissue during wound healing or cell extrusion processes. Cells mediate gap closure through either the assembly of multicellular actin-based contractile cables (purse-string contraction) or the protrusive activity of border cells into the gap (cell crawling). I will present experimental data and numerical modeling that show how these mechanisms can mutually interact to promote efficient epithelial gap closure and how mechanical constraints can regulate these mechanisms. I will first present how geometrical constraints dictate mechanisms of epithelial gap closure. We determine the importance of tissue shape during closure and the role of curvature of cell boundaries in this process. An essential difference between the two closure mechanisms is that cell crawling always pulls the edge of the tissue forward (i.e. towards the gap) while purse string pulls the edge forward or backwards depending on the local geometry. Our study demonstrates how the interplay between these two mechanisms is crucial for closing gaps and wounds, which naturally come in arbitrary shapes. Then I will focus on epithelial closure mechanism during cell extrusion. Within confluent cell layers, cellular motions coupled between neighbors are tightly regulated by the packing density of the epithelium inducing drastic changes in the dynamics of these tissues. I will show how cell density and tissue mechanics regulate the extrusion of cells within a confluent epithelial cell sheet, simultaneously measuring collective movements and traction forces. Epithelial packing and collective cell dynamics dictate the modes of cellular extrusions from lamellipodia crawling of the neighboring cells at low densities to coordinated actin-based contractile purse-string mechanism at higher density.

**9:12AM R35.00005 Self-Driven Jamming of Growing Microbial Populations**, CARL SCHRECK, MORGAN DELARUE, PAWEŁ GNEIWEK, OSKAR HALLATSCHKE, University of California, Berkeley — When cells grow in confined spaces, they assemble into dense populations that interact both chemically and physically. Although in recent years scientists have uncovered a previously hidden layer of mechanical regulation in mammalian tissues that impacts gene expression and development, little is known about the consequences of mechanical constraints on single-celled microbes. This is largely due to a lack of appropriate culturing techniques and accurate computational models. Using physically explicit computer models that are developed alongside microfluidic experiments, we address two fundamental questions: (1) what structures self-assemble in confined geometries due to the cell growth and division process? and (2) how do those structures and associated stresses feed back on to cell physiology? We find that microbial growth in confinement can lead to jamming, heterogeneous stress fields, and intermittent flow that in turn result in spatially and temporally heterogeneous physiological responses. With computer simulations, we further explore the differences between this 'active' flow that is driven internally by cell growth and 'inactive' flow, such as shear and hopper flow, that is driven externally.

**9:24AM R35.00006 Cell Size Clues for the Allee Effect in Vegetative Amoeba Suspension Culture**, CARL FRANCK, BRENDAN RAPPAZZO, XIAONING WANG, IGOR SEGOTA, Cornell University — That cells proliferate at higher rates with increasing density helps us appreciate and understand the development of multicellular behavior through the study of dilute cell systems. However, arduous cell counting with a microscope reveals that in the model eukaryote, *Dictyostelium discoideum* this transition is difficult to ascertain and thereby further explore despite our earlier progress (Phys. Rev. E 77, 041905, (2008)). Here we report preliminary evidence that the slow proliferation phase is well characterized by reduced cell size compared to the wide distribution of cell sizes in the familiar exponential proliferation phase of moderate densities. This observation is enabled by a new system for characterizing cells in stirred suspension cultures. Our technique relies on quickly acquiring magnitude distributions of detected flashes of laser light scattered in situ by cell targets.

**9:36AM R35.00007 Manipulation of long-term dynamics in a colloidal active matter system using speckle light fields**, ERCAG PINCE, SABAREESH K.P. VELU, AGNESE CALLEGARI, PARVIZ ELAHI, Bilkent University, SYLVAIN GIGAN, Universit  Pierre et Marie Curie, GIOVANNI VOLPE, Bilkent University, GIORGIO VOLPE, University College London — Particles undergoing a stochastic motion within a disordered medium is a ubiquitous physical and biological phenomena. Examples can be given from organelles performing tasks in the cytoplasm to large animals moving in patchy environment. Here, we use speckle light fields to study the anomalous diffusion in an active matter system consisting of micron-sized silica particles (diameter 5 m) and motile bacterial cells (*E. coli*). The speckle light fields are generated by mode mixing inside a multimode optical fiber where a small amount of incident laser power is needed to obtain an effective disordered optical landscape for the purpose of optical manipulation. We experimentally show how complex potentials contribute to the long-term dynamics of the active matter system and observed an enhanced diffusion of particles interacting with the active bacterial bath in the speckle light fields. We showed that this effect can be tuned and controlled by varying the intensity and the statistical properties of the speckle pattern. Potentially, these results could be of interest for many technological applications, such as the manipulation of microparticles inside optically disordered media of biological interest.

**9:48AM R35.00008 A Density-Independent Flocking Transition in Confluent Tissues<sup>1</sup>**, MICHAEL CZAJKOWSKI, Syracuse Univ, DAPENG BI, Rockefeller Univ, M. LISA MANNING, M. CRISTINA MARCHETTI, Syracuse Univ — Some of us recently demonstrated a density-independent solid-liquid transition in confluent tissues controlled by cell motility and a cell shape parameter measuring the interplay of cortical tension and cell-cell adhesion. An important insight of this work is that the rigidity and dynamics of cell layers depends sensitively on cell shape. To explore the influence of cell shape on collective states, we have constructed continuum equations that couple a scalar field describing cell-shape anisotropy to cell polarization. The model displays a density independent transition to a polarized state of elongated cells driven by a cellular shape-index parameter. We map out the phase diagram using linear stability analysis and numerical solution of the nonlinear hydrodynamic equations. The proposed transition constitutes a density-independent flocking transition.

**10:00AM R35.00009 Multicellular contractility contributes to the emergence of mesothelioma nodules.<sup>1</sup>**, ANDRAS CZIROK, University of Kansas Medical Center — Malignant pleural mesothelioma (MPM) nodules arise from the mesothelial lining of the pleural cavity by a poorly understood mechanism. We demonstrate that macroscopic multicellular aggregates, reminiscent of the MPM nodules found in patients, develop when MPM cell lines are cultured at high cell densities for several weeks. Surprisingly, the nodule-like aggregates do not arise by excessive local cell proliferation, but by myosin II-driven cell contractility. Contractile nodules contain prominent actin cables that can span several cells. Several features of the in vitro MPM nodule development can be explained by a computational model that assumes uniform and steady intercellular contractile forces within a monolayer of cells, and a mechanical load-dependent lifetime of cell-cell contacts. The model behaves as a self-tensioned Maxwell fluid and exhibits an instability that leads to pattern formation. Altogether, our findings suggest that inhibition of the actomyosin system may provide a hitherto not utilized therapeutic approach to affect MPM growth.

**10:12AM R35.00010 Cilia driven flow networks in the brain**, YONG WANG, MPI Dynamics and Self-Organization, REGINA FAUBEL, MPI biophysical Chemistry, CHRISITIAN WESTENDORF, MPI Dynamics and Self-Organization, GREGOR EICHELE, MPI biophysical Chemistry, EBERHARD BODENSCHATZ, MPI Dynamics and Self-Organization — Neurons exchange soluble substances via the cerebrospinal fluid (CSF) that fills the ventricular system. The walls of the ventricular cavities are covered with motile cilia that constantly beat and thereby induce a directional flow. We recently discovered that cilia in the third ventricle generate a complex flow pattern leading to partitioning of the ventricular volume and site-directed transport paths along the walls. Transient and daily recurrent alterations in the cilia beating direction lead to changes in the flow pattern. This has consequences for delivery of CSF components along the near wall flow. The contribution of this cilia-induced flow to overall CSF flow remains to be investigated. The state-of-art lattice Boltzmann method is adapted for studying the CFS flow. The 3D geometry of the third ventricle at high resolution was reconstructed. Simulation of CSF flow without cilia in this geometry confirmed that the previous idea about unidirectional flow does not explain how different components of CSF can be delivered to their various target sites. We study the contribution of the cilia-induced flow pattern to overall CSF flow and identify target areas for site-specific delivery of CSF-constituents with respect to the temporal changes.

**10:24AM R35.00011 Collective motion of motile cilia: from human airways to model systems**, PIETRO CICUTA, LUIGI FERIANI, MAURIZIO CHIOCCOLI, JURIJ KOTAR, University of Cambridge — Mammalian airways are a fantastic playground of nonlinear phenomena, from the function of individual active filaments, to the emerging collective behaviour, to the rheology of the mucus solution surrounding cilia. We have been investigating the fundamental physics of this system through a variety of model system approaches, both experimental and computational. In the last year we have started measurements on living human cells, observing cilia shape during beating, and measuring speed and coherence of the collective dynamics. We report on significant differences in the collective motion in ciliated cell carpets from a variety of diseases, and we attempt to reconcile the collective dynamical phenotypes to the properties of individual filaments and the mechanics of the environment.

**10:36AM R35.00012 Active matter clusters at interfaces.** , KATHERINE COPENHAGEN, Univ of California - Merced, AJAY GOPINATHAN, University of California - Merced — Collective and directed motility or swarming is an emergent phenomenon displayed by many self-organized assemblies of active biological matter such as clusters of embryonic cells during tissue development and flocks of birds. Such clusters typically encounter very heterogeneous environments. What happens when a cluster encounters an interface between two different environments has implications for its function and fate. Here we study this problem by using a mathematical model of a cluster that treats it as a single cohesive unit whose movement depends on the nature of the local environment. We find that low speed clusters which exert forces but no active torques, encountering an interface with a moderate difference in properties can lead to refraction or even total internal reflection of the cluster. For large speeds and clusters with active torques, they show more complex behaviors crossing the interface multiple times, becoming trapped at the interface and deviating from the predictable refraction and reflection of the low velocity clusters. Our results show a wide range of behaviors that occur when collectively moving active biological matter moves across interfaces and these insights can be used to control motion by patterning environments.

**Session R36 GSNP GSOF: Continuum Descriptions of Discrete Materials II** 339 - Paul Umbanhowar, Northwestern University

**8:00AM R36.00001 Dynamic shear jamming in dense suspensions** , IVO PETERS, University of Southampton, SAYANTAN MAJUMDAR, HEINRICH JAEGER, University of Chicago — Shear a dense suspension of cornstarch and water hard enough, and the system seems to solidify as a result. Indeed, previous studies have shown that a jamming front propagates through these systems until, after interaction with boundaries, a jammed solid spans across the system. Because these fully jammed states are only observed if the deformation is fast enough, a natural question to ask is how this phenomenon is related to the discontinuous shear thickening (DST) behavior of these suspensions. We present a single experimental setup in which we on the one hand can measure the rheological flow curves, but on the other hand also determine if the suspension is in a jammed state. This we do by using a large-gap cylindrical Couette cell, where we control the applied shear stress using a rheometer. Because our setup only applies shear, the jammed states we observe are shear-jammed, and cannot be a result of an overall increase in packing fraction. We probe for jammed states by dropping small steel spheres on the surface of the suspension, and identify elastic responses. Our experiments reveal a clear distinction between the onset of DST and Shear-Jammed states, which have qualitatively different trends with packing fraction close to the isotropic jamming point.

**8:12AM R36.00002 Rheological behavior of partially-wet granular matter** , RAMIN GHELICHI, Postdoctoral Associate, KEN KAMRIN, Assistant Professor, KAMRIN GROUP TEAM — The topic of wet granular material modeling is an open area of study. In this talk we present a comprehensive continuum model for wet granular matter, which is informed by a novel Discrete Element Method (DEM), which tracks the fluid content coating each grain as well as a variable fluid-bridge volume. We have developed a DEM simulation method with a history-dependent potential based on the Hertz-Mindlin contact in compression and evolving capillary forces in tension. The capillary bridge in the simulations forms based on the volume of the fluid on each particle. First, we determine the cohesive force between grains, which is a function of grain separation, bridge volume, grain geometry, and fluid properties. The volume of the bridges also evolves in time, which affects the cut-off distance in bridges and the force-separation function. The other important factor which has been considered in the model is the particle roughness, which has a significant effect on the capillary force function. The effect of fluid viscosity is also considered. The second step in this work is to utilize the DEM results to identify a constitutive model that can explain the plastic behavior (flow rule) of a dense granular assembly under varying degrees of wetness.

**8:24AM R36.00003 Effect of friction on shear jamming<sup>1</sup>** , DONG WANG, JONATHAN BARES, Duke University, JOSHUA DIJKSMAN, Wageningen University, JIE REN, Merck & Co, HU ZHENG, Hohai University, ROBERT BEHRINGER, Duke University — Shear jamming of granular materials was first found for systems of frictional disks, with a static friction coefficient  $\mu \approx 0.6$  (Bi et al. Nature (2011)). Jamming by shear is obtained by starting from a zero-stress state with a packing fraction  $\phi$  between  $\phi_J$  (isotropic jamming) and a lowest  $\phi_S$  for shear jamming. This phenomenon is associated with strong anisotropy in stress and the contact network in the form of force chains, which are stabilized and/or enhanced by the presence of friction. Whether shear jamming occurs for frictionless particles is under debate. The issue we address experimentally is how changing friction affects shear jamming. By applying a homogeneous simple shear, we study the effect of friction by using photoelastic disks either wrapped with Teflon to reduce friction or with fine teeth on the edge to increase friction. Shear jamming is still observed; however, the difference  $\phi_J - \phi_S$  is smaller with lower friction. We also observe larger fluctuations due to initial configurations both at the lowest and the highest friction systems studied. Ongoing work is to use particles made of gelatin to reduce the friction coefficient to the order of 0.01.

**8:36AM R36.00004 Frictionless Shear Jamming, a finite-size phenomenon** , MARCO BAITY-JESI, Universidad Complutense de Madrid, CARL GOODRICH, Harvard University, JAMES SETHNA, Cornell University, ANDREA LIU, University of Pennsylvania — Athermal frictionless spheres jam as their density is increased. A few years ago, it was shown that at sufficiently high density, an initially unjammed system of frictional particles can jam under shear. Here we study shear jamming in packings of frictionless particles, and show that it is a finite-size effect with scalings that can be understood within a generalized scaling theory.

**8:48AM R36.00005 Slow Relaxations in Fluid-Driven Granular Flows** , CARLOS ORTIZ, DOUGLAS DURIAN, DOUGLAS JEROLMACK, Univ of Pennsylvania — Particles in a pack may appear frozen, but exhibit very slow dynamics (creep). To probe long-time dynamics, we construct an annular chamber that mimics an infinitely-long river channel. We drive the packs with a laminar flow and record dynamics by laser scanned particle tracking. The dynamics of “bed load” grains near the surface exhibit relatively fast shear and their velocity profile as a function of depth can be well-described by a local  $\mu(I)$ -rheology. However, grains deep in the pack, which appear frozen by eye, exhibit slow creep dynamics that are not captured by the local model. This transition between bed load and creep occurs at a critical value of the local relaxation time. We find that the timescale for heterogeneous dynamics increases monotonically as a function of depth, but the length scale characterized by the domain size of the heterogeneities achieves a maximum at the transition to creeping. We explore the relation between the important length and time scales of the flow in the creep phase using nonlocal rheology.

**9:00AM R36.00006 Flow of interacting colloidal suspensions through a narrow channel** , RAUL CRUZ HIDALGO, SARA ARIETALEANIZ, University of Navarra, IGNACIO PAGONABARRAGA, University of Barcelona — In this work we numerically study the constitutive behavior of interacting colloidal suspensions at intermediate and high concentrations. The influence of the interaction potential strength on the system's response is examined, in suspensions flowing through narrow channels at low Reynold's numbers. Using Lattice Boltzmann methods, we analyze the rheological response of a colloidal suspension once the steady state is established. In dilute suspensions we always recover a newtonian behavior. At higher volume fractions, the range and strength of the interaction potential has a stronger impact in the behavior of the suspension. While for short range potentials, the non-newtonian response mostly depends on colloid concentration and confinement distance, for a Lennard-Jones potential we identify two rheological responses depending on the potential strength,  $\xi_{LJ}$ , at a given concentration. For weak  $\xi_{LJ}$  the effective viscosity,  $\eta_{eff}$ , decreases until a minimum is reached. On the contrary, at large values of  $\xi_{LJ}$  the effective viscosity  $\eta_{eff}$  increases when increasing the strength of interaction. This behavior has been correlated with the local structure of this complex fluid.

**9:12AM R36.00007 Impact Fragmentation and Crushing of Concrete and Other Solids Due to Kinetic Energy of High Shear Strain Rate**, ZDENEK BAZANT, KEDAR KIRANE, Northwestern University — While numerous studies have dealt with dynamic crack propagation, they have not led to a macroscopic continuum model usable in FE analysis. Recent work on such a model is reviewed. The key idea is that comminution under high-rate shear is driven by the release local kinetic (rather than strain) energy of the shear strain rate field in forming finite-size fragments. At strain rates  $>10^3/s$ , this energy exceeds the maximum possible elastic strain energy by orders of magnitude. It is found that the particle size scales as the  $-2/3$  power of the shear strain rate and as the  $2/3$  power of interface fracture energy, and the released and dissipated kinetic energy as the  $2/3$  power of the shear strain rate. These results explain the long debated phenomenon of “dynamic overstress”. In FE simulations, this kinetic energy of strain rate field can be dissipated either by equivalent viscosity or by the work of increased strength limits. In simulating the impact of missiles into concrete walls, both approaches give nearly equivalent results. A dimensionless indicator of the comminution intensity is also formulated. The theory was inspired by noting that the local kinetic energy of shear strain rate plays a role analogous to the local kinetic energy of eddies in turbulent flow.

**9:24AM R36.00008 Explanation of nonlocal granular fluidity in terms of microscopic fluctuations**, QIONG ZHANG, KEN KAMRIN, Massachusetts Inst of Tech-MIT — A recently proposed granular constitutive law has shown capability to predict nonlocal granular rheology using a variable denoted granular fluidity. This work is aimed at finding the microscopic physical meaning of fluidity in terms of fluctuations such as fluctuation of normalized shear stress and fluctuation of velocity. We try to predict the fluidity as a function of the fluctuation of normalized shear stress, and also test Eyring equation and kinetic theory based on the theoretical prediction proposed in other work. We find a consistent definition for the fluidity to be proportional to the product of the velocity fluctuations and some function of packing fraction divided by the average diameter of the grains. This definition shows predictive ability in multiple geometries for which flow behavior is nonlocal. It is notable that the fluidity is well-defined as a function of kinematic state variables, as one would hope for a quantity of this nature.

**9:36AM R36.00009 Mesoscale poroelasticity of heterogeneous media**, SIAVASH MONFARED, HADRIEN LAUBIE, Massachusetts Inst of Tech-MIT, FARHANG RADJAI<sup>1</sup>, Universite de Montpellier, ROLAND PELLENG, FRANZ-JOSEF ULM, Massachusetts Inst of Tech-MIT — Poroelastic behavior of heterogeneous media is revisited. Lattice Element Method (LEM) is used to model interaction between solid constituents due to a pressurized pore space. Exploring beyond mean-field based theories in continuum microporomechanics, local textural variations and its contribution to the global anisotropic poroelastic behavior of real multiphase porous media are captured. To this end, statistical distributions of mesoscale poroelastic coefficients from numerical simulations on X-ray microscopy scans of two different organic-rich shales with different microtextures are presented. The results are compared with predictions using mean-field based tools of continuum micromechanics. The textural dependency of strain localization and stress chain formation captured in this framework promises a powerful tool for modeling poroelastic response of complex porous composites and a path to incorporate local textural and elastic variations into a continuum description.

**9:48AM R36.00010 Low-frequency oscillations in vibrated granular columns.**, NICOLAS RIVAS, Helmholtz Institute Erlangen-Nuremberg, ANTHONY THORNTON, KIT WINDOWS-YULE, University of Twente, DAVE PARKER, University of Birmingham, STEFAN LUDING, University of Twente — We present simulations, experiments and theoretical treatments of vertically vibrated granular media. The systems considered are quasi-one-dimensional. This column geometry makes it possible to study collective oscillations of the grains with a characteristic frequency that is much lower than the frequency of energy injection (LFOs). Using event-driven molecular dynamics simulations we see that LFOs become slower and more pronounced as the shaking of the container increases. Experimental observations, using the positron emission particle tracking technique, agree well with the simulated data. The conditions necessary for the existence of LFOs are derived from a granular continuum model, which is able to relate the column density profile with the measured characteristic frequencies

**10:00AM R36.00011 Continuum model and simulation of segregating rods**, RICHARD M. LUEPTOW, Northwestern University, YONGZHI ZHAO, Zhejiang University, PAUL B. UMBANHOWAR, Northwestern University — Most studies of segregation of flowing granular materials focus on spherical particles, even though particles are often non-spherical in practical granular systems. Here we focus on the segregation of rod-like (cylindrical) particles of the same diameter but different lengths using continuum theory and DEM simulations based on super-ellipsoids. In the flowing layer of a bounded heap flow, a bidisperse mixture of long and short rods segregates such that the shorter rods percolate toward the lower portion of the flowing layer while longer rods rise toward the upper portion of the flowing layer, much like smaller spherical particles segregate from larger spherical particles. The rods tend to deposit on the underlying bed of particles in the heap such that they are aligned with the flow with the smaller rods deposited upstream of the larger rods due to segregation. The percolation velocities related to segregation for long and short rods depend on the local shear rate and the concentration of the other particle species, just as is the case for small and large spherical particles. Using this percolation velocity and an appropriate value for collisional diffusion, the advection-diffusion-segregation continuum model successfully predicts the segregation of rod-like particles.

**10:12AM R36.00012 Flow and packing properties of frictional shapes from spheres to cubes**, LEONARDO E. SILBERT, Southern Illinois University, K. MICHAEL SALERNO, DAN S. BOLINTINEANU, JEREMY B. LECHMAN, GARY GREEST, Sandia National Laboratories — Though grains in many applications are aspherical and rough, many computational studies of granular flow and packing focus on ideal spherical particles, often without friction. Following Latham [1], we optimally represent arbitrary shapes using overlapping spheres of different sizes. We use discrete element simulations to study the packing and flow of frictional granular superquadric (superball) shapes ranging from spheres to cuboids. When packing particles, friction becomes more important as particle shape becomes more angular. This leads to a larger density change between frictional and frictionless packings. Friction and shape are also important to granular flow. For a planar-shear flow different shapes have similar flow behavior in the zero-friction limit. However, with increasing friction particle shape couples to the tangential frictional forces and becomes more important. Flow results are compared with continuum theories of granular materials. Results from simulations of anisotropic particles and mixtures of shapes will also be discussed.

**10:24AM R36.00013 Scaling Relations for Wheeled Locomotion in Granular Media**, JAMES SLONAKER, KEN KAMRIN, MIT — Vehicular wheel design for use on granular material has not currently been perfected. Resistive Force Theory (RFT) is a reduced-order empirical model for granular drag, which shows promise to help simulate and understand locomotion processes to design more efficient wheels. Here we explore the fundamental scaling relations derived from RFT and their experimental validation. Similar to the non-dimensional scaling relations in fluid mechanics, the relative simplicity of RFT asserts that only one material parameter, the “grain-structure coefficient”, is required, which reduces the complexity of the non-dimensional groups implied by the system. Therefore, wheels with differing input design parameters like size, mass, shape and even gravity, can be tested and their performance related to each other in predictable ways. We experimentally confirmed these relations by testing with 3D printed wheel geometries in a controlled sand bed.

### 10:36AM R36.00014 Scaling of heat transfer in granular materi

YOHANNES, Rutgers University, HEATHER EMADY, Arizona State University, INGRID PARDES, MAHAM GLASSER, FERNANDO MUZZIO, ALBERTO CUITINO, Rutgers University — Several industrial processes and powders, in devices such as rotating drums, to bring about a desired chemical and/or physical transformation. Predicting the heat transfer process can significantly improve the quality of the end product and efficiency. However, there is a need to predict the evolution of the distribution and average of the particles' temperature, particularly for the purpose of manufacturing scale productions. We used discrete element method (DEM) based simulations to study the heat transfer in rotating drums at low temperature. Various physical, mechanical, and thermal properties of particles were considered in the effect of operating conditions such as size of drum, material fill level, and speed of rotation on the heat transfer. We identified timescales relevant to the heat transfer process and developed a relationship between these timescales and the temperature of particles. We also found that the evolution of the temperature distribution, since different particles have different predicted based on these timescales. These findings can be used to predict the required time to heat up all particles.

MAR16-2015-006601

### 10:48AM R36.00015 Structural evolution of Colloidal Gels under Flow

, ARMAN BOROMAND, JOAO MAIA, Case Western Reserve University, SAFA JAMALI, Massachusetts Institute of Technology — Colloidal suspensions are ubiquitous in different industrial applications ranging from cosmetic and food industries to soft robotics and aerospace. Owing to the fact that mechanical properties of colloidal gels are controlled by its microstructure and network topology, we trace the particles in the networks formed under different attraction potentials and try to find a universal behavior in yielding of colloidal gels. Many authors have implemented different simulation techniques such as molecular dynamics (MD) and Brownian dynamics (BD) to capture better picture during phase separation and yielding mechanism in colloidal system with short-ranged attractive force. However, BD neglects multi-body hydrodynamic interactions (HI) which are believed to be responsible for the second yielding of colloidal gels. We envision using dissipative particle dynamics (DPD) with modified depletion potential and hydrodynamic interactions, as a coarse-grain model, can provide a robust simulation package to address the gel formation process and yielding in short ranged-attractive colloidal systems. The behavior of colloidal gels with different attraction potentials under flow is examined and structural fingerprints of yielding in these systems will be discussed.

Kent State University

### 8:00AM R37.00001 The twist-bend nematic phase of bent mesogenic dimers and its mixtures<sup>1</sup>

, MICHAEL TUCHBAND, MIN SHUAI, KERI GRABER, DONG CHEN, LEO RADZIHOVSKY, ARTHUR KLITTNICK, Department of Physics, University of Colorado Boulder, LEE FOLEY, ALYSSA SCARBROUGH, JAN PORADA, MARK MORAN, EVA KORBLOVA, DAVID WALBA, Department of Chemistry, University of Colorado Boulder, MATTHEW GLASER, JOSEPH MACLENNAN, NOEL CLARK, Department of Physics, University of Colorado Boulder, SOFT MATERIALS RESEARCH CENTER TEAM — Binary mixtures of the twist-bend nematic-forming liquid crystal CB7CB with the prototypical rod-like liquid crystal 5CB exhibit a twist-bend nematic phase with properties similar to those reported for neat CB7CB. The linear dependence of the phase transition temperature on concentration indicates that these binary mixtures are nearly ideal. We confirm the presence of nanoscale modulations of the molecular orientation in the mixtures by freeze-fracture transmission electron microscopy (FFTEM). We devise and implement a statistical approach to quantitatively measure the ground state pitch of the twist-bend phase and its mixtures using FFTEM. The addition of 5CB generally shifts the measured ground-state pitch distributions towards larger pitch. The pitch apparently increases discontinuously at higher 5CB concentrations.

### 8:12AM R37.00002 Resonant soft X-ray scattering study of twist bend nematic phase<sup>1</sup>, CHENHUI

ZHU, Advanced Light Source, Lawrence Berkeley National Laboratory, ANTHONY YOUNG, CHENG WANG, , ALEXANDER HEXEMER, Advanced Light Source, Lawrence Berkeley National Laboratory, QUAN LI, , OLEG LAVRENTOVICH, LCI, Kent State University, DAVID WALBA, Department of Chemistry and Biochemistry, University of Colorado Boulder, MICHAEL TUCHBAND, MIN SHUAI, , NOEL CLARK, Department of Physics, University of Colorado at Boulder — Liquid crystals (LCs) form many interesting nano-scale structures, many of which can be probed with X-ray scattering techniques, typically hard X-rays due to its high penetrating power. However, in the hard X-ray regime, the scattering contrast of some LC nanostructures can be extremely low due to their weak electron density modulation. Here we show it is possible to use resonant soft x-rays to probe the helical pitch of the newly discovered twist bend nematic phase [1,2], which is purely a twist bend structure with no electron density modulation. The in-situ temperature dependent measurement will be presented and discussed. This work together with our previous study on the helical nanofilament B4 phase [3] shows the great potential of soft x-ray scattering in liquid crystals. [1] D. Chen, et al. *PNAS*, DOI 1314654110 (2015). [2] V. Borshch, et al. *Nat. Comm.*, **4**, 2635 (2015). [3] C. Zhu, et al. *Nano. Lett.* **15**, 3420 (2015).

### 8:24AM R37.00003 Dynamic Light Scattering on a Twist-Bend nematic Liquid Crystal

, ZEINAB PARSOUI, SHAIKH SHAMID, VOLODYMYR BORSHCH, PAVAN CHALLA, Kent State University, GABRIELA TAMBA, GEORG MEHL, University of Hull, JAMES GLEESON, ANTAL JKLI, OLEG LAVRENTOVICH, DAVID ALLENDER, JONATHAN SELINGER, SAMUEL SPRUNT, Kent State University — We present a dynamic light scattering study performed on the uniaxial and twist-bend nematic ( $N_{TB}$ ) phases of a liquid crystal dimer/monomer mixture. In the nematic phase, in addition to the usual two hydrodynamic director modes, the results reveal a single non-hydrodynamic process that is associated with fluctuations in orientational order in the plane perpendicular to the primary (uniaxial) ordering direction. On the other hand, data from the  $N_{TB}$  phase demonstrate a pair of non-hydrodynamic modes and a single hydrodynamic mode. The non-hydrodynamic modes are strongly temperature-dependent, slowing down as the transition is approached from the  $N_{TB}$  side. Our results may be explained by a Landau-deGennes expansion of free energy for the N to  $N_{TB}$  transition in terms of a helical polarization field, which is nonzero in the  $N_{TB}$  state and is coupled to the heliconical director that characterizes the  $N_{TB}$  state. The short pitch of the structure allows a “coarse-graining” of the free energy that accounts for the observed fluctuation mode structure and properties at optical wavevectors. In the model, the helical axis is the effective director, and the helical planes become smectic-like layers. We estimate an effective compression constant,  $B = 4000$  Pa, for the  $N_{TB}$  “layer” structure.

**8:36AM R37.00004 Layer Thinning in Freely-Suspended Thin Liquid Films of a Symmetric Liquid Crystal Dimer**, SHOKIR PARDAEV, ZEINAB PARSOUZI, JAMES GLEESON, Department of Physics, Kent State Univ - Kent, ANTAL JAKLI, Chemical Physics Interdisciplinary Program and Liquid Crystal Institute, Kent State Univ-Kent, SAMUEL SPRUNT, Department of Physics, Kent State Univ - Kent — We report optical reflectivity and dynamic light scattering (DLS) studies on freely suspended smectic films of a symmetric liquid crystal dimer, which exhibits the phase sequence isotropic—nematic—twist-bend nematic—smectic in cooling. In sufficiently thin films the reflectivity  $R$  is expected to scale as the square of the number of smectic layers ( $N^2$ ) while the frequency  $f$  of underdamped layer fluctuations scales as  $N^{-1/2}$ . On heating thin films drawn in the smectic phase, we observe a sequence of layer thinning transitions, with  $R$  and  $f$  following the expected scaling relations, provided the stepwise melting involves double rather than single layers. We will describe a model to explain the unusual layer thinning process. We thank M. G. Tamba and G. Mehl for providing the liquid crystal compound: NSF grant DMR-1307674.

**8:48AM R37.00005 ABSTRACT WITHDRAWN —**

**9:00AM R37.00006 Giant Magnetic Field-induced Phase Transitions in Dimeric Liquid Crystals.**, SEYYED MUHAMMAD SALILI, MIROSLAW SALAMONCZYK, Liquid Crystal Institute, Kent State University, Kent, OH 44242, USA, MARIA-GABRIELA TAMBA, Department of Nonlinear Phenomena, Institute for Experimental Physics, Otto von Guericke University Magdeburg, Magdeburg, Germany, SAMUEL SPRUNT, Department of Physics, Kent State University, Kent, OH 44242, USA, GEORG MEHL, Department of Chemistry, University of Hull, Hull HU6 7RX, UK, ANTAL JAKLI, Liquid Crystal Institute, Kent State University, Kent, OH 44242, USA, JAMES GLEESON, Department of Physics, Kent State University, Kent, OH 44242, USA, KENT GROUP COLLABORATION, HULL GROUP COLLABORATION — Liquid crystals are responsive to external fields such as electric, magnetic fields. The first experimental observation of dependence of isotropic to nematic phase transition on the applied magnetic field was done using a strong magnetic field on bent-core nematogens and the phase transition temperature exhibited an upshift of 0.7 C at B=30 T [1]. We report on measurements of giant magnetic field-induced isotropic-nematic transition of chainsticks (nunchuks) type dimeric liquid crystals. Upon using the B=25 T split-helix resistive solenoid magnet at NHMFL, we have observed up to 18 C upshift of the isotropic to nematic phase transition temperature at B=22T. We discuss the results within the context of differential thermodynamic potential and the two basic mean-field theories. To our knowledge, this is the first observation of such huge shifts in the phase transitions of thermotropic liquid crystals. [1] T. Ostapenko et al, Phys. Rev. Lett. 101, 247801 (2008).

**9:12AM R37.00007 Smectic Phase Formed by DNA Dimers<sup>1</sup>**, MIROSLAW SALAMONCZYK, Liquid Crystal Institute, Kent State University, JAMES GLEESON, Department of Physics, Kent State University, ANTAL JAKLI, Liquid Crystal Institute, Kent State University, SAMUEL SPRUNT, Department of Physics, Kent State University, JAN DHONT, EMMANUEL STIAKAKIS, Forschungszentrum Julich, Julich, Germany — h — *abstract* — The rapidly expanding bio market is driving the development and characterization of new multifunctional materials. In particular, nucleic acids are under intense study for gene therapy, drug delivery and other bio-safe applications [1,2,3]. DNA is well-known to form a cholesteric nematic liquid crystal in its native form; however, much recent research has focused on self-assembly and mesomorphic behavior in concentrated solutions of short DNA helices [4]. Our work focuses on DNA dimers, consisting of 48 base-pair double-stranded helices connected by a 5 to 20 base flexible single strand, and suspended in a natural buffer. Depending on temperature, concentration and length of the flexible spacer, polarizing optical microscopy and small angle x-ray scattering reveal cholesteric nematic and, remarkably, smectic liquid crystalline phases. A model for smectic phase formation in this system will be presented. [1] J.-L. Lim et al., Int. J. of. Pharm. 490 (2015) 2652] D.-H. Kim et al., Nature Biotech. 23 (2005) 2223] K. Liu et al., Chem. <sup>1</sup>NSF DMR 1307674

**9:24AM R37.00008 Lipid decorated liquid crystal pressure sensors<sup>1</sup>**, TETIANA LOPATKINA, PIOTR POPOV, LAWRENCE HONAKER, ANTAL JAKLI, Chemical Physics Interdisciplinary Program and Liquid Crystal Institute, Kent State University, Kent, OH 44242, ELIZABETH MANN, Department of Physics, Kent State University, Kent, OH 44242, MANN'S GROUP COLLABORATION, JAKLI'S GROUP COLLABORATION — Surfactants usually promote the alignment of liquid crystal (LC) director parallel to the surfactant chains, and thus on average normal to the substrate (homeotropic), whereas water promotes tangential (planar) alignment. A water-LC interface is therefore very sensitive to the presence of surfactants, such as lipids: this is the principle of LC-based chemical and biological sensing introduced by Abbott et al[1]. Using a modified configuration[2], we found that at higher than 10 micro molar lipid concentration, the uniformly dark texture seen for homeotropic alignment between left-, and right-handed circular polarizers becomes unstable and slowly brightens again. This texture shows extreme sensitivity to external air pressure variations offering its use for sensitive pressure sensors. Our analysis indicates an osmotic pressure induced bending of the suspended films explaining both the birefringence and pressure sensitivity. In the talk we will discuss the experimental details of these effects. [1] J. M. Brake, M. K. Daschner, Y.-Y. Luk, and N. L. Abbott, Science (80-. ). 302, 2094 (2003). [2] P. Popov, E. K. Mann, and A. Jakli, Phys. Rev. Appl. 1, 034003 (2014).

**9:36AM R37.00009 2D and 3D Histioid Disclination Networks in Liquid Crystals<sup>1</sup>**, MIAO JIANG, YUBING GUO, OLEG LAVRETOVICH, QI-HUO WEI, Kent State University — Topological defects and disclination lines are of both fundamental interest and practical importance. In this paper, we will show that periodic/non-periodic 2D/3D networks of disclination lines can be created in nematic liquid crystal cells by setting well-designed alignment patterns at the top and bottom substrate surfaces. The desired complex patterns of liquid crystal molecular alignments at the substrates are obtained using a projection photoalignment technique based on plasmonic metamasks. The designs of alignment patterns and their resulting disclination line networks will be presented. These designable topological networks represent a new kind of artificial materials which could be of useful for directing colloidal and molecular assembly.

<sup>1</sup>National Science Foundation CMMI-1436565

**9:48AM R37.00010 Photophysics of guest-host liquid crystal systems containing naphthopyran derivatives**, MARIACRISTINA RUMI, Air Force Rsch Lab - WPAFB, TAMAS KOSA, LUDMILA SUKHOMLINOVA, BAHMAN TAHERI, Alpha Micron Inc., TIMOTHY WHITE, TIMOTHY BUNNING, Air Force Rsch Lab - WPAFB — Photoinduced order-increase changes can be observed in guest-host liquid crystal systems containing certain phototropic species, such as naphthopyrans. We are investigating the dynamics of the naphthopyran photoinduced interconversion reaction and the related liquid crystal order increase process as a function of excitation conditions and temperature. The thermal relaxation from different photostationary states is also been monitored. The guest-host system behavior is compared with that of the same guest species in isotropic media and other photoresponsive materials in liquid crystalline media, to determine if the naphthopyran interconversion reaction is affected by the anisotropy of the environment surrounding the guest molecules. This will provide a better understanding of the mutual influence of the guest and host molecules on the properties of the photoresponsive mixed systems.

### **10:00AM R37.00011 Plasmonic Photopatterning of Complex Molecular Orientations in Liquid Crystals<sup>1</sup>**

, YUBING GUO, MIAO JIANG, CHENHUI PENG, Liquid Crystal Institute, Kent State Univ - Kent, KAI SUN, Department of Material Science, University of Michigan, OLEG YAROSHCHUK, Institute of Physics, National Academy of Sciences of Ukraine, OLEG LAVRENTOVICH, QI-HUO WEI, Liquid Crystal Institute, Kent State Univ - Kent — Aligning liquid crystal (LC) molecules in spatially non-uniform patterns are highly demanded for applications such as programmable origami and liquid crystal enabled nonlinear electrokinetics. We developed a high resolution projection photoalignment technique for patterning arbitrary LC alignment fields. The photoalignment is based on carefully engineered metasurfaces, or dubbed as plasmonic metamasks (PMMs). When illuminated by light, the PMMs generate patterns of both light intensity and polarization. By projecting the light transmitted through the PMMs onto liquid crystal cells coated with photosensitive materials, alignment patterns predesigned in polarization patterns of the PMMs can be imposed in liquid crystals. This technique makes the liquid crystal alignment a repeatable and scalable process similar to conventional photolithography, promising various applications.

<sup>1</sup>National Science Foundation CMMI-1436565

### **10:12AM R37.00012 Flow Meter Based on Freely Suspended Smectic Liquid Crystal Films<sup>1</sup>**

, ADAM GREEN, None, ZHIYUAN QI, CHEOL PARK, MATTHEW GLASER, JOSEPH MACLENNAN, NOEL CLARK, Soft Materials Research Center, University of Colorado, Boulder, CO 80309 — We present the realization of a idealized 2D hydrodynamic system coupled to air-flow, and show that freely suspended films (FSF) of smectic liquid crystals can be used as a novel flow-meter. Freely-suspended films of liquid crystals are one of the closest physical realizations of an idealized 2D fluid. The velocity of air-flow above a film suspended above a channel can be inferred by studying the velocity profile of the smectic film. This velocity profile can be measured using digital video microscopy to track the inclusions present in the moving film. The velocity profile is then fitted to the coupled 2D solutions of an embedded fluid in air, and the velocity of the air can then be extracted. This flow meter serves as a demonstration of a robust test-bed for further exploration of 2D hydrodynamics.

### **10:24AM R37.00013 Optical fibers based on compositions of polymers and liquid crystals for gas detection.**

, PETR SHIBAEV, ANTHONY TANTILLO, Fordham University, Department of Physics — Optical fibers based on compositions of methacrylic and vinyl polymers mixed with low molar mass liquid crystals were prepared and studied as promising gas sensors. A range of concentrations producing anisotropic fibers that are mostly sensitive to the vapors of organic solvents was determined. The fibers were prepared by stretching gel-like compositions of polymers and liquid crystals. Mechanical properties of the compositions leading to the most stable fibers were studied. It was found that under certain conditions the fibers develop multilayered structure with anisotropic (mostly liquid crystalline) core. These fibers are very sensitive to changing gaseous atmosphere and to the presence of organic solvent vapors. The sensitivity of different types of fibers to a variety of organic solvents vapors was determined. Some fibers were crosslinked by using hydrogen bonding molecules. The behavior of these optical fibers with respect to the influence of organic vapors with and without hydrogen donor/acceptor moieties was also analyzed. It was shown that hydrogen bonding increases the mechanical strength of the fibers but does not affect substantially their sensitivity to gases. Optical calculations and model discussion accompany the presentation of experimental data.

### **10:36AM R37.00014 Reorientation and isotropisation of liquid crystals induced by gas diffusion.**

, ANTHONY TANTILLO, Fordham University Department of Physics, PETR SHIBAEV, Fordham University, Department of Physics — Reorientation and isotropisation of liquid crystals induced by organic solvent vapors was studied experimentally in relation to the use of liquid crystals as gas sensors. Reorientation and isotropisation were studied in the droplets deposited on the flat surface and on the tip of the hollow fibers. The anisotropy of gas diffusion was studied in the films and droplets of different sizes deposited on the surfaces with planar and homeotropic conditions. It was revealed that the diffusion coefficients differ approximately by a factor of two for liquid crystals in planar and homeotropic orientations. It was also shown that interference pattern created by passing light in liquid crystalline droplets deposited on the planar surface and on the tip of the hollow fiber can be used in detection of very small concentration of vapors. The model of diffusion is suggested and molecular dynamics simulations of the diffusion in liquid crystals with different molecular orientation are performed. The molecular dynamics simulations were performed on a time scale of about tens nanoseconds. In general they confirm the experimental results, but provide larger differences (by a factor 2 to 4) for diffusion coefficient in liquid crystals with planar and homeotropic orientation.

### **10:48AM R37.00015 Drying, phase separation, and deposition in droplets of sunset yellow chromonic liquid crystal<sup>1</sup>**

, ADAM GROSS, ZOEY S. DAVIDSON, University of Pennsylvania, YONGYANG HUANG, Lehigh University, TIM STILL, University of Pennsylvania, CHAO ZHOU, Lehigh University, A.G. YODH, University of Pennsylvania — We investigate the drying process and the final deposition patterns of multi-phase sessile droplets containing aqueous lyotropic chromonic liquid crystal (LC). The experiments employ a variety of optical techniques including profilometry, polarization optical microscopy and optical coherence microscopy. An unusual hierarchical LC assembly is observed during drying; in particular, LC mesogens are first formed at the start of drying and then compartments of isotropic, nematic and columnar phases arise. Nonuniform evaporation creates concentration gradients in droplets such that LC phases emerge from the outer edge of the drop and advance to the center over the course of drying. Distinct outward flows associated with the “coffee-ring effect” are seen initially, but the assembly of the mesogens creates viscosity, density, and surface tension gradients that effectively introduce new convective flows and complex LC phase boundaries within the drop. Finally, we show that the final deposit shape of chromonic materials changes with rate of evaporation.

### **8:00AM R38.00001 Self-Healing Nanocomposite Hydrogel with Well-Controlled Dynamic Mechanics**

, QIAOCHU LI, Massachusetts Inst of Tech-MIT, SUMEET MISHRA, North Carolina State University, PANGKUAN CHEN, Massachusetts Inst of Tech-MIT, JOSEPH TRACY, North Carolina State University, NIELS HOLTEN-ANDERSEN, Massachusetts Inst of Tech-MIT — Network dynamics is a crucial factor that determines the macroscopic self-healing rate and efficiency in polymeric hydrogel materials, yet its controllability is seldom studied in most reported self-healing hydrogel systems. Inspired by mussel's adhesion chemistry, we developed a novel approach to assemble inorganic nanoparticles and catechol-decorated PEG polymer into a hydrogel network. When utilized as reversible polymer-particle crosslinks, catechol-metal coordination bonds yield a unique gel network with dynamic mechanics controlled directly by interfacial crosslink structure. Taking advantage of this structure-property relationship at polymer-particle interfaces, we next designed a hierarchically structured hybrid gel with two distinct relaxation timescales. By tuning the relative contribution of the two hierarchical relaxation modes, we are able to finely control the gel's dynamic mechanical behavior from a viscoelastic fluid to a stiff solid, yet preserving its fast self-healing property without the need for external stimuli.

**8:12AM R38.00002 Polymer-induced compression of biological hydrogels**, SUJIT DATTA, ASHER PRESKA STEINBERG, RUSTEM ISMAGILOV, California Institute of Technology — Hydrogels – such as mucus, blood clots, and the extracellular matrix – provide critical functions in biological systems. However, little is known about how their structure is influenced by many of the polymeric materials they come into contact with regularly. Here, we focus on one critically important biological hydrogel: colonic mucus. While several biological processes are thought to potentially regulate the mucus hydrogel structure, the polymeric composition of the gut environment has been ignored. We use Flory-Huggins solution theory to characterize polymer-mucus interactions. We find that gut polymers, including those small enough to penetrate the mucus hydrogel, can in fact alter mucus structure, changing its equilibrium degree of swelling and forcing it to compress. The extent of compression increases with increasing polymer concentration and size. We use experiments on mice to verify these predictions with common dietary and therapeutic gut polymers. Our results provide a foundation for investigating similar, previously overlooked, polymer-induced effects in other biological hydrogels.

**8:24AM R38.00003 Thermal-induced ageing of agar solutions: impact on the structural and mechanical properties of agar gels<sup>1</sup>**, BOSI MAO, Centre de Recherche Paul Pascal, AHMED BENTALEB, FRÉDÉRIC LOUERAT, THIBAUT DIVOUX, PATRICK SNABRE, Centre de Recherche Paul Pascal - CNRS — Numerous hydrogels are prepared by cooling down to ambient temperature, aqueous polymer solutions brought to a boil. Although the incubation time of the polymer solution at such a high temperature could be used as a tuning parameter, its impact on the subsequent gelation has been poorly investigated. Here we study the effect of prolonged heating at 80°C on a 1.5% wt solution of agar, a natural polysaccharide. The incubation time is varied from a few hours up to five days. We show that the agar sol. continuously degrades as the result of both the hydrolysis and the intermolecular oxidation of the polymer chains. Furthermore, electronic microscopy and X-ray diffraction experiments reveal that gels formed from older agar sols display an increasingly coarser microstructure composed of micron-sized aggregated pieces of polysaccharides, in contrast with the fibrous-like structure of gels made from fresh sols. Along with structural changes prolonged incubation time leads to weaker gels of lower shear elastic modulus. Finally, macro-indentation experiments coupled to direct visualization show that increasing the incubation time of the agar sol. decreases the yield strain of the gel by a factor of three, while the rupture scenario turns continuously from brittle to ductile-like.

**8:36AM R38.00004 Nonlinear elasticity of alginate gels**, SEYED MEYSAM HASHEMNEJAD, SANTANU KUNDU, Mississippi State University — Alginate is a naturally occurring anionic polysaccharide extracted from brown algae. Because of biocompatibility, low toxicity, and simple gelation process, alginate gels are used in biomedical and food applications. Here, we report the rheological behavior of ionically crosslinked alginate gels, which are obtained by in situ gelation of alginates with calcium salts, in between two parallel plates of a rheometer. Strain stiffening behavior was captured using large amplitude oscillatory shear (LAOS) experiments. In addition, negative normal stress was observed for these gels, which has not been reported earlier for any polysaccharide networks. The magnitude of negative normal stress increases with applied strain and can exceed that of the shear stress at large strain. Rheological results fitted with a constitutive model that considers both stretching and bending of chains indicate that nonlinearity is likely related to the stretching of the chains between the crosslink junctions. The results provide an improved understanding of the deformation mechanism of ionically crosslinked alginate gel and the results will be important in developing synthetic extracellular matrix (ECM) from these materials.

**8:48AM R38.00005 Cryo-imaging and modeling of the super molecular structure of cross-linked gelatin and its applications.**, CLEMENT MARMORAT, State Univ of NY- Stony Brook, ARKADI ARINSTEIN, Technion Israel Institute of Technology- Mechanical Engineering, NAAMA KOIFMAN, YESHAYAHU TALMON, Technion Israel Institute of Technology- Chemical Engineering, EYAL ZUSSMAN, Technion Israel Institute of Technology- Mechanical Engineering, MIRIAM RAFILOVICH, State Univ of NY- Stony Brook — The need for naturally derived materials to synthesize bio-compatible scaffolds is growing. In its natural state, gelatin derives its properties from a network of structured, intertwined, triple helical chains. The mechanical properties can be further controlled by additional enzymatic cross-linking. But, in contrast to simple polymer systems, the response to an imposed deformation is then determined by two competing factors, the establishment of the cross-linked mesh vs. the self-assembly of the fibrils into larger and therefore stronger hierarchical structures. Properties deduced from the response functions to measurements; such as rheology or swelling, are then a combination of these two very different factors, hence impossible to model unless more precise knowledge is available regarding the internal structure. We applied cryogenic-temperature scanning electron microscopy (cryo-SEM) to image the networks. Based on these images, a theoretical model was developed, for which we obtained excellent agreement for the mesh size of both networks, and their mechanical properties. We then used these controlled scaffolds, embedding them with fluorescent beads, to image live cells traction forces at stake during cell migration.

**9:00AM R38.00006 Encoding Mechano-Memories in Actin Networks**, LOUIS FOUCARD, UCLA, dpt of chemistry and biochemistry, SAYANTAN MAJUMDAR, James Franck institute, University of Chicago, dpt of Physics, ALEX LEVINE, UCLA, dpt of chemistry and biochemistry, MARGARET GARDEL, James Franck institute, University of Chicago, dpt of Physics — The ability of cells to sense and adapt to external mechanical stimuli is vital to many of its biological functions. A critical question is therefore to understand how mechanosensory mechanisms arise in living matter, with implications in both cell biology and smart materials design. Experimental work has demonstrated that the mechanical properties of semiflexible actin networks in Eukaryotic cells can be modulated (either transiently or irreversibly) via the application of external forces. Previous work has also shown with a combination of numerical simulations and analytic calculations shows that the broken rotational symmetry of the filament orientational distribution in semiflexible networks leads to dramatic changes in the mechanical response. Here we demonstrate with a combination of numerical and analytic calculations that the observed long-lived mechano-memory in the actin networks arise from changes in the nematic order of the constituent filaments. These stress-induced changes in network topology relax slowly under zero stress and can be observed through changes in the nonlinear mechanics. Our results provide a strategy for designing a novel class of materials and demonstrate a new putative mechanism of mechanical sensing in eukaryotic cells.

**9:12AM R38.00007 Fibril Formation and Phase Separation in Aqueous Cellulose Ethers**, AMANDA MAXWELL, University of Minnesota, Department of Chemistry, PETER SCHMIDT, University of Minnesota, Department of Chemistry and Materials Science, JOHN MCALLISTER, JOSEPH LOTT, University of Minnesota, Department of Chemistry, FRANK BATES, University of Minnesota, Department of Chemistry and Materials Science, TIMOTHY LODGE, University of Minnesota, Department of Chemistry — Aqueous solutions of many cellulose ethers are known to undergo thermoreversible gelation and phase separation upon heating to form turbid hydrogels, but the mechanism and resulting structures have not been well understood. Turbidity, light scattering and small-angle neutron scattering (SANS) are used to show that hydroxypropyl methylcellulose (HPMC) chains are dissolved in water below 50 °C and undergo phase separation at higher temperatures. At 70 °C, at sufficiently high concentrations in water, HPMC orders into fibrillar structures with a well-defined radius of  $18 \pm 2$  nm, as characterized by cryogenic transmission electron microscopy and SANS. The HPMC fibril structure is independent of concentration and heating rate. However, HPMC fibrils do not form a percolating network as readily as is seen in methylcellulose, resulting in a lower hot-gel modulus, as demonstrated by rheology.

**9:24AM R38.00008 Simulation of Polymer Physical Gel With Platelet Fillers**, DI XU, DILIP GERSSAPE, Stony Brook University — Platelet filler such as clays have superior effects on the properties of polymer gels. We used molecular dynamic simulations to study platelet filled composite gels system, in which small hexagonal disks simulate the platelets and gelation is due to short-range attraction between end-monomers and platelets. The properties of platelet filled composites are studied as a function of filler concentration. The mechanism of gelation was found similar to those of pure polymer gels; the polymers and platelets formed organic-inorganic networks, which percolate at high enough filler concentration. It was observed platelets aggregated into local intercalation structure, which significantly differs from typical spherical fillers. This unique intercalation structure is examined by radial distribution function and ordering parameters. We discussed how intercalation would affect the properties of the platelet composites by comparing them with spherical fillers.

**9:36AM R38.00009 A Coarse-Grained Model for Simulating Chitosan Hydrogels**, HONGCHENG XU, Biophysics Program, University of Maryland, College Park, SILVINA MATYSIAK, Biophysics Program, Fischell Department of Engineering, University of Maryland, College Park — Hydrogels are biologically-derived materials composed of water-filled cross-linking polymer chains. It has widely been used as biodegradable material and has many applications in medical devices. The chitosan hydrogel is stimuli-responsive for undergoing pH-sensitive self-assembly process, allowing programmable tuning of the chitosan deposition through electric pulse. To explore the self-assembly mechanism of chitosan hydrogels, we have developed an explicit-solvent coarse-grained chitosan model that has roots in the MARTINI force field, and the pH change is modeled by protonating chitosan chains using the Henderson-Hasselbalch equation. The mechanism of hydrogel network formation will be presented. The self-assembled polymer network qualitatively reproduces many experimental observables such as the pH-dependent strain-stress curve, bulk moduli, and structure factor. Our model is also capable of simulating other similar polyelectrolyte polymer systems.

**9:48AM R38.00010 Bio-Inspired Metal-Coordination Dynamics: A Unique Tool for Engineering Soft Matter Mechanics**, NIELS HOLTEN-ANDERSEN, Massachusetts Institute of Technology — Growing evidence supports a critical role of metal-coordination in soft biological material properties such as self-healing, underwater adhesion and autonomous wound plugging. Using bio-inspired metal-binding polymers, initial efforts to mimic these properties with metal-coordination crosslinked polymer materials have shown promise. In addition, with polymer network mechanics strongly coupled to coordinate crosslink dynamics material properties can be easily tuned from visco-elastic fluids to solids. Given their exploitation in desirable material applications in Nature, bio-inspired metal-coordinate complex crosslinking provides an opportunity to further advance synthetic polymer materials design. Early lessons from this pursuit are presented.

**10:24AM R38.00011 A Molecular Framework for Tunable Functional Response of Programmable Polyesters<sup>1</sup>**, KSHITIJ C. JHA, ABRAHAM JOY, MESFIN TSIGE, Department of Polymer Science, The University of Akron — All-atom molecular dynamics (MD) simulations, using the OPLS force field, were carried out on a library of multifunctional polyesters with peptide-like functional pendant groups. The polyesters are structural peptidomimetics and can be utilized for applications in sensing, and separation, and as biomedical scaffolds. The modular design of the polyesters affords a range of hydrophilic and hydrophobic behavior. We used MD to quantify the hydrogen bond dynamics, end-to-end distance, and radii of gyration with changes in side group functionality, concentration, and temperature. We discerned trends for the physical behavior of polyesters with change in nature and ratio of the side groups. We also observed functional assembly for dissimilar polyesters, and correlated the assembly to the affinity of side groups. The trends in physical behavior and dissimilar assembly can be mined for iterative design towards programmatic assembly of the modular multifunctional polyesters under study.

<sup>1</sup>This work was made possible by funding from the ACS Petroleum Research Fund (ACS PRF 54801- ND5)

**10:36AM R38.00012 Effects of Crowder Structure and Salt on DNA Mobility and Conformation in Crowded Environments<sup>1</sup>**, STEPHANIE M. GORCZYCA, RAE M. ROBERTSON-ANDERSON, University of San Diego — Biological cells are crowded environments in which DNA must move through to perform specific functions. We study how the properties of crowded cell-like environments impact DNA dynamics by tracking individual 115 kbp ring and linear DNA in different crowded environments using single-molecule fluorescence microscopy. We determine the role of crowder structure and salt on DNA diffusion and conformation by measuring the mean-squared center-of-mass displacements, as well as the conformational shape, size, and fluctuations of each molecule. Previously, we used 10 and 500 kDa dextran as crowders and showed that mobility of both ring and linear DNA decreased exponentially with increased crowding, but rings compact while linear DNA elongate. These effects were dependent solely on the reduction in available volume for DNA rather than size or number of crowders. Here we use crowders of similar molecular weight, but different structure to dextran (10 kDa PEG and 400 kDa Ficoll). We find that DNA mobility reduction is independent of crowder structure and that ring and linear DNA undergo more significant compaction. Finally, we characterize the role of salt on DNA mobility and conformation to determine the relative roles of enthalpic versus entropic effects on crowding-induced DNA dynamics.

**10:48AM R38.00013 Altered Sputum Microstructure as a Marker of Airway Obstruction in Cystic Fibrosis Patients**, GREGG DUNCAN, JAMES JUNG, NATALIE WEST, MICHAEL BOYLE, JUNG SOO SUK, JUSTIN HANES, Johns Hopkins University — In the lungs of cystic fibrosis (CF) patients, highly viscoelastic mucus remains stagnant in the lung leading to obstructed airways prone to recurrent infections. Bulk-fluid rheological measurement is primarily used to assess the pathological features of mucus. However, this approach is limited in detecting microscopic properties on the length scale of pathogens and immune cells. We have shown in prior work based on the transport of muco-inert nanoparticles (MIP) in CF sputum that patients can carry significantly different microstructural properties. In this study, we aimed to determine the factors leading to variations between patients in sputum microstructure and their clinical implications. The microrheological properties of CF sputum were measured using multi-particle tracking experiments of MIP. MIP were made by grafting polyethylene glycol onto the surface of polystyrene nanoparticles which prior work has shown prevents adhesion to CF sputum. Biochemical analyses show that sputum microstructure was significantly altered by elevated mucin and DNA content. Reduction in sputum pore size is characteristic of patients with obstructed airways as indicated by measured pulmonary function tests. Our microstructural read-out may serve as a novel biomarker for CF.

**Session R39 DBIO DPOLY GSNP: Physics of Genome Organization: from DNA to Chromatin**

I 342 - John Marko, Northwestern University

**8:00AM R39.00001 New insights into chromatin folding and dynamics from multi-scale modeling<sup>1</sup>** , WILMA OLSON, Rutgers, the State University of New Jersey — The dynamic organization of chromatin plays an essential role in the regulation of gene expression and in other fundamental cellular processes. The underlying physical basis of these activities lies in the sequential positioning, chemical composition, and intermolecular interactions of the nucleosomes—the familiar assemblies of roughly 150 DNA base pairs and eight histone proteins—found on chromatin fibers. We have developed a mesoscale model of short nucleosomal arrays and a computational framework that make it possible to incorporate detailed structural features of DNA and histones in simulations of short chromatin constructs with 3-25 evenly spaced nucleosomes. The correspondence between the predicted and observed effects of nucleosome composition, spacing, and numbers on long-range communication between regulatory proteins bound to the ends of designed nucleosome arrays lends credence to the model and to the molecular insights gleaned from the simulated structures. We have extracted effective nucleosome-nucleosome potentials from the mesoscale simulations and introduced the potentials in a larger scale computational treatment of regularly repeating chromatin fibers. Our results reveal a remarkable influence of nucleosome spacing on chromatin flexibility. Small changes in the length of the DNA fragments linking successive nucleosomes introduce marked changes in the local interactions of the nucleosomes and in the spatial configurations of the fiber as a whole. The changes in nucleosome positioning influence the statistical properties of longer chromatin constructs with 100-10,000 nucleosomes. We are investigating the extent to which the 'local' interactions of regularly spaced nucleosomes contribute to the corresponding interactions in chains with mixed spacings as a step toward the treatment of fibers with nucleosomes positioned at the sites mapped at base-pair resolution on genomic sequences.

<sup>1</sup>Support of the work by USPHS R01 GM 34809 is gratefully acknowledged.

**8:36AM R39.00002 Mitotic chromosome compaction via active loop extrusion.<sup>1</sup>** , ANTON GOLOBORODKO, MAXIM IMAKAEV, Massachusetts Inst of Tech-MIT, JOHN MARKO, Northwestern University, LEONID MIRNY, Massachusetts Inst of Tech-MIT, MIT-NORTHWESTERN TEAM — During cell division, two copies of each chromosome are segregated from each other and compacted more than hundred-fold into the canonical X-shaped structures. According to earlier microscopic observations and the recent Hi-C study, chromosomes are compacted into arrays of consecutive loops of ~100 kilobases. Mechanisms that lead to formation of such loop arrays are largely unknown. Here we propose that, during cell division, chromosomes can be compacted by enzymes that extrude loops on chromatin fibers. First, we use computer simulations and analytical modeling to show that a system of loop-extruding enzymes on a chromatin fiber self-organizes into an array of consecutive dynamic loops. Second, we model the process of loop extrusion in 3D and show that, coupled with the topo II strand-passing activity, it leads to robust compaction and segregation of sister chromatids. This mechanism of chromosomal condensation and segregation does not require additional proteins or specific DNA markup and is robust against variations in the number and properties of such loop extruding enzymes.

**8:48AM R39.00003 Multiscale modeling of three-dimensional genome** , BIN ZHANG, PETER WOLYNES, Rice University — The genome, the blueprint of life, contains nearly all the information needed to build and maintain an entire organism. A comprehensive understanding of the genome is of paramount interest to human health and will advance progress in many areas, including life sciences, medicine, and biotechnology. The overarching goal of my research is to understand the structure-dynamics-function relationships of the human genome. In this talk, I will be presenting our efforts in moving towards that goal, with a particular emphasis on studying the three-dimensional organization, the structure of the genome with multi-scale approaches. Specifically, I will discuss the reconstruction of genome structures at both interphase and metaphase by making use of data from chromosome conformation capture experiments. Computationally modeling of chromatin fiber at atomistic level from first principles will also be presented as our effort for studying the genome structure from bottom up.

**9:00AM R39.00004 The universality of nucleosome organization: from yeast to human** , RAZVAN CHEREJI, NIH — The basic units of DNA packaging are called nucleosomes. Their locations on the chromosomes play an essential role in gene regulation. We study nucleosome positioning in yeast, fly, mouse, and human, and build biophysical models in order to explain the genome-wide nucleosome organization. We show that DNA sequence alone is not able to generate the phased arrays of nucleosomes observed in vivo near the transcription start sites. We discuss simple models which can account for the formation of nucleosome depleted regions and nucleosome phasing at the gene promoters. We show that the same principles apply to different organisms. References: [1] RV Chereji, D Tolkunov, G Locke, AV Morozov - Phys. Rev. E 83, 050903 (2011) [2] RV Chereji, AV Morozov - J. Stat. **9:12AM R39.00005 Elucidate Chromatin Folding at the Mesoscale** , XIANGYUN QIU, George Washington Univ — Knowledge of the three-dimensional structure of chromatin, an active participant of all gene-directed processes, is required to decode its (epi)genetics-structure-function relationships. Albeit often simplified as “beads-on-a-string”, chromatin possesses daunting complexity in its intricate intra- and inter-nucleosome interactions, as well as the myriad types of molecules acting on it. On the other hand, the folding of chromatin from an extended chain of nucleosomes is highly constrained, e.g., by rather bulky nucleosomes and semi-rigid linker dsDNAs. Further given the well-defined nucleosome and dsDNA structures at the nanometer scale, this creates an opportunity for low-resolution structural methods such as small angle scattering to obtain mesoscale structures of chromatin, which can be further refined computationally to yield atomistic structures of chromatin. Here we present results from our recent studies of recombinant nucleosome arrays with solution small angle x-ray scattering (SAXS) and ensemble structure modeling.

**9:24AM R39.00006 Formation of chromosomal domains in interphase by loop extrusion** , GEORGE FREY FUDENBERG, MIT — While genomes are often considered as one-dimensional sequences, interphase chromosomes are organized in three dimensions with an essential role for regulating gene expression. Recent studies have shown that Topologically Associating Domains (TADs) are fundamental structural and functional building blocks of human interphase chromosomes. Despite observations that architectural proteins, including CTCF, demarcate and maintain the borders of TADs, the mechanisms underlying TAD formation remain unknown. Here we propose that loop extrusion underlies the formation TADs. In this process, cis-acting loop-extruding factors, likely cohesins, form progressively larger loops, but stall at TAD boundaries due to interactions with boundary proteins, including CTCF. This process dynamically forms loops of various sizes within but not between TADs. Using polymer simulations, we find that loop extrusion can produce TADs as determined by our analyses of the highest-resolution experimental data. Moreover, we find that loop extrusion can explain many diverse experimental observations, including: the preferential orientation of CTCF motifs and enrichments of architectural proteins at TAD boundaries; TAD boundary deletion experiments; and experiments with knockdown or depletion of CTCF, cohesin, and cohesin-loading factors. Together, the emerging picture from our work is that TADs are formed by rapidly associating, growing, and dissociating loops, presenting a clear framework for understanding interphase chromosomal organization.

**9:36AM R39.00007 TBA** , XIAOWEI ZHUANG, Harvard Univ — No abstract available.

**10:12AM R39.00008 Predictive Computational Modeling of Chromatin Folding**, MIICHELE DI PIERRO, BIN ZHANG, PETER J. WOLYNES, JOSE N. ONUCHIC, Center for Theoretical Biological Physics, Rice University — In vivo, the human genome folds into well-determined and conserved three-dimensional structures. The mechanism driving the folding process remains unknown. We report a theoretical model (MiChroM) for chromatin derived by using the maximum entropy principle. The proposed model allows Molecular Dynamics simulations of the genome using as input the classification of loci into chromatin types and the presence of binding sites of loop forming protein CTCF. The model was trained to reproduce the Hi-C map of chromosome 10 of human lymphoblastoid cells. With no additional tuning the model was able to predict accurately the Hi-C maps of chromosomes 1-22 for the same cell line. Simulations show unknotted chromosomes, phase separation of chromatin types and a preference of chromatin of type A to sit at the periphery of the chromosomes.

**10:24AM R39.00009 Robustness of nucleosome patterns in the presence of DNA sequence-specific free energy landscapes and active remodeling**, JOHANNES NUEBLER, Physik-Department, Technische Universität München, BENEDIKT OBERMAYER, WOLFRAM MBIUS, Max-Delbrück-Center for Molecular Medicine, MICHAEL WOLFF, ULRICH GERLAND, Physik-Department, Technische Universität München — Proper positioning of nucleosomes in eukaryotic cells is important for transcription regulation. When averaged over many genes, nucleosome positions in coding regions follow a simple oscillatory pattern, which is described to a surprising degree of accuracy by a simple one-dimensional gas model for particles interacting via a soft-core repulsion. The quantitative agreement is surprising given that nucleosome positions are known to be determined by a complex interplay of mechanisms including DNA sequence-specific nucleosome stability and active repositioning of nucleosomes by remodeling enzymes. We rationalize the observed robustness of the simple oscillatory pattern by showing that the main effect of several known nucleosome positioning mechanisms is a renormalization of the particle interaction. For example, disorder from sequence-specific affinities leads to an apparent softening, while active remodeling can result in apparent softening for directional sliding or apparent stiffening for clamping mechanisms. We suggest that such parameter renormalization can explain the apparent difference of nucleosome properties in two yeast species, *S. cerevisiae* and *S. pombe*.

**10:36AM R39.00010 The role of Nucleosome Positions on Chromatin Structure: A multi-scale approach**, JOSHUA LEQUIEU, ANDRES CORDOBA, JUAN J. DE PABLO, University of Chicago — Nucleosomes compose the basic unit of chromatin, and their locations are central to the regulation and compaction of eukaryotic genomes. In this work, we examine the coupling between different length scales within chromatin by examining the influence of nucleosome positions on three-dimensional chromatin structure. First, using a detailed molecular model of DNA and proteins, we predict the one-dimensional positioning of nucleosomes and the repositioning mechanisms of nucleosomal DNA. We demonstrate that this mechanism is strongly dependent on DNA sequence and that DNA slides around the histone proteins by either a screw-like or loop-like rearrangement. Next, we couple this detailed model to a coarsened model of chromatin and examine the impact of DNA sequence on chromatin's three-dimensional structure. We show that both the locations of nucleosomes and the mechanisms by which they move have a significant impact on higher-order chromatin structure and that variations in DNA sequence lead to "open" or "closed" regions of chromatin. This approach represents an efficient tool towards understanding the higher order structure of chromatin and how various aspects of chromatin structure are coupled together.

**10:48AM R39.00011 Chromatin extrusion explains key features of loop and domain formation in wild-type and engineered genomes**, ADRIAN SANBORN, SUHAS RAO, Stanford, SU-CHEN HUANG, NEVA DURAND, MIRIAM HUNTLEY, ANDREW JEWETT, IVAN BOCHKOV, DHARMARAJ CHINNAPPAN, ASHOK CUTKOSKY, JIAN LI, KRISTOPHER GEETING, DOUG MCKENNA, ELENA STAMENOVA, Baylor College of Medicine, ANDREAS GNIRKE, ALEXANDRE MELNIKOV, ERIC LANDER, Broad Institute, EREZ AIDEN, Baylor College of Medicine — Our recent kilobase-resolution genome-wide maps of DNA self-contacts demonstrated that mammalian genomes are organized into domains and loops demarcated by the DNA-binding protein CTCF. Here, we combine these maps with new Hi-C, microscopy, and genome-editing experiments to study the physical structure of chromatin fibers, domains, and loops. We find that domains are inconsistent with equilibrium and fractal models. Instead, we use physical simulations to study two models of genome folding. In one, intermonomer attraction during condensation leads to formation of an anisotropic "tension globule." In the other, CTCF and cohesin act together to extrude unknotted loops. Both models are consistent with the observed domains and loops. However, the extrusion model explains a far wider array of observations, such as why the CTCF-binding motifs at pairs of loop anchors lie in the convergent orientation. Finally, we perform 13 genome-editing experiments examining the effect of altering CTCF-binding sites on chromatin folding. The extrusion model predicts *in silico* the experimental maps using only CTCF-binding sites. Thus, we show that it is possible to disrupt, restore, and move loops and domains using targeted mutations as small as a single base pair.

**8:00AM R40.00001 Kinetic roughening: how directionality changes the game**, NUNO ARAUJO, Universidade de Lisboa — The nonequilibrium evolution of growing interfaces has attracted many experimental and theoretical studies over decades. One of the most popular theoretical approaches considers kinetic discrete models to describe particle aggregation on substrates. Albeit simple, these models are expected to contain the relevant physics. Inspired by recent advances in the production of functionalized colloidal particles, with attractive patches on their surface, we have proposed a stochastic model to study the effect of directionality and selective pairwise interactions on the kinetics of aggregation. We find a nontrivial dependence of the bulk and surface properties on the strength and flexibility of the patch-patch interactions, and on the spatial-patch distribution. For three-patch particles, sustained growth is only observed for a finite-range of the distance between patches, yielding two absorbing phase transitions and a tricritical flexibility. For four-patch particles with two distinct patches, i.e. strong and weak bonds, and sufficiently different bonding probabilities, the scaling properties of the interface crossover from the universality class of Kardar-Parisi-Zhang to the critical class of Kardar-Parisi-Zhang with quenched disorder. The latter is observed for an extended range of the parameters revealing the presence of a self-organized critical mechanism. Implications of our findings beyond functionalized particles are also discussed.

**8:36AM R40.00002 Exactly solvable models of growing interfaces: the Arcetri models**, XAVIER DURANG, Korean Institute for Advanced Study, MALTE HENKEL, Université de Lorraine, France — Motivated by an analogy with the spherical model of a ferromagnet, the Arcetri models present new universality classes for the growth of interfaces, distinct from the common Edwards-Wilkinson and Kardar-Parisi-Zhang universality classes. Those models are obtained by treating and replacing the non-linear term in the noisy Burgers equation or the KPZ equation by a mean spherical condition. We studied the consequences of such constraints on the Edwards-Wilkinson (EW) interface.

**8:48AM R40.00003 Infinite-noise criticality: Nonequilibrium phase transitions in fluctuating environments**<sup>1</sup>, THOMAS VOJTA, Missouri Univ of Science and Technology, JOSE HOYOS, Instituto de Física de São Carlos — We study the effects of time-varying environmental noise on nonequilibrium phase transitions in spreading and growth processes. Using the examples of the logistic evolution equation as well as the contact process, we show that such temporal disorder gives rise to a distinct type of critical points at which the effective noise amplitude diverges on long time scales. This leads to enormous density fluctuations characterized by an infinitely broad probability distribution at criticality. We develop a real-time renormalization-group theory that provides a general framework for the effects of temporal disorder on nonequilibrium processes. We also discuss how general this exotic critical behavior is, we illustrate the results by computer simulations, and we touch upon experimental applications of our theory.

**9:00AM R40.00004 Random field disorder at an absorbing state transition in one and two dimensions**<sup>1</sup>, HATEM BARGHATHI, THOMAS VOJTA, Missouri S&T — We investigate the behavior of nonequilibrium phase transitions under the influence of disorder that locally breaks the symmetry between two symmetrical macroscopic absorbing states. In equilibrium systems such “random-field” disorder destroys the phase transition in low dimensions by preventing spontaneous symmetry breaking. In contrast, we show here that random-field disorder fails to destroy the nonequilibrium phase transition of the one- and two-dimensional generalized contact process. Instead, it hampers the dynamics in the symmetry-broken phase. Specifically, the dynamics in the one-dimensional case is described by a Sinai walk of the domain walls between two different absorbing states. In the two-dimensional case, we map the dynamics onto that of the well studied low-temperature random-field Ising model. We also study the critical behavior of the nonequilibrium phase transition and characterize its universality class in one dimension. We support our results by large-scale Monte-Carlo simulations and discuss the applicability of our theory to other systems.

**9:12AM R40.00005 Leveraging large fluctuations for stochastic control in uncertain environments**<sup>1</sup>, IRA SCHWARTZ<sup>2</sup>, Naval Research Lab, CHRISTOFFER HECKMAN, University of Colorado, M. ANI HSIEH, Drexel University — We present the development of a stochastic control strategy that leverages the environmental dynamics and uncertainty to navigate in a stochastic fluidic environment. We assume that the domain is composed of the union of a collection of disjoint regions, each bounded by Lagrangian coherent structures (LCSs). We analyze a passive particle’s noise-induced transition between adjacent LCS-bounded regions and show how most probable escape trajectories with respect to the transition probability between adjacent LCS-bounded regions can be determined. Additionally, we show how the likelihood of transition can be controlled through minimal actuation. The result is an energy efficient navigation strategy that leverages the inherent uncertainty of the surrounding flow field for controlling sensors in a noisy fluidic environment. We experimentally validate the proposed control strategy and show that the single vehicle control parameter exhibits a predictable exponential scaling with respect to the escape times and is effective even in situations where the structure of the flow is not fully known and control effort is costly.

**9:24AM R40.00006 Flux line non-equilibrium relaxation kinetics following current quenches in disordered type-II superconductors**<sup>1</sup>, HARSHWARDHAN CHATURVEDI, HIBA ASSI, Department of Physics, Virginia Tech, ULRICH DOBRAMYSL, The Gurdon Institute, University of Cambridge, U.K., MICHEL PLEIMLING, UWE TÄUBER, Department of Physics, Virginia Tech — We investigate the relaxation dynamics of magnetic vortex lines in disordered type-II superconductors following rapid changes in the external driving current by means of Langevin molecular dynamics simulations for an elastic line model. A system of driven interacting flux lines in a sample with randomly distributed point pinning centers is initially relaxed to a moving non-equilibrium steady state. The current is then instantaneously decreased, such that the final stationary state resides either still in the moving regime, or in the pinned Bragg glass phase. The ensuing non-equilibrium relaxation kinetics of the vortices is studied in detail by measuring the mean flux line gyration radius and the two-time transverse height autocorrelation function. The latter allows us to investigate the physical aging properties for quenches from the moving into the glassy phase, and to compare with non-equilibrium relaxation features obtained with different initial configurations.

**9:36AM R40.00007 Local temperatures and voltages in quantum systems far from equilibrium**<sup>1</sup>, ABHAY SHASTRY, CHARLES STAFFORD, University of Arizona, DEPARTMENT OF PHYSICS COLLABORATION — We show that the local measurement of temperature and voltage for a quantum system in steady state, arbitrarily far from equilibrium, with arbitrary interactions within the system, is unique when it exists. This is interpreted as a consequence of the second law of thermodynamics. We further derive a necessary and sufficient condition for the existence of a solution. In this regard, we find that a solution occurs whenever there is no net population inversion. However, when there is a net population inversion, we may characterize the system with a (unique) negative temperature. These results provide a firm mathematical foundation for our measurement protocol, and sound meaning to such measurements in the thermodynamic sense.

**9:48AM R40.00008 Quasiparticle explanation of "weak thermalization" regime under quench in a non-integrable quantum spin chain** , CHENG-JU LIN, OLEXEI MOTRUNICH, Caltech — Eigenstate Thermalization Hypothesis provides one picture of thermalization in a quantum system by looking at individual eigenstates. However, it is also important to consider how local observables reach equilibrium values dynamically. Quench protocol is one of the settings to study such questions. A recent numerical study [Banuls, Cirac, and Hastings, Phys. Rev. Lett. **106**, 050405 (2011)] of a nonintegrable quantum Ising model with longitudinal field under such quench setting found different behaviors under different initial quantum states. One particular case termed weak thermalization regime showed apparently persistent oscillations of some observables. Here we provide an explanation of such oscillations. We use perturbation theory near the ground state of the model, and identify the oscillation frequency as the quasiparticle mass. With this quasiparticle picture, we can then address the long-time behavior of the oscillations.

**10:00AM R40.00009 How can an autonomous quantum Maxwell demon harness correlated information?**<sup>1</sup> , ADRIAN CHAPMAN, AKIMASA MIYAKE, Univ of New Mexico, CQUIC THERMODYNAMICS TEAM — We study an autonomous quantum system, which exhibits refrigeration under an information-work tradeoff like a Maxwell demon. The system becomes correlated as a single demon qubit interacts sequentially with memory qubits while in contact with two heat reservoirs of different temperatures. Using strong subadditivity of the von Neumann entropy, we derive a global Clausius inequality to show thermodynamical advantages from access to correlated information. It is demonstrated, in a matrix product density operator formalism, that our demon can simultaneously realize refrigeration against a thermal gradient and erasure of information from its memory, which is impossible without correlations. The phenomenon can be even enhanced by the presence of quantum coherence.

**10:12AM R40.00010 Fano-Andreev effect in Quantum Dots in Kondo regime**<sup>1</sup> , PEDRO ORELLANA, ANA MARIA CALLE, MONICA PACHECO, Universidad Tecnica Federico Santa Maria, VICTOR APEL, Universidad Catlica del Norte — In the present work, we investigate the transport through a T-shaped double quantum dot system coupled to two normal leads and to a superconducting lead. We study the role of the superconducting lead in the quantum interferometric features of the double quantum dot and by means of a slave boson mean field approximation at low temperature regime. We inquire into the influence of intradot interactions in the electronic properties of the system as well. Our results show that Fano resonances due to Andreev bound states are exhibited in the transmission from normal to normal lead as a consequence of quantum interference and proximity effect. This Fano effect produced by Andreev bound states in a side quantum dot was called Fano-Andreev effect, which remains valid even if the electron-electron interaction are taken into account, that is, the Fano-Andreev effect is robust against e-e interactions even in Kondo regime.

**10:24AM R40.00011 Quantum critical temperature of a modulated oscillator** , VITTORIO PEANO, University of Erlangen-Nrnberg, LINGZHEN GUO, MICHAEL MARTHALER, Karlsruhe Institute of Technology, MARK DYKMAN, Michigan State University — We show that the rate of switching between the vibrational states of a modulated nonlinear oscillator is characterized by a quantum critical temperature  $T_c \propto \hbar^2$ . Above  $T_c$  there emerges a quantum crossover region where the switching rate displays a steep and characteristic temperature dependence, followed by a qualitatively different temperature dependence for higher  $T$ . In contrast to the crossover between tunneling and thermal activation in equilibrium systems, here the crossover occurs between different regimes of switching activated by quantum fluctuations. The results go beyond the standard real-time instanton technique of the large-deviation theory.

**10:36AM R40.00012 The interplay between universal scaling laws and vortex clustering in two-dimensional quantum turbulence** , AUDUN SKAUGEN, LUIZA ANGHELUTA, Univ of Oslo — The relationship between vortex dynamics and the turbulent energy spectrum is an active research topic in quantum turbulence of superfluids and Bose-Einstein condensates. The energy spectra in quantum turbulence exhibit a Kolmogorov -5/3 scaling law, analogous to classical turbulence. Recent developments show that in two-dimensional quantum flows, this energy spectrum corresponds to an inverse energy cascade, which is realized by clustering of like-signed quantized vortices. We investigate numerically the statistics of quantized vortices in two-dimensional quantum turbulence using the Gross-Pitaevskii equation. We find that a universal -5/3 scaling law in the turbulent energy spectrum is intimately connected with the vortex statistics, such as number fluctuations and velocity, which also show a similar scaling behavior. The -5/3 scaling law appearing in the power spectrum of the vortex number is consistent with a scenario of isolated vortices passively advected by a turbulent superfluid velocity, which is again generated by like-signed vortex clusters. The velocity probability distribution of clustered vortices is also sensitive to spatial correlations, and exhibits a power-law tail with a -5/3 exponent that we can predict analytically from the point vortex model.

**10:48AM R40.00013 Fluctuation loops in a noise-driven linear circuit model** , STEPHEN TEITSWORTH, AKHIL GHANTA, JOHN NEU, Duke University — Understanding the spatio-temporal structure of most probable fluctuation pathways to rarely occurring states is a central problem in the study of noise-driven, non-equilibrium dynamical systems. When the underlying system does not possess detailed balance, the optimal fluctuation pathway to a particular state and relaxation pathway from that state may combine to form a loop-like structure in the system phase space which we call a *fluctuation loop*. Here, we study fluctuation loops in a linear circuit model consisting of coupled RC elements, where each element is driven by its own noise source and, generally, the effective noise strengths of different elements are not equal. Using a stochastic Hamiltonian approach, we determine the optimal fluctuation pathways, and construct corresponding fluctuation loops. Analytical results agree closely with suitably averaged simulation results based on the associated Langevin equation. To better characterize fluctuation loops, we study the time-dependent area tensor that is swept out by individual stochastic trajectories in the system phase space. At long times, the area tensor scales linearly with time, with a coefficient that precisely vanishes when the system satisfies detailed balance.

**8:00AM R41.00001 Taking Action: How Small Brains Make Big Choices** , GWYNETH CARD, HHMI Janelia Research Campus — No abstract available.

**8:36AM R41.00002 Tracking *C. elegans* and its neuromuscular activity using NemaFlex** , FRANK VAN BUSSEL, Department of Mechanical Engineering, Texas Tech University, MIZANUR RAHMAN, JENNIFER HEWITT, Department of Chemical Engineering, Texas Tech University, JERZY BLAWDZIEWICZ, Department of Mechanical Engineering, Texas Tech University, MONICA DRISCOLL, Department of Molecular Biology and Biochemistry, Rutgers University, NATHANIEL SZEWCZYK, MRC/Arthritis Research UK Centre for Musculoskeletal Ageing Research, University of Nottingham, UK, SIVA VANAPALLI, Department of Chemical Engineering, Texas Tech University — Recently, a novel platform has been developed for studying the behavior and physical characteristics of the nematode *C. elegans*. This is NemaFlex, developed by the Vanapalli group at Texas Tech University to analyze movement and muscular strength of crawling *C. elegans*. NemaFlex is a microfluidic device consisting of an array of deformable PDMS pillars, with which the *C. elegans* interacts in the course of moving through the system. Deflection measurements then allow us to calculate the force exerted by the worm via EulerBernoulli beam theory. For the procedure to be fully automated a fairly sophisticated software analysis has to be developed in tandem with the physical device. In particular, the usefulness of the force calculations is highly dependent on the accuracy and volume of the deflection measurements, which would be prohibitively time-consuming if carried out by hand/eye. In order to correlate the force results with muscle activations the *C. elegans* itself has to be tracked simultaneously, and pillar deflections precisely associated with mechanical-contact on the worm's body. Here we will outline the data processing and analysis routines that have been implemented in order to automate the calculation of these forces and muscular activations.

**8:48AM R41.00003 High Throughput Interrogation of Behavioral Transitions in *C. elegans*** , MOCHI LIU, JOSHUA SHAEVITZ, ANDREW LEIFER, Princeton University — We present a high-throughput method to probe transformations from neural activity to behavior in *Caenorhabditis elegans* to better understand how organisms change behavioral states. We optogenetically deliver white-noise stimuli to target sensory or inter neurons while simultaneously recording the movement of a population of worms. Using all the postural movement data collected, we computationally classify stereotyped behaviors in *C. elegans* by clustering based on the spectral properties of the instantaneous posture. (Berman et al., 2014) Transitions between these behavioral clusters indicate discrete behavioral changes. To study the neural correlates dictating these transitions, we perform model-driven experiments and employ Linear-Nonlinear-Poisson cascades that take the white-noise stimulus as the input. The parameters of these models are fitted by reverse-correlation from our measurements. The parameterized models of behavioral transitions predict the worm's response to novel stimuli and reveal the internal computations the animal makes before carrying out behavioral decisions. Preliminary results are shown that describe the neural-behavioral transformation between neural activity in mechanosensory neurons and reversal behavior.

**9:00AM R41.00004 Influence of the Enteric Nervous System on Gut Motility Patterns in Zebrafish<sup>1</sup>** , RYAN BAKER, Dept of Physics, Univ of Oregon, JULIA GANZ, ELLIE MELANCON, JUDITH EISEN, Institute of Neuroscience, University of Oregon, RAGHUVeer PARTHASARATHY, Department of Physics, University of Oregon — The enteric nervous system (ENS), composed of diverse neuronal subtypes and glia, regulates essential gut functions including motility, secretion, and homeostasis. In humans and animals, decreased numbers of enteric neurons lead to a variety of types of gut dysfunction. However, surprisingly little is known about how the number, position, or subtype of enteric neurons affect the regulation of gut peristalsis, due to the lack of good model systems and the lack of tools for the quantitative characterization of gut motion. We have therefore developed a method of quantitative spatiotemporal mapping using differential interference contrast microscopy and particle image velocimetry, and have applied this to investigate intestinal dynamics in normal and mutant larval zebrafish. From movies of gut motility, we obtain a velocity vector field representative of gut motion, from which we can quantify parameters relating to gut peristalsis such as frequency, wave speed, deformation amplitudes, wave duration, and non-linearity of waves. We show that mutants with reduced neuron number have contractions that are more regular in time and reduced in amplitude compared to wild-type (normal) fish. We also show that feeding fish before their yolk is consumed leads to stronger motility patterns.

**9:12AM R41.00005 Improved Software for Quantifying the Behavior of *Drosophila* Larvae** , NATALIE BERNAT, MARC GERSHOW, New York University — A key advantage of small crawling organisms like *C. elegans* and the *Drosophila* larva is that their behaviors may be assayed automatically using computer vision software. Current state of the art software is capable of detecting the positions and postures of crawling larvae and automatically categorize their behaviors in parallel. However, these algorithms, which are based on frame-by-frame analysis of thresholded black and white images, fail to correctly describe the postures of larvae executing sharp bends and have difficulty separating multiple larvae that are physically touching. We present new tracking software that uses intensity information in grayscale images and applies temporal smoothness constraints to positions and postures. We implemented this software as an ImageJ plugin, extending its portability and applicability.

**9:24AM R41.00006 Development of a two photon microscope for tracking *Drosophila* larvae** , DOYCHO KARAGYOZOV, MIRNA MIHOVILOVIC SKANATA, MARC GERSHOW, New York Univ NYU — Current in vivo methods for measuring neural activity in *Drosophila* larva require immobilization of the animal. Although we can record neural signals while stimulating the sensory organs, we cannot read the behavioral output because we have prevented the animal from moving. Many research questions cannot be answered without observation of neural activity in behaving (freely-moving) animals. Our project aims to develop a tracking microscope that maintains the neurons of interest in the field of view and in focus during the rapid three dimensional motion of a free larva.

**9:36AM R41.00007 Chemotaxis of *Caenorhabditis elegans* in complex media: crawling, burrowing, 2D and 3D swimming, and controlled fluctuations hypothesis<sup>1</sup>** , AMAR PATEL, ALEJANDRO BILBAO, Dept. of Mechanical Engineering, Texas Tech University, MIZANUR RAHMAN, SIVA VANAPALLI, Dept. of Chemical Engineering, Texas Tech University, JERZY BLAWDZIEWICZ, Dept. of Mechanical Engineering, Texas Tech University — *Caenorhabditis elegans* is a powerful genetic model, essential for studies in diverse areas ranging from behavior to neuroscience to aging, and locomotion and chemotaxis are the two key observables used. We combine our recently developed theory of nematode locomotion and turning maneuvers [Phys. Fluids 25, 081902 (2013)] with simple models of chemosensation to analyze nematode chemotaxis strategies in 2D and 3D environments. We show that the sharp-turn (pirouette) chemotaxis mechanism is efficient in diverse media; in particular, the nematode does not need to adjust the sensing or motion-control parameters to efficiently chemotax in 2D crawling, 3D burrowing, and 2D or 3D swimming. In contrast, the graduate-turn mechanism becomes inefficient in swimming, unless a phase-shift is introduced between the sensing signal and modulation of body wave to generate the gradual turn. We hypothesize that there exists a new "controlled fluctuations" chemotaxis mechanism, in which the nematode changes the intensity of undulation fluctuations to adjust the persistence length of the trajectory in response to a variation in chemoattractant concentration.

**9:48AM R41.00008 Motor neurons in *Drosophila* flight control: could b1 be the one?** , SAMUEL WHITEHEAD, Department of Physics, Cornell University, TROY SHIRANGI, HHMI, Janelia Farm Campus, ITAI COHEN, Department of Physics, Cornell University — Similar to balancing a stick on ones fingertip, flapping flight is inherently unstable; maintaining stability is a delicate balancing act made possible only by near-constant, often-subtle corrective actions. For fruit flies, such corrective responses need not only be robust, but also fast: the *Drosophila* flight control reflex has a response latency time of ~5 ms, ranking it among the fastest reflexes in the animal kingdom. How is such rapid, robust control implemented physiologically? Here we present an analysis of a putatively crucial component of the *Drosophila* flight control circuit: the b1 motor neuron. Specifically, we apply mechanical perturbations to freely-flying *Drosophila* and analyze the differences in kinematics patterns between flies with manipulated and un-manipulated b1 motor neurons. Ultimately, we hope to identify the functional role of b1 in flight stabilization, with the aim of linking it to previously-proposed, reduced-order models for reflexive control.

**10:00AM R41.00009 System identification and sensorimotor determinants of flight maneuvers in an insect**, SIMON SPONBERG, Georgia Tech, ROBERT HALL, EATAI ROTH, Univ. of Washington — Locomotor maneuvers are inherently closed-loop processes. They are generally characterized by the integration of multiple sensory inputs and adaptation or learning over time. To probe sensorimotor processing we take a system identification approach treating the underlying physiological systems as dynamic processes and altering the feedback topology in experiment and analysis. As a model system, we use agile hawk moths (*Manduca sexta*), which feed from real and robotic flowers while hovering in mid air. Moths rely on vision and mechanosensation to track floral targets and can do so at exceptionally low luminance levels despite hovering being a mechanically unstable behavior that requires neural feedback to stabilize. By altering the sensory environment and placing mechanical and visual signals in conflict we show a surprisingly simple linear summation of visual and mechanosensation produces a generative prediction of behavior to novel stimuli. Tracking performance is also limited more by the mechanics of flight than the magnitude of the sensory cue. A feedback systems approach to locomotor control results in new insights into how behavior emerges from the interaction of nonlinear physiological systems.

**10:12AM R41.00010 Leveraging low-dimensional postures to resolve coiled shapes reveals new reorientation behaviors in the nematode *C. elegans*.**, GREG STEPHENS, VU Amsterdam and OIST Graduate University, ONNO BROEKMANS, VU Amsterdam and Lumicks, WILLIAM RYU, University of Toronto — Low-dimensionality is both a fundamental property of many living systems and an aid in their quantitative analysis. Here, we exploit the low-dimensionality of *C. elegans* body shape to develop a novel postural tracking algorithm which captures both simple worm shapes and also complex, self-occluding coils. We apply our algorithm to a thermally-evoked escape response with relatively simple coils and to more complex, spontaneous turns which occur during foraging. We divide the escape response into three post-stimulus phases, reversal, turn and post-turn, and find that the full distribution of reorientation angles is shaped by independent and significant contributions from all three phases, a result consistent with the release and presence of the monoamine tyramine during the entire response. In spontaneous coils we find two separable peaks of turning posture amplitudes, indicating distinct reorientation behaviors of large-amplitude ventral-side turns; large ventral bearing reorientations occur through a shape sequence similar to the escape response while large dorsal bearing reorientations are accomplished by overturning across the ventral side. We find that these large-amplitude turning events occur independently but with approximately matched rates that adapt on a similar timescale.

**10:24AM R41.00011 Slithering on sand: kinematics and controls for success on granular media.**, PERRIN E SCHIEBEL, TINGNAN ZHANG, Georgia Institute of Technology, JIN DAI, CHAOHUI GONG, MIAO YU, Carnegie Mellon University, HENRY C ASTLEY, Georgia Institute of Technology, MATTHEW TRAVERS, HOWIE CHOSSET, Carnegie Mellon University, DANIEL I GOLDMAN, Georgia Institute of Technology — Previously, we studied the *subsurface* locomotion of undulatory sand-swimming snakes and lizards; using empirical drag response of GM to subsurface intrusion of simple objects allowed us to develop a granular resistive force theory (RFT) to model the locomotion and predict optimal movement patterns. However, our knowledge of the physics of GM at the surface is limited; this makes it impossible to determine how the desert-dwelling snake *C. occipitalis* moves effectively (0.45+/-0.04 bodylengths/sec) on the surface of sand. We combine organism biomechanics studies, GM drag experiments, RFT calculations and tests of a physical model (a snake-like robot), to reveal how multiple factors acting together contribute to slithering on sandy surfaces. These include the kinematics—targeting an ideal waveform which maximizes speed while minimizing joint-level torque, the ability to modulate ground interactions by lifting body segments, and the properties of the GM. Based on the sensitive nature of the relationship between these factors, we hypothesize that having an element of force-based control, where the waveform is modulated in response to the forces acting between the body and the environment, is necessary for successful locomotion on yielding substrates.

**10:36AM R41.00012 Dynamic Control of Walking and Paw-shaking in the Cat**, JESSICA GREEN, GENNADY CYMBALYUK, Georgia State University — Multistable central pattern generators (CPGs) are capable of producing multiple rhythmic patterns with different periods. We developed a model of a half center oscillator, consisting of two reciprocally inhibitory neurons. Each neuron contains two slow inward currents, a  $\text{Na}^+$  current, and a  $\text{Ca}^{++}$  current. We found that a walking rhythm (1 Hz) and a paw-shaking rhythm (10 Hz) do coexist in this model. The kinetics of the inactivations of  $\text{I}_{\text{NaS}}$  and  $\text{I}_{\text{CaS}}$  produce this multistability. A paw-shaking response can be demonstrated as a result of a switch in the multistable model or as a transient response of a nearby monostable model. The duration of this transient paw-shaking response depends on pulse duration and the phase of walking at which the pulse is initiated. We also developed a model of two populations with 20 neurons each, in which there are random inhibitory synapses across the two populations and random excitatory synapses within each population. This population model generates similar behavior as the two neuron model.

**10:48AM R41.00013 Recovery methods of the dragonfly from irregular initial conditions.**, JAMES MELFI, Cornell University, ANTHONY LEONARDO, HHMI Janelia Farms, JANE WANG, Cornell University — We release dragonflies from a magnetic tether in a wide range of initial orientations, which results in them utilizing multiple methods to regain their typical flight orientation. Special focus is placed on dropping them while upside down, as the recovery method used is a purely rolling motion. Filming this stereotypical motion with a trio of high speed cameras at 4000 fps, we capture detailed body and wing kinematics data to determine how the dragonfly generates this motion. By replaying the flights within a computer simulation, we can isolate the significant changes to wing kinematics, and find that it is an asymmetry in the wing pitch which generates the roll. Further investigation demonstrates that this choice is highly dependent upon the state of the dragonfly, and as such our results indicate the dragonfly both tracks its current state, and changes its mid-flight control mechanisms accordingly.

345 - William Phillip, University of Notre Dame

**8:00AM R42.00001 Statistical Mechanical Theory of Penetrant Diffusion in Polymer Melts and Glasses**, RUI ZHANG, KENNETH SCHWEIZER, University of Illinois at Urbana-Champaign — We generalize our force-level, self-consistent nonlinear Langevin equation theory of activated diffusion of a dilute spherical penetrant in hard sphere fluids [1] to predict the long-time diffusivity of molecular penetrants in supercooled polymer liquids and non-aging glasses. Chemical complexity is treated using an a priori mapping to a temperature-dependent hard sphere mixture model where polymers are disconnected into effective spheres based on the Kuhn length as the relevant coarse graining scale. A key parameter for mobility is the penetrant to polymer segment diameter ratio,  $R$ . Our calculations agree well with experimental measurements for a wide range of temperatures, penetrant sizes (from gas molecules with  $R \sim 0.3$  to aromatic molecules with  $R \sim 1$ ) and diverse amorphous polymers, over 10 decades variation of penetrant diffusivity. Structural parameter transferability is good. We have also formulated a theory at finite penetrant loading for the coupled penetrant-polymer dynamics in chemically (nearly) matched mixtures (e.g., toluene-polystyrene) which captures well the increase of penetrant diffusivity and decrease of polymer matrix vitrification temperature with increasing loading. [1] R. Zhang and K. S. Schweizer, J. Chem. Phys., 143, 144906 (2015).

**8:12AM R42.00002 Molecular Dynamics Simulations of Penetrants in Microphase Separated Tapered Diblock Copolymers<sup>1</sup>**, YOUNGMI SEO, JONATHAN R. BROWN, LISA M. HALL, Ohio State Univ - Columbus — Tapered AB diblock copolymers contain pure A and B monomer blocks on the ends with a tapered midblock of intermediate composition, providing taper length as an additional tuning parameter to control microphase separation and interfacial behavior. We model the midblock as a statistical linear gradient from pure A to pure B. Recent experiments with salt dissolved in one of microphases show that a certain length of taper increases ion conductivity while the same length of inverse taper lowers conductivity. We perform coarse-grained molecular dynamics simulations of tapered copolymers with monomer sized penetrants, which have preferential interactions with one microphase, to better understand this observation and the general effects of tapering on dynamics. We calculate penetrant diffusion, polymer relaxation times, and other quantities over the range from 0% (diblock) to 100% (full gradient) taper length, with the taper direction either normal or inverse (with the A side of the taper connected to the pure B block). Normal taper results typically lie between those of diblocks and full gradients, while inverse tapers show strong nonmonotonic behavior as a function of taper length. For intermediate length inverse tapers, penetrant and monomer dynamics are significantly slower than those of diblocks or normal tapers, and this relates to the folding of the inverse chains back and forth across the interface. To provide further insight, we also compare to the dynamics of random copolymers of various compositions.

**8:24AM R42.00003 Mechanism of Concentration Dependence of Water Diffusivity in Polyacrylate Gels.**, SRIRAMVIGNESH MANI, FARDIN KHABAZ, RAJESH KHARE, Texas Tech University — Membrane based separation processes offer an energy efficient alternative to traditional distillation based separation processes. In this work, we focus on the molecular mechanisms underlying the process of separation of dilute ethanol-water mixture using polyacrylate gels as pervaporation membranes. The diffusivities of the components in swollen gels exhibit concentration dependence. We have used molecular dynamics (MD) simulations to study the correlation between the dynamics of solvent (water and ethanol) molecules, polymer dynamics and solvent structure in the swollen gel systems as a function of solvent concentration. Three different polyacrylate gels were studied: (1) poly n-butyl acrylate (PBA), (2) copolymer of butyl acrylate and 2-hydroxyethyl acrylate P(BA50-HEA50), and (3) poly 2-hydroxyethyl acrylate (PHEA). Simulation results show that solvent concentration has a significant effect on local structure of the solvent molecules and chain dynamics; these factors (local structure and chain dynamics), in turn, affect the diffusivity of these molecules. At low concentration, solvent molecules are well dispersed in the gel matrix and form hydrogen bonds with the polymer. Solvent mobility is correlated with polymer mobility in this configuration and consequently water and ethanol molecules exhibit slower dynamics, this effect is especially significant in PHEA gel. At high solvent concentration, water molecules form large clusters in the system accompanied by enhancement in mobility of both the gel network and the solvent molecules.

**8:36AM R42.00004 Structure/property relationships in polymer membranes for water purification and energy applications**, GEOFFREY GEISE, University of Virginia — Providing sustainable supplies of purified water and energy is a critical global challenge for the future, and polymer membranes will play a key role in addressing these clear and pressing global needs for water and energy. Polymer membrane-based processes dominate the desalination market, and polymer membranes are crucial components in several rapidly developing power generation and storage applications that rely on membranes to control rates of water and/or ion transport. Much remains unknown about the influence of polymer structure on intrinsic water and ion transport properties, and these relationships must be developed to design next generation polymer membrane materials. For desalination applications, polymers with simultaneously high water permeability and low salt permeability are desirable in order to prepare selective membranes that can efficiently desalinate water, and a tradeoff relationship between water/salt selectivity and water permeability suggests that attempts to prepare such materials should rely on approaches that do more than simply vary polymer free volume. One strategy is to functionalize hydrocarbon polymers with fixed charge groups that can ionize upon exposure to water, and the presence of charged groups in the polymer influences transport properties. Additionally, in many emerging energy applications, charged polymers are exposed to ions that are very different from sodium and chloride. Specific ion effects have been observed in charged polymers, and these effects must be understood to prepare charged polymers that will enable emerging energy technologies. This presentation discusses research aimed at further understanding fundamental structure/property relationships that govern water and ion transport in charged polymer films considered for desalination and electric potential field-driven applications that can help address global needs for clean water and energy.

**9:12AM R42.00005 Ion transferring in polyelectrolyte networks in electric fields.**, HONGHAO LI, AYKUT ERBAS, Northwestern Univ, JOS ZWANIKKEN, University of Massachusetts Lowell, MONICA OLVERA DE LA CRUZ, Northwestern Univ — Ion-conducting polyelectrolyte gels have drawn the attention of many researchers in the last few decades as they have wide applications not only in lithium batteries but also as stretchable, transparent ionic conductor or ionic cables devices. However, ion dynamics in polyelectrolyte gels has been much less studied analytically or computationally due to the complicated interplay of long-range electrostatic and short-range interactions. Here we propose a coarse-grained non-equilibrium molecular dynamics simulation to study the ion dynamics in polyelectrolyte gels under external electric fields. We found a nonlinear response region where the molar conductivity of polyelectrolyte gels increases with external fields. We propose counterion redistribution under electric fields as the driving mechanism. We also found the ionic conductivity to be modulated by changing polyelectrolyte network topology such as the chain length. Our discovery reveals the essential difference of ion dynamics between electrolytes and polyelectrolyte gels. These results will expand our understanding in charged polymeric systems and help in designing ion-conducting devices with higher conductivity.

**9:24AM R42.00006 Thermodynamics of Ionic Transport through Functionalized Membranes**, VIKRAMJIT RATHEE, SIYI QU, THEODORE DILENSCHNEIDER, WILLIAM A. PHILLIP, JONATHAN K. WHITMER, Chemical and Biomolecular Engineering, University of Notre Dame — Through microphase separation of block copolymers, highly porous solid membranes may be assembled. Further functionalization with amine and sulfonic acid groups has demonstrated promise in exquisitely controlling the flux of charged species, and in particular multivalent ions. Using coarse-grained molecular simulations, we explore the essential thermodynamics underlying salt rejection in charge-functionalized membranes, and develop a model capable of linking the performance of these membranes to their molecular character through free energy calculations.

**9:36AM R42.00007 Theoretical model of Case-II diffusion based on molecular-dynamics study of methanol in PMMA<sup>1</sup>**, JIAYUAN MIAO, Case Western Reserve University, MESFIN TSIGE, University of Akron, PHILIP TAYLOR, Case Western Reserve University — In Case-II diffusion, a sharp diffusion front moves at a nearly constant speed. An obstacle to the theoretical prediction of the form of this front lies in the large mismatch between the time scale of atomic motion, which is measured in femtoseconds, and the time scale of diffusion in a macroscopic sample, which is measured in millions of seconds. We attempt to overcome this limitation by using the short-time results of atomistic molecular-dynamics simulations to construct a stochastic model valid over all time scales. The ability of this model to yield Case-II diffusion behavior was confirmed, and it was then developed into a continuum mathematical model in which the diffusivity  $D$  has a strong dependence on the concentration of the penetrant. We anticipate that solution of the appropriate non-linear diffusion equation will yield an accurate portrayal of the characteristics of the diffusion process.

**9:48AM R42.00008 Multicomponent Diffusion of Penetrant Mixtures in Rubbery Polymers: A Molecular Dynamics Study**, STEFAN BRINGUIER, MARK VARADY, OptiMetrics, Inc. a DCS Company, CRAIG KNOX, Leidos, Inc., JERRY CABALO, R&T Directorate, Edgewood Chemical Biological Center, THOMAS PEARL, OptiMetrics, Inc. a DCS Company, BRENT MANTOOTH, R&T Directorate, Edgewood Chemical Biological Center — The importance of understanding transport of chemical species across liquid-solid boundaries is of particular interest in the decontamination of harmful chemicals absorbed within polymeric materials. To characterize processes associated with liquid-phase extraction of absorbed species from polymers, it is necessary to determine an appropriate physical description of species transport in multicomponent systems. The Maxwell-Stefan (M-S) formulation is a rigorous description of mass transport in multicomponent solutions, in which, mutual diffusivities determine the degree of relative motion between interacting molecules in response to a chemical potential gradient. The work presented focuses on the determination of M-S diffusivities from molecular dynamics (MD) simulations of nerve agent O-ethyl S-[2(diisopropylamino)ethyl] methylphosphonothioate (VX), water, and methanol mixtures within a poly(dimethylsiloxane) matrix. We investigate the composition dependence of M-S diffusivities and compare the results to values predicted using empirical relations for binary and ternary mixtures. Finally, we highlight the pertinent differences in molecular mechanisms associated with species transport and employ non-equilibrium MD to probe transport across the mixture-polymer interface.

**10:00AM R42.00009 Cooperative Reformable Channel System with Unique Recognition of Small Gas Molecules in a two-dimensional ZIF-membrane**, BENYAMIN MOTEVALLI, NEDA TAHERIFAR, ZHE LIU, Department of Mechanical and Aerospace Engineering, Monash University, Clayton, Victoria 3800, Australia — We report a cooperative reformable channel system in a coordination porous polymer, named as ZIF-L. Three types of local flexible ligands coexist in the crystal structure of this polymer, resulting in ultra-flexibility. The reformable channel is able to regulate permeation of a nonspherical guest molecule, such as N<sub>2</sub> or CO<sub>2</sub>, based on its longer molecular dimension, which is in a striking contrast to conventional molecular sieves that regulate the shorter cross-sectional dimension of the guest molecules. Our density functional theory (DFT) calculations reveal that the guest molecule induces dynamic motion of the flexible ligands, leading to the channel reformation, and then the guest molecule reorients itself to fit in the reformed channel. Such a unique “induced fit-in” mechanism causes the gas molecule to pass through 6 membered-ring windows in the c- crystal direction of ZIF-L with its longer axis parallel to the window plane. Our experimental permeance of N<sub>2</sub> through the ZIF-L membranes is about three times greater than that of CO<sub>2</sub>, supporting the DFT simulation predictions.

**10:12AM R42.00010 Predicting the solubility of gases in Nitrile Butadiene Rubber in extreme conditions using molecular simulation**, MUSAB KHAWAJA, NICOLA MOLINARI, ADRIAN SUTTON, Imperial College London, Department of Physics and the Thomas Young Centre for Theory and Simulation of Materials, UK, ARASH MOSTOFI, Imperial College London, Departments of Materials and Physics and the Thomas Young Centre for Theory and Simulation of Materials, UK — In the oil and gas industry, elastomer seals play an important role in protecting sensitive monitoring equipment from contamination by gases - a problem that is exacerbated by the high pressures and temperatures found down-hole. The ability to predict and prevent such permeative failure has proved elusive to-date. Nitrile butadiene rubber (NBR) is a common choice of elastomer for seals due to its resistance to heat and fuels. In the conditions found in the well it readily absorbs small molecular weight gases. How this behaviour changes quantitatively for different gases as a function of temperature and pressure is not well-understood. In this work a series of fully atomistic simulations are performed to understand the effect of extreme conditions on gas solubility in NBR. Widom particle insertion is used to compute solubilities. The importance of sampling and allowing structural relaxation upon compression are highlighted, and qualitatively reasonable trends reproduced. Finally, while at STP it has previously been shown that the solubility of CO<sub>2</sub> is higher than that of He in NBR, we observe that under the right circumstances it is possible to reverse this trend.

**10:24AM R42.00011 Analysis of surface segregation in polymer mixtures: A combination of mean field and statistical associated fluid theories**, JAROSLAW KRAWCZYK<sup>1</sup>, SALVATORE CROCE, BUDDHAPRIYA CHAKRABARTI, Department of Mathematical Sciences, Durham University, South Road, Durham DH1 3LE, United Kingdom., JOS TASCHE, Department of Chemistry, Durham University, South Road, Durham DH1 3LE, United Kingdom. — The surface segregation in polymer mixtures remains a challenging problem for both academic exploration as well as industrial applications. Despite its ubiquity and several theoretical attempts a good agreement between computed and experimentally observed profiles has not yet been achieved. A simple theoretical model proposed in this context by Schmidt and Binder combines Flory-Huggins free energy of mixing with the square gradient theory of wetting of a wall by fluid. While the theory gives us a qualitative understanding of the surface induced segregation and the surface enrichment it lacks the quantitative comparison with the experiment. The statistical associating fluid theory (SAFT) allows us to calculate accurate free energy for a real polymeric materials. In an earlier work we had shown that increasing the bulk modulus of a polymer matrix through which small molecules migrate to the free surface causes reduction in the surface migrant fraction using Schmidt-Binder and self-consistent field theories. In this work we validate this idea by combining mean field theories and SAFT to identify parameter ranges where such an effect should be observable.

**10:36AM R42.00012 Continuum Model for Decontamination of Chemical Warfare Agent from a Rubbery Polymer using the Maxwell-Stefan Formulation**, MARK VARADY, STEFAN BRINGUIER, THOMAS PEARL, OptiMetrics, Inc., a DCS Company, SHAWN STEVENSON, BRENT MANTOOTH, RT Directorate, Edgewood Chemical Biological Center — Decontamination of polymers exposed to chemical warfare agents (CWA) often proceeds by application of a liquid solution. Absorption of some decontaminant components proceed concurrently with extraction of the CWA, resulting in multicomponent diffusion in the polymer. In this work, the Maxwell-Stefan equations were used with the Flory-Huggins model of species activity to mathematically describe the transport of two species within a polymer. This model was used to predict the extraction of the nerve agent O-ethyl S-[2(diisopropylamino)ethyl] methylphosphonothioate (VX) from a silicone elastomer into both water and methanol. Comparisons with experimental results show good agreement with minimal fitting of model parameters from pure component uptake data. Reaction of the extracted VX with sodium hydroxide in the liquid-phase was also modeled and used to predict the overall rate of destruction of VX. Although the reaction proceeds more slowly in the methanol-based solution compared to the aqueous solution, the extraction rate is faster due to increasing VX mobility as methanol absorbs into the silicone, resulting in an overall faster rate of VX destruction.

**8:00AM R43.00001 Collective Dynamics of Oscillator Networks: Why do we suffer from heavy jet lag?** , HIROSHI KORI, Ochanomizu University — The circadian rhythm of the entire body in mammals is orchestrated by a small tissue in the brain called the suprachiasmatic nucleus (SCN). The SCN consists of a population of neurons, each of which exhibit circadian (i.e., approximately 24 h) gene expression. Neurons form a complex network and interact with each other using various types of neurotransmitters. The rhythmic gene expressions of individual cells in the SCN synchronize through such interaction. Jet-lag symptoms arise from temporal mismatch between the internal circadian clock orchestrated by the SCN and external solar time. It may take about one week or even longer to recover from jet lag after a long-distance trip. We recently found that recovery from jet lag is considerably accelerated in the knocked-out (KO) mice lacking the receptors of a certain neurotransmitter in the SCN [1]. Importantly, all other properties of mice including sleep-awake rhythms and breeding seem to be intact. Only the response to the jet lag changes. It was also found that after a few days of jet lag, cells in the SCN desynchronize in the wild type (WT) mice, whereas they do not in KO mice. This desynchrony might be a main reason for heavy jet lag symptoms. To understand the mechanism underlying jet lag, we propose a simple model of the SCN, which is a network of phase oscillators [1]. Despite its simplicity, this model can reproduce important dynamical properties of the SCN. For example, this model reproduces the desynchrony of oscillators after jet lag. Moreover, when intercellular interaction is weaker, this desynchrony is suppressed and the recover from jet lag is considerably accelerated. Our mathematical study provides a deeper understanding of jet lag and an idea how to circumvent heavy jet lag symptoms. [1] Y. Yamaguchi, T. Suzuki, Y. Mizoro, H. Kori, K. Okada, Y. Chen, J.M. **8:36AM R43.00002 Synchronization in neuronal oscillator networks with input heterogeneity and arbitrary network structure** , ELIZABETH DAVISON, BISWADIP DEY, NAOMI LEONARD, Princeton University — Mathematical studies of synchronization in networks of neuronal oscillators offer insight into neuronal ensemble behavior in the brain. Systematic means to understand how network structure and external input affect synchronization in network models have the potential to improve methods for treating synchronization-related neurological disorders such as epilepsy and Parkinson's disease. To elucidate the complex relationships between network structure, external input, and synchronization, we investigate synchronous firing patterns in arbitrary networks of neuronal oscillators coupled through gap junctions with heterogeneous external inputs. We first apply a passivity-based Lyapunov analysis to undirected networks of homogeneous FitzHugh-Nagumo (FN) oscillators with homogeneous inputs and derive a sufficient condition on coupling strength that guarantees complete synchronization. In biologically relevant regimes, we employ Gronwall's inequality to obtain a bound tighter than those previously reported. We extend both analyses to a homogeneous FN network with heterogeneous inputs and show how cluster synchronization emerges under conditions on the symmetry of the coupling matrix and external inputs. Our results can be generalized to any network of semi-passive oscillators.

**8:48AM R43.00003 Independent Noise Can Synchronize Interacting Networks of Pulse-Coupled Oscillators<sup>1</sup>** , HERMANN RIECKE, JOHN MENG, Northwestern University — Structured networks comprised of subnetwork modules are ubiquitous. Motivated by the observation of rhythms and their interaction in different brain areas, we study a network consisting of two subnetworks of pulse-coupled integrate-fire neurons. Through mutual inhibition the neurons in the individual subnetworks can become synchronized and each subnetwork can exhibit coherent oscillatory dynamics, e.g. an ING-rhythm. In the absence of coupling between the networks the rhythms will in general have different frequencies. We investigate the interaction between these different rhythms. Strikingly, we find that increasing the noise level in the input to the individual neurons can synchronize the rhythms of the two networks, even though the inputs to different neurons are uncorrelated, sharing no common component. A heuristic phase model for the coupled networks shows that this synchronization hinges on the fact that only a fraction of the neurons may spike in a given cycle. Thus, the synchronization of the network rhythms differs qualitatively from that of individual oscillators.

**9:00AM R43.00004 A simple experimental realization of the Sakaguchi-Kuramoto model** , DAVID MERTENS, ZHUWEI ZENG, LARS ENGLISH, Dickinson College — We explore the collective phase dynamics of Wien-bridge oscillators coupled resistively. The dynamics of these oscillators were recently shown to follow Sakaguchi's modification to the Kuramoto model. In this talk we outline the steps of that analysis. We then examine results for a variety of experimentally obtained coupling arrangements, including all-to-all and some-to-all. In particular, we provide evidence for the emergence of synchronized clusters, a finite-size effect that is not accounted for in the traditional theories for the Sakaguchi-Kuramoto model.

**9:12AM R43.00005 Experimental studies of a chain of Sakaguchi-Kuramoto oscillators** , HANYU MA, DAVID MERTENS, LARS ENGLISH, Dickinson College, HANYU MA TEAM, LARS ENGLISH COLLABORATION, DAVID MERTENS COLLABORATION — The collective phase dynamics of Wien-bridge oscillators, coupled resistively, were recently shown to follow the Sakaguchi-Kuramoto model. In this talk we present experimental findings for the dynamics of rings of oscillators. For identical speeds and uni-directional nearest-neighbor coupling, we find that the system quickly approaches a steady state of identical nearest-neighbor phase offsets. We then present the effects of adding disorder to the natural speeds. We also discuss the case of bi-directional coupling, in which case chimera behavior is expected.

**9:24AM R43.00006 Title: Chimeras in small, globally coupled networks: Experiments and stability analysis** , JOSEPH D. HART, University of Maryland, College Park, KANIKA BANSAL, None, THOMAS E. MURPHY, RAJARSHI ROY, University of Maryland, College Park — Since the initial observation of chimera states, there has been much discussion of the conditions under which these states emerge. The emphasis thus far has mainly been to analyze large networks of coupled oscillators; however, recent studies have begun to focus on the opposite limit: what is the smallest system of coupled oscillators in which chimeras can exist? We experimentally observe chimeras and other partially synchronous patterns in a network of four globally-coupled chaotic opto-electronic oscillators. By examining the equations of motion, we demonstrate that symmetries in the network topology allow a variety of synchronous states to exist, including cluster synchronous states and a chimera state. Using the group theoretical approach recently developed for analyzing cluster synchronization, we show how to derive the variational equations for these synchronous patterns and calculate their linear stability. The stability analysis gives good agreement with our experimental results. Both experiments and simulations suggest that these chimera states often appear in regions of multistability between global, cluster, and desynchronized states.

**9:36AM R43.00007 ABSTRACT WITHDRAWN** —

**9:48AM R43.00008 Emerging hierarchies in dynamically adapting webs** , ELENI KATIFORI, University of Pennsylvania, JOHANNES GRAEWER, Max-Planck Institute for Dynamics and Self-Organization, MARCELO MAGNASCO, CARL MODES, Rockefeller University — Transport networks play a key role across four realms of eukaryotic life: slime molds, fungi, plants, and animals. In addition to the developmental algorithms that build them, many also employ adaptive strategies to respond to stimuli, damage, and other environmental changes. We model these adapting network architectures using a generic dynamical system on weighted graphs and find in simulation that these networks ultimately develop a hierarchical organization of the final weighted architecture accompanied by the formation of a system-spanning backbone. We quantify the hierarchical organization of the networks by developing an algorithm that decomposes the architecture to multiple scales and analyzes how the organization in each scale relates to that of the scale above and below it. The methodologies developed in this work are applicable to a wide range of systems including the slime mold *Physarum polycephalum*, human microvasculature, and force chains in granular media.

**10:00AM R43.00009 Hybrid percolation transition in complex networks** , BYUNGNAM KAHNG, Seoul National University — Percolation has been one of the most applied statistical models. Percolation transition is one of the most robust continuous transitions known thus far. However, recent extensive researches reveal that it exhibits diverse types of phase transitions such as discontinuous and hybrid phase transitions. Here hybrid phase transition means the phase transition exhibiting natures of both continuous and discontinuous phase transitions simultaneously. Examples include k-core percolation, cascading failures in interdependent networks, synchronization, etc. Thus far, it is not manifest if the critical behavior of hybrid percolation transitions conforms to the conventional scaling laws of second-order phase transition. Here, we investigate the critical behaviors of hybrid percolation transitions in the cascading failure model in inter-dependent networks and the restricted Erdos-Renyi model. We find that the critical behaviors of the hybrid percolation transitions contain some features that cannot be described by the conventional theory of second-order percolation transitions.

**10:12AM R43.00010 Phase Transitions in Networks of Memristive Elements** , FORREST SHELDON, MASSIMILIANO DI VENTRA, Univ of California - San Diego — The memory features of memristive elements (resistors with memory), analogous to those found in biological synapses, have spurred the development of neuromorphic systems based on them (see, e.g., [1]). In turn, this requires a fundamental understanding of the collective dynamics of networks of memristive systems. Here, we study an experimentally-inspired model of disordered memristive networks in the limit of a slowly ramped voltage and show through simulations that these networks undergo a first-order phase transition in the conductivity for sufficiently high values of memory, as quantified by the memristive ON/OFF ratio. We provide also a mean-field theory that reproduces many features of the transition and particularly examine the role of boundary conditions and current- vs. voltage-controlled networks. The dynamics of the mean-field theory suggest a distribution of conductance jumps which may be accessible experimentally. We finally discuss the ability of these networks to support massively-parallel computation. Work supported in part by the Center for Memory and Recording Research at UCSD. [1] Y.V. Pershin and M. Di Ventra, Proc. IEEE, 100, 2071 (2012).

**10:36AM R43.00012 A network model of human aging: Limits, errors, and information** , SPENCER FARRELL, ARNOLD MITNITSKI, KENNETH ROCKWOOD, ANDREW RUTENBERG, Dalhousie University — The Frailty Index (FI) quantifies human aging using the fraction of accumulated age-related deficits. The FI correlates strongly with mortality and accumulates non-linearly and stochastically with age. Clinical data shows a nearly universal limit of  $FI \leq 0.7$ . We computationally model an aging population using a network model of interacting deficits. Deficits damage and repair at rates that depend upon the average damage of connected nodes. The model is parametrized to fit clinical data. We find that attribution errors, especially false negative, allow the model to recover the frailty limit. Mutual information allows us to assess how well the FI can predict mortality. Mutual information provides a non-parametric measure of how the FI predicts mortality. We find that attribution errors have a small effect on the mutual information when many deficits are included in the model. The mutual information of our model and of the clinical data are comparable.

**8:00AM R44.00001 Quantum thermodynamics for arbitrarily small devices** , STEPHANIE WEHNER, Delft Univ of Tech — Quantum thermodynamics for arbitrarily small devices.

**8:36AM R44.00002 Exceeding the Carnot efficiency** , NELLY HUEI YING NG, Delft Univ of Tech, MISCHA WOODS, University College of London, Department of Physics and Astronomy, London WC1E 6BT, United Kingdom, STEPHANIE WEHNER, Delft Univ of Tech — A suitable way of quantifying work for microscopic quantum systems has been constantly debated in the field of quantum thermodynamics. One natural approach is to measure the average increase in energy of an ancillary system, called the battery, after a work extraction protocol. The quality of work extracted is usually argued to be good by quantifying higher moments of the energy distribution, or by restricting the amount of entropy to be low. This limits the amount of heat contribution to the energy extracted, but does not completely prevent it. We show that if one allows for a definition of work that tolerates a non-negligible entropy increase in the battery, then a small scale heat engine (with a similar set up to that of arXiv:1506.02322) can possibly exceed the Carnot efficiency. This can be done without using any additional resources such as coherence or correlations, and furthermore can be achieved by using finite-size quantum heat baths as well.

**8:48AM R44.00003 The maximum efficiency of nano heat engines depends on more than temperature<sup>1</sup>** , MISCHA WOODS, Uni Coll London, & TU Delft, Netherlands & National Uni Singapore, NELLY NG, TU Delft, Netherlands & National Uni Singapore, STEPHANIE WEHNER, TU Delft, Netherlands — Sadi Carnots theorem regarding the maximum efficiency of heat engines is considered to be of fundamental importance in the theory of heat engines and thermodynamics. Here, we show that at the nano and quantum scale, this law needs to be revised in the sense that more information about the bath other than its temperature is required to decide whether maximum efficiency can be achieved. In particular, we derive new fundamental limitations of the efficiency of heat engines at the nano and quantum scale that show that the Carnot efficiency can only be achieved under special circumstances, and we derive a new maximum efficiency for others. A preprint can be found here arXiv:1506.02322 [quant-ph]

**9:00AM R44.00004 Autonomous quantum thermal machines and quantum to classical energy flow** , MAX FRENZEL, DAVID JENNINGS, TERRY RUDOLPH, Imperial College London — We address the issue of autonomous quantum thermal machines that are tailored to achieve some specific thermodynamic primitive, such as work extraction in the presence of a thermal environment, while having minimal or no control from the macroscopic regime. Beyond experimental implementations, this provides an arena in which to address certain foundational aspects such as the role of coherence in thermodynamics, the use of clock degrees of freedom and the simulation of local time-dependent Hamiltonians in a particular quantum subsystem. For small-scale systems additional issues arise. Firstly, it is not clear to what degree genuine ordered thermodynamic work has been extracted, and secondly non-trivial back-actions on the thermal machine must be accounted for. We find that both these aspects can be resolved through a judicious choice of quantum measurements that magnify thermodynamic properties up the ladder of length-scales, while simultaneously stabilizing the quantum thermal machine. Within this framework we show that thermodynamic reversibility is obtained in a particular Zeno limit, and finally illustrate these concepts with a concrete example involving spin-systems.

### 9:12AM R44.00005 Stochastic Independence as a Resource for Small-Scale Thermodynamics

, MATTEO LOSTAGLIO, Imperial College London, MARKUS P. MUELLER, Western Ontario University and Perimeter Institute for Theoretical Physics, MICHELE PASTENA, Heidelberg University — It is well-known in thermodynamics that the creation of correlations costs work. It seems then a truism that if a thermodynamic transformation  $A \rightarrow B$  is impossible, so will be any transformation that in sending  $A$  to  $B$  also correlates among them some auxiliary systems  $C$ . Surprisingly, we show that this is not the case for non-equilibrium thermodynamics of microscopic systems. On the contrary, the creation of correlations greatly extends the set of accessible states, to the point that we can perform on individual systems and in a single shot any transformation that would otherwise be possible only if the number of systems involved was very large. We also show that one only ever needs to create a vanishingly small amount of correlations (as measured by mutual information) among a small number of auxiliary systems (never more than three). The many, severe constraints of microscopic thermodynamics are reduced to the sole requirement that the non-equilibrium free energy decreases in the transformation. This shows that, in principle, reliable extraction of work equal to the free energy of a system can be performed by microscopic engines.

### 9:24AM R44.00006 Quantum coherence, time-translation symmetry and thermodynamics

, KAMIL KORZEKWA, MATTEO LOSTAGLIO, DAVID JENNINGS, TERRY RUDOLPH, Imperial College London — The first law of thermodynamics imposes not just a constraint on the energy content of systems in extreme quantum regimes but also symmetry constraints related to the thermodynamic processing of quantum coherence. We show that this thermodynamic symmetry decomposes any quantum state into mode operators that quantify the coherence present in the state. We then establish general upper and lower bounds for the evolution of quantum coherence under arbitrary thermal operations, valid for any temperature. We identify primitive coherence manipulations and show that the transfer of coherence between energy levels manifests irreversibility not captured by free energy. Moreover, the recently developed thermomajorization relations on block-diagonal quantum states are observed to be special cases of this symmetry analysis.

### 9:36AM R44.00007 Quantum work statistics of charged Dirac particles in time-dependent fields<sup>1</sup>

, SEBASTIAN DEFFNER, AVADH SAXENA, Los Alamos Natl Lab — The quantum Jarzynski equality is an important theorem of modern quantum thermodynamics. We show that the Jarzynski equality readily generalizes to relativistic quantum mechanics described by the Dirac equation. After establishing the conceptual framework we solve a pedagogical, yet experimentally relevant, system analytically. As a main result we obtain the exact quantum work distributions for charged particles traveling through a time-dependent vector potential evolving under Schrödinger as well as under Dirac dynamics, and for which the Jarzynski equality is verified. Special emphasis is put on the conceptual and technical subtleties arising from relativistic quantum mechanics.

<sup>1</sup>SD acknowledges financial support by the U.S. Department of Energy through a LANL Director's Funded Fellowship.

### 9:48AM R44.00008 The second law of quantum thermodynamics as an equality

, JONATHAN OPPENHEIM, University College London — The traditional second law of thermodynamics says that the average amount of work required to change one state into another while in contact with a heat reservoir, must be at least as large as the change in free energy of the system. Here, we consider a fine-grained notion of the free energy, and show that in terms of it, the second law can be written as an equality. We also obtain a generalisation of the Jarzynski fluctuation theorem which holds for arbitrary initial states, not just the case of an initial thermal state. We derive a generalisation of Gibbs-stochasticity, a condition originally found in the approach to thermodynamics inspired by quantum information theory. This generalisation directly incorporates the case of fluctuating work and serves as a parent equation which can be used to derive the second law equality and the generalisation of the Jarzynski equation. We further show that each of these three generalisations can be seen as the quasi-classical limit of three fully quantum identities. This allows for more general and fully quantum fluctuation relations from the information theoretic approach to quantum thermodynamics.

### 10:24AM R44.00009 Recoverability in quantum information theory<sup>1</sup>

, MARK WILDE, Louisiana State Univ - Baton Rouge — The fact that the quantum relative entropy is non-increasing with respect to quantum physical evolutions lies at the core of many optimality theorems in quantum information theory and has applications in other areas of physics. In this work, we establish improvements of this entropy inequality in the form of physically meaningful remainder terms. One of the main results can be summarized informally as follows: if the decrease in quantum relative entropy between two quantum states after a quantum physical evolution is relatively small, then it is possible to perform a recovery operation, such that one can perfectly recover one state while approximately recovering the other. This can be interpreted as quantifying how well one can reverse a quantum physical evolution. Our proof method is elementary, relying on the method of complex interpolation, basic linear algebra, and the recently introduced Renyi generalization of a relative entropy difference. The theorem has a number of applications in quantum information theory, which have to do with providing physically meaningful improvements to many known entropy inequalities. This is based on arXiv:1505.04661, now accepted for publication in Proceedings of the Royal Society A.

<sup>1</sup>I acknowledge support from startup funds from the Department of Physics and Astronomy at LSU, the NSF under Award No. CCF-1350397, and the DARPA Quiness Program through US Army Research Office award W31P4Q-12-1-0019.

### 10:36AM R44.00010 Quantum Decoherence at Finite Temperatures: Theory and Computations<sup>1</sup>

, M.A. NOVOTNY, Mississippi State University, FENGPING JIN, Jülich Supercomputing Centre, SEIJI MIYASHITA, University of Tokyo, SHENGJUN YUAN, Radboud Universiteit, HANS DE RAEDT, University of Groningen, KRISTEL MICHIELSEN, Jülich Supercomputing Centre — The decoherence of a finite quantum system  $S$  coupled to a finite quantum environment  $E$  is considered, where the entirety  $S+E$  is a closed quantum system. The entirety is prepared in a canonical thermal state at a finite temperature. By applying perturbation theory, we find closed form expressions for measures of decoherence and thermalization of  $S$  in terms of the free energies of  $S$  and  $E$ . Hence we have quantified how difficult it is to decohere a particular finite quantum system  $S$  at a fixed temperature, the result being a function of the free energy of  $S$ . We have also quantified how potent a particular finite Hilbert space environment  $E$  at a fixed temperature is at decohering a generic quantum system. To test these predictions, we performed both real and imaginary time calculations for the Schrödinger equation for an entirety with up to 40 quantum spins. The large-scale calculations (vectors in Hilbert space with length up to  $2^{40} \approx 10^{12}$ ) validate our predictions for all temperatures. Preprint arXiv:1502.03996.

<sup>1</sup>MAN supported in part by NSF DMR-1206233.

### 10:48AM R44.00011 Dynamical and thermodynamical control of open quantum Brownian motion<sup>1</sup>

, FRANCESCO PETRUCCIONE, University of KwaZulu-Natal, ILYA SINAYSKIY, National Institute for Theoretical Physics — Open quantum Brownian motion was introduced as a new type of quantum Brownian motion for Brownian particles with internal quantum degrees of freedom. Recently, an example of the microscopic derivation of open quantum Brownian motion has been presented [I. Sinayskiy and F. Petruccione, Phys. Scr. T165, 014017 (2015)]. The microscopic derivation allows to relate the dynamical properties of open Quantum Brownian motion and the thermodynamical properties of the environment. In the present work, we study the possibility of control of the external degrees of freedom of the "walker" (position) by manipulating the internal one, e.g. spin, polarization, occupation numbers. In the particular example of the known microscopic derivation the connection between dynamics of the "walker" and thermodynamical parameters of the system is established. For the system of open Brownian walkers coupled to the same environment controllable creation of quantum correlations is investigated.

**Thursday, March 17, 2016 8:00AM - 10:48AM –**

**Session R45 GQI DAMOP: Hybrid Quantum Systems III** 348 - Guido Burkard, University of Konstanz, Germany

**8:00AM R45.00001 Investigations of a transmon-coupled nanoresonator in a CPW cavity.**

, YU HAO, Syracuse University, FRANCISCO ROXINAL, University of Campinas, MATT LAHAYE, Syracuse University — In this work, we describe our progress developing a qubit-coupled nanomechanical resonator(nmr), which has potential both for fundamental studies in quantum measurement and quantum thermodynamics and applications in quantum information. The hybrid system is composed of a superconducting charge-type transmon qubit and a ultra-high-frequency flexural nmr; both are embedded in, and measured through, a superconducting coplanar-wave-guide(CPW) resonator. Transmission measurements of the CPW cavity allow us to probe the state of transmon as it interacts resonantly with the NMR. In the talk, we'll present the latest measurements of this device at low NMR thermal occupation factors and discuss future prospects for developing this system for more advanced quantum measurements.

**8:12AM R45.00002 Surface acoustic wave resonators in the quantum regime**, RICCARDO MANENTI,

MICHAEL PETERER, ANI NERSISYAN, EINAR MAGNUSSON, ANDREW PATTERSON, PETER LEEK, University of Oxford — Surface acoustic waves (SAWs) are mechanical modes confined to the surface of a piezoelectric crystal that can be excited and detected by electric circuits. These mechanical waves can be trapped between two reflectors producing a SAW resonator. In this talk, I will present an experimental study of SAW resonators at 10 mK [1], in which we find that internal quality factors  $Q_i$  approaching 0.5 million can be reached at 0.5 GHz and that  $Q_i > 10^4$  is achievable above 4 GHz, making SAW resonators promising devices for integration into quantum circuits. I will discuss the loss mechanisms that may be currently limiting these Q-factors, and report on our progress towards coupling these mechanical resonators to superconducting qubits. [1] R. Manenti et al., arXiv:1510.04965

**8:24AM R45.00003 Cavity magnomechanics**, XUFENG ZHANG, CHANGLING ZOU, LIANG JIANG, HONG X. TANG, Yale

University — Mechanical oscillators have been recently widely utilized to couple with optical and microwave photons in a variety of hybrid quantum systems, but they all lack the tunability. The magnetostrictive force provides an alternative mechanism to allow phonon to couple with a different type of information carrier magnon, the collective excitation of magnetization whose frequency can be tuned by a bias magnetic field. Here, we demonstrate an intriguing hybrid system that consists of a magnonic, a mechanical, and a microwave resonator. The magnon-phonon interaction results in hallmark coherent phenomena such as magnomechanically induced transparency/absorption and magnomechanical parametric amplification. The magnetic field dependence of magnon provides our system with unprecedented tunability. Moreover, the great flexibility of our system allows us to achieve triple resonance among magnon, phonon and photon, which drastically enhances the magnomechanical interaction. Our work demonstrates the fundamental principle of cavity magnetomechanics, opening up great opportunities in various applications, such as tunable microwave filter and amplifier, long-lifetime quantum memories, microwave-to-optics conversion.

**8:36AM R45.00004 Continuous dynamical decoupling of a single diamond nitrogen-vacancy center spin with a mechanical resonator<sup>1</sup>**, EVAN MACQUARRIE, TANAY GOSAVI, Cornell University, SUNIL BHAVE, Purdue

University, GREGORY FUCHS, Cornell University — We use coherent interactions between a diamond mechanical resonator and a single nitrogen-vacancy (NV) center spin qubit to engineer a decoherence-protected spin basis. For solid state spin qubits such as the NV center, a dominant source of inhomogeneous dephasing is magnetic field fluctuations due to nearby paramagnetic impurities or instabilities in a magnetic bias field. By dressing the NV center spin states with a  $581 \pm 2$  kHz mechanical Rabi field, we decrease the spin's sensitivity to magnetic fluctuations in a thermally isolated subspace, thus prolonging the Ramsey coherence time from  $T_2^* = 2.7 \pm 0.1 \mu\text{s}$  to  $15 \pm 1 \mu\text{s}$ . We develop a model that quantitatively predicts the relationship between the mechanical Rabi field and the dephasing time. Our model shows that a combination of random magnetic field fluctuations and hyperfine coupling limits the protected coherence time over the range of mechanical dressing fields accessed in our experiment. Finally, we show that amplitude noise in the dressing field will dominate over magnetic noise for larger driving fields.

**8:48AM R45.00005 Towards a highly efficient quantum spin-photon interface for an NV centre based quantum network**, STEFAN BOGDANOVIC, CRISTIAN BONATO, SUZANNE VAN DAM, ANDREAS REISERER, ANNE-MARIJE

ZWERVER, RONALD HANSON, Kavli Institute of Nanoscience Delft, Delft University of Technology, QUANTUM TRANSPORT TEAM — Nitrogen-vacancy (NV) centers in diamond recently emerged as promising candidates for realizing quantum information algorithms due to their remarkable versatility. The spin of these optically active defects can be entangled with their emitted photons, making them an excellent optical interface from the perspective of quantum communication.

Recently, we have demonstrated the first building blocks of such networks, performing kilometer scale entanglement of two NV centers and teleportation of quantum information.(1) However, our current protocols are inefficient due to the low emission of NV centers resonant photons into the zero phonon line (ZPL). Here we present our efforts of coupling a single NV center emitter in a diamond membrane to a fiber-based Fabry-Perot microcavity with high finesse ( $F > 10^4$ ) at cryogenic temperatures. This approach allows spectral tuning of the cavity resonance to the ZPL emission of the NV center, thereby significantly enhancing the resonant photon emission via Purcell effect. Furthermore, the bulk environment of the NV centers protects their spin properties against surface proximity effects, which is of crucial importance for quantum information processing applications.

**9:00AM R45.00006 Investigating the positively charged nitrogen-vacancy center in diamond as a long lived quantum memory**, MATTHIAS PFENDER, NABEEL ASLAM, SINA BURK, HELMUT FEDDER, PHILIPP NEUMANN, 3rd

Institute of Physics, University of Stuttgart, PATRICK SIMON, JOS A. GARRIDO, Walter Schottky Institut, Technische Universität München, JRG WRACHTRUP, 3rd Institute of Physics, University of Stuttgart, 3RD INSTITUTE OF PHYSICS, UNIVERSITY OF STUTTGART TEAM, WALTER SCHOTTKY INSTITUT, TECHNISCHE UNIVERSITÄT MÜNCHEN TEAM — The nitrogen-vacancy (NV) defect in diamond is one of the major candidates for a solid-state quantum processor. Its electron spin is readout and initialized optically. Proximal nuclear spins (e.g.  $^{14}\text{N}$ ,  $^{15}\text{N}$ ,  $^{13}\text{C}$ ) serve as inherently robust qubits, their readout is facilitated via the electron spin in a QND measurement and they exhibit  $T_1$  lifetimes of several minutes. However, for strongly coupled nuclear spins, the coherence time is limited by the electron spin's  $T_1$  lifetime (5 ms @ roomtemperature). In Si:P, this obstacle is overcome by ionizing the P donor into a spinless charge-state. In this work, we employ in-plane gate structures on the diamond surface for deterministic charge state switching of near-surface NVs from  $\text{NV}^-$  over  $\text{NV}^0$  to  $\text{NV}^+$ , while investigating the electron spin properties using the nitrogen nuclear spin as a probe. The positive charge state happens to have no unpaired electrons, therefore the nuclear spin coherence time is prolonged beyond the 5ms-limit imposed by the  $\text{NV}^-$  electron spin. Proper charge state control removes an important roadblock for achieving minute-long coherence times at room-temperature and deterministic quantum system initialization.

**9:12AM R45.00007 Coupling a single InAs quantum dot to mechanical motion of a photonic crystal membrane**, SAMUEL CARTER, ALLAN BRACKER, Naval Research Laboratory, MIJIN KIM, Sotera Defense Solutions, Inc, CHUL SOO KIM, MAXIM ZALALUTDINOV, BRENNAN PURSLEY, Naval Research Laboratory, SOPHIA ECONOMOU, Department of Physics, Virginia Tech, CYPRIAN CZARNOCKI, CAMERON JENNINGS, MICHAEL SCHEIBNER, School of Natural Sciences, University of California, Merced, DANIEL GAMMON, Naval Research Laboratory — Coupling quantum mechanical systems to mechanical motion is attractive for fundamental science, quantum information applications, and sensing. Semiconductor quantum dots (QDs) embedded in suspended photonic crystal structures provide a versatile system for advances in this area. Flexural modes of the suspended membrane as well as localized mechanical modes surrounding optical cavities couple to QDs through strain, with the photonic crystal used to maximize collection of photons from QDs. We have performed high resolution spectroscopy of InAs QDs embedded in photonic crystal structures while optically driving mechanical motion. Using time-correlated photon counting, the strain-induced shift of the QD optical transitions is measured as a function of time. For QDs at the center of the membrane (along the growth direction), the strain is minimum, and the optical transitions shift by only a few  $\mu\text{eV}$ . For QDs shifted 30 nm from the center, the strain induces larger shifts of  $50\mu\text{eV}$ . Measurements in a magnetic field are being performed on charged QDs to determine the coupling of mechanical motion to electron and hole spin transitions.

**9:24AM R45.00008 Inductive cooling in quantum magnetomechanics.**<sup>1</sup>, ERICK ROMERO-SANCHEZ, University of Queensland, JASON TWAMLEY, Macquarie University, WARWICK P. BOWEN, University of Queensland, MICHAEL R. VANNER, University of Oxford — Coupling to light or microwave fields allows quantum control of the motion of a mechanical oscillator, and offers prospects for precision sensing, quantum information systems, and tests of fundamental physics. In cavity electromechanics ground state cooling has been achieved using resolved sideband cooling. Here we present an alternative approach based on a magnetomechanical system that inductively couples an  $LC$  resonator to a mechanical oscillator. The experimental setup consists of a micro cantilever with a pyramidal magnetic tip attached at the end of the beam. The sharp end of the magnetic tip is positioned close to the planar microfabricated inductor of the  $LC$  resonator. The displacement in the position of the end of the cantilever generates a change in flux through the coil inducing an electromotive force in the circuit. The current in the  $LC$  resonator generates a magnetic field, and then a force between the tip and the coil. When they are strongly coupled and the mechanical resonance frequency  $\omega_m$  exceeds the electrical decay rate of the resonator  $\gamma_e$ , resolved sideband cooling can be used to cool the mechanics. We present estimations for the coupling rates and the experimental parameters required for these experiments.

**9:36AM R45.00009 Strain coupling of a mechanical resonator to a single quantum emitter in diamond**<sup>1</sup>, KENNETH LEE, DONGHUN LEE, PREETI OVARTCHAIYAPONG, ANIA JAYICH, University of California Santa Barbara — Hybrid quantum devices are central to the advancement of several emerging quantum technologies, including quantum information science and quantum-assisted sensing. Here, we present a hybrid quantum device in which strain fields associated with resonant vibrations of a diamond cantilever dynamically modulate the energy and polarization dependence of the optical transitions of a single nitrogen-vacancy defect center in diamond. With mechanical driving, we observe optomechanical couplings exceeding 10 GHz. Through resonant excitation spectroscopy, we quantitatively characterize the intrinsic strain environment of a single defect, and use this optomechanical coupling to tune the zero-phonon line of the defect. Through stroboscopic measurements, we show that we are able to match the frequency and polarization dependence of the optical zero-phonon lines of two separate NV centers. The experiments demonstrated here mark an important step toward realizing a monolithic hybrid quantum device capable of realizing and probing the dynamics of non-classical states of mechanical resonators, spin-systems, and photons.

<sup>1</sup>This work was supported with grants from the AFOSR, NSF and DARPA

**9:48AM R45.00010 Microwave-frequency electromechanical resonators incorporating phononic crystals**, K. J. SATZINGER, G. PEAIRS, A. VAINSENER, University of California, Santa Barbara, A. N. CLELAND, University of Chicago — Piezoelectric micromechanical resonators at gigahertz frequencies have been operated in the quantum limit, with quantum control and measurement achieved using superconducting qubits. However, experiments to date have been limited by mechanical dissipation, due to a combination of internal and radiative losses. In this talk, we explore the incorporation of phononic crystals into resonator designs. In phononic crystals, periodic patterning manipulates the acoustic band structure of the material. Through appropriately chosen geometries, these periodic patterns lead to full acoustic bandgaps which can be used to greatly reduce radiation losses from resonant structures. Alternatively, the crystal geometry can be manipulated to allow isolated modes within the bandgap, giving fine control over the spatial structure of the resonator modes. In this talk, we will describe the design, fabrication, and measurement of resonators with phononic crystals.

**10:00AM R45.00011 Superconducting-circuit quantum heat engine with frequency resolved thermal baths**, PATRICK P. HOFER, JEAN-RENÉ SOUQUET, AASHISH A. CLERK, McGill University — The study of quantum heat engines promises to unravel deep, fundamental concepts in quantum thermodynamics. With this in mind, we propose a novel, realistic device that efficiently converts heat into work while maintaining reasonably large output powers. The key concept in our proposal is a highly peaked spectral density in both the thermal baths as well as the working fluid. This allows for a complete separation of the heat current from the working fluid. In our setup, Cooper pairs tunnelling across a Josephson junction serve as the the working fluid, while two resonant cavities coupled to the junction act as frequency-resolved thermal baths. The device is operated such that a heat flux carried entirely by the photons induces an electrical current against a voltage bias, providing work.

**10:12AM R45.00012 Strong nonlinearity of mesoscopic vibrational modes induced by electron-phonon coupling**, KIRILL MOSKOVTSOV, M. I. DYKMAN, Michigan State University — We show that the electron-phonon coupling can lead to a strong nonlinearity of vibrational modes in semiconductor nano- and micro-resonators. For typical mode frequencies, the electron distribution adiabatically follows lattice strain. Therefore strain leads to redistribution of the electron density over the valleys of the conduction band. It also leads to the onset of a spatial charge. The parameter that controls the distribution is the ratio of the deformation potential to the electron chemical potential or temperature. It is  $\sim 10^2$  for many semiconductors of interest even when they are heavily doped. Therefore the change of the electron distribution is strongly nonlinear in the strain. As a consequence, the stress induced by the electron-phonon coupling is also strongly nonlinear. We have found the vibration nonlinearity parameters for  $n$ -doped Si and calculated the amplitude dependence of the frequencies of several low-lying Si resonator modes with account taken of their spatial structure. The results are compared with the recent experimental data that shows strong effect of doping on the vibration nonlinearity.

**10:24AM R45.00013 Novel High Cooperativity Photon-Magnon Cavity QED**, MICHAEL TOBAR, JEREMY BOURHILL, NIKITA KOSTYLEV, MAXIM G. DANIEL CREEDON, School of Physics, University of Western Australia, ARC Centre of Excellence for Engineered Quantum Systems — Novel microwave cavities are presented, which couple photons and magnons in YIG spheres in a super- and ultra-strong way at around 20 mK in temperature. Few/Single photon couplings (or normal mode splitting, 2g) of more than 6 GHz at microwave frequencies are obtained. Types of cavities include multiple post reentrant cavities, which co-couple photons at different frequencies with a coupling greater than the free spectral range, as well as spherical loaded dielectric cavity resonators. In such cavities we show that the bare dielectric properties can be obtained by polarizing all magnon modes to high energy using a 7 Tesla magnet. We also show that at zero-field, collective effects of the spins significantly perturb the photon modes. Other effects like time-reversal symmetry breaking are observed.

**10:36AM R45.00014 Cavity QED with ferromagnetic magnons in a small YIG sphere**, DENGKE ZHANG, Beijing Computational Science Research Center, XIN-MING WANG, Research Center of Laser Fusion, CAEP, TIE-FU LI, Institute of Microelectronics, Tsinghua University, XIAO-QING LUO, Beijing Computational Science Research Center, WEIDONG WU, Research Center of Laser Fusion, CAEP, FRANCO NORI, Center for Emergent Matter Science, RIKEN, J. Q. YOU, Beijing Computational Science Research Center — Hybridizing collective spin excitations in ferromagnetic crystals and a cavity with high cooperativity provides a new research subject in the field of cavity quantum electrodynamics and can also have potential applications to quantum information. In contrast to spin ensembles based on dilute paramagnetic impurities, these spins are strongly exchange-coupled and have a much higher density. Here we report a direct observation of the strong coupling between magnons and microwave photons at both cryogenic and room temperatures by using the same small yttrium-iron-garnet (YIG) ferromagnetic sphere in a 3D copper cavity. We observed strong couplings of the same cavity mode to both ferromagnetic-resonance (FMR, uniform precession) mode and a magnetostatic (MS, non-uniform precession) mode in the quantum limit at 22 mK. Then, at room temperature, we observed a strong coupling of the cavity mode to the FMR mode with slightly increased damping rate. This reveals the robustness of the FMR mode against temperature. However, the coupling to MS mode disappears at room temperature and numerically simulations show that this is due to a drastic increase of the damping rate of the MS mode. Our work unveils quantum-coherence properties of the magnons.

**Thursday, March 17, 2016 8:00AM - 11:00AM –**

**Session R46 GIMS: Optical Spectroscopic Measurements of 2D Materials** 311 - Erin Wood, NIST

**8:00AM R46.00001 Internal Photoemission Spectroscopy of 2-D Materials**, NHAN NGUYEN, National Institute of Standards and Technology, MINGDA LI, SURESH VISHWANATH, RUSEN YAN, SHUDONG XIAO, HUILI XING, Cornell University, GUANGJUN CHENG, ANGELA HIGHT WALKER, QIN ZHANG, National Institute of Standards and Technology — Recent research has shown the great benefits of using 2-D materials in the tunnel field-effect transistor (TFET), which is considered a promising candidate for the beyond-CMOS technology. The on-state current of TFET can be enhanced by engineering the band alignment of different 2D-2D or 2D-3D heterostructures. Here we present the internal photoemission spectroscopy (IPE) approach to determine the band alignments of various 2-D materials, in particular SnSe<sub>2</sub> and WSe<sub>2</sub>, which have been proposed for new TFET designs. The metal-oxide-2-D semiconductor test structures are fabricated and characterized by IPE, where the band offsets from the 2-D semiconductor to the oxide conduction band minimum are determined by the threshold of the cube root of IPE yields as a function of photon energy. In particular, we find that SnSe<sub>2</sub> has a larger electron affinity than most semiconductors and can be combined with other semiconductors to form near broken-gap heterojunctions with low barrier heights which can produce a higher on-state current. The details of data analysis of IPE and the results from Raman spectroscopy and spectroscopic ellipsometry measurements will also be presented and discussed.

**8:12AM R46.00002 Optical Parameter Extraction of Nano-Layered Materials Using Terahertz Time-Domain Spectroscopy<sup>1</sup>**, FARAH VANDREVALA, ERIK EINARSSON, University at Buffalo — We report a data analysis technique for reflection-mode terahertz time-domain spectroscopy (THz-TDS) to extract the complex refractive index of nano-layered materials deposited on optically thick substrates. We measure the Fabry-Perot resonances occurring inside the substrate to determine the Fresnel coefficients at the interface of the material and the substrate. Based on these values, we extract the frequency-dependent optical parameters, including surface conductivity, of the nano-layered materials for frequencies up to 3 THz.

<sup>1</sup>Air Force Research Laboratory award FA8750-15-1-0050

**8:24AM R46.00003 Broadband THz Spectroscopy of 2D Nanoscale Materials<sup>1</sup>**, LU CHEN, SHIVENDRA TRIPATHI, MENGCHEN HUANG, JEN-FENG HSU, BRIAN D'URSO, University of Pittsburgh, HYUNGWOO LEE, CHANG-BEOM EOM, University of Wisconsin-Madison, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh — Two-dimensional (2D) materials such as graphene and transition-metal dichalcogenides (TMDC) have attracted intense research interest in the past decade. Their unique electronic and optical properties offer the promise of novel optoelectronic applications in the terahertz regime. Recently, generation and detection of broadband terahertz (10 THz bandwidth) emission from 10-nm-scale LaAlO<sub>3</sub>/SrTiO<sub>3</sub> nanostructures created by conductive atomic force microscope (c-AFM) lithography has been demonstrated<sup>2</sup>. This unprecedented control of THz emission at 10 nm length scales creates a pathway toward hybrid THz functionality in 2D-material/LaAlO<sub>3</sub>/SrTiO<sub>3</sub> heterostructures. Here we report initial efforts in THz spectroscopy of 2D nanoscale materials with resolution comparable to the dimensions of the nanowire (10 nm). Systems under investigation include graphene, single-layer molybdenum disulfide (MoS<sub>2</sub>), and tungsten diselenide (WSe<sub>2</sub>) nanoflakes.

<sup>2</sup>Y. Ma, *et al.*, Nano Lett. **13**, 2884 (2013)

**8:36AM R46.00004 A novel grating-imaging method to measure carrier diffusion coefficient in graphene**, KE CHEN, YAGUO WANG, Department of Mechanical Engineering, Texas Materials Institute, University of Texas at Austin, DEJI AKINWANDE, SETH BANK, Department of Electrical and Computer Engineering, Microelectronics Research Center, University of Texas at Austin, JUNG-FU LIN, Department of Geological Sciences, Jackson School of Geosciences, University of Texas at Austin — Similar to carrier mobility, carrier diffusion coefficient in graphene determines the response rate of future graphene-based electronics. Here we present a simple, sensitive and non-destructive technique integrated with ultrafast pump-probe spectroscopy to measure carrier diffusion in CVD-grown graphene. In the method, the pump and the probe beams pass through the same area of a photomask with metal strips i.e. a transmission amplitude grating, and get diffracted. The diffracted light is collected by an objective lens and focused onto the sample to generate carrier density grating. Relaxation of this carrier density grating is governed by both carrier recombination and carrier diffusion in the sample. Transient transmission change of the probe beams, which reflects this relaxation process, is recorded. The measured diffusion coefficients of multilayer and monolayer CVD-grown graphene are 2000cm<sup>2</sup>/s and 10000cm<sup>2</sup>/s, respectively, comparable with the reported values of epitaxial graphene and reduced graphene. This transmission grating technique can be used to measure carrier dynamics in versatile 2D materials.

**8:48AM R46.00005 Temperature, Magnetic Field, and Dimensionality Effects on the Raman Spectra of TaSe<sub>2</sub>**, J. R. SIMPSON, Towson University, S. CHOWDHURY, Catholic University of America, A. R. HIGHT WALKER, NIST — In bulk form, TaSe<sub>2</sub> exhibits transitions between commensurate and incommensurate charge-density wave (CDW) phases, and is attracting interest for advanced device applications. In order to explore the evolution of the groundstate CDW phase with layer number, mechanical exfoliation of bulk crystals provides few- to single-layer flakes. In the present work, we extend our opto-thermal Raman measurements<sup>1</sup> on MoS<sub>2</sub> to include other TMDs, specifically TaSe<sub>2</sub>, in both 1T and 2H crystallographic phases. A novel, magneto-Raman microscope system affords measurement of low-frequency (down to 10 cm<sup>-1</sup>) vibrational modes as a function of both temperature (100 to 400) K and magnetic field (0 to 9) T. The dependence of the observed Raman-active phonons on temperature and magnetic field will be discussed and compared with earlier results on MoS<sub>2</sub>. Specifically, we observe the appearance of low-frequency, zone-folded modes in the CDW state, which soften with temperature similar to the higher frequency, in-plane E<sub>2g</sub> mode. Additionally, we compare the measured magneto-Raman results to calculations using *ab initio*, density functional theory.

**9:00AM R46.00006 Ultralow-frequency interlayer Raman modes to probe interfacial coupling in twisted bilayer MoS<sub>2</sub>**<sup>1</sup>, SHENGXI HUANG, MIT, LIANGBO LIANG, RPI, ORNL, XI LING, MIT, ALEXANDER PURETZKY, DAVID GEOHEGAN, BOBBY SUMPTER, ORNL, JING KONG, MIT, VINCENT MEUNIER, RPI, MILDRED DRESSELHAUS, MIT — Interlayer coupling strength plays an important role in tuning the optoelectronic properties of transition metal dichalcogenides (TMDs), which can be studied in twisted bilayer TMDs due to their various stacking configurations. In this work, ultralow-frequency interlayer shear and breathing Raman modes were investigated in twisted bilayer MoS<sub>2</sub>. We found both twisted angle and translational shift can significantly influence the interlayer coupling, leading to notable frequency and intensity changes of low-frequency Raman modes, as confirmed by first-principles density functional theory calculations. Large frequency and intensity variations occur near twisted angles 0° and 60°, but not between 20° and 40°, indicating translational shift does not induce much change of the coupling strength within the latter angle range. In contrast to low-frequency interlayer modes, high-frequency intralayer Raman modes are much less sensitive to interlayer coupling. Therefore, interlayer Raman modes can be used as an effective probe to study the interlayer coupling of 2D materials with different stacking configurations.

<sup>1</sup>The work is supported by DE-SC0001299, NYSTAR C080117.

**9:12AM R46.00007 Photocurrent spectroscopy of 2D materials**, DAVID COBDEN, University of Washington, Seattle — Confocal photocurrent measurements provide a powerful means of studying many aspects of the optoelectronic and electrical properties of a 2D device or material. At a diffraction-limited point they can provide a detailed absorption spectrum, and they can probe local symmetry, ultrafast relaxation rates and processes, electron-electron interaction strengths, and transport coefficients. We illustrate this with several examples, once being the photo-Nernst effect. In gapless 2D materials, such as graphene, in a perpendicular magnetic field a photocurrent antisymmetric in the field is generated near to the free edges, with opposite sign at opposite edges. Its origin is the transverse thermoelectric current associated with the laser-induced electron temperature gradient. This effect provides an unambiguous demonstration of the Shockley-Ramo nature of long-range photocurrent generation in gapless materials. It also provides a means of investigating quasiparticle properties. For example, in the case of graphene on hBN, it can be used to probe the Lifshitz transition that occurs due to the minibands formed by the Moire superlattice. We also observe and discuss photocurrent generated in other semimetallic (WTe<sub>2</sub>) and semiconducting (WSe<sub>2</sub>) monolayers. Work supported by DoE BES and NSF EFRI grants.

**9:48AM R46.00008 Two-Dimensional Transition Metal Dichalcogenides: Controlled Synthesis and Optical Characterization**, ZHONG LIN, The Pennsylvania State University, YONGJI GONG, GONGLAN YE, GANG SHI, Rice University, MICHAEL THEE, ANA LAURA ELIAS, NESTOR PEREA-LOPEZ, SIMIN FENG, YU LEI, CHANJING ZHOU, KAZUNORI FUJISAWA, VICTOR CAROZO, The Pennsylvania State University, ROBERT VAJTAI, Rice University, HUMBERTO TERRONES, Rensselaer Polytechnic Institute, ZHENG LIU, Nanyang Technological University, PULICKEL AJAYAN, Rice University, MAURICIO TERRONES, The Pennsylvania State University — Chemical vapor deposition (CVD) is a bottom-up approach suitable for the synthesis of MoS<sub>2</sub> and WS<sub>2</sub> monolayers. In order to extend the application of CVD, we modified the precursors used during the deposition. We show that by using mixed transition metal precursors of MoS<sub>2</sub>/WO<sub>3</sub> powders, alloyed monolayers of Mo<sub>x</sub>W<sub>1-x</sub>S<sub>2</sub> islands can be synthesized exhibiting a compositional gradient and a tunable optical band gap, as confirmed by Raman and photoluminescence measurements. We further show that adding tellurium powders into the transition metal precursors can lead to a 200 °C reduction in the synthesis temperature for MoS<sub>2</sub> and WS<sub>2</sub> monolayers. The materials synthesized at a reduced temperature maintain a high degree of crystallinity and optical properties.

**10:00AM R46.00009 Accuracy of the 2D sheet model for atomically thin layers**, YILEI LI, TONY HEINZ, Stanford Univ./SLAC National Accelerator Laboratory — The 2D sheet model provides a useful and concise description of the optics of atomically thin layers. The 2D sheet model is mathematically equivalent to the conventional thin slab model in the limit where the optical thickness of the layer is negligible. In this paper, we present a detailed analysis of the accuracy of the 2D sheet model for atomically thin layers by comparing numerically the predicted optical response for representative monolayer 2D materials to that obtained from the conventional thin slab model. The agreement between the optical responses produced by the two models is found to be within 0.1%, demonstrating excellent accuracy of the sheet model. Based on the 2D sheet model, we then derive the frequently applied linearized relations between the optical contrasts and the sheet conductivity. The linearized relations provides good accuracy when the material response is weak, but is shown to produce an inaccuracy of more than 25% in certain wavelength window for even a single atomic layer of MoS<sub>2</sub>. With the expression for optical transmission from the sheet model, we will clarify a confusion that occasionally arises when determining the optical attenuation by a thin layer.

**10:12AM R46.00010 Ultrasensitive Molecular Sensor Using N-doped Graphene through Enhanced Raman Scattering**, SIMIN FENG, Penn State University, MARIA CRISTINA DOS SANTOS, Universidade de Sao Paulo, BRUNO R. CARVALHO, Penn State University, RUITAO LV, Tsinghua University, KAZUNORI FUJISAWA, ANA LAURA ELIAS, MAURICIO TERRONES, Penn State University — As a novel and efficient surface analysis technique, graphene enhanced Raman scattering (GERS) has attracted increasing research attention in recent years. In particular, chemically doped graphene demonstrates much enhanced GERS effects than pristine graphene (PG) and it can be used to efficiently detect trace amount of molecules. However, the GERS mechanism is still an open question. Here, we present a comprehensive study on the GERS effect of PG and nitrogen-doped graphene (NG). By controlling the N-doping in NG, the Fermi level of graphene shifts, and if this shift aligns with the lower unoccupied molecular orbital (LUMO) of a molecule, charge transfer is enhanced, thus significantly amplifying the molecule vibrational Raman modes. We confirmed these findings using different organic fluorescent molecules. Interestingly, Raman signals from these dye molecules can be detected even for concentrations as low as 10<sup>-11</sup> mol/L, thus providing excellent molecular sensing capabilities. In order to explain our results, these NG-molecule systems were modeled using dispersion corrected density functional theory. Furthermore, we demonstrated that when using different laser excitations, it is possible to determine the gaps between the HOMO and LUMO of different molecules.

**10:24AM R46.00011 Optical/Electronic Heterogeneity of WSe<sub>2</sub> at the Nanoscale**, KYOUNG-DUCK PARK, OMAR KHATIB, VASILY KRAVTSOV, RONALD ULBRICHT, Department of Physics, Department of Chemistry, and JILA, University of Colorado at Boulder, GENEVIEVE CLARK, XIAODONG XU, Department of Physics, Department of Materials Science and Engineering, University of Washington at Seattle, MARKUS RASCHKE, Department of Physics, Department of Chemistry, and JILA, University of Colorado at Boulder — Many classes of two-dimensional (2D) materials have emerged as a potential platform for novel electronic and optical devices. However, the physical properties are strongly influenced by nanoscale heterogeneities in the form of nucleation sites, defects, strains, and edges. Here we demonstrate nano-optical imaging of the associated influence on structure and electronic properties with sub-20 nm spatial resolution from combined tip-enhanced Raman scattering (TERS) and photoluminescence (TEPL) spectroscopy and imaging. In monolayer WSe<sub>2</sub> micro-crystals grown by physical vapor deposition (PVD), we observe significant variations in TERS and TEPL near crystal edges and atomic-scale grain boundaries (GBs), consistent with variations in strain and/or exciton diffusion. Specifically, theoretical exciton diffusion lengths (25 nm) at GBs and heterogeneous nanoscale (30-80 nm) PL emission including a spectral blue-shift at edges are experimentally probed. Further, we are able to engineer the local bandgap of WSe<sub>2</sub> crystals by dynamic AFM-control in reversible (24 meV) and irreversible (48 meV) fashions, enabling systematic in-situ studies of the coupling of mechanical degrees of freedom to the nanoscale electronic properties in layered 2D materials.

**10:36AM R46.00012 Photovoltaic Response from Multilayered Transition Metal Dichalcogenides p-n Junctions**, SHAHRIAR MEMARAN, NIHAR PRADHAN, ZHENG GUANG LU, DANIEL RHODES, JONATHAN LUDWIG, QIONG ZHOU, National High Magnetic Field Laboratory, Florida State University, OMOTOLA OGUNSOLU, Department of Chemistry & Biochemistry, FSU, PULICKEL AJAYAN, Department of Mechanical Engineering and Materials Science, Rice University, DMITRY SMIRNOV, NHMFL, ANTONIO FERNANDEZ-DOMINGUEZ, FRANCISCO GARCIA-VIDAL, IFIMAC, Universidad Autonoma de Madrid, LUIS BALICAS, NHMFL — Transition metal dichalcogenides (TMDs) are layered semiconductors with indirect band gaps comparable to Si. These compounds can be grown in large area, while their gap(s) can be tuned by changing their chemical composition or by applying a gate voltage. The experimental evidence collected so far points toward a strong interaction with light, which contrasts with the small photovoltaic efficiencies  $\eta \leq 1\%$  extracted from bulk crystals or exfoliated monolayers. Here, we evaluate the potential of these compounds by studying the photovoltaic response of electrostatically generated p-n junctions composed of approximately 10 atomic layers of MoSe<sub>2</sub> stacked onto the dielectric h-BN. In addition to ideal diode-like response, we find that these junctions can yield, under AM-1.5 illumination, photovoltaic efficiencies  $\eta$  exceeding 14%, with fill factors of  $\sim 70\%$ . Given the available strategies for increasing  $\eta$  such as gap tuning, improving the quality of the electrical contacts, or the fabrication of tandem cells, our study suggests a remarkable potential for photovoltaic applications based on TMDs.

**10:48AM R46.00013 Raman 2D response of graphene in hBN sandwich as a function of doping**<sup>1</sup>, XUANYE WANG, Department of Electrical and Computer Engineering, Boston University, JASON CHRISTOPHER, Department of Physics, Boston University, ANNA SWAN, Department of Electrical and Computer Engineering, Boston University — Graphene on SiO<sub>2</sub> is plagued by accidental strain and charge doping which cause significant deterioration in electrical, thermal and optical properties. The stacking of Van der Waals layers can not only provide better properties, e.g., electrical mobility, but can also be used for novel interactions between layers. Here we use gated and contacted hBN-graphene-hBN heterostructures to calibrate the 2D Raman response to doping, particularly the low doping region less than  $1 \times 10^{12} \text{ cm}^{-2}$ . This will enable the use of the correlation between Raman G and 2D band to determine effects from doping and strain or compression separately. The dielectric environment of hBN as compared to SiO<sub>2</sub> affects the phonon dispersion and the Fermi velocity which results in approximately  $7 \text{ cm}^{-1}$  blue shift in 2D band per side of graphene contacted with hBN. Charge dependent Raman measurements of the G band provide the means to determine the electron-phonon coupling and the Fermi velocity for graphene in an hBN sandwich.

## Thursday, March 17, 2016 8:00AM - 11:00AM – Session R47 DCMF: Kondo Insulator and Semimetal 312 -

**8:00AM R47.00001 Non-universal weak antilocalization effect in cubic topological Kondo insulators**, MAXIM DZERO, Kent State University, MAXIM VAVILOV, University of Wisconsin-Madison, KOSTYANTIN KECHEZH, QuAIL and USRA, NASA Ames Research Center, VICTOR GALITSKI, University of Maryland — In this talk we present the results of our study of the quantum correction to conductivity on the surface of cubic topological Kondo insulators with multiple Dirac bands. We considered the model of time-reversal invariant disorder which induces the scattering of the electrons within the Dirac bands as well as between the bands. When only intraband scattering is present we found three long-range diffusion modes leading to weak antilocalization correction to conductivity which remains independent of the microscopic details such as Fermi velocities and relaxation times. Interband scattering gaps out two diffusion modes leaving only one long-range mode. Depending on the value of the phase coherence time, either three or only one long-range diffusion modes contribute to weak localization correction rendering the quantum correction to conductivity non-universal.

**8:12AM R47.00002 The tunable chirality and circular dichroism of topological Kondo insulator SmB<sub>6</sub> with C<sub>2v</sub> symmetry as a function of Rashba and Dresselhaus parameters**, PARIJAT SENGUPTA, ENRICO BELLOTTI, Boston University — A manifestation of optical chirality is circular dichroism (CD) due to a differential absorption of left- and right-circularly polarized light. This effect is an enabler for the design of meta-materials used in polarization sensitive imaging devices and display technologies. Concurrently, topological insulators with helical surface states offer an active control over chiral handedness that can be observed through a varying degree of polarization-dependent absorption. We show that in a band gap open topological Kondo insulator SmB<sub>6</sub> with C<sub>2v</sub> symmetry at the X point of the surface Brillouin zone, CD can be smoothly varied without any microscopic reconfiguration of the surface. We also show that CD, measured by the degree of circular polarization, can assume both positive and negative values. These findings suggest that left- and right- circularly polarized light can be selectively absorbed in the vicinity of the Dirac point by an adjustment of the Rashba- and Dresselhaus-like parameters that describe the Hamiltonian at the X point. The CD is an experimentally measurable quantity and related to Berry curvature which is an outcome of the parameter-dependent Hamiltonian. We calculate the Berry curvature and establish a pathway to alter CD through the Hamiltonian parameters.

**8:24AM R47.00003 Nonsymmorphic crystalline Kondo semimetals**<sup>1</sup>, PO-YAO CHANG, ONUR ERTEN, PIERS COLEMAN, Center for Materials Theory, Rutgers University — Kondo semimetals, such as CeNiSn and CeRhSb are a class of "failed" heavy fermion insulator that appear to develop line-nodes in the hybridization between the localized f-states and mobile conduction electrons. The classic theory[1,2] for node formation depends on angular momentum blocking in a continuum, and provides no insight into why the node should be stable in a crystalline environment. Here we examine how the semimetallic phase emerges in orthorhombic Kondo systems with nonsymmorphic symmetries. Using a periodic Anderson model that incorporates the key crystallographic symmetries of CeNiSn, we show that hybridization nodal lines are naturally protected within mirror symmetry planes. The shape of the Fermi surface around the nodes in our model agrees with observations in Shubnikov-de Haas oscillations.

**8:36AM R47.00004 Spin fluctuations in the anisotropic Kondo insulator  $\text{CeRu}_4\text{Sn}_6$ <sup>1</sup>**, WESLEY T. FUHRMAN, Institute for Quantum Matter and Johns Hopkins University, J. HAENEL, Vienna University of Technology, J. RODRIGUEZ, NIST NCNR, S. PASCHEN, Vienna University of Technology, C. L. BROHOLM, Institute for Quantum Matter, Johns Hopkins University, NIST — We report and model anisotropic quasi-elastic magnetic neutron scattering from single crystalline  $\text{CeRu}_4\text{Sn}_6$ . For  $T \approx 2\text{K}$  the magnetic neutron scattering is broad in momentum ( $\mathbf{Q}$ ) with a persistent  $1/\hbar\omega$  spectrum throughout the Brillouin zone. This indicates a lack of spatial coherence and no characteristic energy scale beyond the 0.2 meV resolution of the measurement. We find the Q-dependence of the scattering can be modeled by a Kondo-Heisenberg Hamiltonian that describes residual carriers and incompletely compensated localized electrons. These findings support the interpretation of tetragonal  $\text{CeRu}_4\text{Sn}_6$  as an anisotropic or nodal Kondo insulator, markedly different from typical cubic Kondo insulators. We further discuss potential topological implications.

<sup>1</sup>Work at IQM was supported by the U.S. Department of Energy, office of Basic Energy Sciences, Division of Materials Sciences and Engineering under Award DE-FG02-08ER4654. W.T.F. thanks the ARCS foundation and Lockheed Martin for additional support.

**8:48AM R47.00005 Nanoscale Conducting and Insulating Domains on  $\text{YbB}_6$ <sup>1</sup>**, JENNIFER HOFFMAN, University of British Columbia, ZHIHUI ZHU, YANG HE, Harvard University, DAE-JEONG KIM, ZACHARY FISK, University of California, Irvine — Recent photoemission studies on  $\text{YbB}_6$  reported a metallic surface but without f-states pinned at the Fermi level, in contradiction to the theoretical prediction of  $\text{YbB}_6$  as a topological Kondo insulator. Thus the topological nature of  $\text{YbB}_6$  remains unclear and requires a study that can distinguish trivial surface structure and non-trivial topological effects derived from the bulk. We use scanning tunneling microscopy and spectroscopy (STM/STS) to provide a real-space microscopic picture of the surface electronic structure in  $\text{YbB}_6$ . We observe coexisting nanoscale metallic and insulating surface terminations. The surface conductivity of each termination reflects the degree of downward or upward band bending that is determined by the surface polarity. In addition to demonstrating that surface metallic in  $\text{YbB}_6$  stems from band bending at the polar surface, our study suggests the utility of  $\text{YbB}_6$  for creating spin-polarized p-n junctions at the atomic scale.

<sup>1</sup>We acknowledge funding from the National Science Foundation, DMR-1410480.

**9:00AM R47.00006 Quasiparticle Interference Imaging on  $\text{SmB}_6$ <sup>1</sup>**, HARRIS PIRIE, University of British Columbia, Harvard University, YANG HE, Harvard University, MOHAMMAD HAMIDIAN, Harvard University, Cornell University, MICHAEL YEE, Harvard University, DAE-JEONG KIM, ZACHARY FISK, University of California, Irvine, JENNIFER HOFFMAN, University of British Columbia, Harvard University — Theoretical interest in  $\text{SmB}_6$  as a possible topological Kondo insulator with spin-textured Dirac surface states spanning the bulk hybridization gap has been well supported by recent transport, quantum oscillation, and spin-resolved ARPES experiments. However, the influence of surface reconstruction and polarization on the observed dispersion remains unclear. Scanning tunneling microscopy (STM) and spectroscopy (STS) enable simultaneous measurement of local real- and momentum-space structure through quasiparticle interference (QPI) imaging. We use QPI imaging to detect and measure the dispersion of states near the hybridization gap on a non-polar,  $2 \times 1$  reconstructed surface of  $\text{SmB}_6$ . We compare these results with recent theoretical predictions to gain insight into the low energy excitations of  $\text{SmB}_6$ .

<sup>1</sup>This work was supported by the US National Science Foundation under the grant DMR-1410480.

**9:12AM R47.00007 Topological surface states in Kondo insulator  $\text{SmB}_6$  via planar tunneling spectroscopy<sup>\*</sup>**, WAN KYU PARK, LUNAN SUN, ALEX NODDINGS, University of Illinois at Urbana-Champaign, LAURA GREENE, National High Magnetic Field Laboratory and Florida State University, DAE-JEONG KIM, ZACHARY FISK, University of California, Irvine — Samarium hexaboride ( $\text{SmB}_6$ ) belongs to a class of materials called Kondo insulators in which the hybridization between itinerant electrons and local moments leads to an emergent state of matter. With inherently large spin-orbit coupling along with strong correlation,  $\text{SmB}_6$  has been recently predicted to be topological meaning that topologically robust conducting states should exist at its surfaces. Although extensive investigations have provided growing evidence for the existence of such states, corroborative spectroscopic evidences are still lacking unlike in the weakly correlated counterparts. We adopt planar tunneling spectroscopy to unveil their detailed nature and behavior utilizing its inherently high energy resolution. Measurements of tunneling conductance on two different crystal surfaces (001) and (011) reveal the expected linear density of states for two and one Dirac cones, respectively. Moreover, it is found that these topological states cease to be protected well before they merge into the bulk states at the gap edges. Microscopic modeling of the tunneling processes accounting for the interaction with spin excitons as predicted by a recent theory [1] provide consistent explanations for all the observed features, corroborating the proposed picture on the incompletely protected surface states in  $\text{SmB}_6$ . [1] Kapilevich *et al.*, Phys. Rev. B **92**, 085133 (2015). <sup>\*</sup>The work at UIUC is supported by the NSF DMR 12-06766.

**9:24AM R47.00008 Finite temperature topological phase transitions and emergence of Dirac semi-metallic phases in a Kondo lattice<sup>1</sup>**, PO-HAO CHOU, LIANG-JUN ZHAI, Department of Physics, National Tsing Hua University, Taiwan, ROC, CHUNG-HOU CHUNG, Electrophysics Department, National Chiao-Tung University, Taiwan, ROC, TING-KUO LEE, Institute of Physics, Academia Sinica, Nankang, Taiwan, ROC, CHUNG-YU MOU, Department of Physics, National Tsing Hua University, Taiwan, ROC — The energy gap in Dirac materials controls the topology and critical behaviors of the quantum phase transition associated with the critical point when the gap vanishes. However, it is often difficult to access the critical point as it requires tunability of electronic structures. Here by exploiting the many-body screening interaction of localized spins and conduction electrons in a Kondo lattice, we demonstrate that the electronic band structures in a Kondo lattice are tunable in temperature. When spin-orbit interactions are included, we find that below the Kondo temperature, the Kondo lattice is a strong topological insulator at low temperature and undergoes a topological transition to a weak topological insulator at a higher temperature  $T_D$ . At  $T_D$ , Dirac points emerge and the Kondo lattice becomes a Dirac semimetal. Our results indicate that the topological phase transition through a Dirac semi-metallic phase at finite temperatures also manifests profound physics and results in critical-like behavior both in magnetic and transport properties near  $T_D$ .

<sup>1</sup>We acknowledge support from NCTS and Ministry of Science and Technology (MoST), Taiwan.

**9:36AM R47.00009 Pressure-induced exotic states in mixed-valence rare earth hexaborides**, LILING SUN, YAZHOU ZHOU, QI WU, YI-FENG YANG, ZHONGXIAN ZHAO, Institute of Physics, CAS, DAE-JEONG KIM, PRISCILA ROSA, ZACHARY FISK, Department of Physics and Astronomy, University of California, Irvine, RONG YU, Department of Physics, Renmin University of China, QIMAO SI, Department of Physics & Astronomy, Rice University, Houston, JOE THOMPSON, Los Alamos National Laboratory, Los Alamos — Recently, a unique type of well-known compounds, mixed-valence rare earth hexaborides  $\text{RB}_6$  ( $\text{R} = \text{Sm}$  and  $\text{Yb}$ ), receive new interests due to the discovery of the coexistence of metallic surface state and insulating bulk state in  $\text{SmB}_6$ . This encourages people to revisit the  $\text{RB}_6$  with an attempt to establish a new physics that links the correlated electron systems and topological insulators. Pressure is a way to help understanding the underlying mechanism, therefore it is specially needed in establishing this link because the valence state of  $\text{RB}_6$  is sensitive to pressure. In this talk, we will report some progress of high pressure studies on the  $\text{RB}_6$ , mainly focusing on the phenomena of pressure-induced exotic states and corresponding quantum phase transitions. The connections between the related phenomena and the valence states are revealed.

### 9:48AM R47.00010 Tunable Kondo effect and spin textures on topological insulators surfaces<sup>1</sup>

, ILYA VEKHTER, Department of Physics and Astronomy, Louisiana State University, GERARDO ORTIZ, Department of Physics and Center for Exploration of Energy and Matter, Indiana University Bloomington, LEONID ISAEV, JILA, NIST and Department of Physics, University of Colorado Boulder — We consider screening of a spin-1/2 impurity at the surface of a topological insulator, and show that the very existence of Kondo screening strongly depend on details of the bulk material and surface preparation whose details are encoded in time-reversal preserving boundary conditions for electronic wavefunctions. We investigate in detail the formation of the Kondo resonance by studying the "orbital-flip" processes that screen the impurity spin in the resulting strongly spin-orbit coupled system. This mechanism gives rise to spin textures that can be used to experimentally probe signatures of a Kondo resonance in topological insulators, and we give examples relevant to specific materials.

<sup>1</sup>L.I. was supported by the NSF (PIF-1211914 and PFC-1125844), AFOSR, AFOSR-MURI, NIST and ARO individual investigator awards, and also in part by ICAM. I.V. acknowledges support from NSF Grant DMR-1105339.

### 10:00AM R47.00011 Incomplete Protection of the Surface Weyl Cones of Kondo Insulators: Spin Exciton Scattering<sup>1</sup>

, PETER RISEBOROUGH, GARY A<sub>2</sub> KAPILEVICH, ALEX GRAY, Temple Univ, MIKLOS GULACSI, Max Planck Institute for the Physics of Complex Systems, TOMASZ DURAKIEWICZ, Los Alamos National Lab, JAMES L. SMITH, Los Alamos National lab. — The material SmB<sub>6</sub> is a Kondo Insulator, where the lowest-energy bulk electronic excitations are spin excitons. The material also has surface states which are subjected to strong spin-orbit coupling. It has been suggested that SmB<sub>6</sub> is also a topological insulator. Here we show that, despite the absence of time-reversal symmetry breaking and the presence of strong spin-orbit coupling, the chiral spin texture of the Weyl cone is not completely protected. In particular, we show that the spin-exciton mediated scattering produces features in the surface electronic spectrum at energies separated from the surface Fermi-energy by the spin-exciton energy. Despite the features being far removed from the surface Fermi-energy, the features are extremely temperature dependent. The temperature variation occurs over a characteristic scale determined by the dispersion of the spin exciton. The structures may be observed by electron spectroscopy at low temperatures.

### 10:12AM R47.00012 Magnetotransport properties of topological surface states in the presence of ferromagnetic order

, KUNAL TIWARI, WILLIAM COISH, TAMI PEREG-BARNEA, McGill University — The surface of a 3D topological insulator hosts a two dimensional Dirac cone which is robust to weak, non-magnetic perturbation. Its presence will dominate low energy transport since the bulk is gapped. However, once magnetic impurities are introduced to the surface they may gap the Dirac dispersion, suppressing or modifying the systems surface transport properties. In particular, in the presence of uniform ferromagnetic order, the Dirac cone becomes massive and should not conduct for energies near the Dirac point. On the other hand, if the ferromagnetic order has domains with different magnetization directions, current may be carried on the domain walls where the Dirac mass vanishes. Our research aims to elucidate the transport properties of topological insulators in the presence of magnetic domain structures. Our work may be relevant to recent studies on the Kondo topological insulator SmB<sub>6</sub>.

### 10:24AM R47.00013 Universal edge information from wavefunction deformation

, WEN WEI HO<sup>1</sup>, Department of Theoretical Physics, University of Geneva, LUKASZ CINCIO, HEIDAR MORADI, GUIFRE VIDAL, Perimeter Inst for Theo Phys — It is well known that the bulk physics of a topological phase constrains its possible edge physics through the bulk-edge correspondence. Therefore, the different types of edge theories that a topological phase can host is a universal piece of data which can be used to characterize topological order. Here, we argue that beginning from only the fixed point wavefunction (FPW) of a nonchiral topological phase and by locally deforming it, all possible edge theories can be extracted from its entanglement Hamiltonian (EH). We illustrate our claim by deforming the FPW of the Wen-plaquette model, the quantum double of Z<sub>2</sub>. We show that the possible EHs of the deformed FPWs reflect the known possible types of edge theories, which are generically gapped, but gapless if translational symmetry is preserved. We stress that our results do not require an underlying Hamiltonian — thus, this lends support to the notion that a topological phase is indeed characterized by only a set of quantum states and can be studied through its FPWs.

### 10:36AM R47.00014 Landau quantization and spin-momentum locking in topological Kondo insulators<sup>1</sup>

, PEDRO SCHLOTTMANN, Florida State University — SmB<sub>6</sub> has been predicted to be a strong topological Kondo insulator and experimentally it has been confirmed that at low temperatures the electrical conductivity only takes place at the surfaces of the crystal. Quantum oscillations and ARPES measurements revealed several Dirac cones on the (001) and (101) surfaces of the crystal. We considered three types of surface Dirac cones with an additional parabolic dispersion and studied their Landau quantization and the expectation value of the spin of the electrons. The Landau quantization is quite similar in all three cases and would give rise to very similar de Haas-van Alphen oscillations [1]. The spin-momentum locking, on the other hand, differs dramatically. Without the additional parabolic dispersion the spins are locked in the plane of the surface. The parabolic dispersion, however, produces a gradual canting of the spins out of the surface plane.

### 10:48AM R47.00015 Strong correlations in Kondo topological insulators: Two-dimensional heavy fermions, and beyond

, PREDRAG NIKOLIC, George Mason Univ — Samarium hexaboride (SmB<sub>6</sub>) is a candidate topological insulator with strong electron correlations. Empowered by the time-reversal (TR) symmetry and topology, the low-energy surface states of hybridized samarium's d and f orbitals can exhibit a rich two-dimensional heavy-fermion phenomenology. This talk will survey several interesting possibilities for correlated surface states, which depend on microscopic surface conditions. A pronounced participation of the f orbitals is expected to create a heavy-fermion Dirac metal, possibly unstable to spin density waves, superconductivity, or exotic Mott insulators (e.g. algebraic and non-Abelian spin liquids). The opposite limit of localized magnetic moments can produce a non-Fermi liquid of d electrons that exhibits two-dimensional quantum electrodynamics. Ultrathin films made from topological Kondo insulators can host lattices of SU(2) vortices, which need not break the TR symmetry. Landau-Ginzburg theory and numerical model calculations reveal the nature and stability of such vortex lattices, while field theory arguments predict that their quantum melting could yield novel incompressible quantum liquids with non-Abelian fractional excitations.

Session R48 GQI: Decoherence in Superconducting Qubits: Junctions and Fluxonium 349 - Britton Plourde, Syracuse University

**8:00AM R48.00001 Novel Josephson circuit elements for high magnetic field parity detection**, MAJA CASSIDY, Delft University of Technology — Evidence for Majorana modes in semiconductor nanowires to date has relied on DC transport measurements that probe their zero-energy characteristics. However, in order to unambiguously demonstrate the non-Abelian nature of Majoranas, it is necessary to braid them and measure their parity. Superconducting transmon qubits have been shown to be sensitive parity detectors, however traditional designs are incompatible with the strong magnetic fields required for the creation of Majoranas in nanowires. In this talk I will discuss our development of novel superconducting circuit elements such as CPW resonators, tunnel junctions, transmon qubits and on-chip microwave sources that survive magnetic fields in excess of 1T.

**8:36AM R48.00002 Decoherence and Decay of Two-level Systems due to Non-equilibrium Quasiparticles**<sup>1</sup>, SEBASTIAN ZANKER, MICHAEL MARTHALER, GERD SCHN, Karlsruhe Institute of Technology, INSTITUT FÜR THEORETISCHE FESTKÖRPERPHYSIK TEAM — It is frequently observed that even at very low temperatures the number of quasiparticles in superconducting materials is higher than predicted by standard BCS-theory. These quasiparticles can interact with two-level systems, such as superconducting qubits or two-level systems (TLS) in the amorphous oxide layer of a Josephson junction. This interaction leads to decay and decoherence of the TLS, with specific results, such as the time dependence, depending on the distribution of quasiparticles and the form of the interaction. We study the resulting decay laws for different experimentally relevant protocols.

<sup>1</sup>This work was supported by the German-Israeli Foundation for Scientific Research and Development (GIF).

**8:48AM R48.00003 Superconducting resonators with trapped vortices under direct injection of quasiparticles**, IBRAHIM NSANZINEZA, Syracuse University, UMESH PATEL, University of Wisconsin, K. R. DODGE, Syracuse University, R. F. MCDERMOTT, University of Wisconsin, B. L. T. PLOURDE, Syracuse University — Nonequilibrium quasiparticles and trapped magnetic flux vortices can significantly impact the performance of superconducting microwave resonant circuits and qubits at millikelvin temperatures. Quasiparticles result in excess loss, reducing resonator quality factors and qubit lifetimes. Vortices trapped near regions of large microwave currents also contribute excess loss. However, vortices located in current-free areas in the resonator or in the ground plane of a device can actually trap quasiparticles and lead to a reduction in the quasiparticle loss. We will describe experiments involving the controlled trapping of vortices in superconducting resonators with direct injection of quasiparticles using Normal metal-Insulator-Superconductor (NIS)-tunnel junctions.

**9:00AM R48.00004 Robustness of superconducting quantum modes against direct quasiparticle injection**, U. PATEL, Department of Physics, University of Wisconsin, Madison, Wisconsin 53706, I. NSANZINEZA, Department of Physics, Syracuse University, Syracuse, New York 13244, M. G. VAVILOV, Department of Physics, University of Wisconsin, Madison, Wisconsin 53706, B. L. T. PLOURDE, Department of Physics, Syracuse University, Syracuse, New York 13244, R. MCDERMOTT, Department of Physics, University of Wisconsin, Madison, Wisconsin 53706 — Classical Josephson digital logic based on Single Flux Quantum (SFQ) pulses offers a path to high-fidelity coherent control of large-scale superconducting quantum machines. However, an SFQ pulse driver generates nonequilibrium quasiparticles that contribute to qubit relaxation, and steps must be taken to protect the qubit from this decoherence channel. Here we describe experiments to characterize the robustness of high-Q superconducting linear resonators and qubits against direct quasiparticle injection. We use NIS junctions and SFQ elements to controllably inject quasiparticles into the groundplane of superconducting resonator and qubit chips, and we characterize the quasiparticle contribution to dissipation. We examine the effectiveness of groundplane cuts, normal metal quasiparticle traps, and spatially-varying superconducting gaps at protecting the quantum modes against quasiparticle loss. Finally, we discuss strategies for the integration of multiqubit circuits with on-chip SFQ control elements.

**9:12AM R48.00005 Normal Metal Quasiparticle Traps in 3D-Transmon Qubits**<sup>1</sup>, LUKE D. BURKHART, YVONNE Y. GAO, CHEN WANG, KYLE SERNIK, GJS DE LANGE, YIWEN CHU, URI VOOL, LUIGI FRUNZIO, MICHEL H. DEVORET, Department of Applied Physics and Physics, Yale University, GIANLUIGI CATELANI, Peter Grunberg Institut (PGI-2), Forschungszentrum Jülich, LEONID I. GLAZMAN, ROBERT J. SCHOELKOPF, Department of Applied Physics and Physics, Yale University — Quasiparticles are a known source of decoherence in Josephson-junction based superconducting qubits. While equilibrium quasiparticles should not be present in devices operated at dilution refrigeration temperatures well below the superconducting energy gap, non-thermal quasiparticles have been observed in many different superconducting qubits, including 3D-transmons and fluxonium qubits. Vortices induced by applied magnetic fields have been shown to improve non-equilibrium quasiparticle decay rates and improve coherence times by creating regions of the superconductor with vanishing energy gap, which act as quasiparticle traps. We aim to further mitigate quasiparticle-induced limits on coherence by engineering strong trapping via the introduction of normal metal to the superconducting qubit. In this talk, we present recent results regarding normal metal quasiparticle traps in 3D-transmon qubits.

<sup>1</sup>Work supported by ARO, A\*STAR

**9:24AM R48.00006 Gap-engineered quasiparticle traps in the fluxonium artificial atom**<sup>1</sup>, K. SERNIK, G. DE LANGE, U. VOOL, M. HAYS, L.D. BURKHART, Y.Y. GAO, C. WANG, K.M. SLIWA, Department of Applied Physics, Yale University, I.M. POP, Department of Applied Physics, Yale University, and Physikalisches Institut, Karlsruhe Institute of Technology, L. FRUNZIO, L.I. GLAZMAN, R.J. SCHOELKOPF, M.H. DEVORET, Department of Applied Physics, Yale University — Recent experiments have shown that the density of quasiparticles in superconducting quantum circuits exceeds the expected thermal density. In Josephson junction based superconducting qubits, these non-equilibrium quasiparticles can tunnel through the junctions of the circuit, causing decoherence. Quasiparticle traps aim to reduce the density of quasiparticles near the junctions, and therefore the rate of energy loss and dephasing due to tunneling events. These traps must be designed to not introduce any additional losses in the qubit. In this talk we will discuss recent progress in the design and implementation of quasiparticle traps in the fluxonium artificial atom.

**9:36AM R48.00007 Spectroscopy and decoherence of plasmons and fluxons in superconducting fluxonium qubit.**, LONG NGUYEN, YEN-HSIANG LIN, NICHOLAS GRABON, NATALYA SOLOVYIEVA, VLADIMIR MANUCHARYAN, Univ of Maryland-College Park, SUPERCONDUCTING CIRCUITS LAB TEAM — Transition spectrum of a fluxonium circuit changes drastically with respect to the  $p=EJ/EC$  parameter of the small junction, remaining charge-insensitive at all values of  $p$ . At larger values of  $p$ , the spectrum consists of exponentially decoupled fluxon and plasmon transitions. At smaller values, fluxons no longer exist, and plasmons reside mostly in the array inductance. We present spectroscopy of tunable fluxoniums and discuss our findings from the decoherence measurements of various transitions.

**9:48AM R48.00008 The fluxonium as a lambda system<sup>1</sup>**, U. VOOL, A. KOU, W.C. SMITH, K. SERNIAK, S. SHANKAR, S.M. GIRVIN, M.H. DEVORET, Department of Applied Physics, Yale University — A lambda system is a 3-level system in which two low-energy states can transition to a third higher-energy state by a coherent drive but not to each other. Lambda systems are commonly implemented in systems relying on atomic transitions. In the field of superconducting quantum circuits, the fluxonium qubit, an artificial atom consisting of a Josephson junction shunted by a superinductance, is a unique artificial atom with highly non-linear energy levels. At half-flux quantum it has two low-energy states with a long energy lifetime, but it is difficult to perform fast quantum gates in this manifold. Employing the higher 2nd excited state as an intermediate level would be much more efficient. However, selection rules in the fluxonium qubit prohibit transitions between low-energy states and higher-energy states of the same parity. In this talk, we will introduce a way to create formerly forbidden transitions between levels of the fluxonium qubit - thus creating a more interesting artificial atom and a useful tool for future superconducting quantum circuits.

<sup>1</sup>Work supported by ARO, ONR, AFOSR and YINQE

**10:00AM R48.00009 Simultaneous monitoring of fluxonium qubits in a waveguide<sup>1</sup>**, A. KOU, W.C. SMITH, U. VOOL, I.M. POP, K.M. SLIWA, M. HATRIDGE, R.J. SCHOEKOPF, M.H. DEVORET, Department of Applied Physics, Yale University — Building quantum computers and quantum simulators requires separate control and readout of multiple qubits. We present an architecture for multiplexed readout of fluxonium qubits. We measured lifetimes in excess of 100 us for such artificial atoms placed in a wide-bandwidth electromagnetic environment. We use cascaded Josephson parametric converters to measure the quantum jumps of two fluxonium qubits simultaneously. Our method can access correlations between different qubits and can easily be scaled to read out larger numbers of qubits.

<sup>1</sup>Work supported by: ARO, ONR, AFOSR, and YINQE.

**10:12AM R48.00010 A disordered kinetic superinductor<sup>1</sup>**, M. HAYS, G. DE LANGE, K. SERNIAK, Z. WANG, U. VOOL, L. FRUNZIO, M.H. DEVORET, Department of Applied Physics, Yale University — The superinductance is a superconducting circuit element whose reactance exceeds the resistance quantum at the relevant microwave operation frequencies of quantum circuits. It must also be as non-dissipative as possible. Such an element is key to the fluxonium artificial atom, a highly anharmonic, charge insensitive superconducting qubit that has been proposed as the detection circuit for Majorana Fermions. So far fluxonium qubits are made exclusively from arrays of Al-AIOx-Al Josephson junctions. However, aluminium is difficult to employ in conjunction with the strong magnetic fields required in Majorana Fermion experiments. The large kinetic inductance of highly resistive disordered superconducting alloys, such as NbTiN, is currently explored as an alternative material for superinductance in quantum electronic circuits. We report the results of measurement of quality factors and phase-slip rates of high-impedance resonators made from thin-film NbTiN.

<sup>1</sup>Work supported by: ARO, ONR, AFOSR and YINQE

**10:24AM R48.00011 Fabrication and characterization of low loss and high inductance Josephson tunnel junction chains for quantum circuits**, NICHOLAS GRABON, NATALYA SOLOVYEV, LONG NGUYEN, YEN-HSIANG LIN, VLADIMIR MANUCHARYAN, University of Maryland — Linear chains of tightly packed Josephson junctions can realize a very high kinetic inductance circuit element, superinductance, with minimal losses. Superinductance is used in a conventional fluxonium qubit, but it has also been put forward as a key element of a fault-tolerant quantum circuits toolbox [1]. We report fabrication and microwave characterization of linear Al/AIOx/Al Josephson tunnel junction chains and discuss their advantages and limitations as superinductors. [1]: 10.1103/PhysRevA.87.052306

**10:36AM R48.00012 Extending quantum coherence of superconducting flux<sup>1</sup>**, FEI YAN, ARCHANA KAMAL, TERRY ORLANDO, SIMON GUSTAVSSON, Massachusetts Inst of Tech-MIT, WILLIAM OLIVER, Massachusetts Inst of Tech-MIT, Lincoln Laboratory, ENGINEERING QUANTUM SYSTEMS, MIT TEAM — We present the design of a superconducting qubit with multiple Josephson junctions. The design starts with a capacitively shunted flux qubit, and it incorporates particular junction parameter choices for the purpose of simultaneously optimizing over transition frequency, anharmonicity, flux- and charge-noise sensitivity around flux degeneracy. By studying the scaling properties with design parameters, we identify directions to extend coherence substantially.

**10:48AM R48.00013 Quantum memristor in a superconducting circuit<sup>1</sup>**, JUHA SALMILEHTO, Department of Physics, Yale University, New Haven, Connecticut 06520, USA, MIKEL SANZ, University of the Basque Country UPV/EHU, Apartado 644, E-48080 Bilbao, Spain, MASSIMILIANO DI VENTRA, Department of Physics, University of California, San Diego, La Jolla, CA 92093, USA, ENRIQUE SOLANO, University of the Basque Country UPV/EHU, Apartado 644, E-48080 Bilbao, Spain — Memristors, resistive elements that retain information of their past, have garnered interest due to their paradigm-changing potential in information processing and electronics. The emergent hysteretic behaviour allows for novel architectural applications and has recently been classically demonstrated in a simplified superconducting setup using the phase-dependent conductance in the tunnel-junction-microscopic model[1]. In this contribution, we present a truly quantum model for a memristor constructed using established elements and techniques in superconducting nanoelectronics, and explore the parameters for feasible operation as well as refine the methods for quantifying the memory retention. In particular, the memristive behaviour is shown to arise from quasiparticle-induced tunneling in the full dissipative model and can be observed in the phase-driven tunneling current. The relevant hysteretic behaviour should be observable using current state-of-the-art measurements for detecting quasiparticle excitations. Our theoretical findings constitute the first quantum memristor in a superconducting circuit and act as the starting point for designing further circuit elements that have non-Markovian characteristics. **8:00AM R50.00001 Exploring Quantum Many-Body Spin Dynamics with Truncated Wigner Methods** , JOHANNES SCHACHENMAYER, JILA, NIST & Department of Physics, University of Colorado, Boulder — Recent experiments in atomic, molecular, and optical physics offer controlled and clean environments to experimentally study non-equilibrium dynamics of large many-body quantum spin-models with variable range interactions. Thus, efficient computation of such dynamics is of great importance. While in one dimension, time-dependent density matrix renormalization group methods (t-DMRG) have proven effective under certain conditions, computing dynamics in higher dimensional systems remains an outstanding challenge. Recently we formulated the discrete truncated Wigner approximation (DTWA), a semiclassical method based on the truncated Wigner approximation (TWA) that has been proven to be surprisingly accurate in predicting quench dynamics in high-dimensional lattices with up to tens of thousands of quantum spins. Here, we introduce the DTWA and show how it can compute time-evolution of quantum states in experiments that engineer spin-models with polar molecules in optical lattices or with ions in two-dimensional Penning traps. We show, how the DTWA can provide results for the time-evolution of classical and quantum correlations in quench experiments in regimes where other numerical methods are generally unreliable. We report on progress of how to incorporate higher order corrections to the method, and how to adapt it to systems with both spin and bosonic degrees of freedom.

**8:36AM R50.00002 A Quantum Dipolar Spin Liquid** , NORMAN YAO, Department of Physics, UC Berkeley, MICHAEL ZALETEL, Station Q, Microsoft Research, DAN STAMPER-KURN, ASHVIN VISHWANATH, Department of Physics, UC Berkeley — Quantum spin liquids are a new class of magnetic ground state in which spins are quantum mechanically entangled over macroscopic scales. Motivated by recent advances in the control of polar molecules, we show that dipolar interactions between  $S=1/2$  moments stabilize spin liquids on the triangular and kagome lattices. In the latter case, the moments spontaneously break time-reversal, forming a chiral spin liquid with robust edge modes and emergent semions. We propose a simple route toward synthesizing a dipolar Heisenberg antiferromagnet from lattice-trapped polar molecules using only a single pair of rotational states and a constant electric field.

**8:48AM R50.00003 Intrinsic topological superfluidity – fluctuations and response** , K LEVIN, CHIEN-TE WU, BRANDON ANDERSON, RUFUS BOYACK, James Franck Institute — Recent interest in topological superconductivity is based primarily on exploiting proximity effects to obtain this important phase. However, in cold gases it is possible to contemplate “intrinsic” topological superfluidity produced with a synthetic spin-orbit coupling and Zeeman field. It is important for such future experiments to establish how low in temperature one needs to go to reach the ordered phase. Similarly, it will be helpful to have a probe of the normal (pseudogap) phase to determine if the ultimate superfluid order will be topological or trivial. In this talk, we address these issues by considering fluctuation effects in such a superfluid, and calculate the critical transition temperature and response functions. We see qualitative signatures of topological superfluidity in spin and charge response functions. We also explore the suppression of superfluidity due to fluctuations, and importantly find that the temperature scales necessary to reach topological superfluidity are reasonably accessible [1]. [1] Phys. Rev. B 92, 134523 (2015)

**9:00AM R50.00004 Phase diagrams of spinor bosons in two-leg ladders.**<sup>1</sup> , JERESON SILVA VALENCIA, ROBERTO FRANCO, Universidad Nacional de Colombia, MARCOS SERGIO FIGUEIRA, Universidade Federal Fluminense — In the last, years different experimental groups have reported the realization of atomic ladders in the presence of a homogeneous flux [Nat. Phys. 10, 588 (2014)]. These experiments have motivated theoretical calculations on 2-leg ladders with spinless bosons under magnetic fields [PRB 91, 140406(R) (2015)]. In this paper, we consider spinor boson atoms with spin  $S=1$ , such as Rb and Na. Gases of these atoms can be described by the spinor Bose-Hubbard Hamiltonian which has three terms: the kinetic energy, local density-density interaction and local spin-dependent term. Using DMRG, we study  $S=1$  bosons on 2-leg ladders, taking into account both antiferromagnetic and ferromagnetic spin interaction. When both legs are ferromagnetic or antiferromagnetic, we obtained Mott insulator and superfluid phases, similar to the one-dimensional case, but the insulator areas decrease due to the additional kinetic term. The even-odd asymmetry is still observed in the antiferromagnetic case. However, when the local spin interaction has a different sign on each leg, charge density waves for densities  $3/2$  and  $5/2$  appear. The Mott insulator phase for density 1 (2) correspond to the antiferromagnetic-leg (ferromagnetic-leg).

**9:12AM R50.00005 XY-sliding phases – mirage of the Renormalization Group**<sup>1</sup> , STEVEN VAYL, ANATOLY KUKLOV, VADIM OGANESYAN, CSI and the Graduate Center, CUNY — The so called sliding XY phases in layered systems are predicted to occur if the one loop renormalization group (RG) flow renders the interlayer Josephson coupling irrelevant, while each layer still features broken  $U(1)$  symmetry<sup>2</sup>. In other words, such a layered system remains essentially two-dimensional despite the presence of inter-layer Josephson coupling. We have analyzed numerically a layered system consisting of groups of asymmetric layers where the RG analysis predicts sliding phases to occur. Monte Carlo simulations of such a system have been conducted in the dual representation by Worm Algorithm<sup>3</sup> in terms of the closed loops of J-currents<sup>4</sup> for layer sizes varying from  $4 \times 4$  to  $640 \times 640$  and the number of layers – from 2 to 40. The resulting flow of the inter-layer XY-stiffness has been found to be inconsistent with the RG prediction and fully consistent with the behavior of the 3D standard XY model where the bare inter-layer Josephson coupling is much smaller than the intra-layer stiffness. This result emphasizes the importance of the compactness of the  $U(1)$  variable for 2D to 3D transformation.

**9:24AM R50.00006 Spontaneous increase of magnetic flux and chiral-current reversal in bosonic ladders: Swimming against the tide** , TEIMURAZ VEKUA, SEBASTIAN GRESCHNER, Leibniz University of Hannover, MARIE PIRAUD, FABIAN HEIDRICH-MEISNER, Ludwig-Maximilians-University of Munich, IAN MCCULLOCH, The University of Queensland, ULI SCHOLLWOECK, Ludwig-Maximilians-University of Munich — The interplay between the spontaneous symmetry breaking and the wave-like nature of quantum particles in lattice produces an extraordinary behavior of the chiral current of interacting bosonic particles in the presence of a uniform magnetic flux defined on a two-leg ladder. While non-interacting as well as strongly interacting particles, stirred by the magnetic field circulate along the system's boundary in the counterclockwise direction, for certain interactions between particles and at sufficiently low temperature, the circulation direction of chiral current can be spontaneously reversed in vortex lattice states. Chiral-current reversal is counter-intuitive many-body effect produced by synthetic magnetism and it can be observed up to temperatures  $T=0.5J$ , where  $J$  is a hopping rate along ladder. Besides this effect we present first numerical evidence of vortex lattice states in interacting bosonic ladders with flux and a state with spontaneously imbalanced density between the ladder legs.

**9:36AM R50.00007 Dimensional phase transition from 1D behavior to a 3D Bose-Einstein condensate**, AXEL PELSTER, DENIS MORATH, DOMINIK STRAßEL, SEBASTIAN EGGERT, Univ Kaiserslautern, Germany — The emergence of new properties from low-dimensional building blocks is a universal theme in different areas in physics. The investigation of transitions between isolated and coupled low-dimensional systems promises to reveal new phenomena and exotic phases. Interacting 1D bosons, which are coupled in a two-dimensional array, are maybe the most fundamental example of a system which illustrates the concept of a dimensional phase transition. However, recent experiments using ultracold gases have shown a surprising discrepancy between theory and experiment [1] and it is far from obvious if the power laws from the underlying 1D theory can predict the transition temperature and order parameter correctly for all interaction strengths. Using a combination of large-scale Quantum Monte-Carlo simulations and chain mean-field calculations, we show that the behavior of the ordering temperature as a function of inter-chain coupling strength does not follow a universal powerlaw, but also depends strongly on the filling. [1] A. Vogler, R. Labouvie, G. Barontini, S. Eggert, V. Guarrera, and H. Ott, Phys. Rev. Lett. 113, 215301 (2014)

**9:48AM R50.00008 Solving a quantum many-body problem by experiment**, THOMAS SCHWEIGLER, Vienna Center for Quantum Science and Technology, Atominstitut, TU Wien, VALENTIN KASPER, Institut für Theoretische Physik, Universität Heidelberg, SEBASTIAN ERNE, BERNHARD RAUER, TIM LANGEN, Vienna Center for Quantum Science and Technology, Atominstitut, TU Wien, THOMAS GASENZER, Kirchhoff-Institut für Physik, Universität Heidelberg, JÜRGEN BERGES, Institut für Theoretische Physik, Universität Heidelberg, JÖRG SCHMIEDMAYER, Vienna Center for Quantum Science and Technology, Atominstitut, TU Wien — We experimentally study a pair of tunnel-coupled one-dimensional atomic superfluids, which realize the quantum sine-Gordon/massive Thirring models relevant for a wide variety of disciplines from particle to condensed-matter physics. From measured interference patterns we extract phase correlation functions and analyze if, and under which conditions, the higher-order correlation functions factorize into lower ones. This allows us to characterize the essential features of the model solely from our experimental measurements, detecting the relevant quasiparticles, their interactions and the topologically distinct vacua. Our method provides comprehensive insights into a non-trivial quantum field theory and establishes a general method to analyze quantum many-body systems through experiments. The method is also used to investigate the non-equilibrium dynamics following a quench in the tunnel-coupling between the superfluids.

**10:00AM R50.00009 Meissner and Laughlin Phases in bosonic Ladders**, ALEXANDRU PETRESCU, Princeton University, Department of Electrical Engineering, MARIE PIRAUD, Department of Physics and Arnold Sommerfeld Center for Theoretical Physics, Ludwig-Maximilians-Universität München, IAN MCCULLOCH, ARC Centre for Engineered Quantum Systems, School of Mathematics and Physics, The University of Queensland, GUILLAUME ROUX, LPTMS, Univ. Paris-Sud and CNRS, UMR 8626, KARYN LE HUR, CPHT and CNRS, Ecole Polytechnique — We introduce a hard core boson model on a ladder lattice in uniform orbital magnetic flux. This model supports the Meissner effect in the presence of insulating behavior [1,2,3]. When the ratio of particle and flux densities  $\nu$  is close to  $1/2$ , the ground state is a low-dimensional equivalent of the Laughlin state of fractional quantum Hall effect [3]. Using exact analytical methods, the density matrix renormalization group method and exact diagonalization, we identify local observables that distinguish the Laughlin phase from the surrounding vortex and Meissner phases. At  $\nu = 1/2$  the antisymmetric current, currently accessible in ultracold atom experiments [5,6], saturates. Thus remnants of topological order in quasi one dimensional systems can be probed using local observables. Secondly, we show how ground state degeneracy and topology can be probed with Thouless pump experiments on the ladder geometry. [1] A. Petrescu and K. Le Hur, PRL 111, 150601 [2] M. Piraud, F. Heidrich-Meisner, I. P. McCulloch, S. Greschner, T. Vekua, and U. Schollwöck, PRB 91, 140406R [3] A. Petrescu and K. Le Hur, PRB 91, 054520 [4] M. Atala et al, Nat. Phys. 10, 588; B. K. Stuhl et al, Science 349, 1514; M. Mancini et al, Science 349, 1510.

**10:12AM R50.00010 Entanglement entropy of the ground state of the Lieb-Liniger model**, c. M. HERDMAN, P.-N. ROY, University of Waterloo, ROGER MELKO, University of Waterloo and Perimeter Institute for Theoretical Physics, ADRIAN DEL MAESTRO, University of Vermont — We consider the entanglement between two spatial subsystems in the Lieb-Liniger model of contact interacting bosons in continuous space in one dimension. Using a continuous-space ground state path integral quantum Monte Carlo method, we numerically compute the Rényi entropy of the reduced density matrix of the subsystem as a measure of entanglement. Our numerical algorithm is based on the replica method previously introduced by the authors, which we have extended to efficiently study large spatial subsystems using a ratio approach. We confirm a logarithmic scaling of the Rényi entropy with subsystem size that is expected from conformal field theory and compute the non-universal sub-leading constant for interaction strengths ranging over several orders of magnitude. In the strongly interacting limit, we find agreement with the known free fermion result.

**10:24AM R50.00011 Diagrammatic Monte Carlo study of Fermi-polaron systems**, PETER KROISS, LODE POLLET, Department of Physics, Arnold Sommerfeld Center for Theoretical Physics and Center for NanoScience, Ludwig-Maximilians-University Munich — We apply the diagrammatic Monte Carlo approach to three-dimensional Fermi-polaron systems with mass-imbalance, where an impurity interacts resonantly with a noninteracting Fermi sea whose atoms have a different mass. This method allows to go beyond frequently used variational techniques by stochastically summing all relevant impurity Feynman diagrams up to a maximum expansion order limited by the sign problem. Polaron energy and quasiparticle residue can be accurately determined over a broad range of impurity masses. The quantitative exactness of two-particle-hole wave-functions is investigated, resulting in a relative lowering of polaronic energies in the mass-imbalance phase diagram. The application of the method to two-dimensional Fermi-polaron systems is presented.

**10:36AM R50.00012 Recent developments in auxiliary-field quantum Monte Carlo methods for cold atoms<sup>1</sup>**, HAO SHI, PETER ROSENBERG, ETTORE VITALI, SIMONE CHIESA, SHIWEI ZHANG, College of William and Mary — Exact calculations are performed on the two-dimensional strongly interacting, unpolarized, uniform Fermi gas with a zero-range attractive interaction. We describe recent advances in auxiliary-field quantum Monte Carlo techniques, which eliminate an infinite variance problem in the standard algorithm, and improve both acceptance ratio and efficiency. The new methods enable calculations on large enough lattices to reliably compute ground-state properties in the thermodynamic limit. An equation of state is obtained, with a parametrization provided, which can serve as a benchmark and allow accurate comparisons with experiments. The pressure, contact parameter, condensate fraction, and pairing gap will be presented. The same methods are also applied to obtain exact results on the two-dimensional strongly interacting Fermi gas in the presence of Rashba spin-orbit (SOC), providing insights on the interplay between pairing and SOC.

**10:48AM R50.00013 Multiband effects in one-dimensional bosons in optical lattices**, WEI XU, MARCOS RIGOL, Department of Physics, The Pennsylvania State University, University Park, PA 16802, USA — We use path integral quantum Monte Carlo simulations to study quantum phase transitions of ultracold bosons in optical lattices. We restrict our study to one-dimensional systems where, in the absence of the lattice, we recover analytic results for the Lieb-Liniger model. The latter is the model that describes one-dimensional bosons with contact interactions. We first discuss how cold finite systems need to be in order for one to observe ground state physics. We then show that, in shallow lattice potentials, higher Bloch bands lead to renormalized two-body interactions. We present a study the phase diagram of these systems at intermediate interaction strengths in shallow lattice potentials, and report a detailed comparison with the phase diagram of the one-band Bose-Hubbard model.

**8:00AM R52.00001 Azobenzene-based Polymers for Solar Thermal Batteries** , DHANDAPANI VENKATARAMAN, University of Massachusetts Amherst — Azobenzene exists as two isomers, a higher energy cis-isomer and a lower energy trans-isomer. The isomers interconvert under light or heat. Recently, there is a renewed interest in capturing the difference in the energies of the isomers and using azobenzene-based molecules as active layers for solar thermal batteries. My research group has been exploring azobenzene-based polymers as candidates for solar thermal batteries. In this talk, I will show that the azo-benzene moieties can be converted to the cis-form using light and converted back to the trans form using mechanical force. I will provide some of our recent results that indicate that high energy densities can be achieved in these polymers.

**8:36AM R52.00002 Lithiation of  $\text{Ag}_x\text{MnO}_2$ : Insights from first principles** , MERZUK KALTAK, MARIVI FERNANDEZ-SERRA, State Univ of NY- Stony Brook, MARK HYBERTSEN, Center for Functional Nanomaterials, Brookhaven National Laboratory — Stable electrode materials being able to capture high lithium concentrations are attracting considerable interest in science as well as industry. Recently hollandite  $\alpha\text{-MnO}_2$  based structures are moving into the focus of electrochemists and are considered to be promising electrodes for increasing the capacity and efficiency of rechargeable lithium batteries. These favorable properties are mainly due to the tunnel structure consisting out of stacked  $1\times 1$  and  $2\times 2$   $\text{MnO}_2$  octahedra in the z-axis. It has been shown that large ions such as silver or potassium can stabilize and increase the cyclicity of pure hollandite  $\alpha\text{-MnO}_2$  considerably. In this work we present new insights from first principles for lithiated silver hollandite  $\text{Li}_y\text{Ag}_x\text{MnO}_2$  and demonstrate that the formation of oxygen vacancies play an important role for lithium diffusion.

**8:48AM R52.00003 First Principles Investigation of the Geometrical and Electrochemical Properties of  $\text{Na}_4\text{P}_2\text{S}_6$  and  $\text{Li}_4\text{P}_2\text{S}_6$** <sup>1</sup> , LARRY E. RUSH JR., N.A.W. HOLZWARTH, Wake Forest University — First principles simulations are used to examine the structural and physical properties of  $\text{Na}_4\text{P}_2\text{S}_6$  in comparison with its  $\text{Li}_4\text{P}_2\text{S}_6$  analog. Four model structures are considered including the  $C2/m$  structure recently reported by Kuhn and co-workers<sup>2</sup> from their analysis of single crystals of  $\text{Na}_4\text{P}_2\text{S}_6$ , and three structures related to the  $P6_3/mcm$  structure with P site disorder found in 1982 by Mercier and co-workers<sup>3</sup> from their analysis of single crystals of  $\text{Li}_4\text{P}_2\text{S}_6$ . The computational results indicate that both  $\text{Na}_4\text{P}_2\text{S}_6$  and  $\text{Li}_4\text{P}_2\text{S}_6$  have the same disordered ground state structures consistent with the  $P6_3/mcm$  space group, while the optimized  $C2/m$  structures have higher energies by 0.1 eV and 0.4 eV per formula unit for  $\text{Na}_4\text{P}_2\text{S}_6$  and  $\text{Li}_4\text{P}_2\text{S}_6$ , respectively. Simulations of ion migration suggest that  $\text{Na}_4\text{P}_2\text{S}_6$  may have more favorable ionic conductivity compared to  $\text{Li}_4\text{P}_2\text{S}_6$ .

**9:00AM R52.00004 Quinone Derivatives for Lithium-Ion Batteries: First-Principles Density Functional Theory Modeling** , SEUNG SOON JANG, KI CHUL KIM, School of Materials Science and Engineering, Georgia Institute of Technology, Atlanta, GA 30332-0245, USA, TIANYUAN LIU, SEUNG WOO LEE, G. W. Woodruff School of Mechanical Engineering, Georgia Institute of Technology, Atlanta, GA 30332-0405, USA — The Li binding thermodynamics and redox potentials of seven different quinone derivatives are investigated as positive electrode candidates for lithium-ion batteries. First, using the density functional theory (DFT) calculations on the interactions between the quinone derivatives and Li ions, it is found that Li ions are dominantly bound with carbonyl groups of the molecules. Second, it is revealed that the redox chemistry of the quinone derivatives can be tuned by the modification of their chemical structures. Further DFT-based investigations on the redox potentials of the Li-bound quinone derivatives provide an insight on the change in their redox chemistry during the discharging processes. The redox potential and charge capacity are improved by modifying the quinone derivatives with electron-withdrawing carboxylic groups. Through this study, it is also found that the cathodic activity of a quinone derivative during the discharging processes strongly relies on the solvation free energy effect as well as the number of available carbonyl groups for further Li binding. To the best of our knowledge, the changes in the redox potential of the redox-active molecules during the discharging processes is reported for the first time.

**9:12AM R52.00005 Lithiation of  $\text{Li}_2\text{SnO}_3$  and  $\text{Li}_2\text{SnS}_3$  in context of Li-ion battery materials**<sup>1</sup> , JASON HOWARD, N. A. W. HOLZWARTH, Wake Forest University — The closed pack layered crystal material (space group 15 ( $C2/c$ ))  $\text{Li}_2\text{SnO}_3$  has been studied as a possible anode material since the late 1990s.<sup>2,3,4</sup> The material undergoes an irreversible decomposition to  $\text{Li}_2\text{O}$  and  $\text{Li}_x\text{Sn}$  alloys during the first lithiation cycle. The crystal material  $\text{Li}_2\text{SnS}_3$  of the same structure was recently proposed as an electrolyte material.<sup>5</sup> The question is posed whether  $\text{Li}_2\text{SnS}_3$  would be a good electrolyte or whether it could function as an anode material similar to  $\text{Li}_2\text{SnO}_3$ . In this research a model is proposed for the lithiation process of  $\text{Li}_2\text{SnO}_3$  and  $\text{Li}_2\text{SnS}_3$ ;  $\text{Li} - \text{Li}_2\text{SnS}_3$  interfaces are also examined. The results show  $\text{Li}_2\text{SnO}_3$  begins to decompose at approximately  $\text{Li}_{2+0.5}\text{SnO}_3$ . In  $\text{Li}_2\text{SnS}_3$  the lithiation process shows it can lithiate to  $\text{Li}_{2+1}\text{SnS}_3$  without significant lattice distortion, volume expansion, or decomposition.  $\text{Li} - \text{Li}_2\text{SnS}_3$  interfaces are shown to be unstable, showing the formation of  $\text{Li}_2\text{S}$ .

**9:24AM R52.00006 Accelerated materials design of fast oxygen ionic conductors based on first principles calculations** , XINGFENG HE, YIFEI MO, Department of Materials Science and Engineering, University of Maryland, College Park — Over the past decades, significant research efforts have been dedicated to seeking fast oxygen ion conductor materials, which have important technological applications in electrochemical devices such as solid oxide fuel cells, oxygen separation membranes, and sensors. Recently,  $\text{Na}_{0.5}\text{Bi}_{0.5}\text{TiO}_3$  (NBT) was reported as a new family of fast oxygen ionic conductor. We will present our first principles computation study aims to understand the O diffusion mechanisms in the NBT material and to design this material with enhanced oxygen ionic conductivity. Using the NBT materials as an example, we demonstrate the computation capability to evaluate the phase stability, chemical stability, and ionic diffusion of the ionic conductor materials. We reveal the effects of local atomistic configurations and dopants on oxygen diffusion and identify the intrinsic limiting factors in increasing the ionic conductivity of the NBT materials. Novel doping strategies were predicted and demonstrated by the first principles calculations. In particular, the K doped NBT compound achieved good phase stability and an order of magnitude increase in oxygen ionic conductivity of up to  $0.1 \text{ S cm}^{-1}$  at 900 K compared to the experimental Mg doped compositions. Our results provide new avenues for the future design of the NBT materials and demonstrate the accelerated design of new ionic conductor materials based on first principles techniques. This computation methodology and workflow can be applied to the materials design of any (e.g.  $\text{Li}^+$ ,  $\text{Na}^+$ ) fast ion-conducting materials.

**9:36AM R52.00007 TiC<sub>2</sub>: A New Two-Dimensional Sheet beyond MXenes**, TIANSHAN ZHAO, Virginia Commonwealth Univ, SHUNHONG ZHANG, YAGUANG GUO, QIAN WANG, Peking University — MXenes are attracting attention due to their rich chemistry and intriguing properties. Here a new type of metal-carbon-based sheet composed of transition metal centers and C<sub>2</sub> dimers rather than individual C atoms is designed. Taking the Ti system as a test case, density functional theory calculations combined with a thermodynamic analysis uncover the thermal and dynamic stability of the sheet, as well as a metallic band structure, anisotropic Young's modulus and Poisson's ratio, a high heat capacity, and a large Debye stiffness. Moreover, the TiC<sub>2</sub> sheet has excellent Li storage capacity with a small migration barrier, a lower mass density compared with standard MXenes, and better chemical stability as compared to the MXene Ti<sub>2</sub>C sheet. When Ti is replaced with other transition metal centers, diverse new MC<sub>2</sub> sheets containing C=C dimers can be formed, the properties of which merit further investigation.

**9:48AM R52.00008 Diffusion of lithium in titanium oxide**, PATRICK SHEA, Dalhousie University, JIANCHAO YE, BRANDON WOOD, STANIMIR BONEV, Lawrence Livermore National Laboratory — Titanium oxide has generated interest lately as a promising anode candidate for use in lithium-ion batteries. We report first principles calculations on the mobility of lithium atoms in both crystalline and amorphous phases of titanium oxide. Density functional theory calculations of structural properties and diffusion energy barriers are combined with rate theory and a lattice gas model to study diffusion of lithium over a range of concentrations. A summary of results, including significant differences in the mobility between amorphous and crystalline phases, will be presented and discussed.

**10:00AM R52.00009 Computational modeling of the structure and the ionic conductivity of the solid electrolyte materials Li<sub>3</sub>AsS<sub>4</sub> and its Ge substitutions<sup>1</sup>**, AHMAD AL-QAWASMEH, N. A. W. HOLZWARTH, Wake Forest University — Oak Ridge National Laboratory (G. Sahu et al.)<sup>2</sup> reported that the substitution of Ge into Li<sub>3</sub>AsS<sub>4</sub> leads to the composition Li<sub>3.334</sub>Ge<sub>0.334</sub>As<sub>0.666</sub>S<sub>4</sub> with impressively high ionic conductivity. We use ab initio calculations to examine the structural relationships and the ionic conductivity mechanisms for pure Li<sub>3</sub>AsS<sub>4</sub>, Li<sub>3.334</sub>Ge<sub>0.334</sub>As<sub>0.666</sub>S<sub>4</sub>, and other compositions of these electrolytes.

**10:12AM R52.00010 Kinetics and Mechanism of Proton Transfer in Molten Lithium Carbonate: Insights from Static and Dynamic DFT Studies**, XUELING LEI, Benedict College, KEVIN HUANG, University of South Carolina, CHANGYONG QIN, Benedict College — Using static and dynamic DFT methods and a cluster model, the mechanism and kinetics of proton transfer in lithium molten carbonate (MC) were investigated. The migration of proton prefers an inter-carbonate pathway with an energy barrier of 8.0 kcal/mol. At TS, a linkage of O—H—O involving O 2p and H 1s orbitals is formed between two carbonate ions. It is noticeable that the solvation of proton in an ionic liquid is beyond the capacity of a simple cluster model and that the FPMD method is more suitable for such a molecular system. Corrections on the calculated energies using an extracted cluster were performed and the results displayed good consistency with the value of 7.6 kcal/mol and 7.8 kcal/mol from experiment and FPMD simulation, respectively. The calculated trajectory of H indicates that proton has a good mobility in MC, while both carbon and oxygen only move slightly to facilitate the proton migration. Small geometric variations were observed on all involved ions, not just on the local structure where the proton transfer occurs, implying a synergetic process. A better description of this synergetic step can be displayed in the Lewis diagram. Overall, the results indicate that the combination of the static and dynamic DFT methods is of great advantages in treating such ionic liquid systems and can improve the reliability of the calculated results.

**10:24AM R52.00011 A formalism for modeling solid electrolyte/electrode interfaces using first principles methods<sup>1</sup>**, NICHOLAS LEPLEY, Wake Forest Univ, NATALIE HOLZWARTH, Wake Forest University — We describe a scheme based on the interface energy for analyzing interfaces between crystalline solids, quantitatively including the effect of lattice strain. This scheme is applied to the modeling of likely interface geometries of several solid state battery materials including Li metal, Li<sub>3</sub>PO<sub>4</sub>, Li<sub>3</sub>PS<sub>4</sub>, Li<sub>2</sub>O, and Li<sub>2</sub>S. We find that all of the interfaces in this study are stable with the exception of Li<sub>3</sub>PS<sub>4</sub>/Li. For this chemically unstable interface, the partial density of states helps to identify mechanisms associated with the interface reactions. We also consider the case of charged defects at the interface, and show that accurately modeling them requires a careful treatment of the resulting electric fields. Our energetic measure of interfaces and our analysis of the band alignment between interface materials indicate multiple factors which may be predictors of interface stability, an important property of solid electrolyte systems.

**10:36AM R52.00012 Hexagonal BC<sub>3</sub> as a Robust Electrode Material for Li, Na, and K Ion Batteries<sup>1</sup>**, RAJENDRA JOSHI, Department of Physics and Science of Advanced Materials, Central Michigan University, Mount Pleasant, MI, 48859, USA, BURAK ÖZDEMİR, Science of Advanced Materials, Central Michigan University, Mount Pleasant, MI, 48859, USA, JUAN PERALTA, VERONICA BARONE, Department of Physics and Science of Advanced Materials, Central Michigan University, Mount Pleasant, MI, 48859, USA — We propose hexagonal BC<sub>3</sub> as a robust electrode material for Li, Na, and K ion batteries based on first-principles density functional theory calculations. We show that, by intercalating Li, Na, and K in BC<sub>3</sub>, it is possible to form Li<sub>1.5</sub>BC<sub>3</sub>, Na<sub>1</sub>BC<sub>3</sub>, and K<sub>1.5</sub>BC<sub>3</sub> which correspond to a high theoretical capacity of 858 mA h/g, 572 mA h/g, 858 mA h/g, respectively. In addition, this material presents small open circuit voltage variations of 0.49, 0.12, and 0.16 V when used as electrode for Li, Na, and K ion batteries, respectively.

<sup>1</sup>NSF CBET-1335944, NSF DMR-0906617, DOE DE-FG02-10ER16203

**10:48AM R52.00013 Computational Investigation of Chevrel Phase Cathodes for Ca<sup>2+</sup> Ion Batteries**, MANUEL SMEU, Binghamton University - SUNY — While batteries employing Li ions are best suited for applications where portability is important, less expensive alternatives may be employed when size and weight are less critical. Batteries utilizing Ca ions have received very little attention to date due to difficulties in identifying adequate anode materials and electrolytes, although advancements have been made on both fronts. If these challenges can be overcome, Ca can offer an abundant and affordable alternative to Li for grid storage and in other applications where portability is not a priority. For such technologies, appropriate cathodes need to be identified that will allow for reversible intercalation of Ca<sup>2+</sup> ions and that can provide a desirable voltage. To this end, we investigate the Chevrel phase (CP) compounds Mo<sub>6</sub>X<sub>8</sub> (X = S, Se, Te), which can intercalate Mg<sup>2+</sup> and Ca<sup>2+</sup>, among many other ions. We use density functional theory (DFT) to calculate the voltage profiles of various guest intercalation ions (Mg, Ca, Sr, Ba) in the CP material. The electronic properties of this material will be discussed, along with the capacity and the energetics associated with ions diffusing through the CP structure. This work also offers insights into how the cathode properties may be fine-tuned by carefully selecting its constituents.

**11:00AM R52.00014 Investigation of ionic transport in sodium scandium phosphate (NSP) and related compounds**, KAUSTUBH BHAT, STEFAN BLÜGEL, HANS LUSTFELD, Peter Grünberg Institut (PGI-1) and Institute for Advanced Simulation (IAS-1), Forschungszentrum Jülich GmbH, D-52425 Jülich, Germany — Sodium ionic conductors offer significant advantages for application in large scale energy storage systems. In this study, we investigate the different pathways available for sodium ion conduction in NSP and calculate energy barriers for ionic transport using Density Functional Theory (DFT) and the Nudged Elastic Band Method [2]. We identify the structural parameters that reduce the energy barrier, by calculating the influence of positive and negative external pressure on the energy barrier [3]. Lattice strain can be introduced by cation or anion substitution within the NASICON structure. We substitute the scandium atom with other trivalent atoms such as aluminium and yttrium, and calculate the resulting energy barriers. Sodium thiophosphate ( $Na_3PS_4$ ) has previously shown about two orders of magnitude higher ionic conductivity than sodium phosphate ( $Na_3PO_4$ ) [4]. We investigate the effect of substituting oxygen with sulphur in NSP. We acknowledge discussions with our experimental colleagues F. Tietz and M. Guin toward this work. **11:12AM R52.00015 Effects on the optical properties of titanium dioxide by doping with sulfur**, JORGE HERNANDEZ ZELEDON, JAMES LEWIS, West Virginia University —  $TiO_2$  is an attractive material for photocatalytic and photovoltaic applications like water splitting or self cleaning surfaces, but its maximum absorption happens around 4 eV, and the sunlight irradiance peak is between 1.5eV and 3.1eV. In this work we look for the effects of doping  $TiO_2$  with sulfur, as one way to reduce the gap between the conduction and the valence states, in order to increase the efficiency of Sun light absorption. To modify the optic properties we took the  $TiO_2$  rutile structure as basis for random substitutions, in which we randomly select some oxygen atoms and we replace them with sulfur, making  $TiO_2(1-x)S_2x$  for  $x = 0.1$  and  $x = 0.25$ . Here we present our results for the computational calculations of the band gap and absorption as function of concentration. All the process and calculations are made using the FIREBALL software.

**Thursday, March 17, 2016 8:00AM - 11:00AM –**  
**Session R53 FEd FIAP: Building New Pathways in Physics Innovation and Entrepreneurship Education** Hilton Baltimore Holiday Ballroom 4 - Job Ganem, Loyola University Maryland

**8:00AM R53.00001 Tinker, Thinker, Maker and CEO: Reimagining the Physics Student as Engineer, Inventor, and Entrepreneur**, CRYSTAL BAILEY, American Physical Society — Physics degree holders are among the most employable in the world, often doing everything from managing a research lab at a multi-million dollar corporation, to developing solutions to global problems in their own small startups. Employers know that with a physics training, a potential hire has acquired a broad problem-solving skill set that translates to almost any environment, as well as an ability to be self-guided and -motivated so that they can learn whatever skills are needed to successfully achieve their goals. Therefore it's no surprise that the majority of physics graduates find employment in private sector, industrial settings. Yet at the same time, only about 25% of graduating PhDs will take a permanent faculty position—while academic careers are usually the only track to which students are exposed while earning their degrees. In this talk, I will examine the role of physicist as innovator and how this role intersects with other similar STEM disciplines (such as engineering), and provide some insight into how implementing physics innovation and entrepreneurship (PIE) education will benefit both physics departments and the students they serve, regardless of students' eventual career choices. Additionally, I will provide resources to help faculty mentors give their students better information and training for a broader scope of career possibilities, and information about how educators can get involved in the growing community of PIE educators.

**8:36AM R53.00002 Impact of the Joint Task Force on Undergraduate Physics Programs for Innovation and Entrepreneurship Education in Physics**, DOUGLAS ARION, Carthage College and Galileoscope LLC — The Joint Task Force on Undergraduate Physics Programs has worked diligently to develop recommendations for what physics programs could and should be doing to prepare graduates for 21st century careers. While the 'traditional' physics curriculum has served for many years, the demands of the new workforce, and the recognition that only a few percent of physics students actually become faculty - the vast majority entering the workforce and applying their skills to a very diverse range of problems, projects, and products - implies that a review of the education undergraduates receives is in order. The outcomes of this study point to the need to provide greater connection between the education process and the actual skills, knowledge, and abilities that the workplace demands. This presentation will summarize these considerations, and show how entrepreneurship and innovation programs and curricula are a particularly effective means of bringing these elements to physics students.

**9:12AM R53.00003 Introducing a Framework for Physics Innovation and Entrepreneurship (PIE) Education.**<sup>1</sup>, BAHRAM ROUGHANI, Loyola University Maryland — A desired outcome for Physics Innovation and Entrepreneurship (PIE) education is preparing physics majors with an innovative and entrepreneurial mindset who are capable of opportunity recognition and adept in leveraging physics knowledge to address specific needs. Physics as a discipline is well-recognized to prepare students who become problem solvers and critical thinkers, gifted in dealing with abstract ideas and ambiguities in the context of complex and real-world problems. These characteristics when enhanced through appropriate combinations of curricular, co-curricular, and extra-curricular programs can prepare physics majors for careers and future challenges that may involve translating physics knowledge into useful products and services either as part of a technical team within an organization or through startups. A viable PIE education model prepares graduates for various career paths in addition to the traditional options such as pursuing graduate studies or becoming a science teacher. Having a well-defined "third option" for physics will benefit the robustness of the physics discipline through recruitment and retention of prospective students who in principle are interested in physics as a subject, but in practice they may overlook physics as their preferred major primarily because they are uncertain about a viable career path based on an undergraduate physics education.

<sup>1</sup>The "Pathways to Innovation" at Loyola is established based on the program developed by VentureWell and Epicenter (NSF Supported).

**9:48AM R53.00004 Resources to Support Physicists as Versatile and Progressive Innovators**, RANDALL TAGG, University of Colorado Denver — Physicists are trained first with broad fundamental knowledge and then through experience with exquisitely refined and specialized models and instrumentation. This is a superb platform from which to address real-world problems when it is augmented by ready access to additional practical resources. We have explored a systematic three-part approach to providing those resources: (1) creating an organized environment that stockpiles technical artifacts, tools, and instruments; (2) developing curriculum for on-demand learning of new technical competencies; (3) providing a community of like-minded physicists who enjoy connecting physics with innovation. For physicists early in their training or careers, we hope that this is a particularly attractive basis for exploring a wider range of professional options.

**10:24AM R53.00005 Lessons Learned in Student Venture Creation** , EDWARD CANER, Case Western Reserve University — The Physics Entrepreneurship Master's Program (PEP) at Case Western Reserve University is now in its 15th year of operation. PEP is a 27 credit-hour Master of Science in Physics, Entrepreneurship Track. The curriculum can be tailored to the needs of each student. Coursework consists of graduate-level classes in science, business, intellectual property law, and innovation. A master's thesis is required that is based on a real-world project in innovation or entrepreneurship within an existing company or startup (possibly the student's). PEP faculty help students connect with mentors, advisors, partners, funding sources and job opportunities. In this talk I will chronicle several pitfalls that we have encountered with our "real world" student projects and start-up businesses, several of which met their complete demise despite showing great promise for success. I will discuss how we have learned to avoid most of these pitfalls by taking surprisingly simple actions.

**10:36AM R53.00006 Advancing Successful Physics Majors - The Physics First Year Seminar Experience.** , JASON DEIBEL<sup>1</sup>, DOUGLAS PETKIE<sup>2</sup>, Wright State University — In 2012, the Wright State University physics curriculum introduced a new year-long seminar course required for all new physics majors. The goal of this course is to improve student retention and success via building a community of physics majors and provide them with the skills, mindset, and advising necessary to successfully complete a degree and transition to the next part of their careers. This new course sequence assembles a new cohort of majors annually. To prepare each cohort, students engage in a variety of activities that span from student success skills to more specific physics content while building an entrepreneurial mindset. Students participate in activities including study skills, career night, course planning, campus services, and a department social function. More importantly, students gain exposure to programming, literature searches, data analysis, technical writing, elevator pitches, and experimental design via hands-on projects. This includes the students proposing, designing, and conducting their own experiments. Preliminary evidence indicates increased retention, student success, and an enhanced sense of community among physics undergraduate students. The overall number of majors and students eventually completing their physics degrees has nearly tripled.

<sup>2</sup>Chair, Department of Physics

**10:48AM R53.00007 Towson University's Professional Science Master's Program in Applied Physics: The first 5 years<sup>1</sup>** , RAJESWARI KOLAGANI, Towson University — It is a well-established fact that the scientific knowledge and skills acquired in the process of obtaining a degree in physics meet the needs of a variety of positions in multiple science and technology sectors. However, in addition to scientific competence, challenging careers often call for skills in advanced communication, leadership and team functions. The professional science master's degree, which has been nick-named as the 'Science MBA', aims at providing science graduates an edge both in terms of employability and earning levels by imparting such skills. Our Professional Science Master's Program in Applied Physics is designed to develop these 'plus' skills through multiple avenues. In addition to advanced courses in Applied Physics, the curriculum includes graduate courses in project management, business and technical writing, together with research and internship components. I will discuss our experience and lessons learned over the 5 years since the inception of the program in 2010.

<sup>1</sup>The author acknowledges support from the Elkins Professorship of the University System of Maryland

**Session R55 FPS DBIO: The War on Cancer: Physics Enters the Fray** Hilton Baltimore Holiday Ballroom  
6 - Arian Pregoner, Sandia National Laboratories

**8:00AM R55.00001 Why is Physics Important to Cancer Research?** , ANNA D. BARKER, Director, Transformative Healthcare Networks — Cancer is increasingly described as a "disease of the genes", and while the genome (in fact all of the omes) are important information molecules that drive aspects of the initiation and progression of cancer, they are far from the whole story. Cancer is an extraordinarily complex system (in fact a complex of systems) that occurs in three-dimensional space, across multiple scales and often over extended periods of time. The most challenging issues that plague the cancer field such as metastasis, cellular heterogeneity and resistance to therapy are in large part more rationally explained in the context of the physics of these systems vs. genomics. For example, the biology of metastasis has been studied extensively for decades with little progress. Metastatic disease depends on cells acquiring (or expressing innate information) new properties that enable and sustain their ability to migrate to distant sites. Developing a fundamental understanding of key cancer processes ranging from metastasis to immunotherapeutic responses requires that physicists (and mathematicians and engineers) be integrated into a new generation of cancer research period! The presentation will focus on those areas where physics is essential and the hows and whos of achieving the integration required.

**8:36AM R55.00002 Evolution, Physics, and Cancer: Disrupting Traditional Approaches** , ROBERT AUSTIN, Princeton University — Physicists who were recruited to try and assist with the stubbornly constant mortality rates of cancer world-wide over the past 100 years have basically had the invitation withdrawn by the oncology community. The oncologists became annoyed with the independence of thought and the skepticism of some physicists with continuation of the present paradigm of the cancer genome as the rosette stone as the key to cancer. To quote a recent letter in Physics Today: "Curing cancer is a complex biological problem to be solved by biologists". Apparently our mission as minions is to be high-level technicians. But I think that is wrong and will lead to continuation of the string of failures and deceptions foisted on the public at large by the Medical Industrial Complex. I think we really need to re-think cancer as a phenomena which is driven by evolution and may be desired by the organism and be a product of both the aging of the proteome and the genome. Further, searching for mutations (The Cancer Genome) may be completely the wrong direction, searching for protected genes may be as important as looking for mutated genes. I'll try to present the case that physicists should not have been kicked out of the Medical Industrial Complex that keeps the cancer business humming and profitable.

**9:12AM R55.00003 Theoretical Physics and Cancer Research** , KRISTIAN B. BLAGOEV, Physics Div., National Science Foundation, Arlington, VA and Dept., of Biophysics, Johns Hopkins University, Baltimore, MD — Cancer is a multifaceted disease which involves profound disruptions to biological mechanisms and structures that have evolved since the beginning of life. The most dramatic change is the failure of multicellularity and organ homeostasis. Time and time again, this complex disease has evaded the silver bullet cure attempts that rely on simple strategies including targeting dividing cells with broad acting chemotherapies, using radiation to cause DNA damage, and using molecular targeting agents. Even the most recent efforts, such as using immune stimulating agents and activated immune cells, are missing the mark. Against all these efforts, the cancer, even if it retreats, usually returns and often then does not respond to any of our available arsenal. The origin of this persistence is the robustness of life itself. During the past 4 billion years, life has survived many dramatic events and living organisms can be found in the most hostile places on Earth. Based on my research and on analysis of outcomes from several meetings between physicists and cancer researchers, organized by the National Science Foundation, I will argue that we need to integrate theoretical physics approaches to understand the emergence of resistance to treatment and to develop robust and curative interventions in cancer. The adaptive response of living systems to external and internal changes involve many interacting parts and networks. Phenomenological and reductionist approaches must be used synergistically to understand the phenomena at the appropriate spatial and temporal scales. This approach has been successful in understanding inanimate matter in the Universe and should be used in understanding animate matter as well and in particular cancer. I will also argue that public-private partnerships can speed up the process and bring innovation to transform the field.

**9:48AM R55.00004 Information, Physics, and Cancer** , CHRIS ADAMI, Michigan State University — Many researchers have doubts that a "theory of cancer" can exist, given the fact that there are so many different cancer phenotypes. However, such a situation—many significantly different manifestations of an underlying law—is not at all uncommon in physics. I argue that a unified cause for all forms of cancer is possible, but that such a theory must be cast in terms of information and communication theory. I briefly revisit key concepts of that theory, then discuss possible applications to communication in game theory that could lead us to view cancer as a disease that, at its root, is a cellular failure to properly communicate.

**10:24AM R55.00005 The National Cancer Institute's Physical Sciences - Oncology Network** , MICHAEL GRAHAM ESPEY, National Cancer Institute — In 2009, the NCI launched the Physical Sciences - Oncology Centers (PS-OC) initiative with 12 Centers (U54) funded through 2014. The current phase of the Program includes U54 funded Centers with the added feature of soliciting new Physical Science - Oncology Projects (PS-OP) U01 grant applications through 2017; see NCI PAR-15-021. The PS-OPs, individually and along with other PS-OPs and the Physical Sciences-Oncology Centers (PS-OCs), comprise the Physical Sciences-Oncology Network (PS-ON). The foundation of the Physical Sciences-Oncology initiative is a high-risk, high-reward program that promotes a 'physical sciences perspective' of cancer and fosters the convergence of physical science and cancer research by forming transdisciplinary teams of physical scientists (e.g., physicists, mathematicians, chemists, engineers, computer scientists) and cancer researchers (e.g., cancer biologists, oncologists, pathologists) who work closely together to advance our understanding of cancer. The collaborative PS-ON structure catalyzes transformative science through increased exchange of people, ideas, and approaches. PS-ON resources are leveraged to fund Trans-Network pilot projects to enable synergy and cross-testing of experimental and/or theoretical concepts. This session will include a brief PS-ON overview followed by a strategic discussion with the APS community to exchange perspectives on the progression of trans-disciplinary physical sciences in cancer research.

**Thursday, March 17, 2016 11:15AM - 2:15PM —**  
**Session S1 DCMP: Topological Mysteries in Kondo Insulating SmB<sub>6</sub>** Ballroom I - Lu Li, University of Michigan

**11:15AM S1.00001 Topologically protected surface states in SmB<sub>6</sub>** , JING XIA, University of California, Irvine — No abstract available.

**11:51AM S1.00002 Two-dimensional Fermi surfaces in Kondo insulating SmB<sub>6</sub>** , GANG LI, University of Michigan — There has been renewed interest in Samarium Hexaboride, which is a strongly correlated heavy Fermion material. Hybridization between itinerant electrons and localized orbitals lead to an opening of charge gap at low temperature. However, the resistivity of SmB<sub>6</sub> does not diverge at low temperature. Former studies suggested that this residual conductance is contributed by various origins. Recent theoretical developments suggest that the particular symmetry of energy bands of SmB<sub>6</sub> may host a topologically non-trivial surface state, i.e., a topological Kondo insulator. To probe the Fermiology of the possible metallic surface state, we use sensitive torque magnetometry to detect the de Haas van Alphen (dHvA) effect due to Landau level quantization on flux-grown crystals, down to He-3 temperature and up to 45 Tesla. Our angular and temperature dependent data suggest two-dimensional Fermi Surfaces lie in both crystalline (001) and (101) surface planes of SmB<sub>6</sub>.

**12:27PM S1.00003 Unconventional bulk three-dimensional Fermi surface in Kondo insulating SmB<sub>6</sub>** , BENG TAN, University of Cambridge — We report the observation of a paradoxical insulator with a bulk state which is electrically insulating and simultaneously yields quantum oscillations typical of good metals. We present high field measurements of conductivity and magnetic torque in high purity single crystals of the Kondo insulator SmB<sub>6</sub> which reveal an activated behavior characteristics of an insulator with an energy gap at the Fermi energy in the former and quantum oscillation of frequencies characteristics of a large three-dimensional conduction electron Fermi surface similar to the metallic rare earth hexaborides such as PrB<sub>6</sub> and LaB<sub>6</sub> in the latter. The quantum oscillations observed in the magnetic torque measurements are characteristic of an unconventional Fermi liquid – the amplitude strongly increases at low temperatures in a stark contrast to the saturating Lifshitz-Kosevich behavior in conventional metallic states.

**1:03PM S1.00004 Neutron scattering from the Kondo Insulator SmB<sub>6</sub>**<sup>1</sup> , COLLIN BROHOLM, Johns Hopkins University — A review of neutron scattering work probing the Kondo insulator SmB<sub>6</sub> is presented with special emphasis on assessing the topology of the underlying strongly renormalized band structure. A 14 meV excitation dominates the spectrum and is evidence of strong electron correlations [1]. Though the data generally supports the proposal that SmB<sub>6</sub> is a topological Kondo insulator, specific heat and high-resolution neutron scattering data show a continuum of states well below the bulk transport gap, which enrich the problem and may connect to the recent surprising de Haas van Alphen results.

**1:39PM S1.00005 Kondo Breakdown and Quantum Oscillations in SmB<sub>6</sub>**<sup>1</sup> , ONUR ERTEN, Rutgers University — Motivated by the observation of light surface states of SmB<sub>6</sub>, I will discuss the effects of surface Kondo breakdown in topological Kondo insulators, in particular SmB<sub>6</sub>. I will present both numerical and analytic results which show that the decoupling of the localized moments at the surface disturbs the compensation between light and heavy electrons and dopes the Dirac cone. Dispersion of these uncompensated surface states are dominated by inter-site hopping, which leads to much lighter quasiparticles in accordance with ARPES experiments [1]. Another tantalizing result about SmB<sub>6</sub> comes from the recent quantum oscillation experiments which lead to completely controversial interpretations. I will discuss a general theoretical viewpoint considering both bulk and surface scenarios and our new interpretation in terms of Kondo breakdown in topological surface states [2]. [1] V. Alexandrov, P. Coleman, O. Erten, Phys. Rev. Lett. **114**, 177202 (2015) [2] O. Erten, P. Ghaemi, P. Coleman arXiv: 1510.02313 (2015)

**Thursday, March 17, 2016 11:15AM - 2:15PM —**  
**Session S2 GSOFD DFD: Rheology of Dense Particulate Media** Ballroom II - Ted Brzinski, North Carolina State University

**11:15AM S2.00001 Flow of colloidal suspensions and gels<sup>1</sup>**, ROSEANNA ZIA, Cornell University — Our recent studies of yield of colloidal gels under shear show that yield in such gels occurs in distinct stages. Under fixed stress, yield follows a finite delay period of slow solid-like creep. Post yield, the gel fluidizes and may undergo long-time viscous flow or, in some cases, may re-solidify. Under imposed strain rate, the transition from equilibrium to long-time flow is characterized by one or more stress overshoots, signifying a yield process here as well. These rheological changes are accompanied by evolution in morphology and dynamics of the gel network. Similar regimes have been observed in gels subjected to gravitational forcing; the gel initially supports its own weight, or perhaps undergoes slow, weak compaction. This may be followed by a sudden transition to rapid compaction or sedimentation. Various models have been put forth to explain these behaviors based on structural evolution, but this detail is difficult to observe in experiment. Here we examine the detailed microstructural evolution and rheology of reversible colloidal gels as they deform under gravity, identifying the critical buoyant force at which yield occurs, the role played by ongoing gel coarsening, and similarities and differences compared to yield under shear.

**11:51AM S2.00002 A unified description of the rheology of hard particles**, MICHEL HERMES, University of Edinburgh — No abstract available.

**12:27PM S2.00003 Linking Microstructural Changes to Bulk Behavior in Shear Disordered Matter<sup>1</sup>**, DANIEL BLAIR, Georgetown University — Soft and biological materials often exhibit disordered and heterogeneous microstructure. In most cases, the transmission and distribution of stresses through these complex materials reflects their inherent heterogeneity. Through the combination of rheology and 4D imaging we can directly alter and quantify the connection between microstructure and local stresses. We subject soft and biological materials to precise shear deformations while measuring real space information about the distribution and redistribution of the applied stress. In this talk, I will focus on the flow behavior of two distinct but related disordered materials; a flowing compressed emulsion above its yield stress and a strained collagen network. In the emulsion system, I will present experimental and computational results on the dynamical response, at the level of individual droplets, that directly links the particle motion and deformation to the rheology. I will also present results that utilize boundary stress microscopy to quantify the spatial distribution of surface stresses that arise from sheared in-vitro collagen networks. I will outline our main conclusions which is that the strain stiffening behavior observed in collagen networks can be parameterized by a single characteristic strain and associated stress. This characteristic rheological signature seems to describe both the strain stiffening regime and network yielding.

<sup>1</sup>NSF DMR: 0847490

**1:03PM S2.00004 Nonlinear and nonlocal rheology of jammed matter**, BRIAN TIGHE, TU Delft — Emulsions, foams, and grains all jam into a weakly elastic state when confined by pressure. By now the mechanics of jammed matter is well understood in the case of slow, weak, and homogeneous forcing – but in reality, it is rare for all three of these assumptions to hold. Here we demonstrate the complex rheology that results when jammed materials are forced at finite rate, finite amplitude, and finite wavelength. Using computer simulations, we subject dense soft sphere packings to a host of rheological tests, including stress relaxation, flow start-up, oscillatory shear, and standing wave forcing. These allow us to tease apart the influence of viscous, nonlinear, and nonlocal effects, and also to probe the link between particle dynamics and bulk response. We identify strain, time, and length scales that depend critically on the distance to the jamming transition, and which govern the onset of shear thinning, strain softening, and gradient elasticity.

**1:39PM S2.00005 Effects of confinement on nanoparticle flows<sup>1</sup>**, JACINTA CONRAD, University of Houston — The transport properties of nanoparticles that are dispersed in complex fluids and flowed through narrow confining geometries affect a wide range of materials shaping and forming processes, including three-dimensional printing and nanocomposite processing. Here, I will describe two sets of experiments in which we use optical microscopy to probe the structure and transport properties of suspensions of particles that are confined geometrically. First, we investigate the structure and flow properties of dense suspensions of submicron particles, in which the particles interact via an entropic depletion attraction, that are confined in thin films and microchannels. Second, we characterize the transport properties of nanoparticles, dispersed at low concentration in water or in aqueous solutions of high-molecular weight polymers, that are confined in regular arrays of nanoposts or in disordered porous media. I will discuss our results and their practical implications for materials processing as well as for other applications that require confined transport of nanomaterials through complex media.

**Thursday, March 17, 2016 11:15AM - 2:15PM –**  
**Session S3 DMP: Towards Design of Correlated Electron Materials** Ballroom III - Laura H. Greene, Florida State University, NHMFL

**11:15AM S3.00001 Spin-Orbit Coupling, Strong Interactions, and Topological Character<sup>1</sup>**, WARREN E. PICKETT, University of California Davis — In recent years the electronic structure of crystalline solids has come under close scrutiny because of the various types of topological characters that may arise. Most of the work is done at the one-electron (non-interacting) level, and most innovations have arisen from model tight-binding Hamiltonians and their eigenvectors. This talk will focus on a few examples of *discoveries made computationally* through DFT studies of actual materials, thus providing a physical realization as the discovery was made. Competition and partnership between strong interactions and spin-orbit coupling will be emphasized. Examples will include (1) the 'semi-Dirac' point Fermi surface phase in VO<sub>2</sub> thin films, the first member of a class now called *multi Weyl*: massive in some direction, massless in other direction; (2) a nodal loop semimetal phase found in computational studies of thin SrVO<sub>3</sub> films, realized more recently in NbP etc.; (3) the buckled honeycomb lattice of a (111) bilayer of LaMnO<sub>3</sub> encased on LaAlO<sub>3</sub>, which is a Chern insulator and may be a realization of the Weyl-Mott insulator proposed recently by Morimoto and Nagaosa. Acknowledgments: R. Pentcheva, V. Pardo, K.-W. Lee, S. Gangopadhyay.

<sup>1</sup>DOE Grant DE-FG02-04ER46111

**11:51AM S3.00002 Towards prediction of correlated material properties using quantum Monte Carlo methods**, LUCAS WAGNER, Univ of Illinois - Urbana — Correlated electron systems offer a richness of physics far beyond noninteracting systems. If we would like to pursue the dream of designer correlated materials, or, even to set a more modest goal, to explain in detail the properties and effective physics of known materials, then accurate simulation methods are required. Using modern computational resources, quantum Monte Carlo (QMC) techniques offer a way to directly simulate electron correlations. I will show some recent results on a few extremely challenging materials including the metal-insulator transition of VO<sub>2</sub>, the ground state of the doped cuprates, and the pressure dependence of magnetic properties in FeSe. By using a relatively simple implementation of QMC, at least some properties of these materials can be described truly from first principles, without any adjustable parameters. Using the QMC platform, we have developed a way of systematically deriving effective lattice models from the simulation. This procedure is particularly attractive for correlated electron systems because the QMC methods treat the one-body and many-body components of the wave function and Hamiltonian on completely equal footing. I will show some examples of using this downfolding technique and the high accuracy of QMC to connect our intuitive ideas about interacting electron systems with high fidelity simulations. The work in this presentation was supported in part by NSF DMR 1206242, the U.S. Department of Energy, Office of Science, Office of Advanced Scientific Computing Research, Scientific Discovery through Advanced Computing (SciDAC) program under Award Number FG02-12ER46875, and the Center for Emergent Superconductivity, Department of Energy Frontier Research Center under Grant No. DEAC0298CH1088. Computing resources were provided by a Blue Waters Illinois grant and INCITE PhotSuper and SuperMatSim allocations.

**12:27PM S3.00003 Towards the design of novel cuprate-based superconductors**, CHUCK-HOU YEE, Rutgers Univ — The rapid maturation of materials databases combined with recent development of theories seeking to quantitatively link chemical properties to superconductivity in the cuprates provide the context to design novel superconductors. In this talk, we describe a framework designed to search for new superconductors, which combines chemical rules-of-thumb, insights of transition temperatures from dynamical mean-field theory, first-principles electronic structure tools, materials databases and structure prediction via evolutionary algorithms. We apply the framework to design a family of copper oxysulfides and evaluate the prospects of superconductivity.

**1:03PM S3.00004 Itinerant magnetism without magnetic elements<sup>1</sup>**, EMILIA MOROSAN, Rice University — The origin of magnetism in metals has been traditionally discussed in two diametrically opposite limits: itinerant and local moments. Surprisingly, there are very few known examples of materials that are close to the itinerant limit, and their properties are not universally understood. In the case of the two such examples discovered several decades ago, both itinerant ferromagnets (IFMs) ZrZn<sub>2</sub> and Sc<sub>3</sub>In, the understanding of their magnetic ground states draws on the existence of 3d electrons subject to strong spin fluctuations. In this talk I will contrast the physical properties of these two IFMs without magnetic elements with those of the recently discovered first itinerant antiferromagnetic (IAFM) metal with no magnetic constituents, TiAu. The IFMs have surprisingly different properties, with ZrZn<sub>2</sub> showing signatures of mean field, Fermi liquid behavior, while the Sc<sub>3</sub>In compound is characterized by non-mean field magnetization exponents, and displays non fermi liquid behavior in both the FM and the paramagnetic states. The IAFM TiAu orders below a Neel temperature  $T_N \approx K$ , about an order of magnitude smaller than in the IAFM Cr, rendering the spin fluctuations in TiAu more important at low temperatures. Like in the two IFMs, doping induces a quantum phase transition in TiAu, and the quantum critical behavior in all three systems is discussed and compared.

**1:39PM S3.00005 In situ measurements of high temperature growth of correlated systems: a materials by design scheme<sup>1</sup>**, HUA HE<sup>2</sup>, Department of Physics & Astronomy, Texas A & M University — There is great interest in developing new ways to use predictive theory to accelerate materials synthesis. We have previously shown that DFT+DMFT electronic structure calculations are successful at predicting gaps and ordered moments, even when correlations are very strong.<sup>[1,2]</sup> Building on these results, we set out to explore an even closer integration of theory and synthesis, aiming to discover new routes for doping Mott insulators and producing new superconductors. In situ high temperature high energy X-ray diffraction is used to determine the crystal structures of compounds just as they form from the growths, and the structural information is used as input for DFT+DMFT calculations that predict functionality, closing the synthesis loop by suggesting productive new directions. Using this approach, we have investigated the transition metal oxysulfide system Ba-Co-S-O and successfully discovered the new compound BaCoSO, and identified it as an interesting small gap Mott insulator by DFT+DMFT calculations even before any traditional crystal growth is attempted in the lab. Session S4 GQI DCMP: Quantum Dot-Cavity Hybrid Systems Ballroom IV - Guido Burkard, University of Konstanz

**11:15AM S4.00001 Probing light-matter interactions at the level of single photons and electrons<sup>1</sup>**, JASON R. PETTA, Department of Physics, Princeton University — Pioneering experiments by Fujisawa *et al.* examined the detuning dependence of the current in semiconductor double quantum dots (DQDs) and highlighted the important role of electron-phonon coupling in inelastic transport.<sup>1</sup> Later experiments by the same group directly measured orbital relaxations rates, which were consistent with a phonon-mediated relaxation process.<sup>2</sup> By placing semiconductor DQDs inside of high quality factor microwave cavities it is now feasible to achieve charge-cavity coupling rates that are comparable to the phonon emission rate. I will describe recent experiments that examine masing in cavity-coupled semiconductor DQDs. The application of a source-drain bias results in single electron tunneling and population inversion. The interdot tunneling process generates photons and leads to gain in the cavity transmission. We measure the detuning dependence of the gain and find that the gain feature is very broad compared to the cavity linewidth. Recent theory accounts for the broad gain feature by considering a second-order process that involves the simultaneous emission of a cavity photon and a phonon.<sup>3</sup> With sufficient cavity driving, it is feasible to achieve above-threshold maser action, which is verified by comparing the statistics of the emitted microwave field above and below the maser threshold.<sup>4</sup>

**12:27PM S4.00003 Theory of strongly driven cavity coupled quantum dots: from micromasers to BECs of light** , MICHAEL GULLANS, NIST - Natl Inst of Stds & Tech — Embedding a double quantum dot (DQD) in a low loss microwave resonator results in a large electric dipole interaction between the charge states of the DQD and single microwave photons in the resonator. In the regime of a few electrons and photons, this system is reminiscent of well-known models of cavity quantum electrodynamics from atomic physics; however, there are important deviations due to the strong coupling of the DQD to the electronic reservoirs in the leads, as well as phonons in the lattice. In this talk, we explore how external control and driving of this unique hybrid system can be used to induce non-equilibrium states of light in the resonator.

**1:03PM S4.00004 Cavity quantum electrodynamics with carbon nanotube quantum dots** , TAKIS KONTOS, Laboratoire Pierre Aigrain, Ecole Normale Supérieure, CNRS — Cavity quantum electrodynamics techniques have turned out to be instrumental to probe or manipulate the electronic states of nanoscale circuits. Recently, cavity QED architectures have been extended to quantum dot circuits. These circuits are appealing since other degrees of freedom than the traditional ones (e.g. those of superconducting circuits) can be investigated. I will show how one can use carbon nanotube based quantum dots in that context. In particular, I will focus on the coherent coupling of a single spin [1] or non-local Cooper pairs to cavity photons. Quantum dots also exhibit a wide variety of many body phenomena. The cQED architecture could also be instrumental for understanding them. One of the most paradigmatic phenomenon is the Kondo effect which is at the heart of many electron correlation effects. I will show that a cQED architecture has allowed us to observe the decoupling of spin and charge excitations in a Kondo system. [1] J. J. Viennot, M.C. Dartailh, A. Cottet and T. Kontos Science 349 408 (2015).

**11:15AM S5.00001 Coexistence of superconductivity and antiferromagnetism in  $(\text{Li}_{0.8}\text{Fe}_{0.2})\text{OHFeSe}$**  , XIANHUI CHEN, Hefei National Laboratory for Physical Sciences at Microscale and Department of Physics, University of Science and Technology of China, Hefei, Anhui — In this talk, we report the synthesis of an air-stable material,  $(\text{Li}_{0.8}\text{Fe}_{0.2})\text{OHFeSe}$ , which shows superconducting transition temperature up to  $T_c \sim 40$  K, by means of a novel hydrothermal method [1]. The crystal structure is unambiguously determined by a combination of X-ray and neutron powder diffraction and nuclear magnetic resonance. Moreover, antiferromagnetic order is found to coexist with superconductivity. We also grew single crystals of  $(\text{Li,Fe})\text{OHFeSe}$ , and observed a first-order transition from superconductor to AFM insulator with a strong charge doping induced by ionic gating in the thin flakes of single crystal [2].  $T_c$  is continuously enhanced with electron doping by ionic gating up to a maximum  $T_c$  of 43 K, and a striking superconductor-insulator transition occurs just at the verge of optimal doping with highest  $T_c$ . A novel phase diagram of temperature-gating voltage with the superconductor-insulator transition is mapped out, indicating that the superconductor-insulator transition is a common feature for unconventional superconductivity. Lei, Z. J. Xiang, X. F. Lu, N. Z. Wang, J. R. Chang, S. Chang, A. M. Zhang, Q. M. Zhang, X. G. Luo, T. Wu, Z. Sun, and X. H. Chen, arXiv: 1503.02457.

**11:51AM S5.00002 Atomic scale visualization of novel magnetic phase transitions in Fe-based superconductor  $\text{Sr}_4\text{V}_2\text{O}_6\text{Fe}_2\text{As}_2$**  , SEOKHWAN CHOI, Dept. of physics, KAIST, WON-JUN JANG, CAPP, IBS, JONG MOK OK, Dept. of physics, POSTECH, HYUN WOO CHOI, HYUN JUNG LEE, JIN OH JUNG, DONG HYUN SON, Dept. of physics, KAIST, HWAN SOO SUH, SAIT, JUN SUNG KIM, Dept. of physics, POSTECH, YANNIS K. SEMERTZIDIS, CAPP, IBS, JHINHWAN LEE, Dept. of physics, KAIST —  $\text{Sr}_4\text{V}_2\text{O}_6\text{Fe}_2\text{As}_2$  consists of superconducting FeAs layers and Mott insulating  $\text{Sr}_2\text{VO}_3$  layers, and exhibits superconductivity with  $T_c$  near 30 K despite being a parent compound material. Unlike normal Fe-based superconductors, the magnetism of  $\text{Sr}_4\text{V}_2\text{O}_6\text{Fe}_2\text{As}_2$  has complexity due to the presence of two magnetic atomic layers of V and Fe; therefore, the issue of magnetism has been actively debated. In this work, we studied the orbital and magnetic phase transitions in the range of 4 K to 180 K using spin-polarized scanning tunneling microscope. We directly observed the changes of charge density waves of V atomic layer related to the nematicity at 150 K, and spin density waves of V atomic layer resulting from spin ordering of underlying Fe atomic layer below 50 K. Moreover, controlling the sample bias voltage, the hysteresis of magnetic domain is observed at 4 K. Our results show key clues to solve controversy about the magnetism of  $\text{Sr}_4\text{V}_2\text{O}_6\text{Fe}_2\text{As}_2$ .

**12:03PM S5.00003 Observation of coexistence of itinerant electronic states and local moments in parents compound superconductor  $\text{Sr}_4\text{V}_2\text{O}_6\text{Fe}_2\text{As}_2$**  , WON-JUN JANG, Center for Axion and Precision Physics, IBS, SEOKHWAN CHOI, Dept. of physics, KAIST, JONG MOK OK, Dept. of physics, POSTECH, HYUN WOO CHOI, HYUN JUNG LEE, JIN OH JUNG, DONG HYUN SON, Dept. of physics, KAIST, HWAN SOO SUH, Samsung Advanced Institute of Technology, JUN SUNG KIM, Dept. of physics, POSTECH, YANNIS K. SEMERTZIDIS, Center for Axion and Precision Physics, IBS, JHINHWAN LEE, Dept. of physics, KAIST — Using variable temperature scanning tunneling spectroscopy (STS) and quasi-particle interference (QPI) analysis, we studied coexistence of itinerant electronic states and local moments in  $\text{Sr}_4\text{V}_2\text{O}_6\text{Fe}_2\text{As}_2$ . Temperature dependent STS measurements showed Fano resonances resulting from the hybridization between local moments (V) and itinerant electrons (Fe) below 100 K, and the formation of Fano lattice implying collective spin excitations between local moments of V atoms below 50 K. QPI analysis showed replica bands and kink features in Fe-itinerant band, implying the existence of Bosonic modes between  $\text{Sr}_2\text{VO}_3$  layers and FeAs layers. Our results show the collective behaviors of itinerant electrons and local moments, and the possibility of local moments contributing to superconductivity.

**12:15PM S5.00004 Bipartite bosonic modes and magnetic memory effects in superconducting  $\text{Sr}_4\text{V}_2\text{O}_6\text{Fe}_2\text{As}_2$** , JHINHWAN LEE, SEOKHWAN CHOI, HYUN JUNG LEE, KAIST, Physics Dept., WON-JUN JANG, KAIST, Physics Dept., IBS CAPP, JONG MOK OK, POSTECH, Physics Dept., HYUN WOO CHOI, JIN OH JUNG, DONG HYUN SON, KAIST, Physics Dept., HWAN SOO SUH, SAIT, YANNIS SEMERTZIDIS, KAIST, Physics Dept., IBS CAPP, JUN SUNG KIM, POSTECH, Physics Dept. — Using a homemade variable temperature high field spin-polarized STM, we have performed spectroscopic-imaging STM measurement on the parent-state superconductor  $\text{Sr}_4\text{V}_2\text{O}_6\text{Fe}_2\text{As}_2$  with each unit cell composed of superconducting FeAs layer sandwiched by two nearly Mott-insulating  $\text{Sr}_2\text{VO}_3$  layers. The hybridization between the localized V electrons and the itinerant Fe electrons causes electron transfer to the FeAs bands and generates a Gamma-centered electron pocket, as well as a Fano resonance at -18 meV with signature of Fano lattice. In the QPI measurement, we observed two distinct bosonic modes, i.e. the kinks and the partial replicas of the QPI dispersion with characteristic mode energies around 14 meV and 20 meV respectively, which agree with the self-energies due to two distinct electron-boson mode coupling functions in Migdal approximation. In spin-polarized STM mode, we observed atomic scale magnetic memory effect of the V atoms controlled with low energy (around 50 meV) spin-polarized tunneling current and used it to reveal underlying magnetic domains in the FeAs layer. Variable temperature spin-polarized STM measurements on some known antiferromagnetic materials will also be presented and discussed.

**12:27PM S5.00005 Unusual phase transition in a natural heterostructure of iron pnictides and vanadium oxides**, JONG MOK OK, POSTECH, S.-H. BAEK<sup>1</sup>, IFW Dresden, MAN JIN EOM, POSTECH, C. HOCH, R. K. KREMER, Max-Planck-Institut für Festkörperforschung, DONG-HWAN KIM, POSTECH, CHUN-FU CHANG, KYUNG-TAE KO, Max-Planck-Institut für Chemische Physik fester Stoffe, SANG-YOUN PARK, SUNG DAE JI, POSTECH, B. BÜCHNER, IFW Dresden, JAE-HOON PARK, J. H. SHIM, POSTECH, I. I. MAZIN, Naval Research Laboratory, JUN SUNG KIM<sup>2</sup>, POSTECH — We report the unusual phase transition in  $\text{Sr}_2\text{VO}_3\text{FeAs}$  single crystal, where the Mott-insulating vanadium oxides and the high- $T_c$  superconducting iron pnictides form a natural heterostructure. Clear evidence of the phase transition at  $T_0 = 155$  K was observed in the iron pnictide layer, not in the vanadium oxide layer, using bulk and NMR measurements. Neither magnetic ordering with sufficient spin moment nor symmetry change in the crystal structure has been detected at  $T_0$ . At  $T_{mag} \approx 45$  K, far below  $T_0$ , magnetic transition occurs in the iron pnictide layer, while the vanadium oxide layer remains nonmagnetic at low temperatures. The complex evolution of various phases in  $\text{Sr}_2\text{VO}_3\text{FeAs}$  is drastically distinct from the phase transitions found in other iron pnictides or vanadium oxides, highlighting the importance of the additional interlayer coupling between the layers.

**12:39PM S5.00006 Linear Magnetoresistance of  $\text{Ca}_{10}\text{Pt}_n\text{As}_8(\text{Fe}_2\text{As}_2)_5$  ( $n = 3$  and 4)**, JIAYUN PAN, AMAR KARKI, RONGYING JIN, Department of Physics and Astronomy, Louisiana State University — We report the normal-state magnetoresistance (MR) of superconducting  $\text{Ca}_{10}\text{Pt}_n\text{As}_8(\text{Fe}_2\text{As}_2)_5$  ( $n = 3$  and 4) as a function of temperature (50 – 300 K) and magnetic field (0 – 14 Tesla). It is found that MR is positive in a wide temperature range in both transverse ( $H \perp I$ ) and longitudinal ( $H \parallel I$ ) cases. At a fixed temperature and field, we observe MR ( $H \perp I$ ) > MR ( $H \parallel I$ ), suggesting spin-orbital coupling in addition to charge-spin interaction. Remarkably, MR shows linear field dependence between 0 and 14 Tesla in a wide temperature range for both  $n = 3$  and 4. The implication of such unusual field dependence of MR will be discussed.

**12:51PM S5.00007 Correlation induced self-doping in the iron-pnictide superconductor  $\text{Ba}_2\text{Ti}_2\text{Fe}_2\text{As}_4\text{O}$** , J.Z. MA<sup>1</sup>, P. RICHARD, G.F. CHEN, H. MIAO, L.K. ZENG, Institute of Physics, Chinese Academy of Sciences, A.VAN ROEKEGHEM, S. BIERMANN, Centre de Physique Thorique, Ecole Polytechnique, N. XU, M. SHI, Paul Scherrer Institute, Swiss Light Source, Z.H. LIU, J.B. HE, S.C. WANG, Department of Physics, Renmin University, C. CAO, Department of Physics, Hangzhou Normal University, Y.L. SUN, G.H. CAO, Department of Physics, Zhejiang University, T. QIAN, H. DING, Institute of Physics, Chinese Academy of Sciences — The electronic structure of the intercalated iron-based superconductor  $\text{Ba}_2\text{Ti}_2\text{Fe}_2\text{As}_4\text{O}$  ( $T_c \sim 21.5$  K) has been investigated by using ARPES and combined LDA + DMFT calculations. The electronic states near the Fermi level are dominated by both the Fe 3d and Ti 3d orbitals, indicating that the spacing layers separating different FeAs layers are also metallic. By counting the enclosed volumes of the Fermi surface sheets, we observe a large self-doping effect, i.e., 0.25 electrons per unit cell are transferred from the FeAs layer to the  $\text{Ti}_2\text{As}_2\text{O}$  layer, leaving the FeAs layer in a hole-doped state, which is in contrast with the LDA prediction of an electron-doped FeAs layer. This exotic behavior is successfully reproduced by the LDA + DMFT calculations, in which the self-doping effect is attributed to the electronic correlations in the Fe 3d shell. Our work provides an alternative route of effective doping without element substitution for iron-based superconductors.

**1:03PM S5.00008 Numerical Study of a Multiorbital Hubbard Model for the Two-Leg Ladder  $\text{BaFe}_2\text{S}_3$  High- $T_c$  Superconductor Using the Density Matrix Renormalization Group**, NIRAVKUMAR PATEL, The University of Tennessee, Knoxville, Tennessee 37996, USA, ALBERTO NOCERA, GONZALO ALVAREZ, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, RYOTARO ARITA, RIKEN, 2-12-1 Hirasawa, Wako, Saitama 351-0198, Japan, ELBIO DAGOTTO, The University of Tennessee, Knoxville, Tennessee 37996, USA — Iron based high- $T_c$  superconductors have attracted considerable attention because of its unconventional superconducting properties. Here, we analyze the magnetic and pairing characteristics of the recently discovered two-leg ladder material  $\text{BaFe}_2\text{S}_3$  that becomes superconducting by applying pressure [1], using a two-orbital Hubbard model studied via the Density Matrix Renormalization Group technique. The hopping parameters, which spans up to the 2<sup>nd</sup> nearest-neighbor rungs, were obtained from the ab-initio downfolded band structure at ambient and high pressures [2]. The magnetic phase diagram at a realistic Hund coupling  $J/U = 0.25$  is presented varying the Hubbard  $U$ , at select values of the electronic fillings. At half-filling, we find a robust magnetic order in excellent agreement with experiments [1] i.e. antiferromagnetic (ferromagnetic) along the leg (rung) directions. We also discuss a possible tendency for this system to form a paired bound state of holes in a small but finite window of Hubbard  $U$ . The symmetries of this tentative paired ground state will be discussed.

**1:15PM S5.00009 Enhancement of Superconductivity Near a Structural Instability in  $\text{Ba}(\text{Ni}_{1-x}\text{Co}_x)_2\text{As}_2$** , CHRIS ECKBERG, HYUNSOO KIM, PETER ZAVALIJ, PHILIP PICCOLI, Univ of Maryland-College Park, JOHNPIERRE PAGLIONE, University of Maryland-College Park — We present a comprehensive study of single crystals of  $\text{Ba}(\text{Ni}_{1-x}\text{Co}_x)_2\text{As}_2$  synthesized using a flux method. With cobalt substitution, we track the evolution of the structural triclinic phase of  $\text{BaNi}_2\text{As}_2$  and the superconducting ground state with heat capacity and resistivity measurements. We will present our study of the systematic suppression of the low temperature triclinic state with increasing Co concentration as well as a more than threefold enhancement in the superconducting critical temperature, discussing its relation to iron-based superconductors.

**1:27PM S5.00010 Magnetism in  $LnMnSbO$  ( $Ln = La$  or  $Ce$ )<sup>1</sup>**, QIANG ZHANG, Iowa State University, NAVEEN KUMAR CHOGONDAHALI M., Jlich Centre for Neutron Science, KEVIN DENNIS, ALAN GOLDMAN, DAVID VAKNIN, Iowa State University — Neutron diffraction of polycrystalline (PND)  $LnMnSbO$  ( $Ln = La$  or  $Ce$ ) reveals differences between the magnetic ground state of the two compounds due to the strong Ce-Mn coupling compared to La-Mn. The two compounds adopt the  $P4/nmm$  space group down to 1.5 K and whereas magnetization measurements do not show any anomaly at high temperatures, PND reveals a C-type antiferromagnetic (AFM) order below  $T_N = 255$  K for  $LaMnSbO$  and 240 K for  $CeMnSbO$ . While the magnetic structure of  $LaMnSbO$  is preserved to base temperature, a sharp transition at  $T_{SR} = 5$  K in  $CeMnSbO$  due to a spin-reorientation (SR) transition of the  $Mn^{2+}$  from pointing along the  $c$ -axis to the  $ab$ -plane is found. The SR transition in  $CeMnSbO$  is accompanied by a simultaneous long-range AFM ordering of the Ce moments. This indicates that the Mn SR transition is driven by the Ce-Mn coupling similar to recent observation in the isostructural  $CeMnAsO$ . The ordered moments are found to be somewhat smaller than those expected for  $Mn^{2+}$  ( $S = 5/2$ ) in insulators, but large enough to suggest that these compounds belong to the class of local-moment antiferromagnets. The lower  $T_N$  found in this compound compared to the As-based counterpart ( $T_N = 347$  K for  $CeMnAsO$ ) indicates that the Mn- $Pn$  ( $Pn = As$  or  $Sb$ ) hybridization that mediates the exchange Mn-Mn coupling is weaker for the Sb-based compounds.

**1:39PM S5.00011 Collinear antiferromagnetism in trigonal  $SrMn_2As_2$  revealed by single crystal neutron diffraction**, A. KREYSSIG\*, P. DAS\*, N. S. SANGEETHA\*, Z. A. BENSON\*, T. HEITMAN<sup>+</sup>, D. C. JOHNSTON\*, A. I. GOLDMAN\*, \*Ames Laboratory, Dept. of Phys. and Astro., Iowa State University, IA, USA; <sup>+</sup>University of Missouri Research Reactor, MO, USA — FeAs-based compounds and related materials have been an area of intense research in understanding the complex interplay between magnetism and superconductivity. Here we report on the magnetic structure of  $SrMn_2As_2$  that crystallizes in a trigonal structure ( $P\bar{3}m1$ ) and undergoes an antiferromagnetic (AFM) transition at  $T_N \approx 120$  K. The temperature dependence of the magnetic susceptibility remains nearly constant below  $T_N$  with  $H \parallel c$  while it decreases significantly with  $H \parallel ab$ . This shows that the local Mn moments order and lie in the  $ab$  plane instead of aligning along the  $c$  axis as in  $BaMn_2As_2$ . Single crystal neutron diffraction measurements on  $SrMn_2As_2$  determined that the Mn moments are collinearly aligned in a G-type AFM order with AFM alignments between a moment and all nearest neighbors in the basal plane and also perpendicular to it. This manifests that G-type AFM order is robust for Mn122 systems despite different symmetries, i.e. tetragonal for  $BaMn_2As_2$  and trigonal for  $SrMn_2As_2$ . Work at Ames Laboratory was supported by the DOE, BES, Division of Materials Sciences & Engineering, through DE-AC02-07CH11358. This research used resources at University of Missouri Research Reactor.

**1:51PM S5.00012 Anomalous frequency dependent diamagnetism in metal silicide<sup>1</sup>**, ASHUTOSH DAHAL, JAGAT GUNASEKERA, University of Missouri, Columbia, MO, LELAND HARRIGER, NIST Center For Neutron Research, Gaithersburg, MD, DAVID J. SINGH, DEEPAK K. SINGH, University of Missouri, Columbia, MO, LELAND HARRIGER COLLABORATION — Discovery of superconductivity in PbO-type FeSe has generated a lot of interest. Among the samples we synthesize with similar structure, NiSi has showed anomalous but very interesting results. Nickel silicides are important electronic materials that have been used as contacts for field effect transistors, as interconnects and in nanoelectronic devices. The magnetic properties of NiSi are not well known, however. In this presentation, we report a highly unusual magnetic phenomenon in NiSi. The ac susceptibility measurements on NiSi reveal strong frequency dependence of static and dynamic susceptibilities that are primarily diamagnetic at room temperature. The static susceptibility is found to exhibit a strong frequency dependence of the diamagnetic response below 100K, while dynamic susceptibility showed peak type feature at 10KHz frequency around 50K. Detailed neutron scattering measurements on high quality powder sample of NiSi on SPINS cold spectrometer further revealed an inelastic peak around 1.5meV, even though no magnetic order is detected. The inelastic peak dissipates above 100K, which is where the static susceptibility starts to diverge with frequency.

**2:03PM S5.00013 The Long Forgotten Compound: CoTe, and its Epitaxial Film Growth and Properties<sup>1</sup>**, ZHIWEI ZHANG, ZHIHAI ZHU, WILLIAM A. HINES, JOSEPH I. BUDNICK, BARRETT O. WELLS, Physics Department, University of Connecticut — As part of our investigation of Co-doped, Fe-chalcogenide superconductors, we have synthesized films of CoTe, a long forgotten binary compound. Using pulsed laser deposition, we have grown epitaxial films on MgO, CaF<sub>2</sub>, and SrTiO<sub>3</sub> and have found that careful control of growth conditions allows for the synthesis of either (001) or (101) oriented films. X-ray diffraction shows the structure of the films is hexagonal. However, we also find the surprising presence of the nominally disallowed (001) peak. We also report temperature dependent transport and magnetic properties. This material may be of interest as a magnetic semiconductor and for its relationship to chemically doping Fe-based superconductors.

**Session S6 GMAG DMP: Magneto-Optic/Electric and Strain/Shape Induced Magnetism** 302 - Anirudh Sharma, Flinders University

**11:15AM S6.00001 magnetoelectric switching and spin wave generation**, BART SOREE, DAVIDE TIerno, CHRISTOPH ADELMANN, ODYSSEAS ZOGRAFOS, ADRIEN VAYSET, FLORIN CIUBOTARU, imec, SPIN WAVE IMEC TEAM — We have investigated the dynamics of the magnetization in magnetoelectric elements for switching and generation of spin waves. The behavior of the magnetization in the magnetostrictive material coupled to the piezoelectric not only depends on the strain induced by the piezo, but also depends on the relative contribution of the different magnetic anisotropies (shape, magnetocrystalline, magnetoelastic) present in the magnetoelectric element which is coupled to a spin wave bus. Performing micromagnetic simulations allow us to draw several conclusions w.r.t. the switching behavior of magnetoelectric elements as well as conditions to generate spin waves in an effective manner.

**11:27AM S6.00002 Electric field controlled strain induced reversible switching of magnetization in Galfenol nanomagnets delineated on PMN-PT substrate<sup>1</sup>**, HASNAIN AHMAD, Department of Electrical and Computer Engineering, Virginia Commonwealth University, JAYASIMHA ATULASIMHA, Department of Mechanical and Nuclear Engineering, Virginia Commonwealth University, SUPRIYO BANDYOPADHYAY, Department of Electrical and Computer Engineering, Virginia Commonwealth University — We report a *non-volatile* converse magneto-electric effect in elliptical Galfenol (FeGa) nanomagnets of ~300 nm lateral dimensions and ~10nm thickness delineated on a PMN-PT substrate. This effect can be harnessed for energy-efficient non-volatile memory. The nanomagnets are fabricated with e-beam lithography and sputtering. Their major axes are aligned parallel to the direction in which the substrate is poled and they are magnetized in this direction with a magnetic field. An electric field in the opposite direction generates compressive strain in the piezoelectric substrate which is partially transferred to the nanomagnets and rotates their magnetization away from the major axes to metastable orientations. There they remain after the field is removed, resulting in non-volatility. Reversing the electric field generates tensile strain which returns the magnetization to the original state. The two states can encode two binary bits which can be written using the correct voltage polarity, resulting in non-toggle behavior. Scaled memory fashioned on this effect can exhibit write energy dissipation of only ~2 aJ.

**11:39AM S6.00003 Giant magnetoelectric effect in thin magnetic films utilizing inter-ferroelectric transitions.<sup>1</sup>**, PETER FINKEL, MARGO STARUCH, US Naval Research Laboratory — There has recently been much interest to multiferroic magnetoelectric composites based on relaxor ferroelectric single crystals as potential candidates for devices such as magnetic field sensors, energy harvesters, or transducers. Large magnetoelectric coupling coefficient is prerequisite for superior device performance in a broad range of frequencies and functioning conditions. In magnetoelectric heterostructures based on ternary relaxors  $\text{Pb}(\text{In}_{1/2}\text{Nb}_{1/2})\text{O}_3$ - $\text{Pb}(\text{Mg}_{1/3}\text{Nb}_{2/3})\text{O}_3$ - $\text{PbTiO}_3$  (PIN-PMN-PT) crystal better operational range and temperature stability as compared to binary relaxors can be achieved. Giant linear converse magnetoelectric coupling up to  $2 \times 10^{-6} \text{ s m}^{-1}$  were observed in heterostructural composites with multilayered FeCo/Ag deposited on (011) PIN-PMN-PT crystals. Further enhancement of magnetoelectric coupling is demonstrated by utilizing inter-ferroelectric rhombohedral – orthorhombic phase transitions in PIN-PMN-PT. Mechanical clamping was a precondition to utilize this inter-ferroelectric transition mode to bring the crystal to a point just below its transformation threshold when very small perturbations at the input will cause large swings at the output generating a sharp uniaxial increase in strain (~0.5 %) and polarization change, giving rise to nonlinear effects. Details of these results and their implications will be presented.

<sup>1</sup>Giant magnetoelectric effect in thin magnetic fillms utilizing inter-ferroelectric transitions

**11:51AM S6.00004 Exploring Strain Induced Magnetization Effects in Metamagnetic Artificial Multiferroics using Polarized Neutron Reflectometry**, STEVEN BENNETT, ANDREAS HERKLOTZ, ANTHONY WONG, THOMAS WARD, VALERIA LAUTER, Oak Ridge National Laboratory — There is currently a strong drive to realize a controllable magnetic ordering transition for use in next generation spintronic based memory and computation devices. One proposed method to gain such control is the use of a changing strain in a thin film metamagnetic artificial multiferroic system. While basic concepts using electric field actuated piezoelectric strain have been recently demonstrated<sup>1</sup>, there is very little understanding of the details of strains effect on such magnetic phase transitions. Using the depth sensitive method of polarized neutron reflectometry we have been able to probe the fine details of strains contribution to the metamagnetic transition in thin films of metamagnetic  $\text{FeRh}$ <sup>2</sup>. Here we explore the effects of changing lattice strain as a function of depth using both a barium titanate substrate's structural phase transitions<sup>3</sup> and He ion implantation. These studies have discovered a remarkably large coupling between the systems strain state and the switching behavior across the magnetostructural metamagnetic transition. <sup>1</sup> Cherifi, R. O. et al. Nat. Mater. 31, 345–351 (2014), <sup>2</sup> Bennett, S. P. et al. Sci. Rep. 5, 9142 (2015), <sup>3</sup> Bennett, S. P. et al. submitted (2015)

**12:03PM S6.00005 Writing magnetic phase and domain structure in  $\text{FeRh}$  by controlling lattice symmetry with strain doping**, T. ZAC WARD, ANDREAS HERKLOTZ, Oak Ridge National Lab, ANTHONY WONG, Univ. of Tennessee, STEVEN BENNETT, VALERIA LAUTER, Oak Ridge National Lab — Low energy helium ion implantation is an effective approach to strain doping materials which allows one to expand the out-of-plane lattice parameter in epitaxial films without vacancy generation or electron/hole doping the system [1]. The ability to control crystal anisotropy and overcome Poisson's drive to conserve volume can thus offer huge dividends in controlling magnetic properties due to magnetostrictive phenomena. We present recent studies on epitaxial  $\text{FeRh}$  films which demonstrate how controlling crystal symmetry in this important intermetallic material can be used to finely control magnetic properties. We find that the first order magneto-structural phase transition from antiferromagnetic to ferromagnetic can be directly controlled through single axis lattice expansion; this effectively allows us to dictate the transition temperature anywhere between 400K and 150K. Polarized Neutron Reflectometry (PNR) data and scanning Magneto-optic Kerr effect (MOKE) measurements will be presented which demonstrate that this phase control can be confined to a specific region of the film both in depth and/or lateral position. While this holds great promise for magnetocaloric applications, many possibilities remain for devising new functionalities and gaining a deeper understanding of material properties using this technique. [1]H.W. Guo, S. Dong, P.D. Rack, J.D. Budai, A.T. Wong, A. Herklotz, P.C. Snijders, E. Dagotto, and T.Z. Ward, Phys. Rev. Lett. 114, 256801 (2015). Funded by DOE-BES-MSED.

**12:15PM S6.00006 Current Control of Magnetic Anisotropy via Strain in a  $\text{CoFeB}$  Waveguide<sup>1</sup>**, KYONGMO AN, XIN MA, Department of Physics, University of Texas, Austin, Texas 78712, USA, CHI-FENG PAI, Cornell University, Ithaca, New york 14853, USA, JUSANG YANG, KEVIN OLSSON, JAMES ERSKINE, ALLAN MACDONALD, Department of Physics, University of Texas, Austin, Texas 78712, USA, DANIEL RALPH, ROBERT BUHRMAN, Cornell University, Ithaca, New york 14853, USA, XIAOQIN LI, Department of Physics, University of Texas, Austin, Texas 78712, USA — We demonstrate that in-plane charge current can effectively control the spin precession resonance in an  $\text{Al}_2\text{O}_3/\text{CoFeB}/\text{Ta}$  heterostructure. Brillouin Light Scattering (BLS) was used to detect the ferromagnetic resonance field under microwave excitation of spin waves at fixed frequencies. Such control originates from the modified in-plane uniaxial magnetic anisotropy field  $H_K$ , which changes symmetrically with respect to the current direction. Numerical simulation suggests that the anisotropic stress introduced by Joule heating plays an important role in controlling  $H_K$ . The results provide new insights into current manipulation of magnetic properties and have broad implications on spintronic devices.

**12:27PM S6.00007 Incoherent stress-mediated magnetization reversal in shape anisotropic multiferroic nanomagnets<sup>1</sup>**, DHIRITIMAN BHATTACHARYA, MD MAMUN AL-RASHID, VIMAL SAMPATH, NOEL D'SOUZA, SUPRIYO BANDYOPADHYAY, JAYASIMHA ATULASIMHA, Virginia Commonwealth Univ — Strain mediated switching of multiferroic nanomagnets promises to be extremely energy efficient with dissipation per switching event of  $\sim 1$  aJ<sup>[1,2,3]</sup>. Most theoretical approaches to studying the switching dynamics use the macrospin approximation in which all the spins in the nanomagnet are assumed to rotate coherently. However, recent experiments show that while initial and final states are well approximated by this single domain assumption, intermediate states visited during the magnetization rotation process cannot be described by it. In such cases, an interplay between the exchange, magnetostatic and stress anisotropy energies can introduce incoherent magnetization dynamics. Hence, intermediate micromagnetic configurations such as vortex states can be stabilized, particularly in nanomagnets of larger dimensions. In this work, we present rigorous micromagnetic simulations to study the peculiarities of the incoherent switching process in the context of shape anisotropic nanomagnets subjected to stress. 1.Appl. Phys. Lett., 97, 173105, 2010. 2.Appl. Phys. Lett., 99, 063108, 2011. 3.Nanotechnology, 23, 105201, 2012.

**12:39PM S6.00008 Experimental manipulation of magnetic states of magnetostrictive nanomagnets using surface acoustic waves<sup>1</sup>**, VIMAL SAMPATH, DHIRITIMAN BHATTACHARYA, NOEL D'SOUZA, SUPRIYO BANDYOPADHYAY, JAYASIMHA ATULASIMHA, Virginia Commonwealth University — The use of Surface Acoustic Waves (SAW) to assist magnetization switching in magnetostrictive nanomagnets has been theoretically studied [1] and SAW-induced magnetization rotation in micron size magnets has been experimentally demonstrated [2]. We report recent experiments on manipulation of magnetic states of Co nanoscale magnets shaped like elliptical disks ( $\sim 300$  nm major axis, 240 nm minor axis and 10 nm thickness) delineated on bulk 128 Y-cut lithium niobate using SAW. Specifically, isolated nanomagnets that are initially in single domain states with magnetization pointing along the major axis of the ellipse are driven into a vortex state by SAW waves. However, SAW waves can trigger complete magnetization reversal in nanomagnets of moderate shape anisotropy that are dipole coupled to a highly shape anisotropic neighboring nanomagnet. [1] A.K. Biswas, S. Bandyopadhyay & J. Atulasimha, Appl. Phys. Lett., 105, 072408 (2014). [2] S. Davis, A. Baruth & S. Adenwalla, App. Phys. Lett., 97, 232507 (2010). The authors acknowledge the use of high voltage and high frequency pulse generator from Prof. Umit Ozgur's lab and the help of Prof. Gary Atkinson in fabrication of the IDTs for generating the SAW.

**12:51PM S6.00009 Magnetic domain response to strain generated by focused surface acoustic waves<sup>1</sup>**, UDAY SINGH, SHIREEN ADENWALLA, University of Nebraska - Lincoln — The effects of strain on magnetostrictive ferromagnets include changes in the magnetization, anisotropy and domain wall velocities. A ferromagnet (FM) on the surface of a surface acoustic wave (SAW) is subjected to periodic compressive and tensile strain that has resulted in coherent rotation of the magnetization, as well as inducing ferromagnetic resonance in FM films. We describe the response of magnetic domains in Co/Pt multilayers when subjected to the high strains generated by a focused SAW. Annular interdigital transducers (AIDT) patterned on LiNbO<sub>3</sub> form a SAW standing wave pattern with large strain amplitude at the focal center. Domains in [Co(3Å)/Pt(8Å)]<sub>x</sub>5 with perpendicular magnetic anisotropy were observed using a MOKE microscope within this focal region. Controlled magnetic pulses steered a magnetic domain boundary to the large strain region after nucleation. Excitation of the AIDT resulted in a reversible change in the domain wall boundary in the high strain region. We attribute this to magnetic anisotropy changes in the presence of RF strain, which results in changes in the domain configuration to minimize the free energy. We will present results showing both slow and fast magnetization changes in Co/Pt occurring in the presence of high frequency strain. This work is supported by NSF (DMR 1409622) and Nebraska MRSEC (DMR-1420645).

<sup>1</sup>This work is supported by NSF (DMR 1409622) and Nebraska MRSEC (DMR-1420645).

**1:03PM S6.00010 Orientation dependences of surface morphologies and energies of iron-gallium alloys<sup>1</sup>**, MARCIO COSTA, HUI WANG, JUN HU, RUQIAN WU, Department of Physics and Astronomy, University of California, Irvine, SUOK-MIN NA, HYUNSUK CHUN, ALISON B FLATAU, Department of Aerospace Engineering, University of Maryland, College Park, MD, UNIVERSITY OF CALIFORNIA, IRVINE COLLABORATION, UNIVERSITY OF MARYLAND COLLABORATION — Magnetostrictive Fe-Ga alloys (Galfenol) are very promising rare-earth free materials for applications in sensors, actuators, energy-harvesters and spintronic devices. Investigation on surface energies of Galfenol based on density functional calculations (DFT) and contact angle measurements may provide fundamental understandings and guidance to further optimize the performance of Galfenol. DFT calculations predict that Ga-covered (110) surface of Galfenol is more stable in Ga-rich condition, while Ga-covered (001) surface of Galfenol surface become more favorable in Ga-poor condition. Moreover, a full Ga overlayer tends to form on top of Galfenol surfaces regardless their orientation, both in agreement with the experimental observation. Further studies on Ga segregation in the Fe bcc matrix demonstrate that the Fe-Ga separation is unlikely to occur since Ga diffusion toward the surface is effectively self-stopped once the Ga overlayers form on the facets.

**1:15PM S6.00011 Fingerprinting Morphology of Magnetic Shape Memory Alloys Using First Order Reversal Curves (FORC) and Neutron Scattering<sup>1</sup>**, IGOR V. ROSHCHIN, Texas A&M Univ., PAVEL N. LAPA, Texas A&M Univ., Argonne Nat. Lab., KATHRYN L. KRYCKA, BRIAN B. MARANVILLE, CNR, NIST, JAMES A. MONROE, BRIAN E. FRANCO, IBRAHIM KARAMAN, Texas A&M Univ. — In Ni-Mn-In- and Ni-Mn-Sn-based alloys, two magnetic phases with ferromagnetic and antiferromagnetic exchange couplings between two nearest Mn atoms can coexist. The interaction between these phases results in exchange bias (EB). The EB field depends on the cluster sizes. Using the first order reversal curve (FORC) analysis of magnetization for Ni-Co-Mn-Sn and Ni-Co-Mn-In samples with different heat treatment, we can obtain information about cluster sizes of the structural phases in these alloys. This is especially important for polycrystalline alloy samples where dark-field images showing different phases are hard to obtain. Such a Ni-Co-Mn-Sn polycrystalline sample was characterized with small angle neutron scattering (SANS). Analyses of the scattering as a function of wavevector transfer in 50 Oe and 15 kOe applied field yield the average magnetic domain size of  $21.2 \pm 6.6$  nm and a polydispersity of  $0.32 \pm 0.02$  at 300 K, in good agreement with our prediction. The temperature evolution of the domain size will be discussed. Using an off-specular reflectometer in transmission geometry, the same sample was measured at a field of 270 Oe and 5.15 kOe. The fit of the 270 Oe data yields grain sizes of approximately  $0.11$ – $0.12$   $\mu\text{m}$  with polydispersities between 0.98 and 1.27.

**1:27PM S6.00012 Detecting an in-plane rotation of magnetization in GdFeCo films<sup>1</sup>**, FARZANEH HOVEYDA, SERBAN SMADICI, University of Louisville — It is often important to distinguish between magnetization reversal by coherent rotation in different planes and domain wall motion. Magnetization curves were measured at different temperatures with magneto-optical Kerr Effect in longitudinal (L-MOKE) and polar (P-MOKE) geometries on sputter-deposited  $\text{Gd}_x\text{Fe}_y\text{Co}_{1-x-y}$  (GFC) films of variable thickness. Depending on the probed region, the L-MOKE signal measured with decreasing external field  $H_{\text{ext}}$  was found to be lower than the signal observed with increasing  $H_{\text{ext}}$  (negative remanence magnetization). We show that this is due to a contribution to the signal of  $M_{\perp}$ , the magnetization component perpendicular to the scattering plane. This identifies the type of reversal in these GFC films as in-plane coherent rotation of magnetization.  $M_{\perp}$  is also proportional to the torque. Azimuthal measurements on  $\text{Co}_2\text{FeAl}$  samples showed a regular variation of the MOKE signal, in one possible application of these observations to torque measurements.

**1:39PM S6.00013 Nanoscale Confinement of All-Optical Magnetic Switching in TbFeCo<sup>1</sup>**, TIANMIN LIU, TIANHAN WANG, Stanford University, ALEXANDER REID, SLAC National Accelerator Laboratory, MATTEO SAVOINI, Radboud University Nijmegen, XIAOFEI WU, Universität Würzburg, BENNY KONENE, Radboud University Nijmegen, PATRICK GRANITZKA, University of Amsterdam, CATHERINE GRAVES, DANIEL HIGLEY, ZHAO CHEN, Stanford University, GARY RAZINSKAS, Universität Würzburg, MARKUS HANTSCHMANN, Institute Methods and Instrumentation for Synchrotron Radiation Research, ANDREAS SCHERZ, JOACHIM STOHR, SLAC National Accelerator Laboratory, ARATA TSUKAMOTO, College of Science and Technology, BERT HECHT, Universität Würzburg, ALEXEY KIMEL, ANDREI KIRILYUK, THEO RASING, Radboud University Nijmegen, HERMANN DURR, SLAC National Accelerator Laboratory, DURR/STOHR TEAM, THEO RASING TEAM, ARATA TSUKAMOTO TEAM, BERT HECHT TEAM — Gold two-wire antennas structures are placed upon the surface of the all-optical switching film TbFeCo. They resonate with the optical field and create a field enhancement in its vicinity, which is used to confine the area where optical switching can occur. It is demonstrated that single femtosecond optical laser pulses can reverse magnetization in a controllable fashion by such confinement. The magnetic states are imaged using resonant X-ray holography and magnetic circular dichroism. The results not only show the feasibility of controllable switching with antenna assistance but also demonstrate the highly inhomogeneous nature of the switching process, which is attributed to the material's heterogeneity.

**1:51PM S6.00014 Measurements of the Domain Magnetization Direction and its Effects on the Sensitivity of Magneto-optic Field Sensors.**, MANNIX SHINN, ANTHONY GARZARELLA, DONG HO WU, United States Naval Research Laboratory, RONGJIA TAO, Temple University — Bismuth doped, rare earth iron garnet (Bi:RIG) thick films exhibit a large magneto-optic response to external magnetic fields while exhibiting low optical insertion loss, making them ideal candidates for polarimetric magnetic field sensors. It was generally found that the Faraday rotation and overall sensitivity of the sensors depends on the orientation of the local domain magnetization relative to the direction of laser propagation. In arrayed Bi:RIG sensors, it is critical that the optical path of the laser is perpendicular to the easy-axis of each film of the array, in order to avoid magnetically-induced optical incoherence (MIOI). Therefore a precise, localized measurement of the magnetization vector within the films is necessary. Since traditional magnetization measurement techniques do not provide adequate resolution, several new approaches to precisely measure the easy axis were developed and will be described in this presentation. These approaches involve measurements of the directionality of the Faraday response, incoherence in the Malus curves, and damping in the domain wall motion. Such measurements have been instrumental in constructing and optimizing arrayed Bi:RIG sensors, which currently have a sensitivity of  $6 \text{ pT/Hz}^{1/2}$ .

**2:03PM S6.00015 Dynamic Interplay of Coherent Rotations and Domain Wall Motion in Faraday Rotators based on Ferromagnetic Crystals.**, ANTHONY GARZARELLA, DONG WU, MANNIX SHINN, Naval Research Laboratory — Under small, externally-applied magnetic fields, the Faraday rotation in magneto-optic material containing ferromagnetic domains is driven primarily by two principal mechanisms: domain wall motion and coherent domain rotations. Domain wall motion yields a larger Faraday responsivity but is limited by magnetically induced optical incoherence and by damping effects. Coherent domain rotation yields smaller Faraday rotations, but exhibits a flatter and broader frequency response. The two mechanisms occur along orthogonal principal axes and may be probed independently. However, when probed along an oblique angle to the principal axes, the relationship between the Faraday rotation and the external field changes from linear to tensorial. Although this may lead to more complicated phenomena (e.g. a sensitivity axis that depends on RF frequency), the interplay of domain rotation and domain wall motion can be exploited to improve responsivity or bandwidth. The detailed experimental data can be understood in terms of a quantitative model for the magnitude and direction of the responsivity vector. Applications to magnetic field sensors based on arrayed bismuth doped iron garnet films will be emphasized in this presentation.

## Thursday, March 17, 2016 11:15AM - 2:15PM — Session S7 FEd: Physics Education 303 - Robin Selinger, Kent State University

**11:15AM S7.00001 The Impact of Network Embeddedness on Student Persistence**, JUSTYNA ZWOLAK, ERIC BREWE, Florida International University, INSPIRE TEAM — Society is constantly in flux, which demands the continuous development of our educational system to meet new challenges and impart the appropriate knowledge/skills to students. In particular, in order to improve student learning (among other things), the way we are teaching has significantly changed over the past few decades. We are moving away from traditional, lecture-based teaching towards a more interactive approach using, e.g., clicker questions, modeling instruction (MI), and other engagement strategies. A current, major challenge for universities is to increase student retention. I am examining the use of network analysis to investigate academic and social experiences of students in and beyond the classroom. There is a compelling case that transformed physics classes, such as ones that use MI, promote persistence by the creation of learning communities that support the integration of students into the university. I will discuss recent results connecting the MI approach to network structures in the students' interactions and how students' position impacts persistence in taking a subsequent MI vs. traditional lecture-based course.

**11:27AM S7.00002 Using Video Analysis and Biomechanics to Engage Life Science Majors in Introductory Physics**, JEFF STEPHENS, Misericordia University — There is an interest in Introductory Physics for the Life Sciences (IPLS) as a way to better engage students in what may be their only physical science course. In this talk I will present some low cost and readily available technologies for video analysis and how they have been implemented in classes and in student research projects. The technologies include software like Tracker and LoggerPro for video analysis and low cost high speed cameras for capturing real world events. The focus of the talk will be on content created by students including two biomechanics research projects performed over the summer by pre-physical therapy majors. One project involved assessing medial knee displacement (MKD), a situation where the subject's knee becomes misaligned during a squatting motion and is a contributing factor in ACL and other knee injuries. The other project looks at the difference in landing forces experienced by gymnasts and cheer-leaders while performing on foam mats versus spring floors. The goal of this talk is to demonstrate how easy it can be to engage life science majors through the use of video analysis and topics like biomechanics and encourage others to try it for themselves.

**11:39AM S7.00003 Development of a Hands-On Survey Course in the Physics of Living Systems** , MEGAN MATTHEWS, DANIEL I. GOLDMAN, Georgia Institute of Technology — Due to the widespread availability and technological capabilities of modern smartphones, many biophysical systems can be investigated using easily accessible, low-cost, and/or “homemade” equipment. Our survey course is structured to provide students with an overview of research in the physics of living systems, emphasizing the interplay between measurement, mechanism, and modeling required to understand principles at the intersection of physics and biology. The course proceeds through seven modules each consisting of one week of lectures and one week of hands-on experiments, called “microlabs”. Using smartphones, Arduinos, and 3D printed materials students create their own laboratory equipment, including a 150X van Leeuwenhoek microscope, a shaking incubator, and an oscilloscope, and then use them to study biological systems ranging in length scales from nanometers to meters. These systems include population dynamics of rotifer/algae cultures, experimental evolution of multicellularity in budding yeast, and the bio- & neuromechanics involved in animal locomotion, among others. In each module, students are introduced to fundamental biological and physical concepts as well as theoretical and computational tools (nonlinear dynamics, molecular dynamics simulation, and statistical mechanics). At the end of the course, students apply these concepts and tools to the creation of their own microlab that integrates hands-on experimentation and modeling in the study of their chosen biophysical system.

**11:51AM S7.00004 Physics of Health Sciences** , MILLARD BAUBLITZ, BENNETT GOLDBERG, Boston University — A one-semester algebra-based physics course is being offered to Boston University students whose major fields of study are in allied health sciences: physical therapy, athletic training, and speech, language, and hearing sciences. The classroom instruction incorporates high-engagement learning techniques including worksheets, student response devices, small group discussions, and physics demonstrations instead of traditional lectures. The use of pre-session exercises and quizzes has been implemented. The course also requires weekly laboratory experiments in mechanics or electricity. We are using standard pre- and post-course concept inventories to compare this one-semester introductory physics course to ten years of pre- and post-course data collected on students in the same majors but who completed a two-semester course.

**12:03PM S7.00005 Promoting Active Learning: The Use of Computational Software Programs** , TOM DICKINSON, Washington State University — The increased emphasis on active learning in essentially all disciplines is proving beneficial in terms of a student's depth of learning, retention, and completion of challenging courses. Formats labeled flipped, hybrid and blended facilitate face-to-face active learning. To be effective, students need to absorb a significant fraction of the course material prior to class, e.g., using online lectures and reading assignments. Getting students to assimilate and at least partially understand this material prior to class can be extremely difficult. As an aid to achieving this preparation as well as enhancing depth of understanding, we find the use of software programs such as Mathematica® or MatLab®, very helpful. We have written several Mathematica® applications and student exercises for use in a blended format two semester E&M course. Formats include tutorials, simulations, graded and non-graded quizzes, walk-through problems, exploration and interpretation exercises, and numerical solutions of complex problems. A good portion of this activity involves student-written code. We will discuss the efficacy of these applications, their role in promoting active learning, and the range of possible uses of this basic scheme in other classes.

**12:15PM S7.00006 Student Responses to a Flipped Introductory Physics Class with built-in Post-Video Feedback Quizzes** , ROBERTO RAMOS, University of the Sciences — We present and analyze student responses to multiple Introductory physics classes in a university setting, taught in a “flipped” class format. The classes included algebra- and calculus-based introductory physics. Outside class, students viewed over 100 online video lectures on Classical Mechanics, Electricity and Magnetism, and Modern Physics prepared by this author and in some cases, by a third-party lecture package available over YouTube. Inside the class, students solved and discussed problems and conceptual issues in greater detail. A pre-class online quiz was deployed as an important source of feedback. I will report on the student reactions to the feedback mechanism, student responses using data based on anonymous surveys, as well as on learning gains from pre-/post- physics diagnostic tests. The results indicate a broad mixture of responses to different lecture video packages that depend on learning styles and perceptions. Students preferred the online quizzes as a mechanism to validate their understanding. The learning gains based on FCI and CSEM surveys were significant.

**12:27PM S7.00007 Teaching Electrostatics and Entropy in Introductory Physics** , MARK REEVES, George Washington University — Entropy changes underlie the physics that dominates biological interactions. Indeed, introductory biology courses often begin with an exploration of the qualities of water that are important to living systems. However, one idea that is not explicitly addressed in most introductory physics or biology courses is important contribution of the entropy in driving fundamental biological processes towards equilibrium. I will present material developed to teach electrostatic screening in solutions and the function of nerve cells where entropic effects act to counterbalance electrostatic attraction. These ideas are taught in an introductory, calculus-based physics course to biomedical engineers using SCALEUP pedagogy. Results of student mastering of complex problems that cross disciplinary boundaries between biology and physics, as well as the challenges that they face in learning this material will be presented.

**12:39PM S7.00008 ABSTRACT WITHDRAWN —**

**12:51PM S7.00009 High speed video analysis study of elastic and inelastic collisions<sup>1</sup>** , ANDREW BAKER, JACOB BECKEY, VASUDEVA ARAVIND, Clarion University, CLARION TEAM — We study inelastic and elastic collisions with a high frame rate video capture to study the process of deformation and other energy transformations during collision. Snapshots are acquired before and after collision and the dynamics of collision are analyzed using Tracker software. By observing the rapid changes (over few milliseconds) and slower changes (over few seconds) in momentum and kinetic energy during the process of collision, we study the loss of momentum and kinetic energy over time. Using this data, it could be possible to design experiments that reduce error involved in these experiments, helping students build better and more robust models to understand the physical world.

<sup>1</sup>We thank Clarion University undergraduate student grant for financial support involving this project.

**1:03PM S7.00010 Hurricane Balls: A rigid-body-motion student project** , DAVID JACKSON, DAVID MERTENS, BRETT PEARSON, Dickinson College — Hurricane Balls is a spinning-top toy that consists of two metal spheres that are welded (or glued) together. The motion of Hurricane Balls provides a beautiful example of rotational motion in which the angular velocity and angular momentum point in different directions. Because the motion is both captivating to students and extremely reproducible, this system is an ideal example to include in a classical mechanics course. Moreover, the excellent agreement between theory and experiment makes a detailed analysis of Hurricane Balls a perfect topic for an independent student project. This talk will give an overview of the system and will provide some tips on how to make such a project a successful student experience.

**1:15PM S7.00011 First order error corrections in common introductory physics experiments<sup>1</sup>**, JACOB BECKEY, ANDREW BAKER, VASUDEVA ARAVIND, Clarion University, CLARION TEAM — As a part of introductory physics courses, students perform different standard lab experiments. Almost all of these experiments are prone to errors owing to factors like friction, misalignment of equipment, air drag, etc. Usually these types of errors are ignored by students and not much thought is paid to the source of these errors. However, paying attention to these factors that give rise to errors help students make better physics models and understand physical phenomena behind experiments in more detail. In this work, we explore common causes of errors in introductory physics experiment and suggest changes that will mitigate the errors, or suggest models that take the sources of these errors into consideration. This work helps students build better and refined physical models and understand physics concepts in greater detail.

<sup>1</sup>We thank Clarion University undergraduate student grant for financial support involving this project.

**1:27PM S7.00012 Are our textbooks too good to be good? Let students own their textbooks to own the skills**, XIUPING TAO, Winston-Salem State University — The two new yearlong high school courses, AP Physics 1 and 2, are equivalent to the two-semester algebra-based introductory Physics college course. The AP courses have more than 300 instruction hours, while the college course less than 100. This partially explains why college instructors always struggle to cover the important topics to not necessarily prepared students. To make it worse, many college students are not buying or reading textbooks and rely on instructors to get the course content. The fragmented reception is preventing students from getting a complete picture of the course. Not that there is a shortage of textbooks. There are many 1000-page tomes costing \$200 or more, too good to be good. All the struggles contribute to U.S. students' relatively low STEM skills. I propose to let students own their books to own the skills. Students need much shorter (thus manageable) and much more affordable books, and they need to own it for good. Cross-culture comparison reveals that students learn better when they truly own their books (without planning to resell).

**1:39PM S7.00013 Physics and Physics Education at Clarion University**, VASUDEVA ARAVIND, Clarion University — Clarion University is located in the rolling hills of western Pennsylvania. We are a primarily undergraduate public institution serving about 6000 students. We graduate students who take different career paths, one of them being teaching physics at high schools. Since educating teachers of tomorrow requires us to introduce currently trending, research proven pedagogical methods, we incorporate several aspects of physics pedagogies such as peer instruction, flipped classroom and hands on experimentation in a studio physics lab format. In this talk, I discuss some of our projects on physics education, and seek to find potential collaborators interested in working along similar lines.

**1:51PM S7.00014 Learning Through Doing: Teaching Advanced Physics Concepts Through Freshmen Research Immersion**, MATTHEW WAHILA, LOUIS PIPER, Dept. of Physics, Binghamton University, JENNIFER AMEY, WAYNE JONES, Dept. of Chemistry, Binghamton University, MEGAN FEGLEY, NANCY STAMP, Freshmen Research Immersion Program, Binghamton University — Often undergraduates have difficulty grasping advanced concepts in physics due to the seemingly abstract and foreign nature of the time and length scales involved. The Smart Energy Freshmen Research Immersion (FRI) program at Binghamton University was created as a way to address this issue and, in turn, improve undergraduate performance and retention in physics and chemistry. Using real-world research problems as a wider context to frame their understanding, we have developed a course sequence providing a more intuitive and comprehensive understanding of core physics and chemistry concepts over the course of the program. Advanced condensed matter topics, such as optical band gaps, crystal and electronic structure, and electron/hole conduction are introduced to students through hands-on, authentic research activities incorporating materials for real-world device applications. I will discuss how employing p-n junctions as a model device can allow for a natural and intuitive progression from basic to advanced physics and chemistry concepts. This approach illustrates how shifting exotic concepts into a more relatable form through the use of analogy is important for fostering a more intuitive understanding of physical phenomena.

**2:03PM S7.00015 Transferring a Flipped Class in Algebra-based Physics to New Faculty<sup>1</sup>**, LEIGH SMITH, ALEXANDRE SOUSA, Department of Physics, University of Cincinnati — Transferring existing active classroom educational efforts to new faculty is a challenge that must be met to ensure sustainability of changes. We describe a flipped class approach to teaching algebra-based Physics being transferred to a new faculty member. This flipped class includes extensive video and reading-based preparation materials outside of class, and the use of Learning Catalytics for in-class work is developed and tested by one of the authors. These materials are of course idiosyncratic to the style of the developer. Student results using the new materials are compared with students in more standard classes which suggest significant positive benefit over several years. A faculty member decided to use these materials in his own section of the same course. Our experience shows that it takes some time for the new faculty member to use and adapt the materials in a way which matches his own style, which in the end results in equivalently enhanced results. Lessons learned from this transfer process will be discussed.

<sup>1</sup>We acknowledge the financial support of the NSF through DUE 1544001 and 1431350.

**Thursday, March 17, 2016 11:15AM - 2:15PM –**  
**Session S8 DMP: Electrical Transport and Photoexcitations in Organic/Inorganic Perovskites**  
304 - Jisong Huang, University of Nebraska Lincoln

**11:15AM S8.00001 Charge Transport in Hybrid Halide Perovskite Field-Effect Transistors<sup>1</sup>**, OANA JURCHESCU, Wake Forest University, Department of Physics — Hybrid organic-inorganic trihalide perovskite (HTP) materials exhibit a strong optical absorption, tunable band gap, long carrier lifetimes and fast charge carrier transport. These remarkable properties, coupled with their reduced complexity processing, make the HTPs promising contenders for large scale, low-cost thin film optoelectronic applications. But in spite of the remarkable demonstrations of high performance solar cells, light-emitting diodes and field-effect transistor devices, all of which took place in a very short time period, numerous questions related to the nature and dynamics of the charge carriers and their relation to device performance, stability and reliability still remain. This presentation describes the electrical properties of HTPs evaluated from field-effect transistor measurements. The electrostatic gating of provides a unique platform for the study of intrinsic charge transport in these materials, and, at the same time, expand the use of HTPs towards switching electronic devices, which have not been explored previously. We fabricated FETs on SiO<sub>2</sub> and polymer dielectrics from spin coating, thermal evaporation and spray deposition and compare their properties. CH<sub>3</sub>NH<sub>3</sub>PbI<sub>3-x</sub>Cl<sub>x</sub> can reach balanced electron and hole mobilities of 10 cm<sup>2</sup>/Vs upon tuning the thin-film microstructure, injection and the defect density at the semiconductor/dielectric interface. The work was performed in collaboration with Yaochuan Mei (Wake Forest University), Chuang Zhang, and Z. Valy Vardeny (University of Utah).

<sup>1</sup>The work is supported by ONR grant N00014-15-1-2943.

**11:51AM S8.00002 Understanding charge transport in organometal halide field effect transistors.**<sup>1</sup>, SATYAPRASAD P SENANAYAK, BINGYAN YANG, ADITYA SADHANALA, PROF. SIR RICHARD FRIEND, PROF. HENNING SIRRNIGHAUS, Optoelectronics Group, Cavendish Laboratory, University of Cambridge — Organometal halide based perovskite are emerging materials for wide range of electronic applications. A range of optoelectronic applications like high efficiency solar cells, color pure LEDs and optical pumped lasers have been demonstrated. Here, we report the demonstration of a high performance field effect transistor fabricated from iodide perovskite material at room temperature. The devices exhibit clean saturation behavior with electron  $\mu_{\text{FET}} > 3 \text{ cm}^2 \text{V}^{-1} \text{s}^{-1}$  and current modulation in the range of  $10^6 - 10^7$  which are till date the best performance achieved with these class of materials. This high performance is attributed to a combination of novel film fabrication technique and device engineering strategies. Detailed understanding of the observed band-like transport phenomenon is developed by tuning the different sources of dynamic and static disorder prevalent in the system. These finding are expected to pave way for developing next generation electronic application from perovskite materials.

<sup>1</sup>Authors acknowledge EPSRC for funding and SPS acknowledges Royal Society Newton Fellowship

**12:03PM S8.00003 Charge carrier transport properties of methyl-ammonium-lead-trihalide perovskites investigated by the time-of-flight method**<sup>1</sup>, EVAN LAFALCE, CHUANG ZHANG, Z. VALY VARDENY, University of Utah, UNIVERSITY OF UTAH TEAM — We studied the charge transport properties of methyl-ammonium-lead-trihalide perovskites using the photocurrent transient time-of-flight method. Various morphologies that include single-crystals and thin films with different crystalline grain sizes and surface roughness were investigated. The photocurrent transients were recorded as a function of excitation wavelength, intensity, and applied electric field as well as the sample temperature. We found that surface recombination leads to a photocurrent response that is sharply peaked at the band edge. While the carrier mobility depends on the sample preparation and sample temperature, typical values are on the order of  $1 \text{ cm}^2/\text{Vs}$ , consistent with previous reports using similar methods. This value is high compared to other solution-processed semiconductors such as pi-conjugated polymers and quantum dots; however it is relatively low compared to inorganic semiconductors. Therefore determining the mobility limiting factors in hybrid perovskite devices is important for progress in their optoelectronic device performance.

**12:15PM S8.00004 ABSTRACT WITHDRAWN —**

**12:27PM S8.00005 Electronic Structure Approach to Tunable Electronic Properties of Hybrid Organic-Inorganic Perovskites**, GARNETT LIU, Department of Chemistry, Duke University, Durham, NC 27708, WILLIAM HUHN, DAVID B. MITZI, MEMS Department, Duke University, Durham, NC 27708, YOSUKE KANAI, Department of Chemistry, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599, VOLKER BLUM, MEMS Department, Duke University, Durham, NC 27708 — We present a study of the electronic structure of layered hybrid organic-inorganic perovskite (HOIP) materials using all-electron density-functional theory. Varying the nature of the organic and inorganic layers should enable systematically fine-tuning the carrier properties of each component. Using the HSE06 hybrid density functional including spin-orbit coupling (SOC), we validate the principle of tuning subsystem-specific parts of the electron band structures and densities of states in  $\text{CH}_3\text{NH}_3\text{PbX}_3$  ( $\text{X}=\text{Cl}, \text{Br}, \text{I}$ ) compared to a modified organic component in layered  $(\text{C}_6\text{H}_5\text{C}_2\text{H}_4\text{NH}_3)_2\text{PbX}_4$  ( $\text{X}=\text{Cl}, \text{Br}, \text{I}$ ) and  $\text{C}_{20}\text{H}_{22}\text{S}_4\text{N}_2\text{PbX}_4$  ( $\text{X}=\text{Cl}, \text{Br}, \text{I}$ ). We show that tunable shifts of electronic levels indeed arise by varying  $\text{Cl}, \text{Br}, \text{I}$  as the inorganic components, and  $\text{CH}_3\text{NH}_3^+$ ,  $\text{C}_6\text{H}_5\text{C}_2\text{H}_4\text{NH}_3^+$ ,  $\text{C}_{20}\text{H}_{22}\text{S}_4\text{N}_2^+$  as the organic components. SOC is found to play an important role in splitting the conduction bands of the HOIP compounds investigated here. The frontier orbitals of the halide shift, increasing the gap, when  $\text{Cl}$  is substituted for  $\text{Br}$  and  $\text{I}$ .

**12:39PM S8.00006 Electronic properties of  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  (001) surface**, XIN HUANG, TULA PAUDEL, University of Nebraska-Lincoln, SHUAI DONG, Southeast University, China, EVGENY TSYMBAL, University of Nebraska-Lincoln — The energetics and electronic properties of cubic  $\text{CH}_3\text{NH}_3\text{PbBr}_3$  (001) surfaces are studied using a first-principles method. We find that the uncompensated intrinsic dipole moment of a  $\text{CH}_3\text{NH}_3$  molecule induces a band bending, being larger for the  $\text{PbBr}_2$ -terminated surface than for the  $\text{CH}_3\text{NH}_3\text{Br}$ -terminated surface. When the intrinsic dipole are fully compensated, the surface electronic structure shows new states near band edges for both  $\text{MABr}$  and  $\text{PBB}_2$  terminations. We find that for the  $\text{PbBr}_2$ -terminated surface, less dispersive surface states appear just above the bulk valence bands at the center of Brillouin zone ( $\Gamma$  point), while for the  $\text{CH}_3\text{NH}_3\text{Br}$ -terminated surface, more dispersive surface states appear below the conduction bands at the  $\text{M}$  point. These states effectively reduce the band gap and improve optical absorption properties. The  $\text{PbBr}_2$ -terminated surface states are of the  $\text{Pb-p}$  character, and hence are strongly affected by spin-orbit coupling, whereas the  $\text{CH}_3\text{NH}_3\text{Br}$ -terminated surface states are of the  $\text{Pb-s}$  character and hence are not affected by the spin-orbit coupling effect. Our study suggests a way to tune the spin-orbit coupling by selecting an appropriate surface.

**12:51PM S8.00007 Phase stability, electronic structure and phonons in  $\text{CsGeI}_3$** <sup>1</sup>, LING-YI HUANG, WALTER LAMBRECHT, Case Western Reserve Univ — Because  $\text{Ge}$  is smaller than  $\text{Sn}$  and  $\text{Pb}$ ,  $\text{CsGeI}_3$  is promising to overcome the stability problems of the perovskite forms of  $\text{CsSnI}_3$  and  $\text{CsPbI}_3$  halides toward the denser yellow phase in which octahedra are edge as well as cornersharing in one dimensional chains. This phase has higher gaps and is unsuitable for photovoltaics.  $\text{CsGeI}_3$  and other trihalide germanates are found to exist in the cubic perovskite phase at high temperature but in a rhombohedral phase in which the  $\text{Ge}$  is displaced toward three of the halogen neighbors in its surrounding octahedron, accompanied by a rhombohedral distortion of the lattice vectors. We will present density functional total energy calculations and band structures obtained within the quasi-particle self-consistent  $\text{GW}$  method for both the cubic and rhombohedral phase of  $\text{CsGeI}_3$ . For the latter, we find a gap of 1.6 eV in excellent agreement with recent experiments on its absorption edge. We will also present optical dielectric function and effective mass results for this material and discuss the trends for different types of distortions in halides depending on the chemical composition. The phonons at the Brillouin zone center are calculated and compared to experimental Raman spectra.

<sup>1</sup>NSF and DOE

**1:03PM S8.00008 Interface Engineering in Metal Halides Perovskites: from molecules to devices.**, ANNAMARIA PETROZZA, Istituto Italiano di Tecnologia — In this talk we review our recent studies which aim to clarify the relationship between structural and electronic properties from a molecular to mesoscopic level. First we identify the markers for local disorder at molecular level by using Raman Spectroscopy as a probe. Then, we exploit such a tool to explore the role of microstructure on the absorption and emission properties of the semiconductor looking both at polycrystalline thin films and single crystals. We address the controversy surrounding electron hole interactions and excitonic effects. We show that in hybrid lead-halide perovskites dielectric screening also depends on the local microstructure of the hybrid crystals and not only on its chemical composition. This leads to the possibility of band gap engineering and the consequent control of the elementary photo-excitation dynamics that determine the perovskites performances in different optoelectronic devices. Finally, the role of interface engineering, the effect of ion migration, and interface doping on charge extraction will be elucidated to provide a guideline for the design of hysteresis free solar cells. 1)G. Grancini & AR Srimath Kandada et al, Nature Photonics, 9 (10), 695-701, 2015 2) C. Tao et al, Energy Environ. Sci., 8, 2365-2370, 2015

**1:39PM S8.00009 Transient Spectroscopy of Photoexcitations and Morphology Control of Organometal Trihalide Perovskites<sup>1</sup>**, YAXIN ZHAI, EVAN LAFALCE, Univ of Utah, CHUAN-XIANG SHENG, Nanjing University of Science and Technology, CHUANG ZHANG, DALI SUN, ZEEV VALY VARDENY, Univ of Utah — We studied the photoexcitation dynamics in various hybrid perovskites by using broadband ps transient photomodulation (PM) spectroscopy and variable stripe length (VSL) technique. We observed both excitonic and free carriers spectral features in MAPbI<sub>3</sub> but mainly excitonic transition in MAPbI<sub>1.1</sub>Br<sub>1.9</sub> and MAPbI<sub>3-x</sub>Cl<sub>x</sub> films. We also fabricated MAPbBr<sub>3</sub> films with nano-crystal pinning (NCP) treatment, which allows for smaller crystalline grain size. The transient spectra show a narrower and longer-lived photobleaching band in NCP treated films consistent with the increase in the photoluminescence efficiency. In addition the net optical gain measured by VSL is markedly increased up to 300 cm<sup>-1</sup>, and the lasing threshold is concurrently reduced. Measurement of the waveguide losses in the NCP films shows that the improvement in lasing properties can partly be attributed to the reduced optical scattering.

<sup>1</sup>Work supported by the AFOSR through a MURI grant RA 9550-14-1-0037

**1:51PM S8.00010 Photoluminescence and lasing properties of MAPbBr<sub>3</sub> single crystals grown from solution<sup>1</sup>**, SANDIP ARYAL, EVAN LAFALCE, CHUANG ZHANG, YAXIN ZHAI, Z. VALY VARDENY, University of Utah — Recent studies of solution-grown single crystals of inorganic-organic hybrid lead-trihalide perovskites have suggested that surface traps may play a significant role in their photophysics. We study electron-hole recombination in single crystal MAPbBr<sub>3</sub> through such trap states using cw photoluminescence (PL) and ps transient photoinduced absorption (PA) spectroscopies. By varying the depth of the collecting optics we examined the contributions from surface and bulk radiative recombination. We found a surface dominated PL band at the band-edge that is similar to that observed from polycrystalline thin films, as well as a weaker red-shifted emission band that originates from the bulk crystal. The two PL bands are distinguished in their temperature, excitation intensity and polarization dependencies, as well as their ps dynamics. Additionally, amplified spontaneous emission and crystal-related cavity lasing modes were observed in the same spectral range as the PL band assigned to the surface recombination.

**2:03PM S8.00011 Ultrafast Extreme Ultraviolet Spectroscopy of Lead Iodide and Methylammonium Lead Iodide**, MAX VERKAMP, MING-FU LIN, ELIZABETH RYLAND, JOSH VURA-WEIS, University of Illinois at Urbana-Champaign — Methylammonium lead iodide (perovskite) is a leading candidate for use in next-generation solar cell devices. However, the photophysics of perovskite responsible for its strong photovoltaic qualities are not fully understood. Ultrafast extreme ultraviolet (XUV) spectroscopy was used to investigate relaxation dynamics in perovskite and its precursor, lead iodide, with carrier-specific signals arising from transitions from a common inner-shell level (I 4d) to the valence and conduction bands. Ultrashort (30 fs) pulses of XUV radiation in a broad spectrum (40-70 eV) were obtained using high-harmonic generation in a tabletop instrument. Transient absorption measurements with visible pump (3.1 eV) and XUV probe directly observed the relaxation of charge carriers after above band excitation for both perovskite and lead iodide in the femtosecond and picosecond time ranges.

Session S11 GMAG DMP: Thin Film Skyrmions 307 - Wanjun Jiang, Argonne National Laboratory

**11:15AM S11.00001 Synthesizing Skyrmion Molecules in Fe-Gd Thin Films<sup>1</sup>**, J. C. T LEE, Materials Sciences Division, Lawrence Berkeley National Laboratory, J. CHESS, Dept. of Physics, University of Oregon, Eugene, S. A. MONTROYA, Center for Magnetic Recording Research, UC San Diego, X. W. SHI, Dept. of Physics, University of Oregon, Eugene, NOBUMICHI TAMURA, S. K. MISHRA, Advanced Light Source, LBNL, D. H. PARKS, Dept. of Physics, University of Oregon, Eugene, P. FISCHER, MSD, LBNL; and Dept. of Physics, UC Santa Cruz, B. MCMORRAN, Dept. of Physics, University of Oregon, Eugene, S. K. SINHA, Dept. of Physics, UC San Diego, E. FULLERTON, Center for Magnetic Recording Research, UC San Diego, S. D. KEVAN, Dept. of Physics, University of Oregon, Eugene; ALS and MSD, LBNL, S. ROY, Advanced Light Source, LBNL — Controlled creation of tunable skyrmion phases at room temperature holds the promise of advanced spintronics applications using these topological entities. By varying the composition and thickness of an amorphous Fe-Gd thin film and optimizing the applied field protocol, we produced at room temperature an ordered, achiral phase of skyrmion molecules, that is, bound pairs of magnetic skyrmions having the same polarity but opposite helicity. This phase appears between stripe and uniform magnetization phase and its origin lies in the existence of mirror planes in the stripe domain structure. Dipolar, exchange, and anisotropy forces are the dominant interactions in these materials, while the role of bulk and surface chiral exchange interactions is small.

**11:27AM S11.00002 Chirality evaluation of spin spiral in Mn thin film on W(110)**, MASAHIRO HAZE, YASUO YOSHIDA, YUKIO HASEGAWA, The Institute for Solid State Physics, The University of Tokyo — In crystal fields with broken inversion symmetry such as surfaces or interfaces, the Dzyaloshinskii-Moriya interaction (DMI), which is induced by the spin orbit interaction, may have a significant contribution to the formation of spin structures. Because of DMI, magnetic thin films formed on a heavy-elemental substrate such as W often exhibit peculiar spin spiral structures whose chirality is fixed and determined by the polarity of DMI. Investigating the chirality of spin structures is thus important to reveal the formation mechanism of spin structures and, more specifically, to determine whether DMI plays a decisive role on it. Monolayer (ML) Mn thin films formed on W(110), the first surface spin spiral structures, show a cycloidal spin spiral structure propagating along to [1-10] axis. Spin-polarized scanning tunneling microscopy (SP-STM) and theoretical analysis based on density functional calculation revealed left-handed chirality of the structure and concluded that it is driven by DMI. A SP-STM recent study revealed that double layer (DL) Mn thin films on W(110) show a conical spin spiral structure whose propagation direction is along [001]. The chirality and its driving interaction, however, have not been revealed yet. Here in this study, we have investigated the chirality of DL Mn by SP-STM. Our experimental results revealed that the spin spiral structure of DL Mn is homochiral but right-handed, which is opposite to that of ML Mn. In the presentation we will discuss different roles of DMI exerted on the two Mn thin films.

**11:39AM S11.00003 Determination of interfacial Dzyaloshinskii-Moriya exchange interaction from static domain size imaging**, PARNIKA AGRAWAL, IVAN LEMESH, MIT, SARAH SCHLOTTER, Harvard University, GEOFFREY BEACH, MIT — Dzyaloshinskii-Moriya interaction (DMI) has been identified [1-2] as a necessary ingredient for the formation of chiral spin structures such as skyrmions and Néel domain walls in perpendicularly magnetized thin films. Various simulation and experimental studies have tried to quantify DMI from domain wall [2] and skyrmion [3-4] motion with applied currents and magnetic fields. Here, a means to quantify DMI in multilayer films using only static magnetic characterizations is proposed. Static domain structure is observed using magnetic force microscopy (MFM) in multilayer stacks of [Pt(2.5-7.5nm)/CoFeB(0.8nm)/MgO(1.5nm)]<sub>15</sub> where the thickness  $t_{pt}$  of the Pt layer is systematically varied from 2.5 nm to 7.5 nm. A variation of domain size from ~300 nm to ~70 nm is seen in the labyrinthine demagnetized state as  $t_{pt}$  is decreased. It is shown that the domain size as a function of  $t_{pt}$  can be well-fitted analytically by a model in which the domain wall energy is the sole free parameter. Additional measurements of magnetic anisotropy of the film reveal the significant contribution of interfacial DMI (~1.4 mJ/m<sup>2</sup>) to the domain wall energy. Ref: 1.Fert et al., *Nat. Nanotech.*, 8, 152-156 (2013); 2. S. Emori et al., *Nature Materials* 12,611–616 (2013); 3. S. Woo et al., arXiv:1502.07376; 4.W. Jiang et al., arXiv:1502.08028v1

**11:51AM S11.00004 Interface-induced skyrmions in magnetic films and multilayers**, ALBERT FERT, CNRS/THALES and Universit Paris Saclay, Palaiseau, France — The talk is on individual skyrmions induced by interface Dzyaloshinskii-Moriya Interactions (DMI) in thin magnetic films or multilayers. I will present:

1. Ab-initio calculations of the characteristic features of interface DMI [1]: extension of the DMI away from the interface in the magnetic film, thickness dependence, influence of the existence of proximity-induced magnetism in neighbor layers, influence of interface roughness, perspective with new materials. . .
2. Experimental results on small skyrmions at room temperature in (Ir/Co/Pt) $\times$ 10 multilayers [2].
3. Towards applied devices: micromagnetic simulations of the nucleation and current-induced motion of skyrmions [3].

**12:27PM S11.00005 Observation of sub-100 nm Néel skyrmions at room temperature**<sup>1</sup>, S.G.E. TE VELTHUIS, W. JIANG, S. ZHANG, C. PHATAK, W. ZHANG, M.B. JUNGFLIECH, J.E. PEARSON, A. PETFORD-LONG, A. HOFFMANN, Argonne National Laboratory — Magnetic skyrmions are topologically stable spin textures that have attracted tremendous attention in the field of spintronics. As compared to Bloch skyrmions, which are typical for only few bulk chiral magnets, Néel skyrmions in magnetic multilayers [1, 2, 3] may be more ubiquitous and have the advantage that included layers of heavy metals provide efficient current induced spin-orbit torques. By optimizing the stacking structure, we present an experimental strategy towards nanometer-scale skyrmions at room temperature in the absence of a magnetic field. Furthermore, we discuss the experimental challenge of identifying the chiral nature of Néel skyrmions by using Lorentz transmission electron microscopy. Our results constitute an important step for enabling skyrmion based ultra-high density data storage, and for probing topological physics at room temperature. [1] W. Jiang, et al., Science, 349, 283 (2015). [2] S. Woo, et al., arXiv:1502.07376 (2015). [3] C. Moreau-Luchaire, et al., arXiv:1502.07853 (2015).

**12:39PM S11.00006 Skyrmions in thin-film multilayers with interfacially-induced Dzyaloshinskii-Moriya interaction observed by MFM**, MIRKO BACANI, MIGUEL A. MARIONI, JOHANNES SCHWENK, SARA ROMER, XUE ZHAO, ALEXANDRE GUILLER, Empa, Duebendorf, Switzerland, HANS J. HUG, Empa, Duebendorf, Switzerland and Department of Physics, University of Basel, Basel, Switzerland — By proper selection of interfaces in thin-film multilayers one can separately engineer the anisotropy, magnetization and Dzyaloshinskii-Moriya interaction (DMI), which is useful in the design of skyrmion materials. We use high-sensitivity, high-resolution magnetic force microscopy (MFM) in various applied magnetic fields to image the micromagnetic structures in multilayers based on symmetric-interface stacks of Pt/Co/Pt and asymmetric ones of Pt/Co/Ir. The former have domain sizes of several microns, whereas the latter show considerably smaller domain sizes. These are (246 $\pm$ 40) nm independently of the demagnetization process used. We attribute the lower domain size to a net DMI. The calculated DMI in the asymmetric case is too small to support a skyrmion phase, but isolated skyrmions can exist. MFM experiments reveal skyrmions with a diameter below 50 nm, when the field is reduced from positive saturation. In negative fields these skyrmions are either incorporated into expanding domains or burst into a larger domain. Local DMI constants estimated from the bursting fields agree well with the average DMI constant. Our work demonstrates that MFM can detect skyrmions in thin films, and can help accelerate research in this field.

**12:51PM S11.00007 Engineering of the anisotropy and Dzyaloshinskii-Moriya interaction energies in Pt-Co and Pt-Co-Cu heterostructures**, SARAH SCHLOTTER, Harvard University SEAS, GEOFFREY BEACH, Massachusetts Inst of Tech-MIT — It has previously been shown that perpendicular magnetic anisotropy is increased in Pt-Co-Pt structures by placing a Cu spacer between the top, diffuse Co-Pt interface.<sup>1</sup> However, including a spacer layer increases interfacial asymmetry in the system: a prerequisite for a strong Dzyaloshinskii-Moriya interaction (DMI) which governs helical spin structures such as skyrmions and chiral domain walls.<sup>2</sup> We show that the increased asymmetry significantly enhances DMI strength in Pt-Co-Cu-Pt heterostructures as compared to corresponding Pt-Co-Pt systems. We further show that one can control the characteristic length scales governing domain width by engineering the magnetostatic, anisotropy, and DMI energies in heavy-metal/ferromagnet heterostructures. These structures may provide insight into engineering the size of skyrmions in spintronic devices.

**1:03PM S11.00008 Skyrmion bubble stability in thin films with strong Dzyaloshinskii-Moriya interaction**, LUCAS CARETTA, UWE BAUER, ALEXANDRA CHURIKOVA, MAXWELL MANN, GEOFFREY BEACH, Massachusetts Inst of Tech-MIT — The Dzyaloshinskii-Moriya interaction (DMI) at heavy-metal/FM interfaces stabilizes chiral spin textures, such as magnetic skyrmions [1]. Magnetic skyrmions are applicable to energy efficient spintronics [2,3]. However, room temperature stability of skyrmion bubbles (SBs) has not been quantified experimentally. We show when the ratio of the DMI effective field to the perpendicular anisotropy field is large, expanding bubble domains leave behind fine-scale dendritic structure, consisting of coupled 360 degree domain walls (DW). Dendritic structures are manipulated to form stable SBs. We imaged SBs in Pt(3nm)/Co(0.9nm)/Gd(1nm)/GdOx(30nm) films using Kerr microscopy to characterize the stability of SBs. We show that the field stability of SBs is a strong function of the applied in-plane field. Increasing in-plane field reduces the annihilation threshold of the skyrmions. The SB annihilation field becomes deterministic at in-plane fields near the DMI effective field. Simulations show Bloch points are formed in the SB DW at high in-plane fields, leading to the deterministic collapse of the bubbles.[1] A. Fert et al., Nat. Nano., 8, 152-156 (2013) [2] S. Woo et al., arXiv:1502.07376 (2015) [3] A. Fert et al., arXiv:1502.07853 (2015)

**1:15PM S11.00009 Skyrmion-induced bound states on the surface of 3D Topological Insulators**, DIMITRIOS ANDRIKOPOULOS<sup>1</sup>, BART SOREE<sup>2</sup>, Katholieke Univ Leuven — In this work, we study the interaction between the surface state of a 3D Topological Insulator and a skyrmion magnetic texture. The skyrmion texture couples to the spin of the surface state electron with strength  $\Delta_S$ . Vortex and hedgehog skyrmion and anti-skyrmion structures are considered and their interaction is compared. Due to the vortex structure, the interaction of the in-plane components can be neglected and a step function is used to describe the skyrmion magnetization profile. In the hedgehog case, it is shown that the in-plane components cannot be disregarded and thus a realistic description for the skyrmion is required. Working in the micromagnetic framework, we derive a macrospin description for the skyrmion using the variational principle and then numerically solve for the bound states. It is shown that the existence and properties of these states as a function of skyrmion size, strongly depend on the skyrmion type. Both vortex and hedgehog skyrmions or anti-skyrmions can induce bound states with energies  $|E| < \Delta_S$ . For the hedgehog skyrmion case however, bound state appearance depends on the chirality. Finally, the probability densities in these states are computed and it is demonstrated that the electrons are localized throughout the skyrmion region.

**1:27PM S11.00010 Skyrmion-induced bound states in a superconductor<sup>1</sup>**, SERGEY S. PERSHOGUBA, Nordita, Center for Quantum Materials, KTH Royal Institute of Technology, and Stockholm University, Roslagstullsbacken 23, S-106 91 Stockholm, Sweden, SHO NAKOSAI, Condensed Matter Theory Laboratory, RIKEN, Wako, Saitama, 351-0198, Japan, ALEXANDER V. BALATSKY, Institute for Materials Science, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA — We consider a superconductor proximity coupled to a two-dimensional ferromagnetic film with a skyrmion texture. We predict the skyrmion bound states (SBS) that are induced in the superconductor, similar to the well-known Yu-Shiba-Rusinov (YSR) states. Using the T-matrix calculations and numerical modeling we calculate the spin-polarized local density of states in the superconductor in the vicinity of the skyrmion. The SBS wavefunctions have spatial power-law decay. Presence of the SBS suggests the mechanism by which superconductivity could facilitate an effective long-range interaction between skyrmions when their SBS wavefunctions overlap. arXiv:1511.01842

**1:39PM S11.00011 Stability of skyrmion lattices and symmetries of Dzyaloshinskii-Moriya magnets<sup>1</sup>**, UTKAN GÜNGÖRDÜ, RABINDRA NEPAL, Univ of Nebraska - Lincoln, OLEG A. TRETIKOV, Tohoku Univ, KIRILL BELASHCHENKO, ALEXEY A. KOVALEV, Univ of Nebraska - Lincoln — Recently, there has been substantial interest in realizations of skyrmions, in particular in 2D systems due to increased stability resulting from reduced dimensionality. A stable skyrmion, representing the smallest realizable magnetic texture, could be an ideal element for ultra-dense magnetic memories. Here, we use the most general form of the 2D free energy with Dzyaloshinskii-Moriya interactions constructed from general symmetry considerations reflecting the underlying system. We predict that skyrmion phase is robust and it is present even when the system lacks the in-plane rotational symmetry. In fact, the lowered symmetry leads to increased stability of vortex-antivortex lattices with four-fold symmetry and in-plane spirals, in some instances even in the absence of an external magnetic field. Our results relate different hexagonal and square cell phases to the symmetries of materials used for realizations of skyrmions. This will give clear directions for experimental realizations of hexagonal and square cell phases, and will allow engineering of skyrmions with unusual properties. We also predict striking differences in gyro-dynamics induced by spin currents for isolated skyrmions and for crystals where spin currents can be induced by charge carriers or by thermal magnons.

**1:51PM S11.00012 Increasing skyrmion lattice stability: theory and experiment**, ALEX KRUCHKOV, Ecole Polytechnique Federale de Lausanne (EPFL), JONATHAN WHITE, Paul Scherrer Institut (PSI), HENRIK RONNOW, IVICA ZIVKOVIC, Ecole Polytechnique Federale de Lausanne (EPFL) — Magnetic skyrmions are vortices of spins, considered to be topologically protected against perturbations, and envisaged as very possible next-generation information carriers due to their nanoscale size. In chiral ferromagnets they form a two-dimensional hexagonal array - the skyrmion lattice. A key challenge is that bulk skyrmions have been restricted so far to a tiny region in the temperature-field phase diagram. In this work we address theoretically the stability of the skyrmion lattice. We demonstrate that tuning anisotropy can lead to dramatic (20 times) enhancement of the skyrmion phase volume, which has been recently revealed in our experiment.

**2:03PM S11.00013 Enhanced stability of skyrmions in magnets with broken mirror symmetry<sup>1</sup>**, JAMES ROWLAND, Ohio State University, SUMILAN BANERJEE, Weizmann Institute of Science, MOHIT RANDEIRA, Ohio State University — Most previous work on skyrmion phases in chiral magnets with Dzyaloshinskii-Moriya interactions (DMI) focuses on the case of broken bulk inversion symmetry. The skyrmion crystal is then stable only in a limited range of parameter space with easy-axis anisotropy. In this talk I will describe the effects [1] of including broken mirror or surface inversion symmetry which leads to a Rashba DMI, in addition to the Dresselhaus DMI arising from broken bulk inversion. I will show that increasing Rashba DMI leads to a progressively larger domain of stability for skyrmions, especially in the easy-plane anisotropy regime. In the latter regime the topological charge density shows an unusual internal structure, and isolated skyrmions cannot be embedded in a ferromagnetic background. Thus the homotopy group  $\pi_2(S^2)$  method of classifying skyrmions fails. I will discuss a Chern number classification of these non-trivial skyrmions using maps from the 2-torus (the unit cell for skyrmion crystals) to the 2-sphere in spin space. Finally, I will discuss the elliptic cone phase, a new state that emerges for easy-axis anisotropy and broken mirror symmetry. [1] J. Rowland, S. Banerjee, and M. Randeria, arXiv:1509.07508v2.

**Thursday, March 17, 2016 11:15AM - 2:15PM –**  
**Session S12 FIAP GIMS: Prospects and Challenges in Medical Physics and Imaging** 308 - Larry Nagahara, Johns Hopkins University

**11:15AM S12.00001 Future Directions in Medical Physics**, ROBERT JERAJ, University of Wisconsin — Medical Physics is a highly interdisciplinary field at the intersection between physics and medicine and biology. Medical Physics is aiming at development of novel applications of physical processes and techniques in various areas of medicine and biology. Medical Physics had and continues to have profound impact by developing improved imaging and treatment technologies, and helping to advance our understanding of the complexity of the disease. The general trend in medicine towards personalized therapy, and emphasis on accelerated translational research is having a profound impact on medical physics as well. In the traditional stronghold for medical physicists – radiation therapy – the new reality is shaping in the form of biologically conformal and combination therapies, as well as advanced particle therapy approaches, such as proton and ion therapies. Rapid increase in faster and more informative multi-modality medical imaging is bringing a wealth of information that is being complemented with data obtained from genomic profiling and other biomarkers. Novel data analysis and data mining approaches are proving grounds for employment of various artificial intelligence methods that will help further improving clinical decision making for optimization of various therapies as well as better understanding of the disease properties and disease evolution, ultimately leading to improved clinical outcomes.

**11:51AM S12.00002 Opportunities of using Stimulated Emission from Biological Tissue**, S. H. ANDY YUN, Harvard Medical School and Massachusetts General Hospital — Fluorescence or spontaneous emission has been a powerful tool in biomedical applications ranging from biochemical assays and cytometry to microscopy and medical imaging. Here I present the opportunities in the generation and applications of coherent stimulated emission within biological samples.

**12:27PM S12.00003 Future Directions in Medical Physics: Models, Technology, and Translation to Medicine<sup>1</sup>** , JEFFREY SIEWERDSEN, Johns Hopkins University — The application of physics in medicine has been integral to major advances in diagnostic and therapeutic medicine. Two primary areas represent the mainstay of medical physics research in the last century: in radiation therapy, physicists have propelled advances in conformal radiation treatment and high-precision image guidance; and in diagnostic imaging, physicists have advanced an arsenal of multi-modality imaging that includes CT, MRI, ultrasound, and PET as indispensable tools for noninvasive screening, diagnosis, and assessment of treatment response. In addition to their role in building such technologically rich fields of medicine, physicists have also become integral to daily clinical practice in these areas. The future suggests new opportunities for multi-disciplinary research bridging physics, biology, engineering, and computer science, and collaboration in medical physics carries a strong capacity for identification of significant clinical needs, access to clinical data, and translation of technologies to clinical studies. In radiation therapy, for example, the extraction of knowledge from large datasets on treatment delivery, image-based phenotypes, genomic profile, and treatment outcome will require innovation in computational modeling and connection with medical physics for the curation of large datasets. Similarly in imaging physics, the demand for new imaging technology capable of measuring physical and biological processes over orders of magnitude in scale (from molecules to whole organ systems) and exploiting new contrast mechanisms for greater sensitivity to molecular agents and subtle functional / morphological change will benefit from multi-disciplinary collaboration in physics, biology, and engineering. Also in surgery and interventional radiology, where needs for increased precision and patient safety meet constraints in cost and workflow, development of new technologies for imaging, image registration, and robotic assistance can leverage collaboration in physics, biomedical engineering, and computer science. In each area, there is major opportunity for multi-disciplinary collaboration with medical physics to accelerate the translation of such technologies to clinical use.

**1:03PM S12.00004 Imaging and Analytics: The changing face of Medical Imaging** , THOMAS FOO, GE Global Research — There have been significant technological advances in imaging capability over the past 40 years. Medical imaging capabilities have developed rapidly, along with technology development in computational processing speed and miniaturization. Moving to all-digital, the number of images that are acquired in a routine clinical examination has increased dramatically from under 50 images in the early days of CT and MRI to more than 500-1000 images today. The staggering number of images that are routinely acquired poses significant challenges for clinicians to interpret the data and to correctly identify the clinical problem. Although the time provided to render a clinical finding has not substantially changed, the amount of data available for interpretation has grown exponentially. In addition, the image quality (spatial resolution) and information content (physiologically-dependent image contrast) has also increased significantly with advances in medical imaging technology. On its current trajectory, medical imaging in the traditional sense is unsustainable. To assist in filtering and extracting the most relevant data elements from medical imaging, image analytics will have a much larger role. Automated image segmentation, generation of parametric image maps, and clinical decision support tools will be needed and developed apace to allow the clinician to manage, extract and utilize only the information that will help improve diagnostic accuracy and sensitivity. As medical imaging devices continue to improve in spatial resolution, functional and anatomical information content, image/data analytics will be more ubiquitous and integral to medical imaging capability.

**1:39PM S12.00005 NIH Funding for Biomedical Imaging<sup>1</sup>** , RICHARD CONROY, National Institute of Biomedical Imaging and Bioengineering — Biomedical imaging, and in particular MRI and CT, is often identified as among the top 10 most significant advances in healthcare in the 20th century. This presentation will describe some of the recent advances in medical physics and imaging being funded by NIH in this century and current funding opportunities. The presentation will also highlight the role of multidisciplinary research in bringing concepts from the physical sciences and applying them to challenges in biological and biomedical research..

<sup>1</sup>NIH Funding for Biomedical Imaging

## Thursday, March 17, 2016 11:15AM - 2:15PM – Session S13 DMP: 2D Materials: Semimetals 309 - Xuan Gao, Case Western Reserve University

**11:15AM S13.00001 Dirac Semimetals in Two Dimensions** , STEVE YOUNG, US Naval Research Laboratory — Graphene is well-known for its unusual band structure, which features a pair of two dimensional Dirac points – band degeneracies with linear dispersion – at the Fermi level, and has served as the canonical platform for exploring the novel physics that arises near such points. However, spin-orbit interaction breaks the degeneracy at the Dirac points, so that graphene is formally a quantum spin Hall insulator. In this talk I will discuss the theory of two dimensional materials with Dirac points that *persist* in the presence of spin-orbit interaction. These Dirac points are preserved by nonsymmorphic symmetries, which describe lattice invariance under a combined point group operation and fractional translation. This is the only means of protecting Dirac points against spin-orbit coupling in two dimensions, and such Dirac points are unique in marking the transition between topological and trivial insulating states. I will describe the general properties of these Dirac points and the nature of their protection by nonsymmorphic symmetry operations, and contrast them with Dirac points protected by symmorphic symmetries in both the three dimensional case and the spin-orbit-free two dimensional case. I will then delineate the possible configurations of two dimensional Dirac materials, classifying them by protective symmetries. The role of 2D Dirac materials as transition phases will be described in detail, and the topological and trivial phases that result from various modes of symmetry breaking will be explored. Finally, I will discuss the potential for realization of both Dirac materials and their derivative phases, paying special attention to relevant chemical considerations.

**11:51AM S13.00002 Bosonization of Weyl Fermions** , EDUARDO MARINO, UFRJ — The electron, discovered by Thomson by the end of the nineteenth century, was the first experimentally observed particle. The Weyl fermion, though theoretically predicted since a long time, was observed in a condensed matter environment in an experiment reported only a few weeks ago. Is there any linking thread connecting the first and the last observed fermion (quasi)particles? The answer is positive. By generalizing the method known as bosonization, the first time in its full complete form, for a spacetime with 3+1 dimensions, we are able to show that both electrons and Weyl fermions can be expressed in terms of the same boson field, namely the Kalb-Ramond anti-symmetric tensor gauge field. The bosonized form of the Weyl chiral currents lead to the angle-dependent magneto-conductance behavior observed in these systems.

**12:03PM S13.00003 Coulomb interaction effect in tilted Weyl fermion in two dimensions** , HIROKI ISOBE, Massachusetts Institute of Technology, NAOTO NAGAOSA, RIKEN and University of Tokyo — Weyl fermions with tilted linear dispersions characterized by several different velocities appear in some systems including the quasi-two-dimensional organic semiconductor  $\alpha$ -(BEDT-TTF)<sub>2</sub>I<sub>3</sub> and three-dimensional WTe<sub>2</sub>. The Coulomb interaction between electrons modifies the velocities in an essential way in the low energy limit, where the logarithmic corrections dominate. Taking into account the coupling to both the transverse and longitudinal electromagnetic fields, we derive the renormalization group equations for the velocities of the tilted Weyl fermions in two dimensions, and found that they increase as the energy decreases and eventually hit the velocity of light  $c$  to result in the Cherenkov radiation. Especially, the system restores the isotropic Weyl cone even when the bare Weyl cone is strongly tilted and the velocity of electrons becomes negative in certain directions.

**12:15PM S13.00004 Strong Correlation and Topological States in Orbital-Active Dirac Materials**, SHENGLONG XU, CONGJUN WU, University of California, San Diego — Two dimensional Dirac materials, starting with graphene, have drawn tremendous research interests in the past decade. Instead of focusing on the  $p_z$  orbital as in graphene, we go a step further and study its two orbitals counterpart, namely the  $p_x$  and  $p_y$  orbitals on a honeycomb lattice. The model applies to both optical lattices and several solid state systems including organic material, fluoridated tin film, BiX/SBX (X=H.F.Cl.Br). In the band structure, besides the well known Dirac points in the graphene band structure, the orbital degrees of freedom give rise to flat bands as well as quadratic band touching points. These new features provide an even wider playground for searching exotic states of matter. With help of mean field theory and functional renormalization group (FRG) method, we explore the effects of interaction on the system and investigate the consequential interesting states such as ferromagnetism, Wigner crystallization, quantum anomalous Hall states and f-wave superconductivity.

**12:27PM S13.00005 Three-dimensional Anisotropy and Kohler's Rule Scaling of the Magnetoresistance in  $\text{WTe}_2$** <sup>1</sup>, YONG-LEI WANG, Materials Science Division, Argonne National Laboratory & Department of Physics, University of Notre Dame — Tungsten ditelluride ( $\text{WTe}_2$ ) was recently discovered to have extremely large magnetoresistance (XMR) at low temperatures and exhibits a transformative 'turn-on' temperature behavior: when the applied magnetic field  $H$  is above a certain value, the resistivity versus temperature  $\rho(T)$  curve shows a minimum at a field dependent temperature  $T^*(H)$ . Since  $\text{WTe}_2$  is a layered compound with metal layers sandwiched between adjacent insulating chalcogenide layers, it is typically considered to be a two dimensional (2D) material, whereby the anisotropic magnetoresistance is attributed only to the perpendicular component of the magnetic field. Moreover, the 'turn-on' temperature behavior has been interpreted as a magnetic-field-driven metal-insulator transition or attributed to an electronic structure change. In this talk I will report on two scaling behaviors of the magnetoresistance in  $\text{WTe}_2$ . The first shows that the angle dependence of the magnetoresistance follows a conventional 3D anisotropy scaling and hence reveals the electrical 3D nature of  $\text{WTe}_2$  [1]. The second demonstrates that the  $\rho(T, H)$  curves, including those with 'turn-on' temperature behavior, can be scaled with Kohler's rule [2]. The observed Kohler's rule scaling excludes the possible existence of a magnetic-field-driven metal-insulator transition or significant contribution of an electronic structure change to the low-temperature XMR in  $\text{WTe}_2$ . It indicates that both the XMR and the 'turn-on' behavior originate from the high mobilities of the charge carriers, which are strongly temperature dependent in  $\text{WTe}_2$ . We also derived quantitative expressions for the magnetic field dependence of the 'turn-on' temperature  $T^*(H)$  and for the temperature dependence of the resistivity  $\rho(T^*, H)$  at the onset of the XMR behavior.

In collaboration with L. R. Thoutam, Z. L. Xiao, J. Hu, S. Das, Z. Q. Mao, J. Wei, R. Divan, A. Luican-Mayer, G. W. Crabtree, and W. K. Kwok

**1:03PM S13.00006 Electronic Transport in Ultra-Thin  $1\text{T}'\text{-WTe}_2$** , VALLA FATEMI, SARANESH PREMBABU, MIT, MAZHAR N. ALI, Princeton, KENJI WATANABE, TAKASHI TANIGUCHI, Advanced Materials Laboratory, National Institute for Materials Science, Tsukuba, Japan, ROBERT J. CAVA, Princeton, PABLO JARILLO-HERRERO, MIT — We report low-temperature electronic transport measurements of  $1\text{T}'\text{-WTe}_2$  in the few-layer limit. Thin layers of  $\text{WTe}_2$  are obtained by the mechanical exfoliation technique and are subsequently encapsulated between thin hexagonal Boron Nitride crystals via a dry crystal transfer technique. These devices are fabricated entirely inside an inert-atmosphere glove box to avoid degradation. We report on the temperature, magnetic field, and electrostatic gate voltage dependence of these devices for several different thicknesses.

**1:15PM S13.00007 Spin Orbit Induced Electronic Structure and Magnetotransport in  $\text{WTe}_2$** <sup>1</sup>, DAVID J. SINGH, University of Missouri, MINGHU PAN, Huazhong University of Science and Technology, JIAQIANG YAN, University of Tennessee, BIAO YANG, Soochow University, YUNYI ZANG, Tsinghua University, JUNJIE ZHANG, Soochow University, KE HE, Tsinghua University, MENGHAO WU, Huazhong University of Science and Technology, YANFEI ZHAO, Peking University, DAVID MANDRUS, University of Tennessee, JIAN WANG, Peking University, QIKUN XUE, Tsinghua University, LIFENG CHI, QING LI, Soochow University — We report electronic structure studies of  $\text{WTe}_2$ , which shows an XMR behavior and is non-centrosymmetric. We find a spin-orbit split semimetallic band structure with a different Fermi surface topology than that initially reported, including Rashba split bands with Fermi surface around the zone center. The metallic properties are not one dimensional and are best described in terms of an anisotropic 3D metal with compensating low carrier density Fermi surfaces. The spin texture and transport is discussed as the origin of the XMR effect and in particular is consistent with the geometry in which the XMR effect is observed and its angle dependence.

**1:27PM S13.00008 Electronic and Magnetic Anisotropy of Layered  $\text{IrTe}_2$  Single Crystals**<sup>1</sup>, GUIXIN CAO, RONGYING JIN, Louisiana State University, Baton Rouge — Layered  $\text{IrTe}_2$  is known to exhibit extremely rich physical properties with two successive phase transitions at  $T_1 \sim 280$  K and  $T_2 \sim 180$  K. We have grown  $\text{IrTe}_2$  single crystals with typical sizes of  $451.2 \text{ mm}^3$ . This allows us to experimentally investigate physical properties along different directions. While the lattice parameter ratio  $c/a$  is small, both electrical resistivity and magnetic susceptibility show much higher anisotropy. In particular, we only observe resistivity and susceptibility anomaly along the  $ab$  plane at  $T_2$ , indicating the 2D character of electronic and magnetic properties at low temperatures.

<sup>1</sup>This material is based upon work supported by the U.S. Department of Energy under EPSCoR Grant No. DE-SC0012432.

**1:39PM S13.00009 Magnetoresistance Anisotropy in  $\text{WTe}_2$** , LAXMAN RAJU THOUTAM, Northern Illinois University, Argonne National Laboratory, YONGLEI WANG, Argonne National Laboratory, ZHILI XIAO, Northern Illinois University, Argonne National Laboratory, SAPTARSHI DAS, ADINA LUICAN MAYER, RALU DIVAN, Argonne National Laboratory, GEORGE W CRABTREE, Argonne National Laboratory, University of Illinois at Chicago, WAI KWONG KWOK, Argonne National Laboratory — We report the angle dependence of the magnetoresistance in  $\text{WTe}_2$ . Being a layered material,  $\text{WTe}_2$  is considered to be electronically two-dimensional (2D). Our results demonstrate that it is in fact 3D with an anisotropy of effective mass as small as 2. We measured the magnetic field dependence of the sample resistance  $R(H)$  at various angles between the applied magnetic field with respect to the  $c$ -axis of the crystal and found that they can be scaled based on the mass anisotropy, which changes from  $\sim 2$  to  $\sim 5$  with decreasing temperature in the Fermi liquid state. We will also discuss the origin of the turn-on temperature behavior in this material.

**1:51PM S13.00010 Magnetotransport Measurements of Thin Layered WTe<sub>2</sub>** , BOSONG SUN, ZAIYAO FEI, SANFENG WU, JOE FINNEY, PAUL NGUYEN, University of Washington, JIAQIANG YAN, Oak Ridge National Laboratory, TAUNO PALOMAKI, XIAODONG XU, DAVID COBDEN, University of Washington — Tungsten Telluride, a semimetallic layered transition-metal dichalcogenide, was recently found to have extremely large magnetoresistance at helium temperatures. The unconventional non-saturating behavior may be related to near-perfect charge compensation between electron and hole pockets, but this is still debated. Since that discovery there have been several studies of angle-resolved photoemission and quantum transport on the bulk material which found the Fermi surface to be rather complex. It is clear that insights stand to be gained from the variation of the properties on thinning down to a single monolayer. Measurements of thin exfoliated crystals have indicated that the carriers become increasingly localized on approaching the monolayer limit. This may be an intrinsic feature or it may be a result of the disorder produced by oxidation of the surface layers. We report transport measurements on few-layer and monolayer WTe<sub>2</sub> with and without encapsulation in hBN, including the dependence on thickness, crystal axis, temperature, gate voltage and magnetoresistance, which resolve this question.

**2:03PM S13.00011 Magnetotransport properties of nearly-free electrons in two-dimensional hexagonal metals and application to the Mn+1AX<sub>n</sub> phases** , LU SHI, Univ Catholique de Louvain, THIERRY OUISSE, LMGP/INPG, Grenoble, France, BENJAMIN PIOT, LNCMI/CNRS, Grenoble, France, DIDIER CHAUSSSENDE, LMGP/INPG, Grenoble, France, BENOIT HACKENS, Univ Catholique de Louvain — We propose a general model for explaining the weak field magneto-transport properties of the Mn+1AX<sub>n</sub> phases in their crystalline form. By using this model to describe the magnetotransport properties of nearly-free electrons in two-dimensional hexagonal metals, we modify it so as to be applicable for Mn+1AX<sub>n</sub> phases. It is demonstrated that the values of the in-plane Hall coefficient and magnetoresistance are due to the specific shape of the Fermi surface of almost two-dimensional hole and electron bands. If the contribution of the electron pockets to in-plane resistivity can be predicted to be a minor one, in contrast, both holes and electrons should substantially contribute to the overall value of the in-plane Hall coefficient. The relevance of this model is then supported by elementary considerations, analytical computations and a set of experimental data obtained from single crystals of V<sub>2</sub>AlC and Cr<sub>2</sub>AlC as a function of temperature and magnetic field, both in the basal plane and along the c-axis.

**Session S15 DMP: 2D Materials: Superconductivity and Correlations II** 314 - James Eckstein, UIUC

**11:15AM S15.00001 2D superconductivity by ionic gating<sup>1</sup>** , YOSHI IWASA, The University of Tokyo AND RIKEN CEMS — 2D superconductivity is attracting a renewed interest due to the discoveries of new highly crystalline 2D superconductors in the past decade. Superconductivity at the oxide interfaces triggered by LaAlO<sub>3</sub>/SrTiO<sub>3</sub> has become one of the promising routes for creation of new 2D superconductors. Also, the MBE grown metallic monolayers including FeSe are also offering a new platform of 2D superconductors. In the last two years, there appear a variety of monolayer/bilayer superconductors fabricated by CVD or mechanical exfoliation. Among these, electric field induced superconductivity by electric double layer transistor (EDLT) is a unique platform of 2D superconductivity, because of its ability of high density charge accumulation, and also because of the versatility in terms of materials, stemming from oxides to organics and layered chalcogenides. In this presentation, the following issues of electric field induced superconductivity will be addressed; (1) Tunable carrier density, (2) Weak pinning, (3) Absence of inversion symmetry. (1) Since the sheet carrier density is quasi-continuously tunable from 0 to the order of 10<sup>14</sup> cm<sup>-2</sup>, one is able to establish an electronic phase diagram of superconductivity, which will be compared with that of bulk superconductors. (2) The thickness of superconductivity can be estimated as 2 – 10 nm, dependent on materials, and is much smaller than the in-plane coherence length. Such a thin but low resistance at normal state results in extremely weak pinning beyond the dirty Boson model in the amorphous metallic films. (3) Due to the electric field, the inversion symmetry is inherently broken in EDLT. This feature appears in the enhancement of Pauli limit of the upper critical field for the in-plane magnetic fields. In transition metal dichalcogenide with a substantial spin-orbit interactions, we were able to confirm the stabilization of Cooper pair due to its spin-valley locking.

**11:51AM S15.00002 Electrochemical manipulation of two-dimensional materials** , YIJUN YU, FANGYUAN YANG, Fudan University, XIU FANG LU, YA JUN YAN, University of Science and Technology of China, YONG-HEUM CHO, Rutgers University, LIGUO MA, XIAOHAI NIU, Fudan University, SEJOONG KIM, YOUNG-WOO SON, Korea Institute for Advanced Study, DONGLAI FENG, SHIYAN LI, Fudan University, SANG-WOOK CHEONG, Rutgers University, XIAN HUI CHEN, University of Science and Technology of China, YUANBO ZHANG, Fudan University — The electronic properties of a variety of two-dimensional (2D) materials can be modulated by electrochemical modifications on mesoscopic scale. Here we demonstrate a proof-of-concept ionic field-effect transistor (iFET), which is based on reversible modifications of the electronic properties of a wide range of layered materials (e.g. 1T-TaS<sub>2</sub> and 2H-TaS<sub>2</sub>) through gate-controlled electrochemical reactions with mobile ions in the electrolyte. By fine-tuning the electrochemical reactions, we can switch between Mott phase, superconducting phase, metallic phase and insulating phase in a single 1T-TaS<sub>2</sub> iFET device. Such technique opens up new possibilities in searching for the novel state of matter in 2D materials.

**12:03PM S15.00003 Griffiths singularity of quantum phase transition in ion-gated ZrNCl**, YU SAITO, The University of Tokyo, TSUTOMU NOJIMA, Tohoku University, YOSHIHIRO IWASA, The University of Tokyo — Recent technological advances of thin films fabrication, especially mechanical exfoliation, led to discoveries of less-disordered highly-crystalline two-dimensional (2D) superconductors; atomically thin NbSe<sub>2</sub> and ion-gated 2D materials, which show intrinsic properties of 2D superconductors with minimal disorder; for example, metallic ground state [1,2], and unconventional 2D Ising superconductivity due to pure spin-valley locking effect [3-5]. In this talk, we focus on magnetotransport properties of an ionic-liquid gated ZrNCl, which exhibited Griffiths singularity-like behavior in superconductor-metal-insulator transition induced by magnetic fields at low carrier concentrations. The overall behavior is quite similar to the recent results of superconducting Ga thin films, in which quantum Griffiths singularity was observed in vortex-glass state [6]. We will discuss the relationship between Griffiths singularity and quantum tunneling or flux flow of vortices phase (vortex liquid) in our system. [1] Y. Saito et al. Science 350, 409 (2015). [2] A. W. Tsen et al. arXiv 1507.08639 [3] Y. Saito et al. Nature Phys. doi: 10.1038/nphys3580. (arXiv:1506.04146). [4] X. Xi et al. arXiv:1507.08731. [5] J. M. Lu et al. arXiv:1506.07620. [6] Y. Xing et al. Science 350, 542 (2015).

**12:15PM S15.00004 Spin-valley locking of the bulk transition-metal dichalcogenide superconductor NbSe<sub>2</sub>**, L. BAWDEN, Univ of St Andrews, S. COOIL, F. MAZZOLA, Norwegian Univ of Science & Tech., J.M. RILEY, Univ of St Andrews & Diamond Light Source, L. COLLINS-MCINTYRE, Univ of St Andrews, V. SUNKO, Univ of St Andrews & Max Planck Inst. for Chemical Physics of Solids, J. WELLS, Norwegian Univ of Science & Tech., G. BALAKRISHNAN, Univ of Warwick, S. BAHRAMY, Univ of Tokyo & RIKEN, P.D.C. KING, Univ of St Andrews — 2H-NbSe<sub>2</sub> is a metallic transition metal dichalcogenide, which hosts instabilities to a charge density wave phase, and a superconducting phase at low temperatures [1]. To date, it has been assumed that these phases are largely unaffected by the spin degree of freedom. In contrast, from spin- and angle-resolved photoemission measurements, supported by first principles calculations, we reveal that the normal state Fermi surface hosts a complex spin texture. We uncover a rich spin-valley locking of the form also observed in the semiconducting materials of the same family [2], consistent with the recent observation of Ising pairing in the superconducting state of monolayer NbSe<sub>2</sub> [3]. We find that in the normal state of the bulk compound there is persistent spin polarisation which becomes intrinsically linked to the electronic dimensionality, showing a significant dependence on the out-of-plane momentum. This prompts a reinterpretation of the complex phases that emerge in this, and related materials. [1] Wilson JA et al, Phys. Rev. Lett. 32, 882 (1974). [2] Xiao D et al, Phys. Rev. Lett. 108, 196802 (2012); Xu X et al, Nature Phys. 10, 343350 (2014); Riley JM et al, Nature Phys. 10, 835 (2014). [3] Xi X et al, arXiv:1507.08731.

**12:27PM S15.00005 Superconductivity in few-layer NbS<sub>2</sub> and TaS<sub>2</sub> prepared by mechanical exfoliation**, YUESHEN WU, HAILONG LIAN, SHUJIE FAN, MUYAO FAN, HUI XING, SHUN WANG, Shanghai Jiao Tong Univ, YING LIU, Shanghai Jiao Tong Univ; Pennsylvania State Univ — 2D materials with novel physical properties are useful for scientific inquiries and technological applications. The superconducting 2D materials provide an opportunity to explore the superconductivity in the 2D limit. In this work, the superconductivity in few layer 2H-NbS<sub>2</sub> and 2H-TaS<sub>2</sub> are studied. Single crystals are obtained by vapor transport method and flakes are obtained by mechanical exfoliation. In NbS<sub>2</sub> flakes, the superconducting transition temperature (T<sub>c</sub>) monotonically decreases with decreasing thickness. On the other hand, T<sub>c</sub> of TaS<sub>2</sub> flakes appears to monotonically increase as the flake gets thinner and the signature of CDW transition in R vs. T curves eventually disappear. The electric double layer transistors (EDLTs) of NbS<sub>2</sub> and TaS<sub>2</sub> flakes are also being fabricated to tune superconductivity in these 2D crystals. The results on these experiments will be presented.

**12:39PM S15.00006 Characterizing the electronic ground states of single-layer NbSe<sub>2</sub> via STM/STS**, YI CHEN, MIGUEL UGEDA, AARON BRADLEY, UC Berkeley, YI ZHANG, LBNL, SEITA ONISHI, WEI RUAN, CLAUDIA OJEDA-ARISTIZABAL, UC Berkeley, HYEJIN RYU, LBNL, MARK EDMONDS, HSIN-ZON TSAI, ALEXANDER RISS, UC Berkeley, SUNG-KWAN MO, LBNL, DUNGHA LEE, ALEX ZETTL, UC Berkeley, ZAHID HUSSAIN, LBNL, ZHI-XUN SHEN, Stanford University, MICHAEL CROMMIE, UC Berkeley — Layered transition metal dichalcogenides (TMDs) are ideal systems for exploring collective electronic phases such as charge density wave (CDW) order and superconductivity. In bulk NbSe<sub>2</sub> the CDW sets in at TCDW = 33K and superconductivity sets in at T<sub>c</sub> = 7.2K. Below T<sub>c</sub> these electronic states coexist but their microscopic formation mechanisms remain controversial. Here we present an electronic characterization study of a single 2D layer of NbSe<sub>2</sub> by means of low temperature scanning tunneling microscopy/spectroscopy (STM/STS), angle-resolved photoemission spectroscopy (ARPES), and electrical transport measurements. We demonstrate that the CDW order remains intact in 2D and exhibits a robust 3 × 3 superlattice. Superconductivity also still occurs but its onset is depressed to 1.6K. Our STS measurements at 5K reveal a CDW gap of Δ = 4 meV at the Fermi energy, which is accessible via STS due to the removal of bands crossing the Fermi surface in the 2D limit. Our observations are consistent with the predicted simplified (compared to bulk) electronic structure of single-layer NbSe<sub>2</sub>, thus providing new insight into CDW formation and superconductivity in this model strongly-correlated system.

**12:51PM S15.00007 Studies of the epitaxial monolayer NbSe<sub>2</sub> by ultra-low-temperature scanning tunnelling microscope**, SHUAI-HUA JI, State Key Laboratory of Low-Dimensional Quantum Physics, Department of Physics, Tsinghua University, Beijing 100084, China. — Monolayer NbSe<sub>2</sub> has been successfully synthesized by molecular beam epitaxy on the graphitized SiC(0001) surface. Wide substrate temperature window from 200°C to 650°C for the epitaxial growth has been observed. The polycrystalline nature of the epitaxial sheet, which is caused by the weak Van der Waals interaction with substrate, has been evidenced by reflection high-energy electron diffraction and locally by scanning tunnelling microscope. Under the high temperature growth condition, grain size could reach as large as hundreds of nanometers. The shape of grain boundary is strongly depended on the misaligned angle between adjacent grains. Mainly, three type grain boundaries have been identified at the atomic scale by the local scanning probe. The BCS-like superconducting gap and the spatial fluctuation of order parameter have been revealed by ultra-low temperature scanning tunnelling microscope in the sub-Kelvin range.

**1:03PM S15.00008 A New Platform for Engineering Topological Superconductors: Superlattices on Rashba Superconductors.**, YAO LU, KAM TUEN LAW, The Hong Kong University of Science and Technology — The search for topological superconductors which support Majorana fermion excitations has been an important topic in condensed matter physics. In this work, we propose a new experimental scheme for engineering topological superconductors. In this scheme, by manipulating the superlattice structure of organic molecules placed on top of a superconductor with Rashba spin-orbit coupling, topological superconducting phases can be achieved without fine-tuning the chemical potential. Moreover, superconductors with different Chern numbers can be obtained by changing the superlattice structure of the organic molecules.

**1:15PM S15.00009 Trion formation in monolayer transition metal dichalcogenides**, ROMAN YA. KEZERASHVILI, New York City College of Technology, City University of New York, SHALVA M. TSIKLARI, Borough of Manhattan Community College, The City University of New York — We present three-body calculations for trions binding energy in monolayer transition metal dichalcogenides using the method of hyperspherical harmonics (HH). In numerical calculations for a proper treatment of Coulomb screening in two dimensions we assume that electrons and holes are interacted via Keldysh potential [1]. The convergences of binding energy calculations for the ground state of the trion as a function of the grand angular momentum are studied. For the trion binding energy in MoS<sub>2</sub> we obtain 19.2 meV. This value is remarkably close to the experimental one of 18 meV. A comparison with results of other calculations are presented. We also study solutions of a hyperradial equation in a minimal approximation for the ground angular momentum to examine two regimes: a long range and a short range cases when the inter particle distance is much greater and much less than the screening length. For these cases, we find analytical expressions for the energy and wave function for trion states. [1] L. V. Keldysh, JETP Lett. 29, 658 (1979)

**1:27PM S15.00010 Effects of the environment on the switching current in graphene-based Josephson Junctions.** , IVAN BORZENETS, The University of Tokyo, CHUNG-TING KE, FRANCOIS AMET, MING TSO WEI, Duke University, MICHIIHISA YAMAMOTO, The University of Tokyo, YURIY BOMZE, Duke University, SEIGO TARUCHA, The University of Tokyo, GLEB FINKELSTEIN, Duke University — The nature of the switching current and hysteresis (difference between switching and retrapping currents) in graphene-based Josephson junctions depends greatly on the interaction with the environment. Conventional devices result in underdamped Josephson junctions making the true critical current inaccessible. On the other hand, heavily isolating the Josephson junctions places them in the microscopic quantum tunneling regime even at high temperatures, also masking the critical current. We study the critical current, and the switching statistics in graphene Josephson junctions while varying the effects of the environment. Proper isolation of graphene Josephson junctions is necessary to measure the true critical current, especially so for the cases of small currents around the Dirac point. This is true for the case of conventional diffusive as well as the novel ballistic Josephson junctions.

**1:39PM S15.00011 Sub-Kelvin lateral thermal transport in graphene with superconducting contacts** , ANNE DRAELOS, AVERY SILVERMAN, JIYINGMEI WANG, CHUNG-TING KE, MING-TSO WEI, Duke University, IVAN VLASSIOUK, Oak Ridge National Laboratory, FRANCOIS AMET, Appalachian State University, GLEB FINKELSTEIN, Duke University — We studied thermal transport in graphene with superconducting contacts at low temperatures,  $\sim 0.1$  to 3 K, below the Bloch-Grüneisen temperature. The lead (Pb) superconducting electrodes placed along the length of the graphene form a thermal barrier by preventing the outflow of hot electrons, thus allowing us to isolate and study other cooling pathways. We were able to observe a lateral thermal gradient by studying strips ( $5 \times 50 \mu\text{m}$ ) of CVD-grown graphene transferred onto a  $\text{SiO}_2$  substrate. The characteristic length scale of the temperature profile is determined by the competition of the lateral heat flow within the electron system versus the local cooling of electrons by phonon emission. We anticipate extending this measurement in the near future to examine the outstanding question of electron-phonon cooling close to the Dirac point.

**1:51PM S15.00012 Transport properties of high quality heterostructures from unstable 2D crystals prepared in inert atmosphere** , GELIANG YU, School of Physics and Astronomy, University of Manchester, CAO YANG, Centre for Mesoscience and Nanotechnology, University of Manchester, EKATERINA KHESTANOVA, ARTEM MISHCHENKO, School of Physics and Astronomy, University of Manchester, ANDY KRETININ, ROMAN GORBACHEV, Centre for Mesoscience and Nanotechnology, University of Manchester, KONSTANTIN NOVOSELOV, GEIM ANDRE, School of Physics and Astronomy, University of Manchester, MANCHESTER GROUP TEAM — Many layered materials can be cleaved down to individual atomic planes, similar to graphene, but only a small minority of them are stable under ambient conditions. The rest reacts and decomposes in air, which has severely hindered their investigation and possible uses. Here we introduce a remedial approach based on cleavage, transfer, alignment and encapsulation of air-sensitive crystals, all inside a controlled inert atmosphere. To illustrate the technology, we choose two archetypal two-dimensional crystals unstable in air: black phosphorus and niobium diselenide. Our field-effect devices made from their monolayers are conductive and fully stable under ambient conditions, in contrast to the counterparts processed in air.  $\text{NbSe}_2$  remains superconducting down to the monolayer thickness. Starting with a trilayer, phosphorene devices reach sufficiently high mobilities to exhibit Landau quantization. The approach offers a venue to significantly expand the range of experimentally accessible two-dimensional crystals and their heterostructures.

**2:03PM S15.00013 Spin-orbit coupling induced by band hybridization in Graphene/WS2 heterostructures**<sup>1</sup> , BOWEN YANG, UCR, MIN-FENG TU, Caltech, JEONGWOO KIM, UCI, YONG WU, UCR, JASON ALICEA, Caltech, RUQIAN WU, UCI, MARC BOCKRATH, JING SHI, UCR — Graphene are known to have a negligibly small intrinsic spin-orbit coupling (SOC), however, many novel physical phenomena such as the quantum spin Hall effect and the quantum anomalous Hall effect have been predicted if strong SOC exists in graphene. Despite that many theoretical studies have been carried out on the enhancement of the SOC strength in graphene, few experiments have been conducted to confirm the existence of and investigate the physical origin of the enhanced SOC in graphene. Here we demonstrated the introduction of SOC into graphene through the proximity effect by stacking WS2 onto graphene. We studied the magnetoconductance of graphene and found weak antilocalization emerges when graphene is covered by WS2. This is in a clear contrast with the weak localization behavior observed in bare graphene and thus provides an unambiguous evidence of the induced Rashba SOC. By focusing on a high carrier density region, we showed that it is possible to reliably extract the strength of Rashba SOC. Furthermore, via investigating the electric field dependence of the Rashba SOC with a dual-gate device, we found that the origin of this enhanced SOC is the band hybridization between graphene and WS2, in agreement with our theoretical calculations.

## Thursday, March 17, 2016 11:15AM - 2:15PM –

Session S16 DMP: 2D Devices: Mechanical metamaterials 315 - Charlie Johnson, University of Pennsylvania

**11:15AM S16.00001 Hard and Soft Physics with 2D Materials.** , PAUL MCEUEN, Cornell University — With their remarkable structural, thermal, mechanical, optical, chemical, and electronic properties, 2D materials are truly special. For example, a graphene sheet can be made into a high-performance transistor, but it is also the ultimate realization of a thin mechanical sheet. Such sheets, first studied in detail by August Föppl over a hundred years ago, are notoriously complex, since they can bend, buckle, and crumple in a variety of ways. In this talk, I will discuss a number of experiments to probe these unusual materials, from the effects of ripples on the mechanical properties of a graphene sheet, to folding with atomically thin bimorphs, to the electronic properties of bilayer graphene solitons. Finally, I discuss how the Japanese paper art of kirigami (kiru = 'to cut', kami = 'paper') applied to 2D materials offers a route to mechanical metamaterials and the construction of nanoscale machines.

**11:51AM S16.00002 Band Gap Engineering of  $\text{PbI}_2$  by Incommensurate Van der Waals Epitaxy** , YIPING WANG, JIAN SHI, Department of Material Science and Engineering, Rensselaer Polytechnic Institute — Van der Waals epitaxial growth had been thought to have trivial contribution on inducing substantial epitaxial strain in thin films due to its weak nature of Van der Waals interfacial energy. Due to this, electrical and optical structure engineering via Van der Waals epitaxial strain has been rarely studied. However, by appropriate film-substrate selection, we show that significant band structure engineering could be achieved in a soft thin film material  $\text{PbI}_2$  via Van der Waals epitaxy. The thickness dependent photoluminescence of single crystal  $\text{PbI}_2$  flakes was studied and attributed to the substrate-film coupling effect via incommensurate Van der Waals epitaxy. It is proposed that the Van der Waals strain is resulted from the soft nature of  $\text{PbI}_2$  and large Van der Waals interaction due to the involvement of heavy elements. Such strain plays vital roles in modifying the band gap of  $\text{PbI}_2$ . The deformation potential theory is used to quantitatively unveil the correlation between thickness, strain and band gap change. Our hypothesis is confirmed by the subsequent mechanical bending test and Raman characterization.

**12:03PM S16.00003 Introducing lattice strain to graphene encapsulated in hBN** , HIKARI TOMORI, University of Tsukuba and PRESTO-JST, RINEKA HIRAIDE, YOUTI OOTUKA, University of Tsukuba, KENJI WATANABE, TAKASHI TANIGUCHI, National Institute for Materials Science (NIMS), AKINOBU KANDA, University of Tsukuba — Due to the characteristic lattice structure, lattice strain in graphene produces an effective gauge field. Theories tell that by controlling spatial variation of lattice strain, one can tailor the electronic state and transport properties of graphene. For example, under uniaxial local strain, graphene exhibits a transport gap at low energies, which is attractive for a graphene application to field effect devices. Here, we develop a method for encapsulating a strained graphene film in hexagonal boron-nitride (hBN). It is known that the graphene carrier mobility is significantly improved by the encapsulation of graphene in hBN, which has never been applied to strained graphene. We encapsulate graphene in hBN using the van der Waals assembly method. Strain is induced by sandwiching a graphene film between patterned hBN sheets. Spatial variation of strain is confirmed with micro Raman spectroscopy. Transport measurement of encapsulated strained graphene is in progress.

**12:15PM S16.00004 Probing Mechanics of Crumpled Two-Dimensional Membranes and Cantilevers** , RYAN NICHOLL, HIRAM CONLEY, Vanderbilt University, NICKOLAY LAVRIK, IVAN VLASSIOUK, Oak Ridge National Laboratory, YEVGENIY PUZYREV, VIJAYASHREE PARSI SREENIVAS, SOKRATES PANTELIDES, Vanderbilt University, KIRILL BOLOTIN, Vanderbilt University, Freie Universität — Two-dimensional materials (2DMs) are inevitably crumpled in the out-of-plane direction due to both static wrinkling associated with uneven stresses and dynamic wrinkling resulting from flexural phonons. Here, we investigate the effect of this crumpling on mechanical properties of 2DMs – in-plane stiffness and bending rigidity. To carry out these measurements, we developed techniques to fabricate graphene membranes and singly clamped graphene cantilevers that are stable in vacuum and air. The measurements are performed by actuating these devices electrostatically and monitoring their displacement via sensitive interferometric profilometry both at room and low temperatures. We find that crumpling lowers the in-plane stiffness and strongly increases the bending rigidity of 2DMs. Furthermore, we unravel the relative contribution of static and dynamic wrinkling to observed renormalization of the effective mechanical constants.

**12:27PM S16.00005 Electromechanical coupling in atomically thin MoS<sub>2</sub> and graphene** , SAJEDEH MANZELI, MUHAMMED MALIK BENAMEUR, ADRIEN ALLAIN, AMIRHOSSEIN GHADIMI, MAHMUT TOSUN, ANDRAS KIS, Electrical Engineering Institute, Ecole Polytechnique Federale de Lausanne (EPFL), CH-1015 Lausanne, Switzerland, FERNANDO GARGIULO, GABRIEL AUTS, OLEG V. YAZYEV, Institute of Theoretical Physics, Ecole Polytechnique Federale de Lausanne (EPFL), CH-1015 Lausanne, Switzerland — Nanoelectromechanical systems (NEMS) based on novel materials such as graphene and MoS<sub>2</sub> allow studying their electromechanical characteristics. Here, we incorporate single and bilayer MoS<sub>2</sub> and graphene into NEMS and investigated their electromechanical behavior. We observe a Strain-induced bandgap modulation in atomically thin MoS<sub>2</sub> membranes with a thickness dependent modulation rate. Finite element modeling is used to extract the piezoresistive gauge factor for MoS<sub>2</sub>. In the case of graphene, deflection of monolayer graphene nanoribbons results in a linear increase in their electrical resistance where an upper limit is estimated for the gauge factor. Surprisingly, we observe oscillations in the electromechanical response of bilayer graphene. Our numerical simulations indicate that these oscillations arise from quantum mechanical interference in the transition region induced by sliding of individual graphene layers with respect to each other. Our results reveal that atomically thin MoS<sub>2</sub> membranes show strong piezoresistive effect, comparable to the state-of-the-art silicon sensors. Moreover, bilayer graphene conceals unexpectedly novel physics allowing the rare observation of room temperature electronic interference phenomena.

**12:39PM S16.00006 Effect of strain on the electronic transport properties of mono- and bilayer graphene** , FEN GUAN, XU DU, Stony Brook University - SUNY — It has been theoretically proposed that strain can have a significant impact on the electronic and charge transport properties of mono- and bilayer graphene. Experimental study of such "strain engineering" in field effect devices has been limited, mainly due to the challenge in creating an effective tuning knob of strain. Here we report the fabrication and characterization of suspended graphene field effect transistor (FET) on a Polyimide substrate, where uniaxial strain is applied by bending the substrate. Magnetotransport measurement of both mono- and bilayer graphene FETs are carried out with variable strain, from compressive to tensile, over wide range of temperature (4.2-300K). The impact of the strain on the conductivity of graphene will be discussed and compared to the theoretical predictions on strain-induced gauge field and flexural phonon scatterings.

**12:51PM S16.00007 Simulating MEMS Chevron Actuator for Strain Engineering 2D Materials<sup>1</sup>** , MOUNIKA VUTUKURU, JASON CHRISTOPHER, DAVID BISHOP, ANNA SWAN, Boston Univ — 2D materials pose an exciting paradigm shift in the world of electronics. These crystalline materials have demonstrated high electric and thermal conductivities and tensile strength, showing great potential as the new building blocks of basic electronic circuits. However, strain engineering 2D materials for novel devices remains a difficult experimental feat. We propose the integration of 2D materials with MEMS devices to investigate the strain dependence on material properties such as electrical and thermal conductivity, refractive index, mechanical elasticity, and band gap. MEMS Chevron actuators, provides the most accessible framework to study strain in 2D materials due to their high output force displacements for low input power. Here, we simulate Chevron actuators on COMSOL to optimize actuator design parameters and accurately capture the behavior of the devices while under the external force of a 2D material. Through stationary state analysis, we analyze the response of the device through IV characteristics, displacement and temperature curves. We conclude that the simulation precisely models the real-world device through experimental confirmation, proving that the integration of 2D materials with MEMS is a viable option for constructing novel strain engineered devices.

**1:03PM S16.00008 Mechanically tunable strain fields in suspended graphene by micro electromechanical systems** , TYMOFIY KHODKOV, MATTHIAS GOLDSCHKE, JENS SONNTAG, 2A Physik Institut, RWTH, Aachen, SVEN REICHARDT, Facult des Sciences, de la Technologie et de la Communication, Universit du Luxembourg, GERARD VERBIEST, 2A Physik Institut, RWTH, Aachen, STEPHAN TRELLENKAMP, Peter Grnberg Institute 9, FZ, Jlich, CHRISTOPH STAMPFER, 2A Physik Institut, RWTH, Aachen — The discovery of graphene triggered an enormous interest on the class of two-dimensional (2D) materials. 2D materials manifested high sensitivity of their thermal, optical or electric response to applied tensile stress. Therefore, a rigorous and systematic investigation of their mechanical properties is extremely important. On the example of graphene – a top candidate for future flexible electronic devices and sensors – we demonstrate fully controlled and restorable realization of various strain fields in 2D membranes by coupling them to Si-based electrostatic micro-actuators (comb-drives). The comb-drive actuators are capable to provide significant forces and they are made of highly-doped silicon, i.e. they can be operated down to cryogenic temperatures allowing the investigation of quantum effects in electromechanical systems. Using confocal Raman spectroscopy we characterize strain distribution in suspended mono- and bilayer graphene sheets under induced tension (up to 0.5%). A detailed analysis clearly show that graphene samples reproducibly experience strain in different directions only while applying voltages to the micro-actuator. This approach empowers accurate tuning of applied tension in any isolated 2D materials independent on other crucial parameters.

**1:15PM S16.00009 ABSTRACT WITHDRAWN —**

**1:27PM S16.00010 Low dissipative mechanical resonators based on WSe<sub>2</sub> monolayers**, NICOLAS MORELL, ANTOINE RESERBAT-PLANTEY, IOANNIS TSIOUTSIOS, KEVIN SCHADLER, ICFO The Institute of Photonic Sciences, FRANCOIS DUBIN, Institut des NanoSciences de Paris, FRANK KOPPEN, ADRIAN BACHTOLD, ICFO The Institute of Photonic Sciences, QUANTUMNANOMECHANICS TEAM, NANOOPTOELECTRONICS TEAM, NANOSTRUCTURES ET SYSTMES QUANTIQUES TEAM — Atomically thin nano-electromechanical systems (2D-NEMS) combine low mass resonators having resonant frequencies in the MHz-GHz range, wide tunability and low damping. Atomically thin 2D semiconductors, such as transition metal dichalcogenides (TMD), have rich optical properties (direct band gap, spin valley, embedded quantum emitters. . . ), which are linked to their low dimensionality. While optical and electronic properties of WSe<sub>2</sub> have been intensively investigated, there have not been any studies on WSe<sub>2</sub> mechanical resonators. Although TMD NEMs have been fabricated, they have not been measured at cryogenic temperature so far. I will present a new semiconductor 2D-NEMS made of a single layer of WSe<sub>2</sub>. We measured mechanical and photoluminescence spectra of WSe<sub>2</sub> suspended drums at cryogenic temperatures. Our results demonstrate an extremely low damping at low temperature with a quality factor  $Q > 47000$  at  $T=3K$ , which is higher than what can be achieved with graphene NEMs. In addition, we investigated photothermal and optoelectronic effects on the mechanical degree of freedom, revealing the high potential of semiconductor 2D-NEMS for optomechanics experiments.

**1:39PM S16.00011 Folded graphene nanochannels via pulsed patterning of graphene**<sup>1</sup>, RODRIGO G. LACERDA, IVE SILVESTRE, Dept. Física, Universidade Federal de Minas Gerais, CP 702, Belo Horizonte, MG, Brazil, ARTHUR W. BARNARD, School of Applied Eng. Physics, Cornell University, Ithaca, NY 14853, USA, SAMANTHA P. ROBERTS, PAUL MCEUEN, Dept. of Physics, Cornell University, Ithaca, NY 14853, USA — We present a resist-free patterning technique to form electrically contacted graphene nanochannels via localized burning by a pulsed white light source. The technique uses end-point detection to stop the burning process at a fixed resistance. By this method folded graphene nanochannels down to 30 nm in width with controllable resistance ranging from 10 k $\Omega$  to 100 k $\Omega$  is achieved [1]. Folding of the graphene sheet takes place during patterning, which provides very straight edges (zigzag/armchair) as identified by AFM, SEM and TEM. Electrical transport measurements for the nanochannels show a non-linear behavior of the current vs source-drain voltage as the resistance goes above 20 k $\Omega$  indicating conduction tunneling effects. The method described can be interesting not only for fundamental studies correlating edge folded structures with electrical transport but also as a promising path for fabricating graphene devices in situ. This method might also be extended to create nanochannels in other 2D materials. [1] I. Silvestre et al., APL, 106, 153105, 2015.

**1:51PM S16.00012 Shear elastic constants of thin films of the misfit layered compound [(SnSe)<sub>1.05</sub>]<sub>n</sub>[MoSe<sub>2</sub>]<sub>n</sub>**<sup>1</sup>, DONGYAO LI, University of Illinois, GAVIN MITCHSON, DAVID JOHNSON, University of Oregon, ANDRE SCHLEIFE, DAVID CAHILL, University of Illinois — Crystalline materials with interlayer van der Waals bonding typically have low stiffness for shear deformation that reduces the through-plane thermal conductivity and facilitates the use of layered materials as solid-state lubricants. In graphite and MoS<sub>2</sub>,  $c_{44} = 5\text{GPa}$  and  $18\text{GPa}$  respectively. The shear modulus of incommensurate layered materials is expected to be strongly reduced relative to ordered crystals but the magnitude of the suppression is currently unknown. We have recently developed an approach for measuring the shear modulus of thin layers using GHz surface acoustic waves (SAW). [(SnSe)<sub>1.05</sub>]<sub>n</sub>[MoSe<sub>2</sub>]<sub>n</sub> with  $n=1-4$  were prepared as thin films (60 nm) on Si substrates using the modulated elemental reactants technique. The SAW velocity  $v_{SAW}$  of Al/[(SnSe)(MoSe<sub>2</sub>)]/Si structures was measured using a polydimethylsiloxane (PDMS) phase-shift optical mask in a pump-probe system.  $c_{44}$  was determined by fitting the measured  $v_{SAW}$  to the calculated SAW velocity using multi-layer SAW model.  $c_{33}$  was measured by picosecond acoustics.  $c_{11}$ ,  $c_{12}$  and  $c_{13}$  were calculated using density functional theory (DFT) with van der Waals correction. The measured  $c_{33}$  and  $c_{44}$  are compared with the DFT prediction. Experimentally we obtain  $c_{44} = 1.9\text{GPa}$ ,  $1.2\text{GPa}$ , and smaller than  $0.05\text{GPa}$  for  $n=1, 2$  and  $4$ .

**2:03PM S16.00013 Realization of Ripple Induced Pseudomagnetic Fields in Graphene.**<sup>1</sup>, YUHANG JIANG, JINHAI MAO, GUOHONG LI, Rutgers University, DAIARA FARIA, UERJ, Nova Friburgo, RJ-Brazil, ANDREA LATGE, Universidade Federal Fluminense, Niteroi, RJ-Brazil, RAMON CARRILLO-BASTOS, UABC, Ensenada, Baja California, Mexico, NANCY SANDLER, Ohio University, Athens, Ohio, USA, EVA Y. ANDREI, Rutgers University, Piscataway, NJ USA — Strain induced distortions of the honeycomb lattice in graphene produce pseudo-magnetic (PM) fields which change the low energy electronic structure by introducing pseudo Landau levels (LLs), similar to real magnetic fields. The spatial distribution of the PM field is a sensitive function of the strain geometry providing new opportunities for engineering the band structure and transport properties. Here we report on scanning tunneling microscopy (STM), spectroscopy (STS), and numerical simulations on strain-induced PM field generated by quasi 1D ripples in graphene supported by flat substrates, such as hBN or SiO<sub>2</sub>. The ripples are typically  $\sim 1\ \mu\text{m}$  long,  $\sim 20\text{ nm}$  wide and several nm high. Their height profile, which is measured by STM, is compared to numerical simulations from which the local strain and the spatial distribution of the PM field is calculated. An independent measure of the local PM field, obtained from the LLs sequence in STS measurements, gives values comparable to those calculated from the height profile. We further show that the ripple geometry produces regions of alternating PM fields which may be associated with ballistic valley filter channels.

**11:15AM S17.00001 Novel exciton systems in 2D TMD monolayers and heterobilayers<sup>1</sup>**, HONGYI YU, Department of Physics and Center of Theoretical and Computational Physics, The University of Hong Kong — In this talk, two exciton systems in transition metal dichalcogenides (TMDs) monolayer and heterobilayer will be discussed. In TMD monolayers, the strong e-h Coulomb exchange interaction splits the exciton and trion dispersions into two branches with zero and finite gap, respectively<sup>2 3</sup>. Each branch is a center-of-mass wave vector dependent coherent superposition of the two valleys, which leads to a valley-orbit coupling and possibly a trion valley Hall effect. The exchange interaction also eliminates the linear polarization of the negative trion PL emission<sup>4</sup>. In TMD heterobilayers with a type-II band alignment, the low energy exciton has an interlayer configuration with the e and h localized in opposite layers. Because of the inevitable twist or/and lattice mismatch between the two layers, the bright interlayer excitons are located at finite center-of-mass velocities with a six-fold degeneracy<sup>5</sup>. The corresponding photon emission is elliptically polarized, with the major axis locked to the direction of exciton velocity, and helicity determined by the valley indices of the e and h. Some experimental results on the interlayer excitons in the WSe<sub>2</sub>-MoSe<sub>2</sub> heterobilayers will also be presented. The interlayer exciton exhibits a long lifetime as well as a long depolarization time, which facilitate the observation of a PL polarization ring pattern due to the valley dependent exciton-exciton interaction induced expansion<sup>6</sup>.

**11:51AM S17.00002 Engineering topological band with superlattice.<sup>1</sup>**, XIAOOU ZHANG, WENYU SHAN, DI XIAO, Carnegie Mellon Univ — Since the discovery of the quantum Hall effect, the search for topological states has been a major subject of interest in condensed matter physics. Here we propose a general scheme to create nontrivial Chern band by fabricating superlattice structure on a system with non-zero Berry curvature. We analyze the topological band structure by deriving an effective Hamiltonian that incorporates the Berry curvature effect. The Chern number is tunable by the superlattice configurations that are realizable with existing experimental technology.

<sup>1</sup>This work is supported by DOE Basic Energy Sciences Grant No. DE-SC0012509 (D.X. and W.S.) and by AFOSR Grant No. FA9550-14-1-0277 (X.Z.)

**12:03PM S17.00003 Optical properties of quantum dots in buckled graphene-like materials**, THAKSHILA HERATH, VADYM APALKOV, Georgia State University — The band gap of buckled graphene-like materials, such as silicene and germanene, depends on external perpendicular electric field. A specially design profile of electric field produces a quantum dot, i.e., trapping potential for electrons in such materials. We theoretically study the optical properties of such silicene/germanene quantum dots. There are two types of absorption spectra in the quantum dot: interband (optical transitions between the states of the valence and conduction bands) and intraband (transitions between the states of conduction/valence band). The interband absorption spectra have triple-peak structure with peak separation around 10 meV, while intraband absorption spectra, which depend on the number of electrons in the dot, have double-peak structure with separation between the peaks around 15meV. The interband optical spectra as a whole are red-shifted with increasing electric field in the internal region of the quantum dot, while the energy separation between the peaks depends weakly on the electric field. With increasing the size of the quantum dot, the interband and intraband absorption spectra become red shifted as well.

**12:15PM S17.00004 Charge density wave transition in single-layer titanium diselenide**, PENG CHEN, University of Illinois at Urbana-Champaign, YANG-HAO CHAN, Academia Sinica, XINYUE FANG, University of Illinois at Urbana-Champaign, YI ZHANG, Nanjing University, MEI-YIN CHOU, Academia Sinica, SUNG-KWAN MO, ZAHID HUSSAIN, ALEXEI FEDOROV, Lawrence Berkeley National Laboratory, TAI-CHANG CHIANG, University of Illinois at Urbana-Champaign — A single molecular layer of titanium diselenide (TiSe<sub>2</sub>) is a promising material for advanced electronics beyond graphene-a strong focus of current exploration. Such molecular layers are at the quantum limit of device miniaturization and can show enhanced electronic effects not realizable in thick films. We show that single-layer TiSe<sub>2</sub> exhibits a charge density wave (CDW) transition at critical temperature T<sub>C</sub> = 232 K, which is higher than the bulk T<sub>C</sub> = 200 K. Angle-resolved photoemission spectroscopy measurements reveal a small absolute bandgap at room temperature, which grows wider with decreasing temperature T below T<sub>C</sub> in conjunction with the emergence of (2x2) ordering. The results are rationalized in terms of first-principles calculations, symmetry breaking and phonon entropy effects. The observed BCS behaviour of the gap implies a mean-field CDW order in the single layer and an anisotropic CDW order in the bulk.

**12:27PM S17.00005 Spatially Indirect Exciton Condensates in Double Bilayer Graphene**, JUNG-JUNG SU, Department of Electrophysics, National Chiao Tung University, ALLAN H. MACDONALD, Department of Physics, University of Texas at Austin — Many-body interaction effects have a strong influence on the low-energy electronic properties of graphene bilayers because of the nearly quadratic dispersion at the K/K' band-crossing points. In the single graphene bilayer systems, the ground state has an energy gap thought to be a consequence of spin-density wave order and other competing ordered states are believed to be nearby in energy. In systems with two closely spacing bilayer, spatially indirect exciton states are expected in neutral systems with inter-bilayer charge transfer. This transfer can be achieved by applying either a vertical electrical displacement fields or an interbilayer potential bias. Here we report that the different combinations of displacement field and potential bias can give rise to different types of indirect exciton condensate states that are distinguished by the two-dimensional momentum dependence of the spontaneous inter-bilayer coherence. In general a displacement field prefers an excitonic condensate in which the phase coherence between the inner two layers of the four layer system, while the potential bias prefers momentum-independent coherence between remote layers. The complete phase diagram reported exhibits excitonic coherence states mentioned above, and more interestingly, their mixtures.

**12:39PM S17.00006 Exciton-polariton condensation in transition metal dichalcogenide bilayer heterostructure<sup>1</sup>**, KI HOON LEE, JAE-SEUNG JEONG, HONGKI MIN, SUK BUM CHUNG, Seoul Natl Univ — For the bilayer heterostructure system in an optical microcavity, the interplay of the Coulomb interaction and the electron-photon coupling can lead to the emergence of quasiparticles consisting of the spatially indirect exciton and cavity photons known as *dipolariton*, which can form the Bose-Einstein condensate above a threshold density. Additional physics comes into play when each layer of the bilayer system consists of the transition metal dichalcogenide (TMD) monolayer. The TMD monolayer band structure in the low energy spectrum has two valley components with nontrivial Berry phase, which gives rise to a selection rule in the exciton-polariton coupling, e.g. the exciton from one (the other) valley can couple only to the clockwise (counter-clockwise) polarized photon. We investigate possible condensate phases of exciton-polariton in the bilayer TMD microcavity changing relevant parameters such as detuning, excitation density and interlayer distance.

<sup>1</sup>This work was supported in part by the Institute for Basic Science of Korea (IBS) under Grant IBS-R009-Y1 and by the National Research Foundation of Korea (NRF) under the Basic Science Research Program Grant No. 2015R1D1A1A01058071.

**12:51PM S17.00007 Berry Phase Modification to the Energy Spectrum of Excitons<sup>1</sup>**, DI XIAO, JIANHUI ZHOU, WENYU SHAN, Carnegie Mellon Univ, WANG YAO, University of Hong Kong — By quantizing the semiclassical motion of excitons, we show that the Berry curvature can cause an energy splitting between exciton states with opposite angular momentum. This splitting is determined by the Berry curvature flux through the k-space area spanned by the relative motion of the electron-hole pair in the exciton wave function. Using the gapped two-dimensional Dirac equation as a model, we show that this splitting can be understood as an effective spin-orbit coupling effect. In addition, there is also an energy shift caused by other relativistic terms. Our result reveals the limitation of the venerable hydrogenic model of excitons, and it highlights the importance of the Berry curvature in the effective mass approximation.

<sup>1</sup>This work is supported by DOE Basic Energy Sciences Grant No. DE-SC0012509 (D. X. and W. S.) and by AFOSR Grant No. FA9550-14-1-0277 (J. Z.).

**1:03PM S17.00008 Optical and Electronic Properties of doped-MoS<sub>2</sub>: Joint Theoretical/Experimental Study**, MILLER EATON, HANSIKA SIRIKUMARA, HASSANA SAMASSEKOU, DIPANJAN MAZUMDAR, THUSHARI JAYASEKERA, Southern Illinois University Carbondale, LAALITHA LIYANAGE, MARCO BUONGIORNO NARDELLI, University of North Texas — Substitutional doping of transition metal dichalcogenides (TMDs) is an attractive way of engineering their electronic properties. The dependence of optoelectronic properties of TMDs on the dopant is largely under-explored. In this work, we will discuss how different species affect the optical properties of MoS<sub>2</sub>. The electronic structure calculations of doped TMDs are carried out using Density Functional Theory with the recently developed ACBN0 functional, a pseudo-hybrid Hubbard density functional that is a fast, accurate and parameter-free alternative to traditional DFT+U and hybrid exact exchange methods [L.A. Agapito, S. Curtarolo, and M. Buongiorno Nardelli, Phys. Rev. X 5, 011006 (2015)]. We compare our ACBN0 predictions with measurement of the electronic and optical properties of pristine and niobium doped MoS<sub>2</sub> films synthesized via physical vapor deposition and characterized using spectroscopic ellipsometry and optical spectroscopy.

**1:15PM S17.00009 Storing excitons in transition-metal dichalcogenides using dark states<sup>1</sup>**, DANIEL GUNLYCKE, Naval Research Laboratory, FRANK TSENG, NRL/NRC Research Associate, ERGUN SIMSEK, The George Washington University — Monolayer transition-metal dichalcogenides exhibit strongly bound excitons confined to two dimensions. One challenge in exploiting these excitons is that they have a finite life time and collapse through electron-hole recombination. We propose that the exciton life time could be extended by transitioning the exciton population into dark states. The symmetry of these dark states require the electron and hole to be spatially separated, which not only causes these states to be optically inactive but also inhibits electron-hole recombination. Based on an atomistic model we call the Triangular Lattice Exciton (3ALE) model, we derive transition matrix elements and approximate selection rules showing that excitons could be transitioned into and out of dark states using a pulsed infrared laser. For illustration, we also present exciton population scenarios based on different recombination decay constants. Longer exciton lifetimes could make these materials candidates for applications in energy management and quantum information processing.

**1:27PM S17.00010 Excitonic effects in 2D semiconductors: Path Integral Monte Carlo approach**, KIRILL VELIZHANIN, AVADH SAXENA, Los Alamos National Laboratory — One of the most striking features of novel 2D semiconductors (e.g., transition metal dichalcogenide monolayers or phosphorene) is a strong Coulomb interaction between charge carriers resulting in large excitonic effects. In particular, this leads to the formation of multi-carrier bound states (e.g., excitons, trions and biexcitons), which could remain stable at near-room temperatures and contribute significantly to optical properties of such materials. In my talk, I will report on our recent progress in using the Path Integral Monte Carlo methodology to numerically study properties of multi-carrier bound states in 2D semiconductors. Incorporating the effect of the dielectric confinement (via Keldysh potential), we have investigated and tabulated the dependence of single exciton, trion and biexciton binding energies on the strength of dielectric screening, including the limiting cases of very strong and very weak screening. The implications of the obtained results and the possible limitations of the used model will be discussed. The results of this work are potentially useful in the analysis of experimental data and benchmarking of theoretical and computational models.

**1:39PM S17.00011 Theoretical ultra-fast spectroscopy in transition metal dichalcogenides**, ALEJANDRO MOLINA-SANCHEZ, Physics and Materials Science Research Unit, University of Luxembourg, DAVIDE SANGALLI, ANDREA MARINI, ISM-CNR, Monterotondo, Rome, Italy, LUDGER WIRTZ, Physics and Materials Science Research Unit, University of Luxembourg — Semiconducting 2D-materials like the transition metal dichalcogenides (TMDs) MoS<sub>2</sub>, MoSe<sub>2</sub>, WS<sub>2</sub>, WSe<sub>2</sub> are promising alternatives to graphene for designing novel opto-electronic devices. The strong spin-orbit interaction along with the breaking of inversion symmetry in single-layer TMDs allow using the valley-index as a new quantum number [1]. The practical use of valley physics depends on the lifetimes of valley-polarized excitons which are affected by scattering at phonons, impurities and by carrier-carrier interactions. The carrier dynamics can be monitored using ultra-fast spectroscopies such as pump-probe experiments. The carrier dynamics is simulated using non-equilibrium Greens function theory in an ab-initio framework. We include carrier relaxation through electron-phonon interaction. We obtain the transient absorption spectra of single-layer TMD and compare our simulations with recent pump-probe experiments [2]. [1] D. Xiao et. al., Phys. Rev. Lett. **108**, 196802 (2012). X. Xu et. al., Nature Physics **10**, 343 (2014). [2] Y. T. Wang, et. al., Scientific Reports **5**, 8289 (2015).

**1:51PM S17.00012 Interaction Induced Quantum Valley Hall Effect in Graphene<sup>1</sup>**, CRISTIANE MORAIS SMITH<sup>2</sup>, Institute for Theoretical Physics, Utrecht University, Netherlands, EDUARDO C. MARINO, LEANDRO O. NASCIMENTO, Instituto de Física, Universidade Federal do Rio de Janeiro, Brazil, A VAN SERGIO, Departamento de Física, Universidade Federal do Para, Brazil — We use Pseudo Quantum Electrodynamics (PQED) in order to describe the full electromagnetic interaction of the electrons in graphene in a consistent 2D formulation. We first consider the effect of this interaction in the vacuum polarization tensor or, equivalently, in the current correlator to evaluate the Kubo's formula. Thereby, we obtain the usual expression for the minimal conductivity plus corrections due to the interaction. We then predict the onset of an interaction-driven spontaneous Quantum Valley Hall effect by solving the Schwinger-Dyson equation. The obtained Valley-Hall conductivity is exact and universal [1]. **11:15AM S18.00001 Imaging of precessional phase variations in spin Hall devices using picosecond heat pulses**, FENG GUO, JASON BARTELL, GREGORY FUCHS, Cornell University — We introduce a new approach of studying the spin Hall effect in patterned magnetic multilayers by imaging ferromagnetic resonance (FMR) precession phase. Using time-resolved anomalous Nernst effect (TRANE) microscopy, we quantify the amplitude and phase of local magnetic precession, which allows us to image the total driving field vector orientation. In a 5  $\mu\text{m}$  wide channel, we observe a substantial variation of the driving field vector as a function of lateral position that we attribute to variations in the total Oersted field angle and the demagnetization field. Next, using the same device, we compare TRANE phase imaging measurements to all-electrical spin-transfer torque ferromagnetic resonance (STFMR) measurements that sense the spatially averaged precession phase. We find that spatial phase variations introduce a systematic error in the spin Hall efficiency measured using conventional STFMR analysis in our devices. These results underscore the importance of phase-sensitive dynamic imaging to augment all-electrical FMR techniques in quantifying the spin Hall efficiencies of devices.

**11:27AM S18.00002 Magnon excitation and transport in Ferromagnetic Insulator/metal multilayers<sup>1</sup>**, TAO LIU, JIE REN, JIANWEI ZHANG, School of Physics, Tongji University — We studied magnon excitation and transport in a Ferromagnetic Insulator(FI) layer(such as YIG), which connected with Ferromagnetic/normal metal multilayers in two sides. In our modeling, we adopted self-consistent spin dependent Boltzmann equations in metal layers and magnon Boltzmann equation in FI layer. When applying an in-plane current in FM layer, a transverse spin current was generated due to Anomalous Hall effect, after crossing normal metal layer, it will produce magnon excitation at N/FI interface. With carrying spin information, magnon excitation in FI can eventually excite a new spin current at second F/N interface. This is so call magnon-drag effect [1]. In our work, we focused on magnon propagation in FI, with all two-magnon, three magnon, and four magnon scattering. Associated with spin dependent Boltzmann equation, we can investigate magnon excitation and transport properties in FI layer from the interface to bulk scale. The magnon excitation in FI layer is dominated not only by the interface interaction at Normal/FI boundary, but also by the bulk scattering in FI. Our results show the magnon in FI layer has decay behaviors to low energy model. We also showed a new way to manipulate magnon transport in FI. [1] S.L. Zhang and S. Zhang, PRL,109,096603(2012)

**11:39AM S18.00003 Parity-Time Symmetry Breaking in Non-Equilibrium Magnetic Systems**, ALEXEY GALDA, VALERII VINOKUR, Argonne National Laboratory — We introduce generalized non-Hermitian Hamiltonian approach for description of out-of-equilibrium phase transitions in the exemplary context of dissipative non-equilibrium dynamics of an open quantum spin system. The imaginary part of the proposed Hamiltonian describes effects of damping and the applied Slonczewski spin-transfer torque (STT). In the classical limit, our approach reproduces Landau-Lifshitz-Slonczewski dynamics of a large macrospin. We reveal the STT-driven parity-time (PT) symmetry-breaking transition corresponding to a phase transition from precessional magnetization dynamics to controlled switching. Micromagnetic simulations for nanoscale ferromagnetic disks demonstrate the predicted effect. Our findings break ground for a general quantitative description of out-of-equilibrium phase transitions.

**11:51AM S18.00004 Unveiling magnetic Hysteresis**, PAULA MELLADO, ANDRES CONCHA, DAVID AGUAYO, Adolfo Ibez University — Hysteresis manifests as the lack of retraceability of the magnetization curve in magnetic systems. It has been associated with rotation of magnetization and changes of magnetic domains. However, up to date there has been no realization that allows to separate these coupled mechanisms. We introduce a minimal magnetic system where hysteresis is realized in a simple and minimal fashion. The basic units are a few U(1) ferromagnetic altitudinal rotors placed along a one dimensional chain. They exhibit a dissipative dynamics, interacting via magnetic coupling among them and via Zeeman interaction with the external magnetic field. The system displays a hysteretic behavior starting with N=2 rotors which remains qualitatively invariant as more magnets are added to the chain. We explain this irreversibility by using a model that includes Coulombic interactions between magnetic charges located at the ends of the magnets, zeeman coupling and viscous dissipation. We show that interactions between the unit components is the key element responsible for hysteresis and find that the ability to perceive hysteresis, depends on how the time frequencies of damping and interactions inherent to the system compare with the time frequency set by the external field ramping rate.

**12:03PM S18.00005 Combined Molecular Dynamics-Spin Dynamics Simulation of  $\alpha$ -Iron in an External Magnetic Field**, MARK MUDRICK, DILINA PERERA, DAVID P. LANDAU, Univ of Georgia — Using an atomistic model that treats both translational and spin degrees of freedom, combined molecular and spin dynamics simulations have been performed to study dynamic properties of  $\alpha$ -iron. Atomic interactions are described by an empirical many-body potential<sup>1</sup> while spin-spin interactions are handled with a Heisenberg-like Hamiltonian with a coordinate dependent exchange interaction<sup>2</sup>. Each of these interactions are parameterized by first-principles calculations. These simulations numerically solve equations of motion using an algorithm based on the second-order Suzuki-Trotter decomposition for the time evolution operator<sup>3</sup>. Through calculation of the Fourier transform of space-displaced time-displaced correlation functions, vibrational and magnetic excitations have been studied. The application of an external magnetic field up to 10-T has now been included and has been shown to increase the characteristic frequencies of the single-spin-wave excitations. Two-spin-wave interactions have also been investigated.

## 12:15PM S18.00006 Magnetic dynamics studied by high-resolution electron spectroscopy and time-resolved electron microscopy.

, RAJESWARI JAYARAMAN, EPFL - Lausanne — Future information technology requires an increased magnetically encoded data density and novel electromagnetic modes of data transfer. While to date magnetic properties are observed and characterized mostly statically, the need emerges to monitor and capture their fast dynamics. In this talk, I will focus on the spin dynamics i.e. spin wave excitations and the dynamics of a new topological distribution of spins termed “skyrmions”. Wave packets of spin waves offer the unique capability to transport a quantum bit, the spin, without the transport of charge or mass. Here, large wave-vector spin waves are of particular interest as they admit spin localization within a few nanometers. By using our recently developed electron energy loss spectrometer, we could study such spin waves in ultrathin films with an unprecedented energy resolution of 4 meV. By virtue of the finite penetration depth of low energy electrons, spin waves localized at interfaces between a substrate and a thin capping layer can be studied yielding information about the exchange coupling between atoms at the interface. The quantization of spin waves with wave vectors perpendicular to the film gives rise to standing modes to which EELS has likewise access. Such studies when carried out as function of the film thickness again yield information on the layer dependence of the exchange coupling. Magnetic skyrmions are promising candidates as information carriers in logic or storage devices. Currently, little is known about the influence of disorder, defects, or external stimuli on the spatial distribution and temporal evolution of the skyrmion lattice. In this talk, I will describe the dynamical role of disorder in a large and flat thin film of  $\text{Cu}_2\text{OSeO}_3$ , exhibiting a skyrmion phase in an insulating material. We image up to 70,000 skyrmions by means of cryo-Lorentz Transmission Electron Microscopy as a function of the applied magnetic field. In the skyrmion phase, dislocations are shown to cause the emergence and switching between domains with different lattice orientations, and the temporal fluctuation of these domains is filmed. These observations pave the way to the control of a large 2D array of skyrmions.

## 12:51PM S18.00007 Collective Mode Splitting in Coupled Ferromagnet/Oxide Heterostructures<sup>1</sup>

, JUAN G. RAMIREZ, Department of Physics, Universidad de los Andes, Bogotá 111711, Colombia, J. DE LA VENTA, Dep. of Physics, Colorado State University, Fort Collins, CO 80523, USA, SIMING WANG, Lawrence Berkeley National Laboratory, Berkeley, California 94720, USA, THOMAS SAERBECK, Institut Laue-Langevin, 71 avenue des Martyrs, 38000 Grenoble, France, ALI C. BASARAN, Department of Physics, Gebze Technical University, Gebze, Kocaeli 41400, Turkey, X. BATLLE, Departament de Física Fonamental Universitat de Barcelona, 08028 Barcelona, Catalonia, Spain, IVAN K. SCHULLER, Department of Physics, University of California San Diego, La Jolla, CA 92093 USA — The coupling of electronic, magnetic, and structural properties between two dissimilar materials in contact can induce novel functionalities. Here we report on a drastic modification of the magnetization dynamics of thin Nickel films in  $\text{Ni}/\text{V}_2\text{O}_3$  bilayers. We performed temperature-dependent ferromagnetic resonance measurements across the first-order structural phase transition (SPT) of  $\text{V}_2\text{O}_3$ . The results show a strong coupling of the  $\text{V}_2\text{O}_3$  lattice dynamics to the magnon spectra of the Ni film in proximity. We have performed similar measurements across the second-order SPT in  $\text{Ni}/\text{SrTiO}_3$  hybrids. In this later case, only a slight change of the static magnetization was found with no modification of the magnetization dynamics. Our results suggest that the phase coexistence across the first-order SPT of  $\text{V}_2\text{O}_3$  is responsible for the effects observed in the  $\text{Ni}/\text{V}_2\text{O}_3$  hybrids. This suggests the existence of similar effects in other hybrid materials with first-order structural phase transitions.

## 1:03PM S18.00008 Localized spin wave modes in parabolic field wells

, ROBERT MCMICHAEL, Center for Nanoscale Science and Technology, NIST, ELENA TARTAKOVSKAYA, Institute of Magnetism, NAS of Ukraine and Institute of High Technologies, Taras Shevchenko National University of Kiev, MARTHA PARDAVI-HORVATH, School of Engineering and Applied Science, The George Washington University — We describe spin wave modes trapped in parabolic-profile field wells. Trapped spin waves can be used as local probes of magnetic properties with resolution down to 100 nm in ferromagnetic resonance force microscopy.[1,2] Localized modes have been shown to form around field minima from a number of sources, including stray fields from magnetic probe tips [1,3-4] and inhomogeneous magnetostatic fields near film edges.[2] Here, we address the most basic trap, which is a parabolic minimum in the applied field. The magnetic eigenmodes in this trap are tractable enough to serve as approximations in more realistic situations. For a parabolic field, we select basis mode profiles proportional to Hermite functions because they are eigenfunctions of the applied field and exchange parts of the equations of motion. Additionally, we find that these Hermite modes are approximate eigenfunctions of magnetostatic interactions, showing good agreement with micromagnetic calculations. More precise agreement is achieved by diagonalizing the equations of motion using only a few modes. 1. I. Lee et al., Nature 466, 845 (2010). 2. F. Guo et al. Phys. Rev. Lett, 110, 017601 (2013) 3. ## 1:15PM S18.00009 Cavity mediated coherent coupling between yttrium iron garnet magnets

, NICHOLAS LAMBERT, University of Cambridge, JAMES HAIGH, Hitachi Cambridge Laboratory, STEFAN LANGENFELD, University of Cambridge, ANDREW DOHERTY, University of Sydney, ANDREW FERGUSON, University of Cambridge — Strong coupling between the magnetostatic modes of an yttrium iron garnet (YIG) magnet and a microwave frequency electromagnetic cavity is now readily achievable[1,2,3]. Recently, coupling between a magnon and a superconducting qubit mediated by a cavity has also been demonstrated[4]. In this talk, we describe dispersive measurement[5] of the cavity-mediated coupling of magnetostatic modes in two YIG magnets. We find they are strongly coupled even when detuned from the cavity modes. We study the strength of the coupling as a function of the detuning, and find a  $1/\Delta$  dependence when close to individual cavity modes. Dark states of the coupled magnets are observed, in which the symmetry of the microwave drive does not match that of the new eigenstates. Our results are described well within the framework of circuit QED. Such an approach to coupling magnets might be used to phase-lock many spatially separated magnetic oscillators, such as those in spin-torque nano-oscillators or magnetic metamaterials. Phys., 117, 053910 (2015) [4] Tabuchi et al., Science, 349(6246), 405408 (2015) [5] Haigh et al., Phys. Rev. B, 91, 104410 104410 (2015)

## 1:27PM S18.00010 Rabi nutations in a ferromagnetic film

, AMIR CAPUA, CHARLES RETTNER, IBM Almaden Res Ctr, STUART PARKIN, IBM Almaden Res Ctr, Max Plank Inst. Halle — When electromagnetic radiation interacts with a two-level system, energy is transferred back and forth between the quantum system and the electromagnetic radiation at a rate defined by the Rabi frequency. This process takes place as long as coherence prevails, until steady state is reached. Rabi nutations have been observed in a variety of quantum systems (atomic vapors, semiconductors, superconducting qubits, etc.). Here, we observe Rabi nutations in an ultrathin  $\sim 10$  Å perpendicularly magnetized CoFeB film. A hybrid ferromagnetic resonance (FMR) – time resolved magneto optical Kerr effect (TRMOKE) system is used for this observation. Namely, a strong optical pump pulse perturbs the precessing spin system after which a weak optical probe pulse is sent at different times to map its recovery until steady precessional motion is reached again. The responses at the different detunings of magnetic field away from resonance conditions readily indicate the occurrence of the Rabi nutations which are initiated by the pump arriving at  $t=0$ . Excellent agreement with the prediction given by the Rabi formula is found. The method we report presents a new approach to study dynamical phenomena in magnetic materials.

## 1:39PM S18.00011 Propagation of pulsed surface spin-wave signals at millikelvin temperatures<sup>1</sup>

, ARJAN VAN LOO, RICHARD MORRIS, ALEXY KARENOWSKA, Clarendon Laboratory, Department of Physics, University of Oxford — Propagating microwave-frequency magnons in magnetic films attract increasing attention on account of their potential interface with superconducting quantum circuit and qubit systems. Their rich dynamics and slow speeds make magnons an interesting addition to the circuit quantum electrodynamics toolbox and, at the same time, superconducting circuit technology promises to be a powerful tool in the investigation of their quantum properties. We have studied the propagation of pulsed surface spin-wave signals over millimeter distances in yttrium iron garnet waveguides at  $\sim 10$  mK. Input microwave pulses and pulse trains with various envelope shapes were applied to an inductive input antenna, and the resulting magnons were detected by an output antenna of identical design. The shape of the output signal was observed to depend on the frequency content (carrier and pulse shape) of the input pulse. By performing measurements at varying frequencies and magnetic fields we have been able to map out the dispersion relation for surface magnon modes. These experiments were undertaken as a first step towards coupling propagating magnons in thin films to other quantum systems with microwave-frequency transition energies, and superconducting qubits in particular.

## 1:51PM S18.00012 Spin waves of ferromagnetic films<sup>1</sup>

, RODRIGO ARIAS, Universidad de Chile — The spin wave modes of ferromagnetic films have been studied for a long time experimentally as well as theoretically: initially magnetostatic and later dipole-exchange modes. Theoretically dipole-exchange modes have been solved exactly numerically for some configurations and boundary conditions, and there are approximations of their frequency dispersion relations based on infinite series solutions and perturbation theory, valid for arbitrary orientations of an applied magnetic field, and for boundary conditions that allow varying degrees of pinning. A theoretical method that allows to determine with ease the exact frequency dispersion relations of the dipole-exchange modes is presented: it is required to solve numerically a 6x6 linear eigenvalue problem at each wavevector of interest; the spin wave modes inside or outside the sample may be plotted. Analogous calculations may be done to determine magnetostatic modes in detail. The method corresponds to a generalization of Green's theorem to the problem of determining the dipole-exchange modes of a ferromagnetic film: convolution integral equations for the magnetization and magnetostatic potential are derived on the surfaces of the film that become simple local algebraic equations in Fourier space, or for specific wavevectors.

Session S19 GMAG DMP FIAP: Cooperative Phenomena: Spin-Orbit Coupling and Antiferromagnetism 318 - Ian Gilbert, NIST

## 11:15AM S19.00001 Electron correlation, spin-orbit coupling, intersite effects and the metal-insulator transition in pyrochlore iridates<sup>1</sup>

, RUNZHI WANG, ARA GO, ANDREW MILLIS, Columbia University — We perform density functional theory (DFT) plus single-site and cluster dynamical mean-field theory (DMFT/CDMFT) calculations to study the metal-insulator transition in the pyrochlore iridates  $\text{Lu}_2\text{Ir}_2\text{O}_7$ ,  $\text{Y}_2\text{Ir}_2\text{O}_7$  and  $\text{Eu}_2\text{Ir}_2\text{O}_7$ . The calculations include spin-orbit coupling. Single-site DMFT calculations indicate that the Lu compound is much more insulating than the Y or Eu materials but predict that the critical interaction strength is almost exactly the same for the Eu and Y compounds, although experimentally the metal-insulator transition temperatures are quite different. We further carry out the cluster DMFT (CDMFT) and observe much larger differences, consistent with experiments, demonstrating the crucial role played by spatial correlations.

## 11:27AM S19.00002 Magnetization and transport properties of single $\text{RPd}_2\text{P}_2$ (R=Y, La-Nd, Sm-Ho, Yb)<sup>1</sup>

, GIL DRACHUCK, ANNA BOEHMER, SERGEY L. BUD'KO, PAUL CANFIELD, Iowa State University/Ames Lab — Single crystals of  $\text{RPd}_2\text{P}_2$  (R=Y, La-Nd, Sm-Ho, Yb) were grown using a self-flux method and were characterized by room-temperature powder X-ray diffraction, anisotropic temperature and field dependent magnetization and temperature dependent in-plane resistivity. Anisotropic magnetic properties, arising mostly from crystal electric field (CEF) effects, were observed for most magnetic rare earths. The experimentally estimated CEF parameters  $B_0^2$  were calculated from the anisotropic paramagnetic  $\theta_{ab}$  and  $\theta_c$  values. Ordering temperatures, as well as the polycrystalline averaged paramagnetic Curie-Weiss temperature,  $\theta_{ave}$ , were extracted from magnetization and resistivity measurements.

<sup>1</sup>Work done at Ames Laboratory was supported by US Department of Energy, Basic Energy Sciences, Division of Materials Sciences and Engineering under Contract NO. DE-AC02-07CH111358.

## 11:39AM S19.00003 Dynamic scaling invariance at low temperatures

, VLADIMIR UDODOV, Katanov Khakas State University, KATANOV KHAKAS STATE UNIVERSITY TEAM — Using thermodynamic arguments we prove that the conventional consequences of the dynamic scale hypothesis change their character in the limit as the critical temperature  $T_c$  approaches zero. In particular, for liquid helium-4, the critical exponent  $\alpha$  associated with the heat capacity ( $\alpha < 0$ ) and other exponents related by the following new relation

$$\nu(z-1) = (1 + S_I - \alpha)/6, \quad T_C = T_\lambda \geq 0, \quad (3)$$

$$S_I = \left(\frac{T_C}{T}\right)^n, \quad T \geq T_C, \quad (4)$$

where  $n$  is a positive constant [1] and  $z$  is the dynamic critical exponent,  $\nu$  – the critical exponent of the correlation length. It is important that now the exponent  $z$  depends on  $T$  and  $T_\lambda$ . If  $T_\lambda = 0$  and  $T > 0$ , then the  $S_I$ -function [1] is zero and Eq. (??) becomes

$$\nu(z-1) = (1 - \alpha)/6, \quad T_C = 0, \quad (T > 0, \alpha < 0). \quad (5)$$

Eq. (??) can be applied, for example, to a mixture of liquid  $\text{He}^3$  and  $\text{He}^4$ . The results are valid for multi-component order parameter. 1. Udodov V. Violating of the Essam-Fisher and Rushbrooke Relationships at Low Temperatures// World Journal of Condensed Matter Physics. — 2015. — .5. — 2. — . 55-59. <http://dx.doi.org/10.4236/wjcmp.2015.52008>.

## 11:51AM S19.00004 Application of Novel Molecular Field Theory to Helical Antiferromagnetic Ordering in $\text{EuCo}_2\text{P}_2$ <sup>\*</sup>, D. C. JOHNSTON, N. S. SANGEETHA, Iowa State Univ — A formulation of Weiss molecular field theory (MFT) was recently advanced for antiferromagnetic (AFM) systems of identical crystallographically-equivalent local moments interacting by Heisenberg exchange that does not utilize the concept of magnetic sublattices.<sup>1</sup> This formulation has the attractive feature that the magnetic and thermal properties in magnetic fields $H \rightarrow 0$ depend only on the interactions of a representative spin with its neighbors, and thus allows the properties of collinear and coplanar noncollinear AFM structures to be understood and modeled on the same footing. Neutron diffraction measurements showed that $\text{EuCo}_2\text{P}_2$ with the bct $\text{ThCr}_2\text{Si}_2$ -type structure undergoes an AFM transition to a coplanar noncollinear $c$ -axis helical AFM structure below the ordering temperature $T_N = 66.5$ K.<sup>2</sup> Here we report the properties and apply our MFT to model the anisotropic magnetic susceptibility of single-crystal $\text{EuCo}_2\text{P}_2$ below $T_N$ .

## 12:03PM S19.00005 Investigation of Quantum Phase Transitions of Spin-3/2 AKLT Systems On the Hexagonal Lattice via the Tensor-Network Method<sup>1</sup>, TZU-CHIEH WEI, CHING-YU HUANG, C.N. Yang Institute for Theoretical Physics, Stony Brook University — The spin-3/2 Affleck-Kennedy-Lieb-Tasaki (AKLT) state on the hexagonal lattice is an example of valence-bond solid state (VBS), which is recently shown to provide resource for quantum computation and is also a nontrivial symmetry protected topologically ordered state if the translation invariance is imposed in addition to the rotation symmetry. Niggemann et al. previously studied a deformation of the AKLT model and derived a one-parameter family of ground states (parametrized by $a$ ) that are deformed from the AKLT point ( $a = \sqrt{3}$ ). By mapping to a free-fermion eight-vertex model, they identified a VBS to Néel transition at $a_{c2} \approx 2.5425$ . We employ the tensor-network method to directly compute the Néel order parameter and obtain results that agree with theirs. We also study the regime where the deformation parameter $a$ decreases close to zero. We find that there is a transition at $a_{c1} \approx 0.58$ to an XY phase, which is characterized by algebraically decaying correlations, rotation invariance of spins in the $x$ - $y$ plane and the induced magnetization being aligned with the direction of the extend field.

## 12:15PM S19.00006 Inelastic neutron scattering study and magnetic excitations on the low-dimensional antiferromagnet $\alpha\text{-Cu}_2\text{V}_2\text{O}_7$ , GANATEE GITGEATPONG, Mahidol University, YANG ZHAO, University of Maryland, YIMING QIU, NIST Center for Neutron Research, KITTIWIT MATAN, Mahidol University — Magnetic excitations of the low-dimensional antiferromagnet $\alpha\text{-Cu}_2\text{V}_2\text{O}_7$ have been investigated using inelastic neutron scattering. The study reveals unusual commensurate splitting of magnetic excitation branches centered at a wave vector $(0, \pm\delta, 0)$ with $\delta = 0.25$ away from a magnetic zone center, where a magnetic Bragg peak is observed. The energy gap of 0.75 meV at $(0, \pm\delta, 0)$ was found to decrease as a function of temperature and the magnetic excitations become diffusive and disappear above 35 K coincident with $T_N = 33.4$ K. A recent experiment at the Multi Axis Crystal Spectrometer, MACS, to map the excitations over a large momentum space clearly shows the splitting of the dispersion at most of the allowed magnetic reflections. This commensurate splitting of the spin-wave-type excitations without the magnetic Bragg reflections at the same commensurate wave vectors has not yet been previously observed and remains unexplained. In the presentation, the experimental data will be shown and the possible explanation will also be discussed.

<sup>1</sup>This work was supported in part by the National Science Foundation.

## 12:27PM S19.00007 Tunable Collective Modes in the Dilute Ising Magnet $\text{LiHo}_{0.045}\text{Y}_{0.955}\text{F}_4$ , D.M. SILEVITCH, California Institute of Technology, G. AEPPLI, Paul Scherrer Institute, T.F. ROSENBAUM, California Institute of Technology — Collections of quantum mechanical spins with dipolar interactions exhibit a complex set of states and excitations due to the long range and alternating sign of the dipolar potential. We use nonlinear ac magnetic susceptibility on the dilute dipole Ising magnet $\text{LiHo}_{0.045}\text{Y}_{0.955}\text{F}_4$ to study the behavior of coupled clusters of spins. Pump-probe spectroscopy excites Fano resonance behavior between coherent, isolated spin clusters and a background spin bath. The evolution of these clusters exhibits universal behavior as a function of several different tuning parameters such as static transverse field, ac pump field, and thermal connectivity to a heat reservoir. We discuss our results within the framework of many-body localization.

## 12:39PM S19.00008 Physical properties of $\text{RMg}_2\text{Cu}_9$ ( $R = \text{Y, Ce-Nd, Gd-Dy}$ )<sup>1</sup>, TAI KONG, SERGEY BUD'KO, PAUL CANFIELD, Ames Laboratory/Iowa State University — $\text{RMg}_2\text{Cu}_9$ is a family of hexagonal compounds with a single rare earth site that has a $\bar{6}m2$ local symmetry. In this talk, magnetic, electric transport and specific heat data measured on single crystals of $\text{RMg}_2\text{Cu}_9$ synthesized using Ta crucible will be presented and discussed. Due to a strong CEF effect, all local moment bearing members (except for isotropic $\text{GdMg}_2\text{Cu}_9$ ) in the present study show a higher magnetic susceptibility when external field is applied along the $ab$ -plane than along the $c$ -axis. For $R = \text{Ce, Nd, Gd-Dy}$ , the compounds order antiferromagnetically above 2 K. The ordering temperature deviates from de Gennes scaling with $\text{GdMg}_2\text{Cu}_9$ ordering at a lower temperature than $\text{TbMg}_2\text{Cu}_9$ . $\text{PrMg}_2\text{Cu}_9$ does not order magnetically down to 2 K and might have a singlet ground state. This series of compounds offer an opportunity to study in-plane anisotropy of rare earth in a hexagonal CEF configuration, following our previous work on in-plane 4-state clock model in a tetragonal system, for example: $\text{HoNi}_2\text{B}_2\text{C}$ (P.C. Canfield et al. PRB 55, 970) and $\text{DyAgSb}_2$ (K.D. Myers et al. PRB 59, 1121).

<sup>1</sup>This work is supported by the US DOE, Basic Energy Sciences under Contract No. DE-AC02-07CH11358

## 12:51PM S19.00009 Multiplicative logarithmic corrections to quantum criticality in three-dimensional dimerized antiferromagnets, YANQI QIN, Institute of Physics, Chinese Academy of Sci (CAS), BRUCE NORMAND, Department of Physics, Renmin University of China, Beijing 100872, China, ANDERS SANDVIK, Department of Physics, Boston University, 590 Commonwealth Avenue, Boston, Massachusetts 02215, USA, ZI YANG MENG, Institute of Physics, Chinese Academy of Sci (CAS) — We investigate the quantum phase transition in an $S=1/2$ dimerized Heisenberg antiferromagnet in three spatial dimensions. By means of quantum Monte Carlo simulations and finite-size scaling analyses, we get high-precision results for the quantum critical properties at the transition from the magnetically disordered dimer-singlet phase to the ordered Neel phase. This transition breaks $O(N)$ symmetry with $N=3$ in $D=3+1$ dimensions. This is the upper critical dimension, where multiplicative logarithmic corrections to the leading mean-field critical properties are expected; we extract these corrections, establishing their precise forms for both the zero-temperature staggered magnetization, $m_s$ , and the Neel temperature, $T_N$ . We present a scaling ansatz for $T_N$ , including logarithmic corrections, which agrees with our data and indicates exact linearity with $m_s$ , implying a complete decoupling of quantum and thermal fluctuation effects close to the quantum critical point. These logarithmic scaling forms have not previously identified or verified by unbiased numerical methods and we discuss their relevance to experimental studies of dimerized quantum antiferromagnets such as $\text{TiCuCl}_3$ . Ref.: arXiv:1506.06073

<sup>1</sup>This work is supported by the US DOE, Basic Energy Sciences under Contract No. DE-AC02-07CH11358

**1:03PM S19.00010 Magnon-induced nonanalyticities in thermodynamic and transport properties of quantum ferromagnets<sup>1</sup>**, SRIPOORNA BHARADWAJ, DIETRICH BELITZ, Department of Physics and Institute of Theoretical Science, University of Oregon, Eugene, OR 97403, THEODORE R. KIRKPATRICK, Institute for Physical Science and Technology, and Department of Physics, University of Maryland, College Park, MD 20742 — Soft modes and their effects on thermodynamic and transport properties are of great interest. An example of a nonanalyticity induced by Goldstone modes is the divergence of the longitudinal susceptibility,  $\chi_L(k) \sim 1/k^{4-d}$ , in a classical isotropic Heisenberg ferromagnet in  $2 < d < 4$  dimensions everywhere in the ordered phase. Here we investigate the fate of this nonanalyticity in a quantum ferromagnet. Power counting at  $T = 0$  suggests a weaker singularity,  $\chi_L(k) \sim k^{d-2}$ , due to the additional frequency integration. We find that this term has a zero prefactor due to spin conservation. Consistent with this, a corresponding term in an antiferromagnet has a nonzero prefactor. A small but nonzero temperature restores the nonanalyticity in a ferromagnet, and the prefactor vanishes linearly with  $T$ . Similarly, magnetic impurities violate the spin conservation and lead to a nonanalytic term even at  $T = 0$ . We explore all of these effects by means of nonlinear sigma models for both ferromagnets and antiferromagnets, and by an effective field theory for itinerant ferromagnets, and discuss the crossover from the classical result to the  $T = 0$  limit in detail.

**1:15PM S19.00011 Magnetic phase transitions and magnetization reversal in MnRuP<sup>1</sup>**, P. LAMPEN-KELLEY, D. MANDRUS, University of Tennessee and Oak Ridge National Lab — The ternary phosphide MnRuP is an incommensurate antiferromagnetic metal crystallizing in the non-centrosymmetric Fe<sub>2</sub>P-type crystal structure. Below the Neel transition at 250 K, MnRuP exhibits hysteretic anomalies in resistivity and magnetic susceptibility curves as the propagation vectors of the spiral spin structure change discontinuously across  $T_1 = 180$  K and  $T_2 = 100$  K. Temperature-dependent X-ray diffraction data indicate that the first-order spin reorientation occurs in the absence of a structural transition. A strong magnetization reversal (MR) effect is observed upon cooling the system through  $T_N$  in moderate dc magnetic fields. Positive magnetization is recovered on further cooling through  $T_1$  and maintained in subsequent warming curves. The field dependence and training of the MR effect in MnRuP will be discussed in terms of the underlying magnetic structures and compared to anomalous MR observed in vanadate systems.

**1:27PM S19.00012 ARPES study of the Kitaev Candidate RuCl<sub>3</sub>**, XIAOQING ZHOU, HAOXIANG LI, JUSTIN WAUGH, STEPHEN PARHAM, University of Colorado at Boulder, HEUNG-SIK KIM, HAE-YOUNG KEE, JENNIFER SEARS, YOUNG-JUNE KIM, University of Toronto, DANIEL DESSAU, University of Colorado at Boulder — RuCl<sub>3</sub> has been identified as a spin-orbital-assisted Mott insulator with possible Kitaev magnetic orders at low temperature by X-ray absorption, susceptibility, specific heat and Raman scattering[1-3]. Here we report high resolution ARPES spectroscopy measurements on single crystal RuCl<sub>3</sub>, and compare it with DFT calculations with and without magnetic order. Furthermore, the possible spin-orbital-assisted Mott transition is investigated through electron doping. [1] K.W.Plumb et al., Phys. Rev. B, 90, 041112 (2014). [2] J.A.Sears et al., Phys. Rev. B, 94, 144420 (2015). [3] L. J. Sandilands et al. Phys. Rev. Lett. 114, 147201 (2015).

**1:39PM S19.00013 Lifshitz-type metal-to-insulator transition via strong relativistic renormalization in NaOsO<sub>3</sub>**, BONGJAE KIM, PEITAO LIU, ZEYNEP ERGÖNENC, University of Vienna, Faculty of Physics, Computational Materials Physics, ALESSANDRO TOSCHI, Institut für Festkörperphysik, Technische Universität Wien, SERGI KHMELEVSKYI, University of Vienna, Faculty of Physics, Computational Materials Physics and Department of Physics, Budapest University of Technology and Economics, CESARE FRANCHINI, University of Vienna, Faculty of Physics, Computational Materials Physics — Using *ab initio* band structure methods in the framework of density functional theory (DFT), we study the mechanism responsible for the metal-to-insulator transition (MIT) in the 5d oxide NaOsO<sub>3</sub> and reinterpret its previously proposed Slater nature. We show that spin-orbit coupling (SOC) causes a strong relativistic renormalization of the electronic correlation that moves the system to a weakly interacting itinerant limit, where the physics of itinerant magnetism prevails. This is the opposite effect as compared to the widely studied iridates, where SOC drives the formation of a relativistic Mott state. By mapping the magnetically constrained non-collinear DFT calculation using spin-fluctuation theory, we explain the MIT of the system in connection with the anomalies observed in the experimental resistivity curve. We show that the continuous MIT is associated to the progressive disappearance of electron and hole pockets in the Fermi surface, typical of a Lifshitz-type MIT, and is mediated by spin-fluctuations. We discuss the inconsistencies of a pure Slater interpretation and propose that NaOsO<sub>3</sub> should be classified as a magnetically-driven relativistic Lifshitz insulator.

**1:51PM S19.00014 Spin-texture induced by oxygen vacancies in Strontium perovskites (001) surfaces: A theoretical comparison between SrTiO<sub>3</sub> and SrHfO<sub>3</sub>**, MAIA VERGNIO, Donostia International Physics Center, ANDRÉS-CAMILO GARCA-CASTRO, ERIC BOUSQUET, Physique Théorique des Matériaux, Université de Lige, B-4000 Sart-Tilman, Belgium, ALDO HUMBERTO ROMERO, Physics Department, West Virginia University, WV-26506-6315, Morgantown, USA — The electronic structure of SrTiO<sub>3</sub> and SrHfO<sub>3</sub> (001) surfaces with oxygen vacancies is studied by means of first-principles calculations. We reveal how oxygen vacancies within the first atomic layer of the SrTiO<sub>3</sub> surface (i) induce a large antiferrodistortive motion of the oxygen octahedra at the surface, (ii) drive localized magnetic moments on the Ti-3d orbitals close to the vacancies and (iii) form a two-dimensional electron gas localized within the first layers. The analysis of the spin-texture of this system exhibits a splitting of the energy bands according to the Zeeman interaction, lowering of the Ti-3d<sub>xy</sub> level in comparison with  $d_{xz}$  and  $d_{yz}$  and also an in-plane precession of the spins. No Rashba-like splitting for the ground state neither for *ab initio* molecular dynamics trajectory at 400K is recognized as suggested recently by A. F. Santander-Syro *et al.* [?]. Instead, a sizeable Rashba-like splitting is observed when the Ti atom is replaced by a heavier Hf atom with a much larger spin-orbit interaction. However, we observe the disappearance of the magnetism and the surface two-dimensional electron gas when full structural optimization of the SrHfO<sub>3</sub> surface is performed. Our results uncover

**2:03PM S19.00015 Quantum Impurities develop Fractional Local Moments in Spin-Orbit Coupled Systems<sup>1</sup>**, ADHIP AGARWALA, VIJAY B. SHENOY, Indian Institute of Science Bangalore — Systems with spin-orbit coupling have the potential to realize exotic quantum states which are interesting both from fundamental and technological perspectives. We investigate the new physics that arises when a correlated spin-1/2 quantum impurity hybridizes with a spin-orbit coupled Fermi system. The intriguing aspect uncovered is that, in contrast to unit local moment in conventional systems, the impurity here develops a *fractional local moment* of 2/3. The concomitant Kondo effect has a high Kondo temperature ( $T_K$ ). Our theory explains these novel features including the origins of the fractional local moment and provides a recipe to use spin-orbit coupling ( $\lambda$ ) to enhance Kondo temperature ( $T_K \sim \lambda^{4/3}$ ). These results will be useful in shedding light on a range of experiments, including those of magnetic impurities at oxide interfaces. Our predictions can also be directly tested in cold-atom systems where the spin-orbit coupling can be engendered via a uniform synthetic non-Abelian gauge field. In addition, this work opens up new directions of research in spin-orbit coupled Kondo lattice systems. Reference: arXiv:1509.07328

**11:15AM S20.00001 Tensor Network Algorithms for Braiding Anyons**, BABATUNDE AYENI, SUKHWINDER SINGH, Centre for Engineered Quantum Systems, Macquarie University, ROBERT PFEIFER, Dept. of Physics & Astronomy, GAVIN BRENNEN, Centre for Engineered Quantum Systems, Macquarie University — Anyons are point-like (quasi)particles which exist only in two-dimensional systems and have exchange statistics that are neither bosonic nor fermionic. These particles were first proposed as a mere theoretical curiosity, but it was later shown that they arise in topological states of matter and that certain species of non-Abelian anyons can be used for low error quantum computation. Despite the importance of anyons, fundamentally and technologically, comparatively little is understood about their many body behaviour especially when the non local effects of braiding are taken into account. This largely due to the lack of efficient numerical methods to study them. In order to circumvent this problem, and to broaden our understanding of the physics of anyons, the authors have developed several numerical methods based on tensor network algorithms including: anyonic Matrix Product States (MPS), anyonic Time Evolving Block Decimation (TEBD), anyonic Density Matrix Renormalization Group (DMRG), and Anyonic U(1) MPS. These can be used to simulate static interacting and itinerant braiding anyons on a finite or infinite lattice. We have used our methods to study the phase diagrams of some species, such as Abelian Z3 anyons and non-Abelian Fibonacci and Ising.

**11:27AM S20.00002 A Tensor Network Framework for Topological Order in Higher Dimensions**, BURAK SAHINOGLU, University of Vienna, MICHAEL WALTER, Stanford University, DOMINIC WILLIAMSON, University of Vienna — We present a general scheme for constructing topological lattice models in any space dimension using tensor networks. Our approach relies on finding "simplex tensors" that satisfy a finite set of tensor equations. Given any such tensor, we construct a discrete topological quantum field theory (TQFT) and local commuting projector Hamiltonians on any lattice. The ground space degeneracy of these models is a topological invariant that can be computed via the TQFT, and the ground states are locally indistinguishable when the ground space is nondegenerate on the sphere. Any ground state can be realized by a tensor network obtained by contracting simplex tensors. Our models are exact renormalization fixed points, covering a broad range of models in the literature. Lastly, we identify symmetries on the virtual level of the tensor networks of our models that generalize the topological invariance properties beyond fixed point models. This framework combined with recent tensor network techniques is convenient for studying excitations, their statistics, phase transitions, and ultimately for classification of gapped phases of many-body theories in 3+1 and higher dimensions.

**11:39AM S20.00003 Some tensor-network diagnostics for a class of 2D SPT states with internal symmetry**, ABHISHODH PRAKASH, TZU-CHIEH WEI, Stony Brook University — We demonstrate some diagnostic techniques to characterize certain 2D tensor network states with internal symmetries that are classified by the third group cohomology of the symmetry group. We use the discussions of Else et al. [Phys. Rev. B 90, 235137 (2014)] to extract data that determines the phase of matter from the tensors that make up a specific class of wave functions. This is possible because the symmetry transformation at the 'physical' level, which is of product form, translates to a symmetry in the 'virtual' level which may no longer be of product form. An appropriate analysis of the virtual-space symmetry helps us obtain the topological information (the 3-cocycle twist) that places the wave function in the classification scheme. This reproduces the results of Chen et al. [Phys. Rev. B 87, 155114 (2013)] without using projection operators in merging two 'Matrix Product Operators' of the symmetry representation of two group actions.

**11:51AM S20.00004 Weak-coupling instabilities of SU(N) fermions on the Bernal-stacked honeycomb bilayer in presence of on-site Hubbard Interactions<sup>1</sup>**, SUMIRAN PUJARI, University of Kentucky, THOMAS C. LANG, University of Innsbruck, RIBHU K. KAUL, University of Kentucky — Bernal-stacked bilayer graphene hosts an interesting 'non-relativistic' semi-metallic dispersion different from monolayer graphene. At this quadratic band touching, short-range interactions are marginal and hence cause instabilities to a variety of ground states. In this work we consider the instabilities of even  $N$  species of fermions on the Bernal bilayer with an  $SU(N)$ -symmetric contact interaction. For  $SU(2)$  fermions with an on-site Hubbard interaction the ground state has been found to be to a magnetic Nél state for all strengths of the interaction. In contrast, the leading weak coupling instability for  $N > 2$  is a non-magnetic ground state, which is gapped and odd under time reversal. On the other hand, at strong coupling we expect Nél or VBS ground states of the effective self-conjugate  $SU(N)$  spin models. Motivated by this observation, we investigate the phase diagram for even  $N > 2$  using determinantal quantum Monte Carlo computations.

**12:03PM S20.00005 A many-body interpretation of Majorana bound states, and conditions for their localisation**, THOMAS O'BRIEN, Lorentz Institute, ANTHONY WRIGHT, University of Queensland — We derive a condition for the existence of completely or exponentially localised Majorana bound states (with the potential for non-Abelian statistics) in a generic many-body system. We discuss the relationship between the existence of these operators and the protection of the ground state degeneracy from local perturbations. We use our methods to study the exponential decay of the Majorana bound states in the non-interacting Kitaev chain, finding complete agreement between our many-body calculation and single-particle results. We then apply these results to various interacting systems which have previous evidence for Majorana bound states.

**12:15PM S20.00006 Hybrid-Space Density Matrix Renormalization Group Study of the Two-Dimensional Hubbard Model**, GEORG EHLERS, REINHARD M. NOACK, Philipps-University Marburg — We investigate the ground state of the two-dimensional Hubbard model on a cylinder geometry at intermediate coupling and weak doping. We study properties such as the behavior of the ground-state energy, pair-field correlations, and the appearance of stripes. We find striped ground states generically, with the width of the stripes depending on the filling, the boundary conditions, and the circumference of the cylinder. Furthermore, we analyse the interplay between the different stripe configurations and the decay of the pairing correlations. Our analysis is based on a hybrid-space density matrix renormalization group (DMRG) approach, which uses a momentum-space representation in the transverse and a real-space representation in the longitudinal direction. Exploiting the transverse momentum quantum number makes significant speedup and memory savings compared to the real-space DMRG possible. In particular, we obtain computational costs that are independent of the cylinder width for fixed size of the truncated Hilbert space.

**12:27PM S20.00007 Improving the efficiency of the Finite Temperature Density Matrix Renormalization Group method<sup>1</sup>**, ALBERTO NOCERA, GONZALO ALVAREZ, Oak Ridge National Laboratory — I review the basics of the finite temperature DMRG method, and then show how its efficiency can be improved by working on reduced Hilbert spaces and by using canonical approaches. My talk explains the applicability of the ancilla DMRG method beyond spins systems to t-J and Hubbard models, and addresses the computation of static and dynamical observables at finite temperature. Finally, I discuss the features of and roadmap for our DMRG++ codebase.

**12:39PM S20.00008 Geometric stability of the many-body localized phase in two and higher dimensions** , ANUSHYA CHANDRAN, Perimeter Institute, ARIJEET PAL, Oxford University, CHRIS LAUMANN, University of Washington, ANTONELLO SCARDICCHIO, Abdus Salam ICTP — Isolated disordered quantum systems need not equilibrate and be described by statistical mechanics; this is the phenomenon of many-body localization (MBL). In higher dimensions, the existence of MBL is a delicate question due to the possibility of inclusions of lower dimensional "thermal" regions. In this talk, I will argue that MBL is stable in higher dimensions by analyzing the geometry of a MBL insulator coupled to a thermal edge and develop a phenomenology of such systems.

**12:51PM S20.00009 Many-body localization characterized from a one-particle perspective** , SOUMYA BERA, MPI-PKS Dresden, HENNING SCHÖMERUS, Lancaster, UK, FABIAN HEIDRICH-MEISNER, LMU, Munich, JENS BARDARSON, MPI-PKS Dresden — We show that the one-particle density matrix can be used to characterize the interaction-driven many-body localization transition in closed fermionic systems. The eigenstates of density matrix are localized in the many-body localized phase and spread out when one enters the delocalized phase, while the eigenvalues reveals the distinctive Fock-space structure of the many-body eigenstates, exhibiting a step-like discontinuity in the localized phase. The associated one-particle occupation entropy is small in the localized phase and large in the delocalized phase, with diverging fluctuations at the transition. We analyze the inverse participation ratio of the natural orbitals and found that it is independent of system size in the localized phase.

**1:03PM S20.00010 Characterizing gapped phases of a 1D spin chain with on-site and spatial symmetries<sup>1</sup>** , COLIN WEST, ABHISHODH PRAKASH, TZU-CHIEH WEI, State Univ of NY- Stony Brook — We investigate the phase diagram of a spin-1 chain whose Hamiltonian is invariant under translation, lattice inversion and a global  $A_4$  symmetry in the spin degrees of freedom. The classification scheme by Chen, Gu, and Wen allows us to enumerate all possible phases under the given symmetry. Then, we determine which of these phases actually occur in the two-parameter Hamiltonian. Using numerical methods proposed by Pollmann and Turner (2012) we determine the characteristic projective parameters for the Symmetry Protected Topological (SPT) phases. In addition, we present a method for determining the projective commutation parameter in these phases. The resulting phase diagram is rich and contains at least nine different SPT phases.

**1:15PM S20.00011 Continuous Matrix Product States for Spin-1/2 Fermions with Mass- and Spin-Imbalance** , SANGWOO S. CHUNG, C. J. BOLECH, Univ of Cincinnati — Recently, we have proposed a continuous matrix product states (cMPS) ansatz that can approximate ground states of interacting spin-1/2 fermions with spin-imbalance in 1D. We now extend that effort to describe a more general system, having both spin- and mass-imbalance. With mass-imbalance, there is no exact solution for the Gaudin-Yang Hamiltonian, and this is one of the first applications of the fermionic cMPS on non-integrable systems.

**1:27PM S20.00012 Controlled quantum transport in a disordered one-dimensional lattice** , SAHEL ASHHAB, Qatar Environment and Energy Research Institute, Hamad Bin Khalifa University, Qatar Foundation, Doha, Qatar — We investigate the effect of disorder on the transfer of quantum states across a one-dimensional lattice with varying levels of control resources. We find that the application of properly designed control signals, even when applied only to the two ends of the lattice, allows perfect state transfer up to disorder strengths that would not allow a generic quantum state to propagate the length of the lattice. At sufficiently large disorder strengths, however, the local control signals fail to send the quantum state from one end of the system to the other end. Our results shed light on the interplay between disorder and controlled transport in one-dimensional systems.

**1:39PM S20.00013 Inhomogeneous CDMFT and nonmagnetic impurities in graphene<sup>1</sup>** , M. CHARLEBOIS, D. SÉNÉCHAL, A.-M. GAGNON, A.-M.S. TREMBLAY, Université de Sherbrooke — In cluster dynamical mean-field theory (CDMFT), we usually apply the self-consistency condition on an infinite super-lattice of identical clusters. However, in some problems a large unit cell is required, for instance in the presence of a periodically repeated impurity. Since the impurity solver (exact diagonalization) can only treat small clusters, we break the unit cell into multiple small clusters that can be solved individually. This new technique is called inhomogeneous CDMFT (1) and is analogous to inhomogeneous DMFT (2). In this presentation, we will explain both the CDMFT and inhomogeneous CDMFT self-consistency loops within a unified, simple picture. We then apply this technique to a nonmagnetic impurity in graphene and study the emerging magnetism. Our results take into account dynamical correlations; nevertheless they qualitatively agree with previous mean-field and density functional theory studies.

**1:51PM S20.00014 Spin selective localization transition in disordered interacting system in two dimensions: A quantum Monte-Carlo study** , SHASHI KUNWAR, Indian Inst of Tech-Madras, PRABUDDHA CHAKRABORTY, Indian Statistical Institute Chennai, RAJESH NARAYANAN, Indian Inst of Tech-Madras — The phenomenon of Anderson localization wherein non-interacting electrons are localized by quenched impurities is a subject matter that has been extremely well studied. However, localization transition under the combined influence of interaction and quenched disorder is less well understood. In this context we study the localization transition in a two-dimensional Hubbard model under the influence of a spin-selective disorder i.e, disorder which is operational on just one of the spin-species. The model is analyzed by laying recourse to a Quantum Monte Carlo based scheme. Using this approach we show the possibility of a metal-insulator transition. However, we will show that this metal-insulator transition is extremely sensitive to the filling-fraction inherent in the system. Our results will be encapsulated in a phase diagram.

**2:03PM S20.00015 Real space study of current flow through nanoscopic Kondo lattices** , JOHN VAN DYKE, DIRK MORR, University of Illinois at Chicago — We study current flow through a nanoscopic Kondo lattice in real space and with finite applied voltage. We show how the presence of a defect, such as an f-electron vacancy, modifies the current flow in its vicinity, depending on lead geometry and coupling to phonons. Finally, we report a self-consistent calculation of the change in the hybridization between the conduction and f-electrons caused by the applied bias.

**11:15AM S21.00001 Coupling phase transition kinetics and hydrodynamics: Models for solid-solid and liquid-solid transformation in dynamically driven materials<sup>1</sup>**, JONATHAN BELOF, LORIN BENEDICT, ALEXANDER CHERNOV, BURL HALL, SEBASTIEN HAMEL, TOMORR HAXHIMALI, BABAK SADIGH, LUIS ZEPEDA-RUIZ, Lawrence Livermore National Laboratory — High pressure and high strain-rate experiments are opening a new frontier toward the study of material science under extreme conditions. As the energy density of experimental platforms is increased, the timescale for observation is typically decreased to the point where the time dependence of phase transitions is now a subject of direct study. We will present new phase transition kinetics models that have been developed with unique considerations that arise in shock-wave driven phase transformation, highlighting applications of the methodology to the simulation of recent experiments of iron and water.

<sup>1</sup>This work is performed under the auspices of the U. S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

**11:27AM S21.00002 Construction of a kinetics model for liquid-solid transitions built from atomistic simulations<sup>1</sup>**, LORIN BENEDICT, LUIS ZEPEDA-RUIZ, TOMORR HAXHIMALI, SEBASTIEN HAMEL, BABAK SADIGH, ALEXANDER CHERNOV, JONATHAN BELOF, Lawrence Livermore National Laboratory — We discuss work in progress towards a kinetics model for dynamically-driven liquid-solid transitions built from MD simulations. The growth of solid particles within a liquid is studied for a range of conditions, and careful attention is paid to the construction of an accurate multi-phase (equilibrium) equation of state for the system under consideration, in order to provide a framework upon which the non-equilibrium physics is based.

<sup>1</sup>his work was performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. Lawrence Livermore National Security, LLC.

**11:39AM S21.00003 A mean-field thermodynamic description of the kinetics of overdriven interfaces.<sup>1</sup>**, TOMORR HAXHIMALI, JONATHAN BELOF, BABAK SADIGH, Lawrence Livermore National Laboratory — A key aspect of an accurate description of shock-induced structural phase transitions is the rigorous computation of the dynamics of the interfaces between coexisting phases. In the wake of the shock, the system will be exposed to strong gradient fields that give rise to overdriven interfaces during the induced phase transformation. In this work we take a mean-field approach using a time-dependent Ginzburg-Landau formalism to describe the dynamics of such overdriven interfaces. We make a connection of the mean-field result to a quasi-Langevin description, the Kardar-Parisi-Zhang (KPZ) equation, of the kinetics of the interface. Further, larger coarse-grained descriptions of the phase transition such as the Kolmogorov-Johnson-Mehl-Avrami (KJMA) model, which are commonly coupled to hydrodynamic equations that describe the evolution of the temperature and pressure during the shock propagation, ignore the details of the dynamics and structure of the interfacial regions. Overlaying the KPZ description of the interface evolution to these coarse-grained methods will result in physically more accurate multiscale models for shock propagation. We will present results from our efforts in this regard.

<sup>1</sup>This work is performed under the auspices of the U. S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

**11:51AM S21.00004 Dynamic materials response at multiscales: Experiments and simulations<sup>1</sup>**, SHENG-NIAN LUO, The Peac Institute of Multiscale Sciences, Chengdu, Sichuan, 630031, P. R. China — One of the grand challenges in materials physics is dynamic responses to impulsive loading, including shock waves, radiation, and pulsed fields, due to their highly transient nature and extremely complex microstructure effects. Dynamic responses, such as plasticity, damage, cavitation, phase changes, and chemical reactions, are inherently multiscale and heavily dependent on microstructure. One has to resort to a suite of tools, including experiments, modeling and simulations, and theory. However, the gaps in spatial or temporal scales between experiments and simulations are still wide, while cross-scale theories are still in early development. To this end, we exploit large-scale molecular dynamics simulations, electron microscopy, and ultrafast synchrotron X-ray imaging and scattering, to probe materials response at length scales ranging from lattice to micron, and time scales, from picosecond to second. For examples, simultaneous, high-speed, X-ray imaging (mesoscale strain-field mapping) and diffraction measurements along with macroscopic measurements have been achieved. Based on classical nucleation theory and large-scale molecular dynamics simulations, we demonstrate the equivalence between length and time scales for nucleation events, which provides a framework to bridge different scales. Certainly, advancing multiscale science requires sustained, concerted, experimental, modeling and theoretical efforts.

<sup>1</sup>We have benefited from the colleagues at the Advanced Photon Source, and the Peac Institute of Multiscales Sciences.

**12:27PM S21.00005 Accelerating Molecular Dynamics Simulations to Investigate Shock Response at the Mesoscales.**, AVINASH DONGARE, GARVIT AGARWAL, University of Connecticut, RAMAKRISHNA VALISETTY, RAJU NAMBURU, US Army Research Laboratory, ARUNACHALAM RAJENDRAN, University of Mississippi — The capability of large-scale molecular dynamics (MD) simulations to model dynamic response of materials is limited to system sizes at the nanoscales and the nanosecond timescales. A new method called quasi-coarse-grained dynamics (QCGD) is developed to expand the capabilities of MD simulations to the mesoscales. The QCGD method is based on solving the equations of motion for a chosen set of representative atoms from an atomistic microstructure and retaining the energetics of these atoms as would be predicted in MD simulations. The QCGD method allows the modeling of larger size systems and larger time-steps for simulations and thus is able to extend the capabilities of MD simulations to model materials behavior at mesoscales. The success of the QCGD method is demonstrated by reproducing the shock propagation and failure behavior of single crystal and nanocrystalline Al microstructures as predicted using MD simulations and also modeling the shock response and failure behavior of Al microstructures at the micron length scales. The scaling relationships, the hugoniot behavior, and the predicted spall strengths using the MD and the QCGD simulations will be presented. This work is sponsored by the US Army Research Office under Contract# W911NF-14-1-0257.

**12:39PM S21.00006 Corrections of Hayes Equation of State for Phase Transform under Dynamic Loading.**, TAO CHONG<sup>1</sup>, USTC — **Abstract:** The experimental results of iron under ramp wave and shock compression are simulated with Hayes equation of state (EOS) for phase transition. The calculated results are consistent with the experimental data under shock, and don't agree well with the data under ramp wave loading. The reason for the problem is that the bulk modulus in Hayes model is constant (i.e., Bulk sound speed is constant). The sound speed corresponds to the slope of the Rayleigh line when materials leap from the initial state to the final state under shock loading, therefore, the bulk modulus can be considered as a constant. However, under ramp loading, material from initial to the final state is consecutive, and the bulk modulus is not a constant any more but a function of pressure and temperature. The bulk modulus of Hayes EOS is corrected with Murnaghan EOS, and the corrected Hayes EOS is applies to simulate the experimental results. The results show that the calculated data agree well with the experimental data under both shock and ramp wave loadings. .

<sup>1</sup>I hope you give me an oral presentation, otherwise I might not be able to attend the meeting

**12:51PM S21.00007 Mercury Induced by Pressure to act as a Transition Metal in Mercury Fluorides**, JORGE BOTANA, Beijing CSRC, XIAOLI WANG, Institute of Condensed Matter Physics, Linyi University, CHUNJU HOU, School of Science, Jiangxi University of Science and Technology, DADONG YAN, Department of Physics, Beijing Normal University, HAIQING LIN, Beijing CSRC, YANMING MA, State Key Lab of Superhard Materials, Jilin University, MAO-SHENG MIAO, Department of Chemistry and Biochemistry, California State University — The question of whether Hg is a transition metal remains open for stable solids. In our work we propose that high-pressure techniques will help prepare unusual oxidation states[1] of Hg in Hg-F compounds. By means of *ab initio* calculations and an advanced structure-search algorithm we find that under high pressure charge is transferred from the Hg d orbitals to the F, and becomes a transition metal.[2] HgF<sub>3</sub> and HgF<sub>4</sub> have been found to be stable compounds at high pressure. HgF<sub>4</sub> consists of planar molecules, a typical geometry for d<sup>8</sup> metallic centers. HgF<sub>3</sub> is an example of metallic and ferromagnetic compound, with an electronic structure analogous to transparent conductors due to the Hg d<sup>9</sup> configuration.

**1:03PM S21.00008 Can high pressure I-II transitions in semiconductors be affected by plastic flow and nanocrystal precipitation in phase I?**, B. A. WEINSTEIN, SUNY at Buffalo, Physics Dept., Buffalo, NY 14260 USA, G. P. LINDBERG, Rochester Precision Optics, W. Henrietta, NY 14586 USA — Pressure-Raman spectroscopy in ZnSe and ZnTe single crystals reveals that Se and Te nano-crystals (NCs) precipitate in these II-VI hosts for pressures far below their I-II phase transitions.[1] The inclusions are evident from the appearance and negative pressure-shift of the A<sub>1</sub> Raman peaks of Se and Te (trigonal phase). The Se and Te NCs nucleate at dislocations and grain boundaries that arise from pressure-induced plastic flow. This produces chemical and structural inhomogeneities in the zincblende phase of the host. At substantially higher pressures, the I-II transition proceeds in the presence of these inhomogeneities. This can affect the transition's onset pressure  $P_t$  and width  $\Delta P_t$ , and the occurrence of metastable phases along the transition path. Precipitation models in metals show that nucleation of inclusions depends on the Peierls stress  $\tau_p$  and a parameter  $\alpha$  related to the net free energy gained on nucleation. For favorable values of  $\tau_p$  and  $\alpha$ , NC precipitation at pressures below the I-II transition could occur in other compounds. We propose criteria to judge whether this is likely based on the observed ranges of  $\tau_p$  in the hosts, and estimates of  $\alpha$  derived from the cohesive energy densities of the NC materials. One finds trends that can serve as a useful guide, both to test the proposed criteria, and to decide when closer scrutiny of phase transition experiments is warranted, e.g., in powders where high dislocation densities are initially created. **1:15PM S21.00009 Tin phase transition in terapascal pressure range described accurately with Quantum Monte Carlo.**, ROMAN NAZAROV, RANDOLPH HOOD, MIGUEL MORALES, Lawrence Livermore Natl Lab — The accurate prediction of phase transitions is one of the most important research areas in modern materials science. The main workhorse for such calculations, Density functional theory (DFT), employs different forms of approximate exchange-correlation functionals which may lead to overstabilization of one phase compared to another, therefore, predict incorrectly phase transition pressures. A recent example of such deficiency has been demonstrated in Sn: no bcc to hcp phase transition has been observed in Sn when dynamically compressed to 1.2 TPa while DFT predicts a transition to occur at 0.16-0.2 TPa [1]. To overcome the limitations of DFT, we have employed diffusion quantum Monte Carlo (DMC) method which treats the many body electron problem directly. In order to get highly accurate results we systematically assess the effect of controllable approximations of DMC such as fixed node approximation, finite-size effects and the use of pseudopotentials. Based on metrologically accurate DMC equation of states we construct the pressure-temperature phase diagram and demonstrate its good agreement with experiment in contrast to DFT calculations. [1] A. Lazicki et al., X-Ray Diffraction of Solid Tin to 1.2 TPa. Phys. Rev. Lett. 115, 075502 (2015).

**1:27PM S21.00010 Phase conversion in silicon and carbon nanomaterials at extreme pressure**, MATTHEW CRANE, BENNETT SMITH, EVAN ABRAMSON, PETER PAUZAUSKIE, University of Washington — The high pressures and temperatures accessible in laser-heated diamond anvil cells (LH-DAC) have produced fundamental insights by identifying metastable states with extraordinary properties. However, the actual conditions necessary to access a metastable state depend on the kinetics of phase transformation. The explosion of research in nanomaterials has generated interest in exploring how phase transformations occur in materials with high radii of curvature, and how we can leverage these effects. We present work investigating phase transformations in Si- and C-based nanomaterials with high radii of curvature. We have loaded a LH-DAC with Si nanowires (NWs) and examined the phase at a range of pressures to discover a recoverable phase transition to a wurtzite crystal structure. For C materials, we have synthesized a pyrolyzed carbon aerogel, an amorphous carbon sol gel with size features of ~10 nm and incredibly low density and thermal conductivity (~10<sup>-2</sup> W/m-K). We investigate spatial resolution of heating under pressure and the effect of temperature on resulting material electronic structure. Finally, we model heating with Mie theory to provide insights into the phase transformations of nanomaterials.

**1:39PM S21.00011 ABSTRACT WITHDRAWN —**

**1:51PM S21.00012 Equilibrium phase boundary between hcp-cobalt and fcc-cobalt**, HYUNCHAE CYNN, MAGNUS J. LIPP, WILLIAM J. EVANS, BRUCE J. BAER, Lawrence Livermore Natl Lab — In 2000 (Yoo et al., PRL), fcc-cobalt was reported as a new high pressure phase transforming from ambient hcp-cobalt starting at around 105 GPa and 300 K. Both cobalts coexist up to 150 GPa and thereafter only fcc-cobalt was found to be the only stable phase to 200 GPa. Our recent synchrotron x-ray diffraction data on cobalt are at odds with the previous interpretation. We will present our new finding and elaborate on our understanding in terms of the equilibrium phase boundary of cobalt. We will also compare our previous work on xenon (Cynn et al., 2001, PRL) with our new results on cobalt. This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344. Portions of this work were performed at HPCAT (Sector 16), APS, Argonne National Laboratory. HPCAT operations are supported by DOE-NNSA under Award No. DENA0001974 and DOE-BES under Award No. DE-FG02-99ER45775. The Advanced Photon Source is a U.S. Department of Energy (DOE) Office of Science User Facility operated for the DOE Office of Science by Argonne National Laboratory under Contract No. DE-AC02-06CH11357.

**2:03PM S21.00013 Atomistic simulation of Shock Induced Structural Phase Transition of Single Crystal Copper**, NILANJAN MITRA, ANUPAM NEOGI, Indian Institute of Technology Kharagpur — It is well known that pure Single crystal copper subjected to shock wave loading of different intensities results in development of different types of plasticity mechanisms. Beyond that regime of shock wave intensity it has also been shown in several literature that single crystal Cu shows melting. A regime of shock loading has been identified in this research in which single crystal Cu undergoes a structural phase transition. Identification of this structural phase transition mechanism as well as the resulting phase has not only been done using radial distribution functions and structure factor but also with virtual X-Ray diffraction. Phonon dispersion at these high temperatures and pressures have also been investigated. The effect of crystallographic orientation and initial temperature of the sample has been investigated in this simulation study.

**11:15AM S22.00001 Scalable real space pseudopotential density functional codes for materials in the exascale regime<sup>1</sup>**, CHARLES LENA, JAMES CHELIKOWSKY, GRADY SCHOFIELD, University of Texas at Austin, ARIEL BILLER, LEEOR KRONIK, Weizmann Institute of Science, YOUSEF SAAD, University of Minnesota, JACK DESLIPPE, National Energy Research Scientific Computing Center — Real-space pseudopotential density functional theory has proven to be an efficient method for computing the properties of matter in many different states and geometries, including liquids, wires, slabs, and clusters with and without spin polarization. Fully self-consistent solutions using this approach have been routinely obtained for systems with thousands of atoms. Yet, there are many systems of notable larger sizes where quantum mechanical accuracy is desired, but scalability proves to be a hindrance. Such systems include large biological molecules, complex nanostructures, or mismatched interfaces. We will present an overview of our new massively parallel algorithms, which offer improved scalability in preparation for exascale supercomputing. We will illustrate these algorithms by considering the electronic structure of a Si nanocrystal exceeding  $10^4$  atoms.

**11:27AM S22.00002 Large DFT: to 100K atoms and beyond.**, JONATHAN MULLIN, Army Research Laboratory — A quantum mechanical (QM) approach to materials science provides a gold standard atomistic picture of the mechanisms responsible for a range of phenomena seen in macroscopic and experimental situations. The need to understand materials science problems from atomistic to macroscale was the impetus for ARL to initiate the Enterprise for Multiscale Material Research. This long term project attempts to redefine how materials science questions are posed, and solved. To support this goal, current state-of-the-art QM capabilities need to be extended in the number of atoms which can be treated and the length scale of the dynamics which can be simulated. This extension is referred to as large scale QM, both large spatially and temporally. This will enable fundamental advances in the understanding of materials science problems.

**11:39AM S22.00003 Real Space Multigrid (RMG) Open Source Software Suite for Multi-Petaflops Electronic Structure Calculations**, EMIL BRIGGS, MIROSLAV HODAK, WENCHANG LU, JERRY BERNHOLC, YAN LI, North Carolina State University — RMG is a cross platform open source package for ab initio electronic structure calculations that uses real-space grids, multigrid pre-conditioning, and subspace diagonalization to solve the Kohn-Sham equations. The code has been successfully used for a wide range of problems ranging from complex bulk materials to multifunctional electronic devices and biological systems. RMG makes efficient use of GPU accelerators, if present, but does not require them. Recent work has extended GPU support to systems with multiple GPU's per computational node, as well as optimized both CPU and GPU memory usage to enable large problem sizes, which are no longer limited by the memory of the GPU board. Additional enhancements include increased portability, scalability and performance. New versions of the code are regularly released at [sourceforge.net/projects/rmgdft/](http://sourceforge.net/projects/rmgdft/). The releases include binaries for Linux, Windows and Macintosh systems, automated builds for clusters using cmake, as well as versions adapted to the major supercomputing installations and platforms.

**11:51AM S22.00004 Understanding Strongly Correlated Materials thru Theory Algorithms and High Performance Computers**, GABRIEL KOTLIAR, Rutgers University and Brookhaven National Laboratories — A long standing challenge in condensed matter physics is the prediction of physical properties of materials starting from first principles. In the past two decades, substantial advances have taken place in this area. The combination of modern implementations of electronic structure methods in conjunction with Dynamical Mean Field Theory (DMFT), in combination with advanced impurity solvers, modern computer codes and massively parallel computers, are giving new system specific insights into the properties of strongly correlated electron systems enable the calculations of experimentally measurable correlation functions. The predictions of this "theoretical spectroscopy" can be directly compared with experimental results. In this talk I will briefly outline the state of the art of the methodology, and illustrate it with an example the origin of the solid state anomalies of elemental Plutonium.

**12:27PM S22.00005 Large-scale quantum transport calculations for electronic devices with over ten thousand atoms**, WENCHANG LU, YAN LU, ZHONGCAN XIAO, MIROSLAV HODAK, EMIL BRIGGS, JERRY BERNHOLC, North Carolina State University — The non-equilibrium Greens function method (NEGF) has been implemented in our massively parallel DFT software, the real space multigrid (RMG) code suite. Our implementation employs multi-level parallelization strategies and fully utilizes both multi-core CPUs and GPU accelerators. Since the cost of the calculations increases dramatically with the number of orbitals, an optimal basis set is crucial for including a large number of atoms in the active device part of the simulations. In our implementation, the localized orbitals are separately optimized for each principal layer of the device region, in order to obtain an accurate and optimal basis set. As a large example, we calculated the transmission characteristics of a Si nanowire p-n junction. The nanowire is along (110) direction in order to minimize the number dangling bonds that are saturated by H atoms. Its diameter is 3 nm. The length of 24 nm is necessary because of the long-range screening length in Si. Our calculations clearly show the I-V characteristics of a diode, i.e., the current increases exponentially with forward bias and is near zero with backward bias. Other examples will also be presented, including three-terminal transistors and large sensor structures.

**12:39PM S22.00006 Implementing Parquet equations using HPX<sup>1</sup>**, SAMUEL KELLAR, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, Louisiana, BIBEK WAGLE, Department of Computer Science and Engineering, Louisiana State University, Baton Rouge, Louisiana, SHUXIANG YANG, KA-MING TAM, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, Louisiana, HARTMUT KAISER, Center of Computation and Technology, Louisiana State University, Baton Rouge, Louisiana, JUANA MORENO, MARK JARRELL, Department of Physics and Astronomy, Louisiana State University, Baton Rouge, Louisiana — A new C++ runtime system (HPX) enables simulations of complex systems to run more efficiently on parallel and heterogeneous systems. This increased efficiency allows for solutions to larger simulations of the parquet approximation for a system with impurities. The relevancy of the parquet equations depends upon the ability to solve systems which require long runs and large amounts of memory. These limitations, in addition to numerical complications arising from stability of the solutions, necessitate running on large distributed systems. As the computational resources trend towards the exascale and the limitations arising from computational resources vanish efficiency of large scale simulations becomes a focus. HPX facilitates efficient simulations through intelligent overlapping of computation and communication. Simulations such as the parquet equations which require the transfer of large amounts of data should benefit from HPX implementations.

**12:51PM S22.00007 Asperities, Crack Front Waves and Crack Self Healing**, PANKAJ RAJAK, RAJIV KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, Univ of Southern California — We have performed petascale simulations to study nanomaterial systems capable of sensing and repairing damage in high temperature/high pressure operating conditions. The system we have studied is a ceramic nanocomposite consisting of silicon carbide/silicon dioxide core/shell nanoparticles embedded in alumina. We observe that the interaction of the crack with core/shell asperities gives rise to crack-front waves. We also study crack healing by diffusion of silica into the crack as a function of nanoparticle size and inter-particle distance. Our results are well supported by experimental observations.

**1:03PM S22.00008 Biophysical Discovery through the Lens of a Computational Microscope**, ROMMIE AMARO, University of California, San Diego — With exascale computing power on the horizon, improvements in the underlying algorithms and available structural experimental data are enabling new paradigms for chemical discovery. My work has provided key insights for the systematic incorporation of structural information resulting from state-of-the-art biophysical simulations into protocols for inhibitor and drug discovery. We have shown that many disease targets have druggable pockets that are otherwise “hidden” in high resolution x-ray structures, and that this is a common theme across a wide range of targets in different disease areas. We continue to push the limits of computational biophysical modeling by expanding the time and length scales accessible to molecular simulation. My sights are set on, ultimately, the development of detailed physical models of cells, as the fundamental unit of life, and two recent achievements highlight our efforts in this arena. First is the development of a molecular and Brownian dynamics multi-scale modeling framework, which allows us to investigate drug binding kinetics in addition to thermodynamics. In parallel, we have made significant progress developing new tools to extend molecular structure to cellular environments. Collectively, these achievements are enabling the investigation of the chemical and biophysical nature of cells at unprecedented scales.

**1:39PM S22.00009 Multiscale Dynamics in Soft-Matter Systems: Enzyme Catalysis, Sec-Facilitated Protein Translocation, and Ion-Conduction in Polymers.**, THOMAS MILLER, California Institute of Technology — Nature exhibits dynamics that span extraordinary ranges of space and time. In some cases, these dynamical hierarchies are well separated, simplifying their understanding and description. But chemistry and biology are replete with examples of dynamically coupled scales. In this talk, we will discuss the use of high-performance computing and new simulation methods that enable the inclusion of nuclear quantum effects, such as zero point energy and tunneling, in the reaction dynamics of enzymes, as well as coarse-graining strategies to enable minute-timescale simulations of protein targeting to cell membranes and ion-conduction in polymer electrolytes for lithium-ion battery applications.

**Session S23 DMP GERA FIAP: Thermoelectrics Theory I** 322 - Joseph Feser, University of Delaware

**11:15AM S23.00001 Phonon Heat Conduction In Nanostructures: Ballistic, Coherent, Localized, Hydrodynamic, and Divergent Modes<sup>1</sup>**, GANG CHEN, Massachusetts Institute of Technology — In this talk, we will discuss different modes of heat conduction in nanostructures. Ballistic transport happens when phonon mean free path is longer than the characteristic size of the structure. We will discuss how we compute phonon mean free path distributions based on first-principles and measure the distributions with optical pump-probe techniques by exploring ballistic phonon transport processes. In superlattice structures, ballistic phonon transport across the whole thickness of the superlattices implies phase coherence. We observed this coherent transport in GaAs/AlAs superlattices with fixed periodic thickness and varying number of periods. Simulations show that although high frequency phonons are scattering by roughness, remaining long wavelength phonons maintain their phase and traverse the superlattices ballistically. Accessing the coherent heat conduction regime opens a new venue for phonon engineering. We show further that phonon heat conduction localization happens in GaAs/AlAs superlattice by placing ErAs nanodots at interfaces. This heat-conduction localization phenomenon is confirmed by nonequilibrium atomic Green's function simulation. These ballistic and localization effects can be exploited to improve thermoelectric energy conversion materials via reducing their thermal conductivity. In another opposite, we will discuss phonon hydrodynamic transport mode in graphene via first-principle simulations. In this mode, phonons drift with an average velocity under a temperature gradient, similar to fluid flow in a pipe. Conditions for observing such phonon hydrodynamic modes will be discussed. Finally, we will talk about the one-dimensional nature of heat conduction in polymer chains. Such 1D nature can lead to divergent thermal conductivity. Inspired by simulation, we have experimentally demonstrated high thermal conductivity in ultra-drawn polyethylene nanofibers and sheets.

**11:51AM S23.00002 Green-Kubo Modal Analysis**, ASEGUN HENRY, Georgia Institute of Technology — A new method for direct calculation of the modal contributions to thermal conductivity, which is termed Green-Kubo modal analysis (GKMA) will be presented. The GKMA method combines the lattice dynamics formalism with the Green-Kubo formula for thermal conductivity, such that the thermal conductivity becomes a direct summation of modal contributions, where one need not define the phonon velocity. As a result, the GKMA method can be applied to any material/group of atoms, where the atoms vibrate around stable equilibrium positions, which includes crystalline line compounds, non-stoichiometric compounds, random alloys, amorphous materials and even rigid molecules. By using molecular dynamics simulations to obtain the time history of each mode's contribution to the heat current, one naturally includes anharmonicity to full order and can obtain insight into the interactions between different modes through the cross-correlations. Several example materials will be discussed and the specific attention will be devoted to new fundamental questions that arise from the changes in mode character that occur in disordered systems. The GKMA method provides new insight into the nature of phonon transport, as it casts the problem in terms of mode-mode correlation instead of scattering, and provides a general unified formalism that can be used to understand phonon-phonon interactions in essentially any class of materials or structures where the atoms vibrate around stable equilibrium sites.

**12:03PM S23.00003 On The Solenoidal Heat Flux in Quasi-Ballistic Thermal Conduction<sup>1</sup>**, ASHOK RAMU, JOHN BOWERS, UC Santa Barbara — The Boltzmann transport equation for phonons is recast directly in terms of the heat-flux by means of iteration followed by truncation at the second order in the spherical harmonic expansion of the distribution function. This procedure displays the heat-flux in an explicitly coordinate-invariant form, and leads to a natural decomposition into two components, namely the solenoidal component in addition to the usual irrotational component. The solenoidal heat-flux is explicitly shown to arise in a right-circular cylinder when the transport is in the quasi-ballistic regime. These findings are important in the context of phonon resonators that utilize the strong quasi-ballistic thermal transport reported recently in silicon membranes at room temperature. Effects due to circulating heat fluxes are noted in the effective thermal conductivity of silicon discs.

**12:15PM S23.00004 Active Extraction of Near-field Thermal Radiation** , DING DING, TAEYONG KIM, AUSTIN MINNICH, Caltech — Radiative heat transport between materials supporting surface-phonon polaritons is greatly enhanced when the materials are placed at sub-wavelength separation as a result of the contribution of near-field surface modes. However, the enhancement is limited to small separations due to the evanescent decay of the surface waves. In this work, we propose and numerically demonstrate an active radiative cooling (ARC) scheme to extract these modes to the far-field. Our approach exploits the monochromatic nature of near-field thermal radiation to drive a transition in a laser gain medium, which, when coupled with external optical pumping, allows the resonant surface mode to be emitted into the far-field. We also provide further insights into our ARC scheme by applying the theoretical framework used for laser cooling of solids (LCS) to ARC. We show that LCS and ARC can be described with the same mathematical formalism by replacing the electron-phonon coupling parameter in LCS with the electron-photon coupling parameter in ARC. Using this framework, we examine the predictions of the formalism for LCS and ARC using realistic parameters and find that ARC can achieve higher efficiency and extracted power over a wide range of conditions. Our study demonstrates a new approach to manipulate near-field thermal radiation for thermal management.

**12:27PM S23.00005 Spectral Analysis of Surface Controlled Phonon Transport in Nanophononic Metamaterials<sup>1</sup>** , SANGHAMITRA NEOGI, University of Colorado at Boulder, DAVIDE DONADIO, University of California Davis — Phonon engineering in nanostructured semiconductors has shown promises to further advance the performance of energy applications beyond the state-of-the-art limit. In nanostructured materials, phonon transport is greatly affected by the surface nanoscale character[1]. The concept of nanophononic metamaterial (NPM) was introduced recently [2] to affect nanoscale thermal transport with the inclusion of local surface resonators. We carried out a systematic investigation of phonon transport in locally resonant silicon-based NPMs. We used classical equilibrium molecular dynamics and a Boltzmann transport equation approach with the relaxation time approximation to investigate the nature of phononic thermal transport in nanopatterned silicon membranes with thicknesses of the order of 10 nm and below. We find the presence of local surface resonators has a significant effect on the phonon dispersion and has a direct consequence of suppression of group velocities of phonons in the NPMs. We completed the investigation by relating nanoscale resonant character (geometry and material composition) with phonon scattering, and consequently, phonon transport in the locally resonant silicon membrane NPMs. [1] Neogi et al, ACS nano, 9(4), 3820-3828 (2015) [2] Davis & Hussein, PRL, 12, 055505 (2014)

<sup>1</sup>This project is funded by the program FP7-ENERGY-2012-1-2STAGE under contract number 309150.

**12:39PM S23.00006 Nanophononic metamaterial: Thermal conductivity reduction by full-spectrum resonance hybridizations.** , MAHMOUD HUSSEIN, HOSSEIN HONARVAR, LINA YANG, University of Colorado Boulder — Engineered manipulation of phonons can yield beneficial thermal properties in semiconducting materials. One pivotal application relates to thermoelectric materials, or the concept of converting energy in the form of heat into electricity and vice-versa. The ability to use nanostructuring to reduce the thermal conductivity without negatively impacting the power factor provides a promising avenue for achieving high values of the thermoelectric energy conversion figure-of-merit, ZT. Here, we propose a novel nanostructured material configuration that seeks to achieve this goal. Termed “nanophononic metamaterial,” the configuration is based on a freestanding silicon membrane with a periodic array, or random forest, of nanopillars erected on the surface. The nanopillars qualitatively alter the base membrane phonon spectrum due to a hybridization mechanism between their local resonances and the underlying atomic lattice dispersion. Using equilibrium molecular dynamics simulations, we predict a factor of 10 drop in the thermal conductivity compared to the corresponding uniform membrane value despite the fact that the nanopillars add more phonon modes to the spectrum.

**12:51PM S23.00007 Design principles of interfacial thermal conductance** , CARLOS POLANCO, ROUZBEH RASTGARKAFSHGARKOLAEI, JINGJIE ZHANG, NAM LE, PAMELA NORRIS, AVIK GHOSH, Univ of Virginia — We explore fundamental principles to design the thermal conductance across solid interfaces by changing the composition and disorder of an intermediate matching layer. In absence of phonon-phonon interactions, the layer addition involves two competing effects that influence the conductance. The layer can act as an impedance matching bridge to increase the mode-averaged phonon transmission. However, it also reduces the relevant modes that conserve their momenta transverse to the interface, so that the net result depends on features such as the overlap of conserving modes and the dispersivity of the transverse subbands. Moving into the interacting anharmonic regime, we find that the added layer aids conductance when the decreased resistances at the contact-layer boundaries compensate for the layer resistance. In fact, we show that the maximum conductance corresponds to an exact matching of the two separate contact-layer resistances. For instance, if we vary just the atomic mass across layers, then maximum conductance happens when the intervening layer mass is the geometric mean of the contact masses. We conjecture that the best interfacial layer is one that is compositionally graded into many geometric means in other words, an exponential variation in thermal impedance.

**1:03PM S23.00008 Modal Contributions to Heat Conduction across Crystalline and Amorphous Si/Ge Interfaces** , KIARASH GORDIZ, ASEGUN HENRY, Georgia Institute of Technology — Until now, our entire understanding of interfacial heat transfer has been based on the phonon gas model and Landauer formalism. Based on this framework, it is difficult to offer any intuition on heat transfer between two solid materials if one side of the interface is an amorphous structure. Here, using the interface conductance modal analysis (ICMA) method, we investigate the modal contributions to thermal interface conductance (TIC) through crystalline (c) and amorphous (a) Si/Ge interfaces. It is revealed that around 15% of the conductance through the cSi/cGe interface arises from less than 0.1% of the modes of vibration in the structure that exist between 12-13THz and because of their large eigenvectors around the interface are classified as interfacial modes. Correlation maps show that these interfacial modes exhibit strong correlations with all the other modes. The physics behind this strong coupling ability is studied by calculating the mode-level harmonic and anharmonic energy distribution among all the atoms in the system. It is found that these interfacial modes are enabled by the large degree of anharmonicity near the interface, which is higher than the bulk and ultimately allows this small group of modes to couple to other modes of vibration. In addition, unlike the cSi/cGe, correlation maps for aSi/cGe, cSi/aGe, and aSi/aGe interfaces show that the majority of contributions to TIC arise from auto-correlations instead of cross-correlations. The provided analysis sheds light on the nature of localized vibrations at interfaces and can be enlightening for other investigations of localization.

**1:15PM S23.00009 SiC-Si interfacial thermal and mechanical properties of reaction bonded SiC/Si ceramic composites** , CHUN-YEN HSU, FEI DENG, PRASHANT KARANDIKAR, CHAOYING NI, University of Delaware — Reaction bonded SiC/Si (RBSC) ceramic composites are broadly utilized in military, semiconductor and aerospace industries. RBSC affords advanced specific stiffness, hardness and thermal. Interface is a key region that has to be considered when working with any composites. Both thermal and mechanical behaviors of the RBSC are highly dependent on the SiC-Si interface. The SiC-Si interface had been found to act as a thermal barrier in restricting heat transferring at room temperature and to govern the energy absorption ability of the RBSC. However, up to present, the role of the SiC-Si interface to transport heat at higher temperatures and the interfacial properties in the nanoscale have not been established. This study focuses on these critically important subjects to explore scientific phenomena and underlying mechanisms. The RBSC thermal conductivity with volume percentages of SiC at 80 and 90 vol% was measured up to 1,200 C, and was found to decrease for both samples with increasing environmental temperature. The RBSC with 90 vol% SiC has a higher thermal conductivity than that of the 80 vol%; however, is still significantly lower than that of the SiC. The interfacial thermal barrier effect was found to decrease at higher temperatures close 1200 C. A custom-made *in-situ* tensile testing device which can be accommodated inside a ZEISS Auriga 60 FIB/SEM has been setup successfully. The SiC-Si interfacial bonding strength was measured at 98 MPa. The observation and analysis of crack propagation along the SiC-Si interface was achieved with *in-situ* TEM.

**1:27PM S23.00010 Kapitza resistance at segregated boundaries in  $\beta$ -SiC**, NIPUN GOEL, EDMUND WEBB III, ALPARSLAN OZTEKIN, JEFFREY RICKMAN, SUDHAKAR NETI, Lehigh University — Silicon Carbide is a candidate material for high-temperature thermoelectric applications for harvesting waste heat associated with exhaust from automotive and furnaces as well hot surfaces in solar towers and power electronics. However, for SiC to be a viable thermoelectric material, its thermoelectric figure of merit must be improved significantly. In this talk we examine the role of grain-boundary segregation on phononic thermal transport, an important factor in determining the figure of merit, via non-equilibrium molecular dynamics simulations. In particular, we consider the role of dopant concentration and dopant/matrix interactions on the enhancement of the Kapitza resistance of symmetric tilt grain boundaries. We find that the calculated resistance depends on the segregation profile, with increases of more than a factor of 50 (relative to an unsegregated boundary) at the highest dopant concentrations. Finally, we relate the calculated phonon density of states to changes in the Kapitza resistance.

**1:39PM S23.00011 Heat current characteristics in nanojunctions: The effect of external magnetic fields<sup>1</sup>**, D. MELISA DOMINGUEZ, Universidad de Antioquia, JULIANA RESTREPO, Universidad Antonio Nario, BORIS A. RODRIGUEZ, Universidad de Antioquia, R CHITRA, Institute of Theoretical Physics ETH — We study the heat current in the simplest hybrid device of a two level system weakly coupled to two heat baths. We consider both metallic and semiconducting baths with external magnetic fields applied on the central spin and the baths. By using a reduced density matrix approach together with a simple Born-Markov approximation we calculate the heat current. Our goal is to investigate the effect of the applied fields in the transient and steady state heat current, the ensuing rectification and the possibility of using our setup as a building block for a quantum thermal diode.

**1:51PM S23.00012 Estimating thermal conductivity and thermoelectricity in PbTiO<sub>3</sub> from first principles**, ANINDYA ROY, Johns Hopkins University — A combination of density functional theory and Boltzmann transport equation is used in this study to calculate the lattice thermal conductivity ( $\kappa_L$ ) of PbTiO<sub>3</sub> (PTO). We cannot apply this procedure to determine  $\kappa_L$  in presence of imaginary phonon modes ("soft modes"). Hence the tetragonal structure of PTO is used in these calculations, and the predicted  $\kappa_L$  is extrapolated to higher temperature using insights from experiments. The computed  $\kappa_L$  of PTO is low, possibly due to the anharmonicity associated with the ferroelectric/paraelectric transition. Electronic transport parameters such as the Seebeck coefficient and the electrical conductivity are also determined (under constant scattering time approximation in semiclassical Boltzmann theory) for PTO. The low  $\kappa_L$  and the electronic transport parameters together indicate excellent thermoelectric properties of PTO ( $zT > 1.5$  at 1000 K). As a technologically important ferroelectric/piezoelectric material, PTO is used in alloys and in layered structures. These morphologies could bring down the  $\kappa_L$  further, improving its thermoelectric performance. Synthesis of electrically conducting samples of PTO would allow us to verify the above predictions.

**2:03PM S23.00013 Rayleigh surface waves, phonon mode conversion, and thermal transport in nanostructures**, LEON MAURER, IRENA KNEZEVIC, University of Wisconsin-Madison — We study the effects of phonon mode conversion and Rayleigh (surface) waves on thermal transport in nanostructures. We present a technique to calculate thermal conductivity in the elastic-solid approximation: a finite-difference time-domain (FDTD) solution of the elastic or scalar wave equations combined with the Green-Kubo formula. The technique is similar to an equilibrium molecular dynamics simulation, captures phonon wave behavior, and scales well to nanostructures that are too large to simulate with many other techniques. By imposing fixed or free boundary conditions, we can selectively turn off mode conversion and Rayleigh waves to study their effects. In the example case of graphenelike nanoribbons with rough edges, we find that mode conversion among bulk modes has little effect on thermal transport, but that conversion between bulk and Rayleigh waves can significantly reduce thermal conductivity. With increasing surface disorder, Rayleigh waves readily become trapped by the disorder and draw energy away from the propagating bulk modes, which lowers thermal conductivity. We discuss the implications on the accuracy of popular phonon-surface scattering models that stem from scalar wave equations and cannot capture mode conversion to Rayleigh waves.

**11:15AM S24.00001 Using charged defects in BN to create rewritable graphene quantum dots and visualize quantum interference**, JAIRO VELASCO JR., University of California, Santa Cruz — Heterostructures of graphene and hexagonal boron nitride (BN) are highly tunable platforms that enable the study of novel physical phenomena and technologically promising nanoelectronic devices. Common control schemes employed in these studies are electrostatic gating and chemical doping. However, these methods have significant drawbacks, such as complicated fabrication processes that introduce contamination and irreversible changes to material properties, as well as a lack of flexible control. To address these problems we have developed a new method that employs light and/or electric field excitation to control defect charge (from the single impurity level to ensembles) in the underlying BN. We have used optoelectronic and scanning tunneling spectroscopy measurements to characterize these BN defects. We find that by manipulating defect charge in BN it is possible to create rewritable tip-induced doping patterns such as gate-tunable graphene pn junctions and quantum dots. This creates new opportunities for mapping the electronic states of confined electrons in graphene and to visualize their quantum interference behavior.

**11:51AM S24.00002 Quantum Imaging of Interaction-Induced Spontaneous Broken-Symmetry Phases in Molecular Graphene**, DOMINIK RASTAWICKI, YAN SUN, YANG LIU, YI-TING CHEN, HARI C. MANOHARAN, Stanford University — We present a survey of quantum states with interaction-induced broken symmetries observed in molecular graphene, assembled with atomic manipulation. These materials are assembled with atomic precision by patterning the Cu(111) two-dimensional electron gas surface state by single molecules; the molecules function as local potentials which form a coherently coupled system of electron quantum dots in a honeycomb lattice embedding massless Dirac fermions and tunable graphene properties. By crafting different local molecular arrangements together with varying lattice constants, we are able to probe a large parameter space of the strength of the intersite hopping parameter (bond strength), the doping level, and the interaction strength. The assembled nanomaterials are probed through STM/STS measurement, differential conductance maps, and quasiparticle interference with Fourier-transform STS. We observe both spontaneous nematic states and sublattice symmetry breaking in molecular graphene at very low band filling factors, and a nematic state in graphene variants where kinetic energy is effectively quenched. We show it is possible to modify and enhance the symmetry breaking effects by controlling certain boundary conditions and lattice geometry.

**12:03PM S24.00003 Vertical gating of sketched nanodevices<sup>1</sup>**, YUN-YI PAI, University of Pittsburgh, DONG-WOOK PARK, University of Wisconsin at Madison, MENGCHEN HUANG, ANIL ANNADI, University of Pittsburgh, HYUNGWOO LEE, ZHENQIANG MA, CHANG-BEOM EOM, University of Wisconsin at Madison, PATRICK IRVIN, JEREMY LEVY, University of Pittsburgh — Conductive-atomic force microscope (c-AFM) lithography at the  $\text{LaAlO}_3/\text{SrTiO}_3$  interface has enabled the creation of various classes of nanostructures, such as nanoscale transistors<sup>2</sup>, single-electron transistors<sup>3</sup> and has proven to be a promising testbed for mesoscopic physics<sup>4</sup>. To date, these devices have used lithographically-defined side gates, which are limited by leakage currents. To reduce leakage and improve the electric field effect, we have investigated nanostructures with in-situ grown gold top gate. We will discuss designs of logic devices such as inverters, NAND, and NOR gates. In the quantum regime, we compare the performance of in-situ vertical top gates and that of written coplanar side gates with Quantum Dot devices.

**12:15PM S24.00004 Fabrication of Ultralow Density Interconnected Pure Metal Foams<sup>1</sup>**, EDWARD C. BURKS, DUSTIN A. GILBERT, KAI LIU, University of California, Davis, SERGEI O. KUCHEYEV, JEFFREY D. COLVIN, Lawrence Livermore National Laboratory, THOMAS E. FELTER, Sandia National Laboratory — Ultra-low density metallic nanostructures have been shown to possess interesting thermal, electrical, magnetic, chemical and mechanical properties due to their extremely high surface areas, nanoscale geometries and high porosities. Here we report the synthesis of pure metal foams using interconnected metallic nanowires with densities as low as 0.1% of their bulk density that are still mechanically stable. The highly porous monoliths are macroscopic in size (several mm) and can be created in a wide variety of shapes for application-specific needs. Preliminary studies of such metal foams have already revealed fascinating mechanical and magnetic properties, since the physical dimensions of the foams are below some of the basic length scales that govern the material properties. These foams have been used as targets for ultrabright x-ray sources. They also have a wide variety of other potential applications such as photovoltaic devices, supercapacitors, catalysts, coatings, fuel cells, etc.

<sup>1</sup>This work has been supported by DTRA BRCALL08-Per3-C-2-0006, and in part by NSF DMR-1008791 and DMR-1543582. Work at LLNL was performed under the auspices of the U.S. DOE by LLNL under Contract DE-AC52-07NA27344.

**12:27PM S24.00005 Attraction by Repulsion: Pairing Electrons using Electrons.**, SHAHAL ILANI, Weizmann Institute of Science — One of the fundamental properties of electrons is their mutual Coulombic repulsion. If electrons are placed in a solid, however, this basic property may change. A famous example is that of superconductors, where coupling to lattice vibrations makes electrons attractive and leads to the formation of bound pairs. But what if all the degrees of freedom in the solid are electronic? Is it possible to make electrons attract each other only by their repulsion to other electrons? Such an 'excitonic' mechanism for attraction was proposed fifty years ago by W. A. Little, with the hope that it could lead to better and more exotic superconductivity. Yet, despite many efforts to synthesize materials that possess this unique property, to date there is still no evidence for electronic-based attraction. In this talk I will present our recent experiments that observe this unusual electronic attraction using a different, bottom-up approach. Our experiments are based on a new generation of quantum devices made from pristine carbon nanotubes, combined with precision cryogenic manipulation. Using this setup we can now assemble the fundamental building block of the excitonic attraction and demonstrate that two electrons that naturally repel each other can be made attractive using an independent electronic system as the binding glue. I will discuss the lessons learned from these experiments on what is achievable with plain electrostatics, and on the possibility to use the observed mechanism for creating exotic states of matter.

**1:03PM S24.00006 ABSTRACT WITHDRAWN —**

**1:15PM S24.00007 Universality of Non-equilibrium Fluctuations in Strongly Correlated Quantum Liquids.**, MEYDI FERRIER, Univ. Paris sud, TOMONORI ARAKAWA, TOKURO HATA, RYO FUJIWARA, Univ. Osaka, RAPHAELLE DELAGRANGE, RICHARD DEBLOCK, Univ. Paris sud, RUI SAKANO, ISSP, Univ. Tokyo, AKIRA OGURI, Univ. Osaka city, KENSUKE KOBAYASHI, Univ. Osaka — In a quantum dot, Kondo effect occurs when the spin of the confined electron is entangled with the electrons of the leads forming locally a strongly correlated Fermi-liquid. Our experiments were performed in such a dot formed in a single carbon nanotube, where Kondo effect with different symmetry groups, namely SU(2) and SU(4), shows up. In the latter case, as spin and orbital degrees of freedom are degenerate, two channels contribute to transport and Kondo resonance emerges for odd and even number of electrons. With our sample it was possible to investigate both symmetries near the unitary limit. In the Kondo regime, strong interaction creates a peculiar two-particle scattering which appears as an effective charge  $e^*$  for the quasi-particles. We have extracted the signature of this effective charge in the shot noise for both symmetry in good agreement with theory<sup>1</sup>. This result demonstrates that theory of the Kondo effect can be safely extended out of equilibrium even in the unconventional SU(4) symmetry.

**1:27PM S24.00008 In-plane electrical transport across cavity-quantum well system in Bose-Einstein condensate phase**, MING XIE, ALLAN MACDONALD, University of Texas at Austin — Cavity polaritons are coupled states of quantum well excitons and vertical cavity photons which can undergo Bose-Einstein condensation under appropriate circumstances. The macroscopic condensate state can be described by two coupled order parameters - the coherent exciton field and the coherent photon field. When the dominant process for electron transfer between conduction and valence bands is by scattering off the photon condensate, electrical bias voltages can be used to control the condensate. We study the in-plane transport properties of electrical current through the cavity-quantum well system, and show how the coherent photon fields respond to the current flow. The possibility of tailoring light via electrical current and vice versa simultaneously might lead to interesting new applications.

**1:39PM S24.00009 Fano Resonance in an Electrically Driven Plasmonic Device**, YUVAL VARDI, EYAL COHEN-HOSHEN, GUY SHALEM, ISRAEL BAR-JOSEPH, Department of Condensed Matter Physics, Weizmann Institute of Science, Rehovot 76100, Israel — Electrically driven plasmonic devices offer unique opportunities as a research tool and for practical applications. In such devices, current that flows across a metallic tunnel junction excites a plasmon, which gives rise to light emission. This local nature of the excitation allows access into "dark" modes, which are not easily excited by far field illumination. We present an electrically driven plasmonic device, based on a gold nanoparticle single-electron-transistor, and investigate the light emission due to the tunneling current. The applied voltage determines the emitted spectral lineshape, enables an excellent control of the plasmonic spectrum. We show that the use of this structure allows us to characterize the electrical properties of the two tunnel barriers, and determine their role in the light emission process. Furthermore, we find a Fano resonance, resulting from interference between the nanoparticle and electrodes dipoles. This resonance is seen due to the local nature of the excitation, and is manifested as a sharp asymmetrical spectral dip. We show that the spectral position of this resonance can be conveniently controlled by the design of the structural parameters. Such devices may be a step toward the realization of an on-chip nano-optical emitters and sensors.

**1:51PM S24.00010 Classical decoherence in a nanomechanical resonator** , OLIVIER MAILLET, ANDREW FEFERMAN, RASUL GAZIZULIN, HENRI GODFRIN, OLIVIER BOURGEOIS, EDDY COLLIN, CNRS/Neel Inst, ULT GRENOBLE TEAM — Decoherence can be viewed either in its quantum picture, where it stands for the loss of phase coherence of a superposition state, or as its classical equivalent, where the phase of an oscillating signal is smeared due to frequency fluctuations. Little is known about quantum coherence of mechanical systems, as opposed to electromagnetic degrees of freedom. Indeed the bridge between quantum and classical physics is under intense investigation, using in particular classical nanomechanical analogues of quantum phenomena. Here we report on a model experiment in which the coherence of a high quality silicon-nitride mechanical resonator is defined in the classical picture. Its intrinsic properties are characterized over an unprecedentedly large dynamic range. By engineering frequency fluctuations, we can create artificial pure dephasing and study its effects on the dynamics of the system. Finally, we develop the methods to characterize pure dephasing that can be applied to a wide range of mechanical devices.

**2:03PM S24.00011 A self-saturating mechanical oscillator with linear feedback** , CHANGYAO CHEN, Argonne National Lab, DAMIAN ZANETTE, Centro Atmico Bariloche, DAVID CZAPLEWSKI, JEFFREY GUEST, DANIEL LOPEZ, Argonne National Lab — Oscillators, opposed to resonators, produce a prescribed periodic signal without any external frequency reference. In order to maintain stable oscillations, there needs to be an amplitude limiting mechanism, which is usually realized by saturating at least one of the sustaining amplifiers. Here we demonstrate a simple oscillator structure that solely relies on the nonlinearity inherent to the constituent mechanical resonator to limit the oscillating amplitude, while the performance of the feedback loop remains in the linear regime. To validate the model, we experimentally demonstrate the principle using a non-linear silicon microelectromechanical (MEMS) resonator, and perform comprehensive characterizations that agree well with the theoretical predictions.

**11:15AM S25.00001 Instability of three-band Luttinger liquids: renormalization group analysis and possible application to  $K_2Cr_3As_3$**  , JIAN-JIAN MIAO, FU-CHUN ZHANG, YI ZHOU, Zhejiang Univ — Motivated by recently discovered quasi-one-dimensional superconductor  $K_2Cr_3As_3$  with  $D_{3h}$  lattice symmetry, we study one-dimensional three-orbital Hubbard models with generic electron repulsive interaction described by intra-orbital repulsion  $U$ , inter-orbital repulsion  $U'$ , and Hund's coupling  $J$ . As extracted from density functional theory calculation, two of the three atomic orbitals are degenerate and the third one is non-degenerate, and the system is presumed to be at incommensurate filling. With the help of bosonization, we have usual three-band Luttinger liquids in the normal state. Possible charge density wave (CDW), spin density wave (SDW) and superconducting instabilities are analyzed by one-loop renormalization group. The ground state depends on the ratio  $J/U$ . For the physical relevant parameter region,  $0 < J/U < 1/2$ , the ground states are superconducting states. When  $0 < J/U < 1/3$ , spin singlet superconducting state is favored. While spin triplet superconductor will be favored when  $1/3 < J/U < 1/2$ . The spin density wave state can be achieved only in the unphysical parameter region  $J/U > 1/2$ .

**11:27AM S25.00002 Evaluations of  $MgB_2$  Coatings on 2" Copper Discs for Superconducting Radio Frequency Applications.** , WENURA WITHANAGE, TENG TAN, NAMHOON LEE, HUTA BANJADE, Temple University, GRIGORY EREMEEV, Thomas Jefferson National Accelerator Facility, PAUL WELANDER, SLAC National Accelerator Laboratory, ANNE-MARIE VALENTE-FELICIANO, Thomas Jefferson National Accelerator Facility, ROBERT KUSTOM, Argonne National Laboratory, MATTHUS WOLAK, Temple University, ALIREZA NASSIRI, Argonne National Laboratory, XIAOXING XI, Temple University — We propose that coating the inner walls of copper RF cavities with superconducting  $MgB_2$  ( $T_c = 39$  K) can result in a viable alternative to the already established niobium-based SRF technology. This approach improves the thermal conductivity, allows for operation at higher temperatures, and reduces the need for large helium refrigeration, thereby resulting in lower operational costs. For our studies, we grew  $MgB_2$  films via hybrid physical chemical vapor deposition (HPCVD) on 2" Cu substrates. Since Mg and Cu readily form an alloy at higher temperatures, the HPCVD setup was modified in order to achieve lower deposition temperatures, minimize alloy formation, and provide high quality  $MgB_2$  films. This method yielded  $MgB_2$  coatings on 2" Cu discs with transition temperatures around 38 K. The samples were characterized with regards to their RF attributes and showed similar performance in comparison to Nb reference samples. The presented results show that  $MgB_2$  coated copper can be a suitable alternative for use in SRF cavities.

**11:39AM S25.00003 Electronic Pair-Binding and Hund's Rule Violations in Doped  $C_{60}$** <sup>1</sup> , HONG-CHEN JIANG, Stanford Institute for Materials and Energy Sciences, SLAC National Accelerator Laboratory, STEVEN KIVELSON, Department of Physics, Stanford University — We calculate the electronic properties of the t-J model on a  $C_{60}$  molecule using the density-matrix renormalization group and show that Hund's first rule is violated and that for an average of three added electron per molecule, an effective attraction (pair-binding) arises for intermediate values of  $t=J$ . Specifically, it is energetically favorable to put four electrons on one  $C_{60}$  and two on a second rather than putting three on each. Our results show that a dominantly electronic mechanism of superconductivity is possible in doped  $C_{60}$ .

**11:51AM S25.00004 The Role of Halogen Bonding in Metal Free phosphors** , HOSSEIN HASHEMI, JAEHUN JUNG, AVI BREGMAN, JOHN KIEFFER, JINSANG KIM, University of Michigan — Metal-organic phosphors can achieve theoretical efficiencies four times greater than their fluorescent analogues in Electroluminescence device, but they still have stability issue in case of blue emitting heavy-metal complexes and the price of transition metal like iridium has skyrocketed which discourages commercialization of OLEDs for solid-state lighting. By minimizing radiative loss due to vibrational effects and enhancing spin-orbit coupling via halogen bonding between aldehyde and heavy halide in an organic crystal, efficient room-temperature phosphorescence has been achieved. Therefore, the enhanced spin-orbit coupling necessary for phosphorescence is thought to be due to the halogen bonding that is present in the crystalline form. Here, the electronic and optical properties of purely organic phosphor candidates are explored using density functional theory (DFT), time-dependent density functional theory (TDDFT), GW and BSE methods. These calculations are compared with the absorption, fluorescence, and phosphorescence experimental spectra in their crystals as well as solution forms to elucidate the underlying the role of halogen bonding for phosphorescence mechanism. These results are used to guide future metal-free organic phosphors.

**12:03PM S25.00005 Camelback-shaped band reconciles heavy-electron behavior with weak electronic Coulomb correlations in superconducting  $\text{TiNi}_2\text{Se}_2$** , CHRISTIAN MATT, NAN XU, Swiss Light Source, Paul Scherrer Institut, CH-5232 Villigen PSI, Switzerland, A. VAN ROEKEGHEM, S. BIERMANN, École Polytechnique, CNRS-UMR7644, 91128 Palaiseau, France, P. RICHARD, X. SHI, S.-F. WU, H. W. LIU, D. CHEN, T. QIAN, H. DING, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, H. WANG, Q. MAO, J. DU, M. FANG, Department of Physics, Zhejiang University, Hangzhou 310027, China, N. PLUMB, M. RADOVIC, J. MESOT, M. SHI, Swiss Light Source, Paul Scherrer Institut, CH-5232 Villigen PSI, Switzerland — Combining photoemission spectroscopy, Raman spectroscopy, and first-principles calculations, we characterize superconducting  $\text{TiNi}_2\text{Se}_2$  as a material with weak electronic Coulomb correlations leading to a bandwidth renormalization of 1.4. We identify a camelback-shaped band, whose energetic position strongly depends on the selenium height. While this feature is universal in transition metal pnictides, in  $\text{TiNi}_2\text{Se}_2$  it lies in the immediate vicinity of the Fermi level, giving rise to a pronounced van Hove singularity (VHS). The resulting heavy band mass resolves the apparent puzzle of a large normal-state Sommerfeld coefficient in this weakly correlated compound. The correlation effect evolution in pnictides upon d-shell filling in the presence of significant Hund's exchange coupling will also be discussed.

**12:15PM S25.00006 The happy marriage between electron-phonon superconductivity and Mott physics in  $\text{Cs}_3\text{C}_{60}$ : A first-principle phase diagram**, MASSIMO CAPONE, International School for Advanced Studies (SISSA) and CNR-IOM, YUSUKE NOMURA, École Polytechnique, SHIRO SAKAI, Riken Center for Emergent Matter Science, Japan, GIANLUCA GIOVANNETTI, CNR-IOM and International School for Advanced Studies (SISSA), RYOTARO ARITA, Riken Center for Emergent Matter Science, Japan — The phase diagram of doped fullerides like  $\text{Cs}_3\text{C}_{60}$  as a function of the spacing between fullerene molecules is characterized by a first-order transition between a Mott insulator and an s-wave superconductor with a dome-shaped behavior of the critical temperature. By means of an ab-initio modeling of the bandstructure, the electron-phonon interaction and the interaction parameter and a Dynamical Mean-Field Theory solution, we reproduce the phase diagram and demonstrate that phonon superconductivity benefits from strong correlations [1] confirming earlier model predictions [2]. The role of correlations is manifest also in infrared measurements carried out by L. Baldassarre [3]. The superconducting phase shares many similarities with "exotic" superconductors with electronic pairing, suggesting that the anomalies in the "normal" state, rather than the pairing glue, can be the real common element unifying a wide family of strongly correlated superconductors including cuprates and iron superconductors. [1] Y. Nomura, S. Sakai, K. Nakamura, M. Capone, and R. Arita, Science Advances 1, e1500568 (2015) [2] M. Capone et al., Science 296, 2364 (2002); M. Capone et al., Rev. Mod. Phys. 81, 943 (2009) [3] L. Baldassarre et al. Sci. Rep. 5, 15240 (2015)

**12:27PM S25.00007 Optimal High- $T_C$  Superconductivity in  $\text{Cs}_3\text{C}_{60}$** , DALE HARSHMAN, College of William and Mary, ANTHONY FIORY, New Jersey Institute of Technology — The highest superconducting transition temperatures in the  $(A_{1-x}B_x)_3\text{C}_{60}$  superconducting family are seen in the A15 and FCC structural phases of  $\text{Cs}_3\text{C}_{60}$  (optimized under hydrostatic pressure), exhibiting measured values for near-stoichiometric samples of  $T_C^{\text{meas.}} = 37.8$  K and 35.7 K, respectively. It is argued these two Cs-intercalated  $\text{C}_{60}$  compounds represent the optimal materials of their respective structures, with superconductivity originating from Coulombic  $e$ - $h$  interactions between the  $\text{C}_{60}$  molecules, which host the  $n$ -type superconductivity, and mediating holes associated with the Cs cations. A variation of the interlayer Coulombic pairing model [Harshman and Fiory, J. Supercond. Nov. Magn. 28, 2967 (2015), and references therein] is introduced in which  $T_C^{\text{calc.}} \propto 1/\ell\zeta$ , where  $\ell$  relates to the mean spacing between interacting charges on surfaces of the  $\text{C}_{60}$  molecules, and  $\zeta$  is the average radial distance between the surface of the  $\text{C}_{60}$  molecules and the neighboring Cs cations. For stoichiometric  $\text{Cs}_3\text{C}_{60}$ ,  $T_C^{\text{calc.}} = 38.08$  K and 35.67 K for the A15 and FCC macrostructures, respectively; the dichotomy is attributable to differences in  $\zeta$ .

**12:39PM S25.00008 Electrical transport properties of  $\text{C}_{60}$  superconductors in the vicinity of Mott metal-insulator transition**, YUKI MATSUDA, Department of Physics, Tohoku Univ., SATOSHI HEGURI, WPI-AIMR, Tohoku Univ., YUKI MATSUDA, Department of Physics, Tohoku Univ., KATSUMI TANIGAKI, WPI-AIMR, Tohoku Univ., Department of Physics, Tohoku Univ. — It was revealed in 2008 that  $\text{Cs}_3\text{C}_{60}$  showed superconductivity up to 38K under high pressure [1]. As the lattice constant is increased, the superconducting critical temperature ( $T_C$ ) decreases after experiencing the maximum  $T_C$  and finally  $\text{Cs}_3\text{C}_{60}$  becomes a Mott insulator [2]. This result suggests that  $\text{C}_{60}$  superconductors cannot be simply explained by the BCS theory [1-4]. There are strong electron correlations in the vicinity of Mott metal-insulator transition. Electrical transport properties are required because they provide us importantly intrinsic information on the electronic states, but the systematical electrical transport measurements have not been made due to the experimental difficulties. It will be reported that we have successfully obtained the electrical transport properties of expanded  $\text{C}_{60}$  superconductors in pellet form by using a specially designed pressure cell. [1] A. Y. Ganin et al., Nat. Mater. 7, 367 (2008). [2] A. Y. Ganin et al., Nature 466, 221 (2010). [3] Y. Takabayashi et al., Science, 323, 1585 (2009). [4] R. H. Zadic et al., Sci. Adv. 1, e1500059 (2015).

**12:51PM S25.00009 Isotope Effect on Electron-Phonon Coupling in Multiband Superconductor  $\text{MgB}_2$** , DAIXIANG MOU, VALENTIN TAUFOR, YUN WU, LUNAN HUANG, SERGUEI BUD'KO, PAUL CANFIELD, ADAM KAMINSKI, Division of Materials Science and Engineering, Ames Laboratory — We systematically investigate the isotope effect of electron-phonon coupling in multi-band superconductor  $\text{MgB}_2$  by laser based Angle Resolved Photoemission Spectroscopy. The kink structure around 70 meV on two  $\sigma$  bands, which is caused by electron coupling to  $E_{2g}$  phonon mode, is shifted to higher binding energy in  $\text{Mg}^{10}\text{B}_2$  than that in  $\text{Mg}^{11}\text{B}_2$ . The measured shifting energy of 3.5 meV is consistent with theoretical calculation based on harmonic phonon in  $\text{MgB}_2$ . Our temperature dependent measurement also indicates the isotope effect of kink structure is not dependent on superconducting transition.

**1:03PM S25.00010 Momentum-resolved electronic structure of the superconductor parent compound  $\text{BaBiO}_3$** , N.C. PLUMB, Z. RISTIC, J. PARK, Z. WANG, C.E. MATT, N. XU, Swiss Light Source, Paul Scherrer Institut, CH-5232 Villigen PSI, Switzerland, B.Q. LV, Beijing National Laboratory for Condensed Matter Physics and Institute of Physics, Chinese Academy of Sciences, Beijing 100190, China, D. GAWRYLUK, E. POMJAKUSHINA, K. CONDER, Laboratory for Developments and Methods, Paul Scherrer Institut, CH-5232 Villigen PSI, Switzerland, Y. WANG, S. JOHNSTON, Department of Physics and Astronomy, University of Tennessee, Knoxville, Tennessee 37996-1200, USA, J. MESOT, Paul Scherrer Institut, CH-5232 Villigen PSI, Switzerland, M. SHI, M. RADOVIC, Swiss Light Source, Paul Scherrer Institut, CH-5232 Villigen PSI, Switzerland — We use *in situ* angle-resolved photoemission to study thin films of  $\text{BaBiO}_3$ , a parent compound of bismuthate superconductors with  $T_c$  up to 30 K. By simple electron counting,  $\text{BaBiO}_3$  should be metallic. However, in analogy with many unconventional and high- $T_c$  superconductor families, it is instead insulating, and superconductivity emerges with doping. Our experiments reveal a folded band structure consistent with known  $\text{BiO}_6$  breathing distortions. However, charge ordering often thought to accompany the distortions is virtually nonexistent. The data combined with DFT calculations indicate that states near  $E_F$  are primarily oxygen-derived. Hence  $\text{BaBiO}_3$  appears to be characterized by negative charge transfer energy. This can account for the seeming discrepancy between the atomic structure and "missing" charge order. It should also be relevant for understanding the doping evolution and superconductivity in bismuthates.

**1:15PM S25.00011 Comparison of Tunneling in Fe-based Superconductors with Multi-band  $\text{MgB}_2$** , JOHN ZASADZINSKI, Physics Department, Illinois Institute of Technology, Chicago, IL, USA, MARIA IAVARONE, Physics Department, Temple University, Philadelphia, PA, USA —  $\text{MgB}_2$  is an s-wave, phonon coupled, multiband superconductor that exhibits novel tunneling spectra including a subtle dip feature due to quasiparticle transfer between bands. Since this feature mimics the above-gap spectral dip feature observed in Fe-based superconductors, typically attributed to a strong coupling boson, it is worthwhile to consider whether quasiparticle transfer is relevant. We first show that the dip in  $\text{MgB}_2$  appears in the  $\pi$ -band, DOS ( $\Delta = 2.4$  meV) and is due to quasiparticle transfer to the  $\sigma$ -band with  $\Delta = 7.2$  meV. Reviewing the spectral dip in Fe-based superconductors, including new data on FeSe crystals, there are inconsistencies with quasiparticle transfer as the origin. The conclusion is that the spectral dip is more likely due to a boson, the resonance spin excitation, as found in cuprate superconductors.

**1:27PM S25.00012 Robust Resistive Critical Field in Noncentrosymmetric B20 AuBe**, DJ REBAR, JF DITUSA, P ADAMS, J BALL, D BROWNE, I VEKHTER, D YOUNG, J PRESTIGIACOMO, Louisiana State University, JY CHAN, The University of Texas at Dallas — AuBe is a chiral-structured (B20 structure) superconductor. The B20 structure in magnetic systems was discovered to host a magnetic topological structure, the Skyrmin lattice, and our research focused on what behavior the same structure would effect in a superconducting system. Samples were arc-melted in an Ar atmosphere and characterized via powder XRD. Specific heat measurement revealed bulk superconductivity with an exponential form below  $T_c$  while magnetization showed Type I behavior near the  $T_c$  of 3.2 K and a crossover to Type II behavior at approximately 1.2 K. Resistance measurement revealed a critical field that deviates from that found in magnetization measurements at approximately 2.4 K linearly rising with decreasing T to approximately  $3.5 \times H_{c2}$  at  $T=0.3K$ . The resistive critical field was also found to be robust against a Cr film deposited on the surface of AuBe. We find similarity between this superconductivity crossover behavior and robust low temperature critical field with other noncentrosymmetric superconductors in literature. Additionally, we measured the de Haas-van Alphen effect in polycrystalline samples and derived an effective electron mass of 0.16 $m_0$  for a small spherical piece of Fermi surface.

**1:51PM S25.00014 Angle Resolved Thermal Conductivity of Superconducting CeCoIn<sub>5</sub> along the Nodal Direction<sup>1</sup>**, ROMAN MOVSHOVICH, DUK Y. KIM, SHIZENG LIN, FRANZISKA WEICKERT, ERIC D. BAUER, FILIP RONNING, JOE D. THOMPSON, Los Alamos National Laboratory — The thermal conductivity measurement in a rotating magnetic field is a powerful probe of the structure of the superconducting energy gap. The four-fold oscillation in thermal conductivity of CeCoIn<sub>5</sub>, with the heat current in the anti-nodal direction, has revealed the d-wave nature of its order parameter. We have measured the thermal conductivity with the heat current along the [110] (nodal) direction and the magnetic field rotating in the *ab*-plane. In contrast to the smooth oscillation found with the heat current along the anti-nodal direction, a sharp increase of thermal conductivity was observed when the magnetic field is also in the [110] direction, parallel to the heat current. This suggests that the scattering of the nodal quasiparticle is strongly suppressed along the magnetic field direction. In addition, a smaller increase of the thermal conductivity was observed when the magnetic field is approximately 30 degree away from the nodal direction, perhaps due to a Fermi surface anomaly.

<sup>1</sup>Work at Los Alamos was performed under the auspices of the U.S. Department of Energy, Office of Basic Energy Sciences, Division of Materials Sciences and Engineering.

**2:03PM S25.00015 electric dipole superconductor in bilayer exciton system<sup>1</sup>**, QING-FENG SUN, QING-DONG JIANG, ZHI-QIANG BAO, X.C. XIE, ICQM, School of Physics, Peking University, Beijing, 100871, China — Recently, it was reported that the bilayer exciton systems could exhibit many new phenomena, including the large bilayer counterflow conductivity, the Coulomb drag, etc. These phenomena imply the formation of exciton condensate superfluid state. On the other hand, it is now well known that the superconductor is the condensate superfluid state of the Cooper pairs, which can be viewed as electric monopoles. In other words, the superconductor state is the electric monopole condensate superfluid state. Thus, one may wonder whether there exists electric dipole superfluid state. In this talk, we point out that the exciton in a bilayer system can be considered as a charge neutral electric dipole. And we derive the London-type and Ginzburg-Landau-type equations of electric dipole superconductivity. From these equations, we discover the Meissner-type effect (against spatial variation of magnetic fields), and the dipole current Josephson effect. The frequency in the AC Josephson effect of the dipole current is equal to that in the normal (monopole) superconductor. These results can provide direct evidence for the formation of exciton superfluid state in the bilayer systems and pave new ways to obtain the electric dipole current.

**11:15AM S26.00001 Two Dimensional Transition Metal Dichalcogenide and Their Heterostructures Through Chemical Vapor Deposition Synthesis**, JING KONG, Massachusetts Institute of Technology — In recent years tremendous efforts have been devoted to the research on two dimensional materials. Among them transition metal dichalcogenides (TMDs) have attracted significant attention owing to their unique structures, remarkable properties, and great potential for a wide range of applications in electronics, [ENREF.1](#) optoelectronics, valleytronics, catalysis, etc. The synthesis of high quality large area mono- and few-layer TMD materials is highly desirable for their applications. In this talk I will present the chemical vapor deposition (CVD) approach we have developed to synthesis these TMD materials and their heterostructures.

**11:51AM S26.00002 2D Crystal heterostructures properties and growth by molecular beam epitaxy<sup>1</sup>**, GRACE HUILI XING<sup>2</sup>, Cornell University — Two-dimensional (2D) crystals such as transition metal dichalcogenides (TMDs) along with other families of layered materials including graphene, SnSe<sub>2</sub>, GaSe, BN etc, has attracted intense attention from the scientific community. One monolayer of such materials represent the thinnest “quantum wells”. These layered materials typically possess an in-plane hexagonal crystal structure, and can be stacked together by interlayer van der Waals interactions. Therefore, it is possible to create novel heterostructures by stacking materials with large lattice mismatches and different properties, for instance, superconductors (NbSe<sub>2</sub>), metals, semi-metals (graphene), semiconductors (MoS<sub>2</sub>) and insulators (BN). Numerous novel material properties and device concepts have been discovered, proposed and demonstrated lately. However, the low internal photoluminescence efficiency (IPE, <1%) and low carrier mobility observed in the 2D semiconductors suggest strongly that the materials under investigation today most likely suffer from a high concentration of defects. In this talk, I will share our progress and the challenges we face in terms of preparing, characterizing these 2D crystals as well as pursuing their applications.

**12:27PM S26.00003 Quantum emission from hexagonal boron nitride monolayers**, IGOR AHARONOVICH, TOANTRONG TRAN, KEREM BRAY, MICHAEL J. FORD, MILOS TOTH, University of Technology Sydney, MTEE COLLABORATION — Artificial atomic systems in solids are widely considered the leading physical system for a variety of quantum technologies, including quantum communications, computing and metrology. To date, however, room-temperature quantum emitters have only been observed in wide-bandgap semiconductors such as diamond and silicon carbide, nanocrystal quantum dots, and most recently in carbon nanotubes. Here, we demonstrate room-temperature, polarized single-photon emission from a colour centre in two-dimensional hexagonal boron nitride. The emitters emit at the red and the near infrared spectral range and exhibit narrowband ultra bright emission (~full width at half maximum of below 10 nm with more than three million counts/s). Density functional theory calculations indicate that vacancy-related defects are a probable source of the emission. Our results demonstrate the unprecedented potential of van der Waals crystals for large-scale nanophotonics and quantum information processing.

**12:39PM S26.00004 Synthesis and Oxidation Resistance of h-BN Thin Films<sup>1</sup>**, DAVID STEWART, ROBERT MEULENBERG, ROBERT LAD, Univ of Maine — Hexagonal boron nitride (h-BN) is an exciting 2D material for use in sensors and other electronic devices that operate in harsh, high temperature environments. Not only is h-BN a wide band gap material with excellent wear resistance and high temperature stability, but recent reports indicate that h-BN can prevent metallic substrates from oxidizing above 600°C in low O<sub>2</sub> pressures. However, the PVD of highly crystalline h-BN films required for this oxidation protection has proven challenging. In this work, we have explored the growth of h-BN thin films by reactive RF magnetron sputtering from an elemental B target in an Ar/N<sub>2</sub> atmosphere. The film growth rate is extremely slow and the resulting films are atomically smooth and homogeneous. Using DC biasing during deposition and high temperature annealing treatments, the degree of film crystallinity can be controlled. The oxidation resistance of h-BN films deposited on inert sapphire and reactive metal substrates such as Zr and ZrB<sub>2</sub> has been examined by techniques such as XPS, XRD, and SEM after oxidation between 600 and 1200°C under varying oxygen pressures. The success of h-BN as a passivation layer for metallic substrates in harsh environments is shown to depend greatly on its crystalline quality and defects.

**12:51PM S26.00005 Surface Analysis of Hexagonal Boron Nitride Grown by Chemical Vapor Deposition**, ZACHARY ROBINSON, State Univ of NY - Brockport, J.K. HITE, C.R. EDDY JR., V.M. BERMUDEZ, B.N. FEIGELSON, U.S. Naval Research Laboratory — Hexagonal boron nitride (hBN) is an important material for development of 2-dimensional heterostructures. Chemical vapor deposition of hBN on Cu-foil substrates is one possible route towards large-scale production of hBN films with low defect density. Therefore, studying the growth kinetics of hBN on different orientations of Cu is an important first step towards understanding and controlling the growth process. In this work, hBN was simultaneously grown on Cu(111), Cu(100), Cu(110), and Cu-foil in order to investigate how the different substrate orientations affect the hBN overlayer. The post-growth crystallographic orientations were measured with electron backscatter diffraction (EBSD), and film coverages we measured with XPS. In addition, a grazing-incidence infrared reflection absorption spectroscopy (IRRAS) technique was developed to quickly characterize each hBN film. It was found that the growth rate was inversely proportional to the surface free energy of the Cu surface, with Cu(111) having the most h-BN surface coverage. The Cu foil predominately crystallized with a (100) surface orientation, and had a film coverage very close to the Cu(100).

**1:03PM S26.00006 Two-dimensional boron based nanomaterials: electronic, vibrational, Raman, and STM signatures**, DANIEL V. P. MASSOTE, Department of Physics, Applied Physics, and Astronomy, Rensselaer Polytechnic Institute, Troy, New York 12180, LIANGBO LIANG, Center for Nanophase Materials Sciences, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, NEERAV KHARCHE, VINCENT MEUNIER, Department of Physics, Rensselaer Polytechnic Institute — Because boron has only three electrons on its outer shell, planar mono-elemental boron nanostructures are expected to be much more challenging to assemble than their carbon counterparts. Several studies proposed schemes in which boron is stabilized to form flat semiconducting sheets consisting of a hexagonal lattice of boron atoms with partial hexagon filling (PRL 99 115501, ACSNano 6 7443-7453). Other structures were proposed based on results from an evolutionary algorithm (PRL 112 085502). These structures are metallic and one even features a distorted Dirac cone near the Fermi level. Experimental evidence for 2D boron is still lacking but the recently proposed molecular synthesis of a flat all-boron molecule is a promising route to achieve this goal (Nat.Comms. 5 3113). Our research aims at providing a first-principles based description of these materials' properties to help in their identification. DFT is used to calculate phonon dispersion and associated Raman scattering spectra. We report some marked discrepancy between our findings and results from the recent literature and address the deviation using two methods for phonon dispersion. We also simulated STM images at various bias potentials to reveal the electronic symmetry of each material.

**1:15PM S26.00007 Observation of Dirac electrons in germanene on diboride thin films**, ANTOINE FLEURENCE, RAINER FRIEDLEIN, Japan Advanced Institute of Science and Technology, HIROYUKI YAMANE, Institute for Molecular Science, HOWON KIM, Institute for Solid State Physics, YUUTO AWATANI, Japan Advanced Institute of Science and Technology, SHINYA YOSHIMOTO, KOZO MUKAI, TAKANORI KOITAYA, YUKIO HASEGAWA, JUN YOSHINOBU, Institute for Solid State Physics, NOBUHIRO KOSUGI, Institute for Molecular Science, YUKIKO YAMADA-TAKAMURA, Japan Advanced Institute of Science and Technology — Germanene is a single atom thick honeycomb lattice of Ge atoms. Just like silicene, free-standing germanene is predicted to feature  $\pi$  bands forming graphene-like Dirac cones [1]. Epitaxial germanene was already claimed to form on number of substrates [2-4], but no evidence for the existence of a  $\pi$  electronic system has been reported yet. In the present work, we demonstrate experimentally that Ge atoms segregated on the (0001) surface of zirconium diboride (ZrB<sub>2</sub>) thin films grown on Ge(111) form a germanene layer. ZrB<sub>2</sub>(0001) with germanene is ( $\sqrt{3}\times\sqrt{3}$ )-reconstructed at low-temperature and ( $\sqrt{3}\times\sqrt{3}$ )-reconstructed at room temperature. The ( $\sqrt{3}\times\sqrt{3}$ ) reconstruction originates from the matching of this unit cell with the (4X4) unit cell of a Ge honeycomb lattice. Evidence for its germanene nature stems from the observation of the Dirac cone-like dispersion at the K point of its Brillouin zone. [1] S. Cahangirov et al., Phys. Rev. Lett. 102, 236804 (2009). [2] L. Li et al., Adv. Mater. 26, 4820 (2014). [3] M. E. Dávila et al., New J. Phys. 16, 095002 (2014). [4] M. Derivaz et al., Nano Lett. 15, 2510 (2015).

**1:27PM S26.00008 Silicene Evolution from Silicon Herringbones on Ru(0001)**, YANFANG ZHANG, Institute of Physics, Chinese Academy of Sciences, China, LI HUANG, Institute of Chemistry, and Institute of Physics, Chinese Academy of Sciences, China, WENYAN XU, YANDE QUE, EN LI, JINBO PAN, SHIXUAN DU, Institute of Physics, Chinese Academy of Sciences, China, YUNQI LIU, Institute of Chemistry, Chinese Academy of Sciences, China, YUYANG ZHANG, SOKRATES T. PANTELIDES, Vanderbilt University, United States, HONGJUN GAO, Institute of Chemistry, Chinese Academy of Sciences, China — Silicon-based 2D materials can potentially be integrated into Si-based electronics. Buckled silicene, an analog of graphene, was recently fabricated on a Ag (111) substrate and used to make a field effect transistor. Here, we report that, when Ru (0001) is used as a substrate, low Si coverage produces a herringbone structure, a new silicon phase. With increasing Si coverage, the elbow sites of the herringbone develop into nucleation sites of silicene. At even higher coverage, narrow Si ribbons with honeycomb structure develop between herringbones. Finally, with even higher Si coverage, a ( $\sqrt{3}\times\sqrt{3}$ ) silicene monolayer forms in registry on ( $\sqrt{7}\times\sqrt{7}$ ) Ru(0001). Scanning tunneling microscopy (STM) was used to image the structures. The growth process was confirmed by density functional theory (DFT) calculations. This work may contribute to precise control of growth of silicene and other silicon structures.

**1:39PM S26.00009 Phosphorenes with Non-Honeycomb Structures: A Much Extended Family<sup>1</sup>**, MENGHAO WU, HUAHUA FU, Huazhong University of Science and Technology, LING ZHOU, Miami University, KAILUN YAO, Huazhong University of Science and Technology, XIAO CHENG ZENG, University of Nebraska-Lincoln, HUAZHONG UNIVERSITY OF SCIENCE AND TECHNOLOGY TEAM, UNIVERSITY OF NEBRASKA-LINCOLN TEAM — We predict a new class of monolayer phosphorous allotropes, namely,  $\varepsilon$ -P,  $\zeta$ -P,  $\eta$ -P and  $\theta$ -P. Distinctly different from the monolayer  $\alpha$ -P (black) and previously predicted  $\beta$ -P (Phys. Rev. Lett. 112, 176802 (2014)),  $\gamma$ -P and  $\delta$ -P (Phys. Rev. Lett. 113, 046804 (2014)) with buckled honeycomb lattice, the new allotropes are composed of P<sub>4</sub> square or P<sub>5</sub> pentagon units that favor tricoordination for P atoms. The new four phases, together with 5 hybrid phases, are confirmed stable by first-principles calculations. In particular, the  $\theta$ -P is shown to be equally stable as the  $\alpha$ -P (black) and more stable than all previously reported phosphorene allotropes. Prediction of nonvolatile ferroelastic switching and structural transformation among different phases under strains points out their potential applications via strain engineering.

<sup>1</sup> MHW was supported by start-up fund from Huazhong University of Science and Technology.

**1:51PM S26.00010 Synthesis and characterizations of heterojunction of monolayer semiconductors.** , YI-HSIEN LEE, XIN-QUAN ZHANG, YU-WEN TSENG, KUANG-HUA HUANG, CHUN-AN CHEN , BO-HAN CHEN, National Tsing-Hua University — Monolayers of van der Waals materials, including graphene, and MoS<sub>2</sub>, offered a burgeoning field in fundamental physics, and optoelectronics.[1-5] Recently, atomically thin heterostructures of monolayer TMDc with various geometrical and energy band alignments are expected to be the key materials for next generation flexible optoelectronics. The individual TMDc monolayers can be adjoined vertically or laterally to construct diverse heterostructures which are difficult to reach with the laborious pick up-and-transfer method of the exfoliated flakes. The ability to produce copious amounts of high quality layered heterostructures on diverse surfaces is highly desirable but it has remained a challenging issue. Here, we have achieved a direct synthesis of various heterostructures of monolayer TMDc.[6] The synthesis was performed using CVD with aromatic molecules as seeding promoters. We will discuss possible growth behaviors, and we examine the symmetry and the interface of these heterostructures using optical analysis and scanning TEM. **11:15AM S27.00001 Thermal Conductivity of 3D CNT-Polymer Composites with Controlled Dispersion** , MENA KLITTICH, XUE WANG, ALI DHINOJWALA, University of Akron — The high thermal conductivity of isolated carbon nanotubes (CNTs) has inspired its use as a thermal filler for insulative polymers. However, the performance of these composites has consistently been sub par. Extensive analyses of these complex systems have resulted in the conclusion that resistance at the CNT/polymer interface due to phonon mismatch and poor physical binding, as well as the weakly bonded tube-tube interactions restrict the effectiveness of CNTs in practice. Experimental comparisons of CNT treatments, coatings, functionalization, and interactions with various polymers have proved challenging, due to the interconnected nature of the composite properties. Here, we have reversed the paradigm and used a constant CNT structure that is then modified post-growth to allow for direct comparisons of polymer composites.

**11:27AM S27.00002 Multiscale Modeling of Heat Conduction in Carbon Nanotube Aerogels** , FENG GONG, DIMITRIOS PAPAVALASSIOU, University of Oklahoma, HAI DUONG, National University of Singapore — Carbon nanotube (CNT) aerogels have attracted a lot of interest due to their ultrahigh strength/weight and surface area/weight ratios. They are promising advanced materials used in energy storage systems, hydrogen storage media and weight-conscious devices such as satellites, because of their ultralight and highly porous quality. CNT aerogels can have excellent electrical conductivity and mechanical strength. However, the thermal conductivity of CNT aerogels are as low as 0.01-0.1 W/mK, which is five orders of magnitude lower than that of CNT (2000-5000 W/mK). To investigate the mechanisms for the low thermal conductivity of CNT aerogels, multiscale models are built in this study. Molecular dynamic (MD) simulations are first carried out to investigate the heat transfer between CNT and different gases (e.g. nitrogen and hydrogen), and the thermal conductance at CNT-CNT interface. The interfacial thermal resistances of CNT-gas and CNT-CNT are estimated from the MD simulations. Mesoscopic modeling of CNT aerogels are then built using an off-lattice Monte Carlo (MC) simulations to replicate the realistic CNT aerogels. The interfacial thermal resistances estimated from MD simulations are used as inputs in the MC models to predict the thermal conductivity of CNT aerogels. The volume fractions and the complex morphologies of CNTs are also quantified to study their effects on the thermal conductivity of CNT aerogels. The quantitative findings may help researchers to obtain the CNT aerogels with expected thermal conductivity.

**11:39AM S27.00003 Thermal conductivity of a film of single walled carbon nanotubes measured with infrared thermal imager<sup>1</sup>** , YA FENG, TAIKI INOUE, RONG XIANG, SHOHEI CHIASHI, Department of Mechanical Engineering, The University of Tokyo, SHIGEO MARUYAMA, Department of Mechanical Engineering, The University of Tokyo; Energy NanoEngineering Lab. AIST — Heat dissipation has restricted the modern miniaturization trend with the development of electronic devices. Theoretically proven to be with high axial thermal conductivity, single walled carbon nanotubes (SWNT) have long been expected to cool down the nanoscale world. Even though the tube-tube contact resistance limits the capability of heat transfer of the bulk film, the high intrinsic thermal conductivity of SWNT still glorify the application of films of SWNT network as a thermal interface material. In this work, we proposed a new method to straightly measure the thermal conductivity of SWNT film. We bridged two cantilevered Si thin plate with SWNT film, and kept a steady state heat flow in between. With the infrared camera to record the temperature distribution, the Si plates with known thermal conductivity can work as a reference to calculate the heat flux going through the SWNT film. Further, the thermal conductivity of the SWNT film can be obtained through Fourier's law after deducting the effect of thermal radiation. The sizes of the structure, the heating temperature, the vacuum degree and other crucial impact factors are carefully considered and analyzed.

<sup>1</sup>The author Y. F. was supported through the Advanced Integration Science Innovation Education and Research Consortium Program by the Ministry of Education, Culture, Sport, Science and Technology

**11:51AM S27.00004 Investigation of the Thermal Behavior of Single-Walled Carbon Nanotubes and Tungsten Oxide Nanostructures Using Raman Spectroscopy<sup>1</sup>** , PRABHAKAR MISRA, DANIEL CASIMIR, RAUL F. SANCHEZ, Howard Univ, CHRISTINA CRAIG, University of Dallas, Irving, SARAH BARTLEY, Agnes Scott College, SHANKAR BALIGA, General Monitors, Inc — Thermal conductivity measurements of a variety of Single-Walled Carbon Nanotube (SWCNT) samples via Raman shifts of the G<sup>+</sup> band frequency around 1592 cm<sup>-1</sup> recorded with a 780 nm laser as a function of laser power (0 – 25 mW) have allowed quantitative estimates of the purity levels of the SWCNTs. In addition, Raman spectra of a variety of tungsten oxide (WO<sub>3</sub>) nanomaterial samples, namely WO<sub>3</sub> on silicon substrate, as well as nanopowder and nanowires, exhibited clear variation in O-H band features around 1550 cm<sup>-1</sup> due to effects of ambient humidity, as well as other spectral features due to gas (NO<sub>x</sub>) exposure have been documented, as a function of varying temperature (in the range 27 – 200C). Thermal characteristics of SWCNTs and WO<sub>3</sub> samples, along with the associated Molecular Dynamics simulations performed, will prove useful for thermal energy storage and gas sensing applications.

**12:03PM S27.00005 Tuning Thermoelectric Properties of Chirality Selected Single Wall Carbon Nanotubes**, KAZUHIRO YANAGI, YUKI OSHIMA, YOSHIMASA KITAMURA, YUTAKA MANIWA, Dept. of Physics, Tokyo Metropolitan University — Thermoelectrics are a very important technology for efficiently converting waste heat into electric power. Hicks and Dresselhaus proposed an important approach to innovate the performance of thermoelectric devices, which involves using one-dimensional materials and properly tuning their Fermi level (PRB 1993). Therefore, understanding the relationship between the thermoelectric performance and the Fermi level of one-dimensional materials is of great importance to maximize their thermoelectric performance. Single wall carbon nanotube (SWCNT) is an ideal model for one-dimensional materials. Previously we reported continuous p-type and n-type control over the Seebeck coefficients of semiconducting SWCNT networks with diameter of 1.4 nm through an electric double layer transistor setup using an ionic liquid as the electrolyte (Yanagi et al, Nano Lett. 14, 6437 2014). We clarified the thermoelectric properties of semiconducting SWCNTs with diameter of 1.4 nm as a function of Fermi level. In this study, we investigated how the chiralities or electronic structures of SWCNTs influence on the thermoelectric properties. We found the significant difference in the line-shape of Seebeck coefficient as a function of gate voltage between the different electronic structures of SWCNTs.

**12:15PM S27.00006 Insights into heat transfer mechanisms of biased CNTs**, NORVIK VOSKANIAN, EVA OLSSON, Chalmers University of Technology, Applied Physics, JOHN CUMINGS, University of Maryland, Department of Materials Science and Engineering — There has been considerable interest in studying carbon nanotubes for thermal management applications and as components of electronic devices. For typical conductors, the electrical current results in temperature increase, but for the case of carbon nanotubes (CNTs) supported on SiN membranes, it has been shown that the traditional joule heating mechanisms are supplemented by remote heating of the substrate [1]. Using a thermal imaging technique based on Transmission Electron Microscopy [2], we demonstrate further evidence of this remote heating mechanism which suggests a non-equilibrium state between the electron temperature and phonon temperature of the CNT. We quantify the amount of remote heating as a ratio,  $\beta$ , between the power dissipation directly in the SiN divide by the total power applied. We find that initially  $\beta$  is high, but at higher applied voltage bias,  $\beta$  decreases, presumably because more hot electrons are available to scatter off carbon optical phonons, producing an increasing amount of traditional Joule heating. 1. K. Baloch, et al. *Nature Nano.* 7(5), 316-319 (2012). 2. T. Brintlinger, et. al. *Nano Lett.* 8, 582-585 (2008).

**12:27PM S27.00007 Argon Adsorption on Open Carbon Nanohorns<sup>1</sup>**, BRICE RUSSELL, Southern Illinois University Carbondale, ANGEL CALVILLO, None, PRAVIN KHANAL, ALDO MIGONE, Southern Illinois University Carbondale, SUMIO IJIMA, MASAKO YUDASAKA, National Institute of Advanced Industrial Science and Technology — We have measured adsorption isotherms for argon adsorbed on a 0.1692 g sample of chemically-opened carbon nanohorns. Two clear substeps are visible in the adsorption data, corresponding to groups of stronger binding sites (lower pressure substep) and weaker binding sites (higher pressure substep). We have measured adsorption at eight different temperatures in the range between approximately 70 and 110 K. The space at the interior of the individual nanohorns is accessible to sorbates in these chemically opened nanohorns. Consequently, higher loadings are obtained on these samples when compared to those measured on unopened (as-produced) nanohorns. Results for the kinetics of adsorption, the effective specific surface area, and the isosteric heat of adsorption as a function of sorbent loading will be presented and compared to results from other gases adsorbed on nanohorns.

<sup>1</sup>This work was supported by the NSF through grant DMR-1006428

**12:39PM S27.00008 CF<sub>4</sub> Adsorption on Open Carbon Nanohorns<sup>1</sup>**, PRAVIN KHANAL, BRICE RUSSELL, ALDO MIGONE, Southern Illinois University Carbondale, SUMIO IJIMA, MASAKO YUDASAKA, National Institute of Advanced Industrial Science and Technology — We have measured adsorption isotherms at ten different temperatures between 90.4 K and 163.8 K for CF<sub>4</sub> on a sample of chemically-opened carbon nanohorns. The interior of the individual nanohorns is accessible to sorbates in these chemically-opened nanohorns. Two substeps are visible in the adsorption data, one corresponding to groups of stronger binding sites (lower pressure substep) and another corresponding to weaker binding sites (higher pressure substep). The stronger binding sites are interstitial pore-like spaces within the nanohorn aggregates and intra-nanohorns pores while the weaker binding sites are the outer surfaces of the individual and interior sites located away from the tips of the nanohorns. Results for the effective specific surface area, the kinetics of adsorption, and the isosteric heat of adsorption as a function of sorbent loading will be presented and compared to adsorption results with other sorbates on open carbon nanohorns.

<sup>1</sup>This work was supported by the NSF through grant DMR-1006428.

**12:51PM S27.00009 Pull out instability in double walled carbon nanocones**, ARINDAM RAJ, Material Science and Engineering, Indian Inst of Tech-Kanpur, SHAKTI S GUPTA, Mechanical Engineering, Indian Inst of Tech-Kanpur, DEEPTI VERMA, Department of Chemical Engineering and Materials Science, University of Minnesota — Here, we present a molecular mechanics (MM) based study to show sharp changes in the variation of potential energy and wall morphology in double walled carbon nanocones (DWCNCs), when the constituent cones are pulled away from each other. In the MM simulations, bonded and non-bonded interactions among carbon atoms are prescribed using MM3 potential. The process of pulling out is simulated by constraining the base atoms of an inner cone and incrementally moving the tip atoms of the outer cone in the coaxial direction. In the relaxed state DWCNCs, the wall to wall normal distance between the cones is found to be 3.4Å, consistent with that obtained in two-layered graphene sheets. For each incremental step of separation, the minimum energy configuration of the entire system is obtained and the associated potential energy recorded. The instability leads to loss of concentricity of the cross-sections of cones in the sense that the wall of the outer cone deforms, making a single-sided cam-lobe type structure. DWCNCs of two different apex angles show the pull-out instability at almost the same separation distance.

**1:03PM S27.00010 Boron Nitride Coated Carbon Nanotube Arrays with Enhanced Compressive Mechanical Property**, LIN JING, ROLAND YINGJIE TAY, HONGLING LI, Nanyang Tech Univ, SIU HON TSANG, Temasek Laboratory@NTU, DUNLIN TAN, BOWEI ZHANG, ALFRED IING YOONG TOK, EDWIN HANG TONG TEO, Nanyang Tech Univ — Vertically aligned carbon nanotube (CNT) array is one of the most promising energy dissipating materials due to its excellent temperature invariant mechanical property. However, the CNT arrays with desirable recoverability after compression is still a challenge. Here, we report on the mechanical enhancement of the CNT arrays reinforced by coating with boron nitride (BN) layers. These BN coated CNT (BN/CNT) arrays exhibit excellent compressive strength and recoverability as compared to those of the as-prepared CNT arrays which totally collapsed after compression. In addition, the BN coating also provides better resistance to oxidation due to its intrinsic thermal stability. This work presented here opens a new pathway towards tuning mechanical behavior of any arbitrary CNT arrays for promising potential such as damper, vibration isolator and shock absorber applications.

**1:15PM S27.00011 Microwave Induced Welding of Carbon Nanotube-Thermoplastic Interfaces for Enhanced Mechanical Strength of 3D Printed Parts**, CHARLES SWEENEY, BLAKE LACKEY, Texas AM University Department of Chemical Engineering, MOHAMMAD SAED, Texas Tech University, MICAH GREEN, Texas AM University Department of Chemical Engineering — Three-dimensional (3D) printed parts produced by fused-filament fabrication of a thermoplastic polymer have become increasingly popular at both the commercial and consumer level. The mechanical integrity of these rapid-prototyped parts however, is severely limited by the interfillament bond strength between adjacent extruded layers. In this report we propose for the first time a method for welding thermoplastic interfaces of 3D printed parts using the extreme heating response of carbon nanotubes (CNTs) to microwave energy. To achieve this, we developed a coaxial printer filament with a pure polylactide (PLA) core and a CNT composite sheath. This produces parts with a thin electrically percolating network of CNTs at the interfaces between adjacent extruded layers. These interfaces are then welded together upon microwave irradiation at 2.45GHz. Our patent-pending method has been shown to increase the tensile toughness by 1000% and tensile strength by 35%. We investigated the dielectric properties of the PLA/CNT composites at microwave frequencies and performed in-situ microwave thermometry using a forward-looking infrared (FLIR) camera to characterize the heating response of the PLA/CNT composites upon microwave irradiation.

**1:27PM S27.00012 Mechanical properties of aligned carbon nanotube architectures: origin from 3D morphology**, ITAI Y. STEIN, BRIAN L. WARDLE, MIT — The scale-dependent properties of carbon nanotubes (CNTs) continue to motivate their study for next-generation material architectures. While recent work has shown that aligned CNT arrays can be made on the cm-scale, such systems exhibit properties that are orders of magnitude below those predicted by existing theories. This deviation mainly stems from the rudimentary assumptions made about the CNT morphology: CNTs are either devoid of local curvature (i.e. waviness) or have waviness that is easy to model, e.g. using helices and sine waves. Here, we use a simulation framework comprised of  $10^5$  CNTs with realistic 3D stochastic morphologies to elucidate the role morphology plays in the orders of magnitude over-prediction of the effective stiffness of aligned CNT structures. Application to aligned CNT polymer and carbon matrix nanocomposites reveals that the elimination of the torsion deformation mechanism, which dominates the effective compliance of CNT arrays, through CNT interactions with the matrix is responsible for the stiffness enhancement in CNT nanocomposites. This work paves the way to more accurate property prediction of CNT nanocomposites, and further work to predict the transport properties of aligned CNT architectures is planned.

**1:39PM S27.00013 Nanoscale Analysis of Interwall Interaction in a Multiwalled Carbon Nanotube by Tip-Enhanced Raman Spectroscopy**, SONGPOL CHAUNCHAIYAKUL, TAKESHI YANO, KAMONCHANOK KHOK-LANG, PAWEŁ KRUKOWSKI, MEGUMI AKAI-KASAYA, AKIRA SAITO, YUJI KUWAHARA, Osaka University — Raman spectroscopy is a useful tool for the study of carbon materials, but its spatial resolution is limited by the optical diffraction limit. Recently, we constructed a scanning tunneling microscope-based tip-enhanced Raman spectroscopy (STM-TERS) system in ultrahigh vacuum, which overcomes the optical diffraction limit, and enables the investigation of single-molecular Raman spectra simultaneously with topographic imaging. We have investigated position-sensitive Raman spectra along the tube axis of an isolated multiwalled carbon nanotube, which is a result of the different number of nanotube walls at each location. We found that the intensity ratio between the 2D to the G band increases with the number of walls. This indicates that the quantum interference between Raman scattering pathways affects each Raman mode differently. The interaction between nanotube walls induces splitting of the  $\pi$  and  $\pi^*$  bands which increases the number of the 2D band scattering pathways owing to double resonance, eventually increasing the probability of scattering for the 2D band relative to the G band. These results provide a deeper understanding of the single-molecule interaction of carbon materials in the nanoscale.

**1:51PM S27.00014 Title: Experimental and analytical study of frictional anisotropy of nanotubes<sup>1</sup>**, ELISA RIEDO, YANG GAO, TAI-DE LI, CUNY Advanced Science Research Center, HSIANG-CHIH CHIU, National Taiwan Normal University, SUENNE KIM, Hanyang University, CHRISTIAN KLINKE, University of Hamburg, ERIO TOSATTI, International School for Advanced Studies (SISSA), and CNR-IOM Democritos and International Centre for Theoretical Physics (ICTP) — The frictional properties of Carbon and Boron Nitride nanotubes (NTs) are very important in a variety of applications, including composite materials, carbon fibers, and micro/nano-electromechanical systems. Atomic force microscopy (AFM) is a powerful tool to investigate with nanoscale resolution the frictional properties of individual NTs. Here, we report on an experimental study of the frictional properties of different types of supported nanotubes by AFM. We also propose a quantitative model to describe and then predict the frictional properties of nanotubes sliding on a substrate along (longitudinal friction) or perpendicular (transverse friction) their axis. This model provides a simple but general analytical relationship that well describes the acquired experimental data. As an example of potential applications, this experimental method combined with the proposed model can guide to design better NTs-ceramic composites, or to self-assemble the nanotubes on a surface in a given direction.

**2:03PM S27.00015 Structure and Properties of HELICAL CARBON NANOTUBES through MD Simulations.**, AKSHAY DAHIYA, Department of Mechanical Engineering, Indian Institute of Technology Ropar, DEEPTI VERMA, Chemical Engineering and Materials Science Department, University of Minnesota, SHAKTI S GUPTA, Department of Mechanical Engineering, Indian Institute of Technology Kanpur — Helical Carbon Nanotubes (HCNTs) are coiled 3-valent carbon networks which represent pure carbon helix. Here we study the geometries of two classes: hexagonal helix containing purely polyhex networks and the second class with 5- and 7-membered rings besides hexagons. We followed a model of hexagonal, single wall HCNTs, and determined their relaxed configuration using MD simulations based on Tersoff potential. A race-track like structure is observed in the cross-section of HCNTs upon minimization. For generating class two helix, the adjacency matrix eigenvector's (AME) method is applied which utilizes 3-coordinated tiling of the plane by 5-, 6-, and 7-membered ring for the construction of helical structures. The application of the AME method to torusenes is crucial for class two helix generation as it is based on an appropriate choice of bi-lobial eigenvectors triplet which can be selected on the basis of their nodal properties as verified here. After 3-D transformations the final structure was obtained with the help of MM3-potential based MD simulations on Tinker commercial code. The spring constants of HCNTs are computed through MD simulations.

**Session S28 DMP: Advances in Topological Materials II** 327 - Liang Wu, University of California, Berkeley

**11:15AM S28.00001 Recent results on materials aspects of the investigation of new topological states of matter<sup>1</sup>**, ROBERT CAVA, Department of Chemistry, Princeton University, Princeton NJ — Investigation of the electronic states of matter that are determined by topological physics has exploded in recent years through parallel progress in theory, experimental characterization, device fabrication and new materials development. In our group working in this area, the speaker has been responsible for the development of new materials to allow the experimentalists to probe the emergence of new topological properties, and to help embody the concepts of our theorists in real materials. The field is fast-moving, with particular thrusts at the present time toward Weyl and Dirac semimetals, and in this talk I will describe the materials aspects of our work in the past year in these areas, specifically as they are related to our strong collaborations with the groups of N.P. Ong, A. Yazdani, and B.A. Bernevig at Princeton, T. Valla and J. Tao at Brookhaven, and A. Vishwanath at Berkeley.

<sup>1</sup>The support of our work in this area by the NSF through its MRSEC program, grant DMR 1420541, and the ARO through its MURI on topological insulators, grant W911NF-12-1-0461, is gratefully acknowledged.

**11:51AM S28.00002 Observation of Weyl nodes and Fermi arcs in TaP** , MING SHI, N. XU, Paul Scherrer Institute, Switzerland, H. M. WENG, Institute of Physics, Chinese Academy of Sciences, B. Q. LV, C. E. MATT, J. PARK, F. BISTI, V. N. STROCOV, D. GAWRYLUK, E. POMJAKUSHINA, K. CONDER, N. C. PLUMB, M. RADOVIC, Paul Scherrer Institute, Switzerland, G. AUTS, O. V. YAZYEV, cole Polytechnique Fdrale de Lausanne, Switzerland, Z. FANG, X. DAI, T. QIAN, Institute of Physics, Chinese Academy of Sciences, J. MESOT, Paul Scherrer Institute, Switzerland, H. DING, Institute of Physics, Chinese Academy of Sciences — A Weyl semimetal possesses topologically unavoidable crossings of spin-polarized bands dispersing linearly along all momentum directions, called Weyl nodes, connected by topological surface arcs. The crossing points have fixed chirality and behave the same as massless Weyl fermions, leading to exotic properties like chiral anomaly. To have the transport and other novel properties dominated by Weyl fermions, it is required that Weyl nodes (1) locate nearly at the chemical potential and (2) are well separated in momentum space and enclosed by pairs of individual Fermi surfaces with nonzero Fermi Chern numbers. By investigating the electronic structure of TaP using angle-resolved photoemission spectroscopy and first-principles calculation, we establish that TaP is a Weyl semimetal with only single type of Weyl fermions with well-separated Weyl nodes locating at the chemical potential, distinguished from TaAs where there are two types of Weyl fermions contributing to the low-energy physical properties. We have also observed Fermi arcs on the Ta-terminated surface, which appear in a different pattern from that on the As-terminated surface observed in TaAs and NbAs.

**12:03PM S28.00003 Fermiology in the Weyl semimetals (Nb,Ta)(As,P)** , QIU RUN ZHANG, SHAHRIAR MEMARAN, DANIEL RHODES, BIN ZENG, SUVADIP DAS, EFSTRATIOS MANOUSAKIS, RYAN BAUMBACH, LUIS BALICAS, National High Magnetic Field Laboratory, NASSER ALIDOUST, M. ZAHID HASAN, Princeton University — We present a detailed angular and temperature dependent study of the quantum oscillatory phenomena in the Weyl semimetals, (Ta,Nb)(As,P) under high magnetic fields. In general we find that the P compounds exhibit larger Fermi surfaces with lighter effective masses when compared to the As ones. We show that for (Nb,Ta)As we can reach the quantum limit with the currently available magnetic fields, which seemingly leads to an electronic phase transition.

**12:15PM S28.00004 Discovery of a Weyl fermion state with Fermi arcs in niobium arsenide<sup>1</sup>** , NASSER ALIDOUST, SU-YANG XU, ILYA BELOPOLSKI, GUANG BIAN, HAO ZHENG, DANIEL S SANCHEZ, TITUS NEUPERT, M ZAHID HASAN, Princeton University, ZHUJUN YUAN, CHENGLONG ZHANG, SHUANG JIA, Peking University, DAIXIANG MOU, YUN WU, LUNAN HUANG, ADAM KAMINSKI, Iowa State University, VLADIMIR N STROCOV, Paul Scherrer Institute, BAOKAI WANG, ARUN BANSIL, Northeastern University, TAY-RONG CHANG, HORNG-TAY JENG, National Tsing Hua University, GUOQING CHANG, CHI-CHENG LEE, SHIN-MING HUANG, HSIN LIN, National University of Singapore — Three types of fermions play a fundamental role in our understanding of nature: Dirac, Majorana and Weyl. A Weyl semimetal is a novel crystal whose low-energy electronic excitations behave as Weyl fermions. Here, we present the experimental discovery of the Weyl semimetal state in an inversion-symmetry-breaking single-crystalline solid, niobium arsenide (NbAs). Utilizing the combination of soft X-ray and ultraviolet photoemission spectroscopy, we systematically study both the surface and bulk electronic structure of NbAs. We experimentally observe both the Weyl cones in the bulk and the Fermi arcs on the surface of this system. Our ARPES data, in agreement with our theoretical calculations, identify the Weyl semimetal state in NbAs, which provides a platform to test the potential of Weyltronics.

<sup>1</sup>The work at Princeton and Princeton-led ARPES measurements were supported by Gordon and Betty Moore Foundations EPiQS Initiative, grant GBMF4547 (Hasan), and by U.S. DOE DE-FG-02-05ER46200.

**12:27PM S28.00005 Discovery of the first Weyl fermion semimetal and topological Fermi arcs in TaAs<sup>1</sup>** , SUYANG XU, ILYA BELOPOLSKI, NASSER ALIDOUST, Princeton University, MADHAB NEUPANE, Los Alamos National Laboratory, GUANG BIAN, Princeton University, CHENGLONG ZHANG, Peking University, RAMAN SANKAR, National Taiwan University, GUOQING CHANG, National University of Singapore, ZHUJUN YUAN, Peking University, CHI-CHENG LEE, SHIN-MING HUANG, National University of Singapore, HAO ZHENG, Princeton University, JIE MA, Oak Ridge National Laboratory, DANIEL SANCHEZ, Princeton University, BAOKAI WANG, ARUN BANSIL, Northeastern University, FANGCHENG CHOU, National Taiwan University, PAVEL SHIBAYEV, Princeton University, HSIN LIN, National University of Singapore, SHUANG JIA, Peking University, M. ZAHID HASAN, Princeton University — Weyl semimetals have opened a new era in condensed matter physics and materials science. They host Weyl fermions as emergent quasiparticles and admit a topological classification that protects Fermi arc surface states on the boundary. This unusual electronic structure has deep analogies with particle physics and leads to unique topological properties. We report the experimental discovery of the first Weyl semimetal, TaAs. We directly observe Fermi arcs on the surface, as well as the Weyl fermion cones and Weyl nodes in the bulk of TaAs single crystals. We find that Fermi arcs terminate on the Weyl fermion nodes, consistent with their topological character. Our work opens the field for the experimental study of Weyl fermions in physics and materials science.

<sup>1</sup>The work at Princeton and Princeton-led ARPES measurements were supported by the Gordon and Betty Moore Foundations EPiQS Initiative through grant GBMF4547 (Hasan) and by U.S. Department of Energy DE-FG-02-05ER46200.

**12:39PM S28.00006 Electronic structures and evolution in a transition metal pnictide Weyl semimetal family** , YULIN CHEN, Oxford University — Topological Weyl semimetals (TWSs) represent a novel state of quantum matter which not only possesses Weyl fermions (massless chiral particles that can be viewed as magnetic monopoles in momentum space) in the bulk and unique Fermi arcs generated by topological surface states, but also exhibits appealing physical properties such as extremely large magnetoresistance and ultra-high carrier mobility. By performing angle-resolved photoemission spectroscopy (ARPES) on compounds from a transition metal pnictide family (NbP, TaP and TaAs), we systematically investigated their electronic structures and discovered the unique surface “Fermi-arcs” and linear bulk band dispersion across the Weyl points. Furthermore, we also illustrated their Fermiology evolution with the spin-orbit coupling (SOC) strength. Our experimental findings not only reveal the mechanism to realize and fine-tune the electronic structures of TWSs, but also provide a rich material base for exploring many exotic physical phenomena (for example, chiral magnetic effects, negative magnetoresistance, and the quantum anomalous Hall effect) and novel future applications.

**12:51PM S28.00007 Experimental discovery of a topological Weyl semimetal state in TaP<sup>1</sup>** , SU-YANG XU, ILYA BELOPOLSKI, DANIEL SANCHEZ, Princeton Univ, CHENG GUO, Peking University, GUOQING CHANG, National University of Singapore, CHENGLONG ZHANG, Peking University, GUANG BIAN, Princeton Univ, ZHUJUN YUAN, HONG LU, YIYANG FENG, Peking University, TAY-RONG CHANG, National Tsing Hua University, PAVEL SHIBAYEV, Princeton Univ, MYKHAILO PROKOPOVYCH, Paul Scherrer Institute, NASSER ALIDOUST, HAO ZHENG, Princeton Univ, CHI-CHENG LEE, SHIN-MING HUANG, National University of Singapore, RAMAN SANKAR, National Taiwan University, HORN-TAY JENNY, National Tsing Hua University, ARUN BANSIL, Northeastern University, TITUS NEUPERT, Princeton Univ, VLADIMIR STROCOV, Paul Scherrer Institute, HSIN LIN, National University of Singapore, SHUANG JIA, Peking University, M. ZAHID HASAN, Princeton Univ — We observed Weyl fermion cones and nodes in the bulk and the Fermi arcs on the surface of Weyl semimetal TaP. Also, we found that the surface states show an unexpectedly rich structure, including both topological Fermi arcs and topologically trivial closed contours in the vicinity of the Weyl points. A rigorous scheme for directly demonstrating the bulk-boundary correspondence and, hence, establishing the Weyl semimetal state in TaP is discussed.

<sup>1</sup>The work at Princeton and Princeton-led ARPES measurements were supported by the Gordon and Betty Moore Foundations EPiQS Initiative through grant GBMF4547 (Hasan) and by U.S. Department of Energy DE-FG-02-05ER46200

**1:03PM S28.00008 Spin polarization of the Fermi arcs in the Weyl semimetal TaAs<sup>1</sup>**, SU-YANG XU, ILYA BELOPOLSKI, DANIEL SANCHEZ, Princeton Univ, MADHAB NEUPANE, Princeton Univ; Los Alamos National Laboratory, GUOQING CHANG, National University of Singapore, KOICHIRO YAJI, University of Tokyo, ZHUJUN YUAN, CHENGLONG ZHANG, Peking University, KENTA KURODA, University of Tokyo, GUANG BIAN, Princeton Univ, TAY-RONG CHANG, National Hua University, NASSER ALIDOUST, HAO ZHENG, Princeton Univ, CHI-CHENG LEE, SHIN-MING HUANG, GUANG-HAN HSU, National University of Singapore, HORNG-TAY JENG, National Tsing Hua University, ARUN BANSIL, Northeastern University, ARIS ALEXANDRADINATA, Yale University, TITUS NEUPERT, Princeton Univ, TAKESHI CONDO, SHIK SHIN, Institute of Solid State Physics (ISSP), HSIN LIN, National University of Singapore, SHUANG JIA, Peking University, M. ZAHID HASAN, Princeton Univ — In a Weyl semimetal, Weyl fermion quasiparticle excitations correspond to points of bulk band degeneracy separated in  $k$ -space and connected on the surface by Fermi arcs. Our spin-resolved ARPES measurements on the experimentally discovered Weyl semimetal TaAs have revealed that the Fermi arcs have spin polarization larger than 80% and that the spin texture is in-plane and does not match with that of the bulk Weyl cones where they meet.

<sup>1</sup>The work at Princeton and Princeton-led ARPES measurements were supported by the Gordon and Betty Moore Foundations EPiQS Initiative through grant GBMF4547 (Hasan) and by U.S. Department of Energy DE-FG-02-05ER46200.

**1:15PM S28.00009 Observation of surface states derived from topological Fermi arcs in the Weyl semimetal NbP<sup>1</sup>**, ILYA BELOPOLSKI, SU-YANG XU, DANIEL SANCHEZ, Princeton University, GUOQING CHANG, National University of Singapore, CHENG GUO, Peking University, MADHAB NEUPANE, Los Alamos National Laboratory, HAO ZHENG, Princeton University, CHI-CHENG LEE, SHIN-MING HUANG, National University of Singapore, GUANG BIAN, NASSER ALIDOUST, Princeton University, TAY-RONG CHANG, National Tsing Hua University, BAOKAI WANG, National University of Singapore, XIAO ZHANG, Peking University, ARUN BANSIL, Northeastern University, HORNG-TAY JENG, National Tsing Hua University, HSIN LIN, National University of Singapore, SHUANG JIA, Peking University, ZAHID HASAN, Princeton University — The recent experimental discovery of the first Weyl semimetal (WSM) provides the first observation of a Weyl fermion in nature and demonstrates a novel type of anomalous surface state band structure, consisting of Fermi arcs. NbP may realize the first WSM in the limit of weak spin-orbit coupling. Here we study the surface states of NbP by ARPES and we find that we cannot show Fermi arcs based on our experimental data alone. However, the excellent agreement between our data and calculations suggests that NbP is a WSM and that we observe trivial surface states which evolve continuously from topological Fermi arcs above the Fermi level.

<sup>1</sup>The work at Princeton and Princeton-led ARPES measurements were supported by the Gordon and Betty Moore Foundation EPiQS Initiative through grant GBMF4547 (Hasan) and by the U.S. Department of Energy, DE-FG-02-05ER46200.

**1:27PM S28.00010 Observation of Fermi Arcs in non-Centrosymmetric Weyl Semi-metal Candidate NbP**, DIFEI XU, State Key Laboratory of Surface Physics, Department of Physics, and Laboratory of Advanced Materials, Fudan University, YONGPING DU, National Laboratory of Solid State Microstructures, Collaborative Innovation Center of Advanced Microstructures, and College of Physics, Nanjing Univ., ZHEN WANG, YUPENG LI, Department of Physics, and State Key Lab of Silicon Materials, Zhejiang University, XIAOHAI NIU, QI YAO, State Key Laboratory of Surface Physics, Department of Physics, and Laboratory of Advanced Materials, Fudan University, PAVEL DUDIN, Diamond Light Source, Harwell Science and Innovation Campus, ZHUAN XU, Department of Physics, Zhejiang University, XIANGANG WAN, National Laboratory of Solid State Microstructures, Collaborative Innovation Center of Advanced Microstructures, and College of Physics, Nanjing Univ., DONGLAI FENG, State Key Laboratory of Surface Physics, Department of Physics, and Laboratory of Advanced Materials, Fudan University — We report the surface electronic structure of niobium phosphide NbP single crystal on (001) surface by vacuum ultraviolet angle-resolved photoemission spectroscopy. Combining with our first principle calculations, we identify the existence of the Fermi arcs originated from topological surface states. Furthermore, the surface states exhibit circular dichroism pattern, which may correlated with spin texture. Our results not only provide critical evidence for the existence of the Weyl Fermions in NbP, but also lay foundations for further investigations.

**1:39PM S28.00011 Observation of Fermi arc spin texture in TaAs**, TIAN QIAN, BAIQING LV, HONGMING WENG, GENFU CHEN, HONG DING, Institute of Physics, Chinese Academy of Sciences — We have investigated the spin texture of surface Fermi arcs in the recently discovered Weyl semimetal TaAs using spin- and angle-resolved photoemission spectroscopy. The experimental results demonstrate that the Fermi arcs are spin-polarized. The measured spin texture fulfills the requirement of mirror and time reversal symmetries and is well reproduced by our first-principles calculations, which gives strong evidence for the topologically nontrivial Weyl semimetal state in TaAs. The consistency between the experimental and calculated results further confirms the distribution of chirality of the Weyl nodes determined by first-principles calculations.

**1:51PM S28.00012 Complete Fermi Surface and Surface State in WTe<sub>2</sub> Revealed by High-Resolution Laser-Based Angle-Resolved Photoemission Spectroscopy**, CHENLU WANG, YAN ZHANG, GUODONG LIU, Institute of Physics, Chinese Academy of Sciences, ZHIQIANG MAO, Department of Physics and Engineering Physics, Tulane University, SHAOLONG HE, LIN ZHAO, Institute of Physics, Chinese Academy of Sciences, CHUANGTIAN CHEN, ZUYAN XU, Technical Institute of Physics and Chemistry, Chinese Academy of Sciences, XINGJIANG ZHOU, Institute of Physics, Chinese Academy of Sciences — WTe<sub>2</sub>, an unique transition metal dichalcogenide, attracts considerable attention recently, which shows an extremely large magnetoresistance (MR) with no saturation under very high field. In this talk, we will present our high resolution laser-ARPES study on WTe<sub>2</sub>. Our distinctive ARPES system is equipped with the VUV laser and the time-of-flight (TOF) electron energy analyzer, being featured by super-high energy resolution, simultaneous data acquisition for two-dimensional momentum space and much reduced nonlinearity effect. With this advanced apparatus, the very high quality of electronic structure data are obtained for WTe<sub>2</sub> which gives a full picture of the Fermi surface. Meanwhile, the obtained systematic temperature dependence of its electronic state leads us to a better understanding on the origin of large magnetoresistance in WTe<sub>2</sub>.

**2:03PM S28.00013 First-principles study of temperature effects in topological insulator phase diagrams<sup>1</sup>**, GABRIEL ANTONIUS, STEVEN LOUIE, University of California at Berkeley and Lawrence Berkeley National Lab — Recent studies have identified several tunable three-dimensional topological insulators. Upon varying experimental parameters such as pressure or doping, these materials exhibit a transition between a trivial and a topological insulating phase. We present a first-principles study of temperature effects in the family of alloyed BiTeS<sub>2</sub> / BiTeSe<sub>2</sub> topological phase transition materials. Through the electron-phonon coupling, the electronic bands being renormalized at finite temperature allow for a topological phase transition at some critical temperature. We find a temperature-doping phase diagram having a confined topological phase region, with the topological phase suppressed at high temperature. We also discuss the converse scenario in which phonons might favour the topological phase, as previously anticipated.

Session S29 DCMP DMP: Two-dimensional Topological Insulators: Growth, Structure and Electronic Properties 328 - Hua Chen, University of Texas, Austin

**11:15AM S29.00001 Quantum Anomalous Hall Effect in Low-buckled Honeycomb Lattice with In-plane Magnetization**, YAFEI REN<sup>1</sup>, University of Science and Technology of China, HUI PAN, FEI YANG, XIN LI, Beihang University, ZHENHUA QIAO, University of Science and Technology of China, ZHENHUA QIAO'S GROUP TEAM, HUI PAN'S GROUP TEAM — With out-of-plane magnetization, the quantum anomalous Hall effect has been extensively studied in quantum wells and two-dimensional atomic crystal layers [1]. Here, we investigate the possibility of realizing quantum anomalous Hall effect (QAHE) in honeycomb lattices with in-plane magnetization. We show that the QAHE can only occur in low-buckled honeycomb lattice where both intrinsic and intrinsic Rashba spin-orbit coupling appear spontaneously. The extrinsic Rashba spin-orbit coupling is detrimental to this phase. In contrast to the out-of-plane magnetization induced QAHE, the QAHE from in-plane magnetization is achieved in the vicinity of the time reversal symmetric momenta at  $M$  points rather than Dirac points. In monolayer case, the QAHE can be characterized by Chern number  $C = \pm 1$  whereas additional phases with Chern number  $C = \pm 2$  appear in chiral stacked bilayer system. The Chern number strongly depends on the orientation of the magnetization. The bilayer system also provides additional tunability via out-of-plane electric field, which can reduce the critical magnetization strength required to induce QAHE. It can also lead to topological phase transitions from  $C = \pm 2$  to  $\pm 1$  and finally to 0. [1] Review article: arXiv:1509.09016

**11:27AM S29.00002 The theoretical studies of topology electronic states in HgTe Hall Bar and Quantum Dot**, JIN-XIAN QU, SHU-HUI ZHANG, WEN YANG, Beijing CSRC — In recent years, there is an extensive attention on the new properties of topology materials and their potential applications. Our interest is on the physics in the quantum confined systems based on topology materials. To consider two such systems, i.e., quantum dot and Hall bar constructed on the HgTe quantum well, we study the electronic properties and their dependence on various material parameters with and without an in-plane electric field. For both systems, we find that 1) the exotic edge states appear in bulk energy gap, resulting from the non-trivial topological property of quantum well system. 2) by the magnetic doping, there are tunable phase transitions, e.g., transition from trivial insulating phase to topological insulating phase or anomalous quantum Hall insulating phase. 3) the in-plane electric field can introduce effective control on the electronic states.

**11:39AM S29.00003 A new structure of two-dimensional allotropes of group V elements**, PING LI, WEIDONG LUO, Shanghai Jiao Tong University — The elemental two-dimensional (2D) materials such as graphene, silicene, germanene, and black phosphorus have attracted considerable attention due to their fascinating physical properties. Structurally they possess the honeycomb or distorted honeycomb lattices, which are composed of six-atom rings. Here we find a new structure of 2D allotropes of group V elements composed of eight-atom rings, which we name as the octagonal tiling (OT) structure. First-principles calculations indicate that these allotropes are dynamically stable and are also thermally stable at temperatures up to 600 K. These allotropes are semiconductors with band gaps ranging from 0.3 to 2.0 eV, thus they are potentially useful in near- and mid-infrared optoelectronic devices. OT-Bi is also a 2D topological insulator (TI) with a band gap of 0.33 eV, which is the largest among the reported elemental 2D TIs, and this gap can be increased further by applying compressive strains.

**11:51AM S29.00004 Topological phase transition in layered transition metal dichalcogenides**, DUK-HYUN CHOE, HA-JUN SUNG, KEE JOO CHANG, Department of Physics, KAIST — Despite considerable interests in transition metal dichalcogenides (TMDs), such as  $\text{MX}_2$  with  $M = (\text{Mo}, \text{W})$  and  $X = (\text{S}, \text{Se}, \text{Te})$ , the physical origin of their topological nature is still in its infancy. The conventional view of topological phase transition (TPT) in TMDs is that the band inversion occurs between the metal  $d$  and chalcogen  $p$  orbital bands. More precisely, the former is pulled down below the latter. Here we introduce an explicit scheme for analyzing TPT in topological materials and find that the TPT in TMDs is different from the conventional speculation. When the  $1T$  phase undergoes a structural transformation to the  $1T'$  phase in monolayer  $\text{MX}_2$ , the band topology changes from trivial to non-trivial, leading to the TPT. We discuss the exact role of the metal  $d$  and chalcogen  $p$  orbital bands during the TPT. Our finding would provide clear guidelines for understanding the topological nature not only in TMDs but also in other topological materials yet to be explored.

**12:03PM S29.00005 Effects of edge terminations on monolayer topological crystalline insulators via group theory and DFT<sup>1</sup>**, GERSON J. FERREIRA, AUGUSTO L. ARAUJO, Federal University of Uberlandia, ERNESTO O. WRASSE, Universidade Tecnológica Federal do Parana, TOME M. SCHMIDT, Federal University of Uberlandia — Topological crystalline insulators (TCIs) are a counterpart of usual topological insulators in materials where the topological edge (or surface) states are protected by the underlying crystal symmetries. Here we discuss the band structure of IV-VI monolayer materials, where the edge states are protected by mirror symmetry, considering ribbons cutted in different orientations and distinct edge terminations. We show that although the Chern numbers and the topological classification remain a bulk property, the nature of edge terminations and orientation play a significant role in TCIs. For each ribbon an effective Hamiltonian is derived by group theory and proper boundary conditions are presented. These show good agreement with DFT calculations and illustrate the effects of the distinct reduced symmetry of each ribbon type.

**12:15PM S29.00006 Antiperovskite  $\text{Sr}_3\text{PbO}$  thin films grown by molecular beam epitaxy**, DEBAKANTA SAMAL, HIROYUKI NAKAMURA, HIDENORI TAKAGI, Max Planck Institute for Solid State Research — Several antiperovskite compounds have recently been predicted to host bulk three dimensional Dirac dispersion as well as surface states protected by crystal symmetry. Here, we present fabrication of cubic antiperovskite  $\text{Sr}_3\text{PbO}$  films epitaxially grown on  $\text{LaAlO}_3$  by molecular beam epitaxy. Fabricated films were capped with polymer without breaking vacuum to facilitate ex-situ transport characterization. All of the films showed metallic temperature dependence. The Hall effect measurement suggests that the carrier type is hole, whose density is around  $5 \times 10^{19} \text{ cm}^{-3}$ . Details of magnetotransport at low temperature is also described.

**12:27PM S29.00007 Spin-Phonon coupling in a candidate 2D atomic crystal magnetic semiconductor<sup>1</sup>**, YAO TIAN, University of Toronto, HUIWEN JI, ROBERT CAVA, Princeton University, KENNETH BURCH, Boston College —  $\text{Cr}_2\text{Ge}_2\text{Te}_6$  is a particularly interesting material since it is in the very rare class of ferromagnetic semiconductors and possesses a layered, nearly two dimensional structure due to van Der Waals bonds. The van Der Waals bonds make it a candidate two dimensional atomic crystal, which is predicted as a platform to study 2D semiconducting ferromagnets and for single layered spintronics devices. Spin-phonon coupling can be a key factor for the spin relaxation in a spintronics devices. We use polarized temperature dependent Raman scattering to study  $\text{Cr}_2\text{Ge}_2\text{Te}_6$ . The spin-phonon coupling has been confirmed in three ways: below  $T_C$  we observe a split of two phonon modes due to the breaking of time reversal symmetry; an anomalous hardening of an additional three modes; and dramatic decrease of the phonon lifetimes upon warming into the paramagnetic phase. Our results also suggest the possibility of probing the magneto-elastic coupling using Raman spectroscopy, opening a door for the further study of exfoliated 2D  $\text{Cr}_2\text{Ge}_2\text{Te}_6$ . We gratefully acknowledge support from the National Science Foundation (Grant No. DMR-1410846)

**12:39PM S29.00008 Magnetism at grain boundary interfaces in the colossal permittivity dielectric material; In+Nb Co-Doped Rutile**, ADAM BERLIE, ISIS Neutron and Muon Source, STFC Rutherford Appleton Laboratory, Chilton, Oxfordshire, OX11 0QX, United Kingdom., IAN TERRY, Department of Physics, Durham University, South Road, Durham, DH13LE, United Kingdom., STEPHEN COTTRELL, ISIS Neutron and Muon Source, STFC Rutherford Appleton Laboratory, Chilton, Oxfordshire, OX11 0QX, United Kingdom., WANBIAO HU, YUN LIU, Research School of Chemistry, Australian National University, Acton, Canberra, 2601, Australia. — With the emphasis in recent years on understanding novel materials with potential technological applications this work seeks to understand magnetic ordering within the colossal-permittivity material, In+Nb co-doped rutile ( $\text{TiO}_2$ ). Evidence for a spin-freezing transition was reported from a step like feature in the dielectric data below 50 K but this was largely glossed over. Within this work we show that below 300 K there is a slowing down of magnetic fluctuations associated with the electronic magnetism due to the defect-dipoles created by the co-doping, but the muon spectroscopy results are strongly suggestive of the behaviour being localised to the edges/interfaces of particles/grains. The  $T_C$  is strongly dependent on the doping level of the samples that presents novel way to control the magnetism and ultimately magneto-electric coupling within a dielectric material.

**12:51PM S29.00009 Photoconductivity of transparent perovskite oxide semiconductors  $\text{BaSnO}_3$  and  $\text{SrTiO}_3$  epitaxial thin films**, JISUNG PARK, USEONG KIM, KOOKRIN CHAR, Seoul Natl Univ, INSTITUTE OF APPLIED PHYSICS, DEPARTMENT OF PHYSICS AND ASTRONOMY, SEOUL NATIONAL UNIVERSITY, SEOUL TEAM — We have measured the photoconductivity (PC) of epitaxial thin films of transparent semiconductor  $\text{BaSnO}_3$  (BSO) and  $\text{SrTiO}_3$  (STO) at room temperature. The epitaxial thin films of BSO and STO were grown by pulsed laser ablation technique on the MgO substrates to exclude any conductance from the substrate owing to its large bandgap ( $\sim 7.8$  eV). Despite the same crystalline structure and similar band gap sizes ( $\sim 3.2$  eV), the PC of BSO behaved very differently. The slowly varying component in the PC of BSO is much larger than that of STO; the PC of BSO increased slowly, reached higher magnitude after the same duration of illumination, and persisted longer than many hours after the light was turned off, whereas the PC of STO showed little persistent conductivity. The spectral responses of the PC of BSO and STO showed their highest peaks below 400 nm when measured by a UV monochromator system, suggesting that the electron-hole pair generation is the main mechanism of the PC for both materials. The higher mobility of BSO should be partially responsible for the higher PC. The large persistent PC of BSO seems related to the dislocations that trap electrons easily.

**1:03PM S29.00010 Change In The Electronic Structure And Optical Absorption Of Cuprate Delafossites Via B-site Alloying**, RAMON BEESLEY, GIHAN PANAPITIYA, JAMES LEWIS, West Virginia University, LEWIS GROUP TEAM — Delafossite oxides are a family of materials with the form  $\text{ABO}_2$ , where the A-site is a monovalent cation ( $\text{Cu}, \text{Ag}, \text{Au}$ ) and the B-site is a trivalent cation ( $\text{Ga}, \text{Al}, \text{In}$ ). Delafossites typically have a wide optical band gap, this band gap may be tuned by adding a second B-site element forming an  $\text{AB}_{(1-x)}^1\text{B}_{(x)}^2\text{O}_2$  alloy. We investigate changes in the electronic structure of  $\text{CuAlO}_2$ ,  $\text{CuGaO}_2$ , and  $\text{CuInO}_2$  when alloyed with  $\text{CuFeO}_2$ . Using the FIREBALL program to optimize the atomic structure, calculate the total and partial density of states, calculate the valence band edge for each alloy level, and investigate the clustering factor of the second B-site atom, it is found that alloying with  $\text{Fe}$  creates midgap states caused by  $\text{Fe}-\text{O}$  interactions. From the partial density of state, each type of atoms contribution to the change in the valence band edge can be seen. Observed changes to the materials include increased optical absorption in the visible range, and symmetry breaking because of the deformation in the crystal structure. The  $\text{CuFeO}_2$  alloying percentages range from 0-5%. We are synthesizing these alloys to experimentally verify the changes in the optical absorption spectra.

**1:15PM S29.00011 Growth, structural, dielectric and magnetic properties of epitaxial multiferroic  $\text{NaMnF}_3$  thin films<sup>1</sup>**, AMIT KC, PAVEL BORISOV, West Virginia Univ, DAVID LEDERMAN, West Virginia Univ, University of California Santa Cruz — Epitaxial  $\text{NaMnF}_3$  thin films were grown on  $\text{SrTiO}_3$  (100) single crystal substrates via molecular beam epitaxy (MBE). The orthorhombically distorted perovskite fluoride  $\text{NaMnF}_3$  ( $Pnma$  space group) has been predicted to have a polar instability at low temperatures due to  $\text{MnF}_6$  octahedral tilts. Structural, magnetic and dielectric properties were studied. Thin film structural quality as a function of the substrate temperature and film thickness was investigated using X-ray diffraction (XRD), in-situ reflection high-energy electron diffraction (RHEED), and atomic force microscopy (AFM). The best films were smooth and single phase grown with four different twin domains. Magnetic characterization was performed using superconducting quantum interference device (SQUID) magnetometry. In-plane magnetization measurements revealed antiferromagnetic ordering with a Neel temperature  $T_N = 66$  K. For the dielectric studies,  $\text{NaMnF}_3$  films were grown on top of  $\text{SrRuO}_3$  (100) buffer layers grown via pulsed laser deposition that were used as bottom electrodes. Dielectric spectroscopy was performed at different temperatures between 11K and room temperature in a frequency range 100 Hz to 100 kHz. Significant temperature dependent dielectric properties were observed.

**1:27PM S29.00012 Molecular Beam Epitaxial (MBE) Growth and Characterization of Thin Films of Semiconductor Tin**, P. FOLKES, P. TAYLOR, C. RONG, B. NICHOLS, H. HIER, R. BURKE, US Army Rsch Lab - Adelphi, M. NEUPANE, US Army Rsch Lab - Aberdeen — Recent theoretical predictions that a two-dimensional monolayer of semiconductor tin is a two-dimensional topological insulator and experimental evidence of three-dimensional topological insulator behavior in strained ultrathin films of semiconductor tin grown by MBE on InSb has generated intense research interest. This research is primarily focused on the MBE growth and topological characteristics of ultrathin films of semiconductor tin. In this talk we present results of a study on the MBE growth and the transport, structural and optical characterization of thin films of semiconductor tin on several different substrates.

**1:39PM S29.00013 Phase dependent structural and electronic properties of Lanthanum Orthophosphate ( $\text{LaPO}_4$ )**, MAHESH NEUPANE, US Army Research Laboratory, Aberdeen Proving Ground, MD, GREGORY GARRETT, SERGEY RUDIN, US Army Research Laboratory, Adelphi, MD, JAN ANDZELM, US Army Research Laboratory, Aberdeen Proving Ground, MD — Lanthanum orthophosphate ( $\text{LaPO}_4$ ) belongs to the family of rare-earth (RE) orthophosphates. The La-ion lacks valence 4f-electron, so for it to exhibit f-electron dependent physics, it must be doped with additional RE elements. In the bulk form,  $\text{LaPO}_4$  exist in both a stable monoclinic and a metastable hexagonal phase, which both possess indirect energy transition characteristics. Though the overall optoelectronic properties of the RE-doped  $\text{LaPO}_4$  depend on the accuracy of the observed bulk energy gap, the reported experimental and theoretical energy gaps varies between  $\sim 8^{1,2}$  and  $\sim 5^3$  eV, respectively. Through this theoretical study, we attempt to establish a correlation between electronic properties of bulk  $\text{LaPO}_4$  and various levels of first principle theories. Compared to experimental data, the PBE0 functional over-predicts energy gaps and the energy differences between the indirect-to-direct transition energies by 25%. The HSE06 gives a good description of electronic properties and predicts the energy gaps to be 7.68 (monoclinic) and 7.29 eV (hexagonal). Analysis on the structural stability also reveals that the total energy difference between the two phases is 6meV, consistent with the experimentally observed instantaneous pressure and temperature dependent phase transition. [1] J. Lumin. 72–74, 255, 1997, [2] J. Lumin. 15-18, 255, 1977, [3] App. Surface Science, 268, 458-463, 2013.

**1:51PM S29.00014 Landau Theory of Trifluoride Negative Thermal Expansion Materials<sup>1</sup>**, GIAN GUZMAN-VERRI, U of Costa Rica and Argonne Natl Lab, RICHARD BRIERLEY, Yale University, PETER LITTLEWOOD, Argonne Natl Lab and U of Chicago — Negative thermal expansion (NTE) is a desirable property in designing materials that are dimensionally stable and resistant to thermal shocks. Transition metal trifluorides (MF<sub>3</sub>, M=Al, Cr, Fe, Ga, In, Ti, V) are a class of materials with ReO<sub>3</sub> structure that exhibit large, isotropic, and tunable NTE over a wide temperature range, which makes them attractive material candidates. They exhibit large coefficients of thermal expansion near their cubic-to-rhombohedral structural phase change, which can be thermally or pressure induced. Though they have recently been the subject of intense experimental research, little work has been done on the theory side and it has almost exclusively focused on zero temperature properties. In this talk, we construct a simple Landau theory of trifluorides and use it to calculate the temperature dependence of the elastic constants, soft phonon frequencies, and volume expansion near their structural transition. We compare our results to existing experimental data on trifluorides.

**2:03PM S29.00015 Type-II Dirac cones as unified topological origin of the exotic electronic properties of WTe<sub>2</sub><sup>1</sup>**, LUKAS MUECHLER, Dept. of Chemistry, Princeton University, ARIS ALEXANDRADINATA, Dept. of Physics, Yale University, TITUS NEUPERT, Princeton Center for Theoretical Science, ROBERTO CAR, Dept. of Chemistry, Princeton University — WTe<sub>2</sub> is a recently discovered layered material with remarkable electronic properties. Transport measurements show an extremely large non-saturating magnetoresistance (MR) with mobilities as high as 167 000 cm<sup>2</sup>/Vs at 2 K. Furthermore, recent photoemission experiments discovered circular dichroism in the bulk band structure. We propose a unified explanation for these exotic observations by relating key properties of the bulk electronic structure to that of to that of the mono- and bi-layer material. In particular, we demonstrate that the monolayer is a novel type-II Dirac semimetal in absence of spin-orbit coupling, with Dirac cones that are sufficiently anisotropic to simultaneously harbor electron and hole pockets. The band structure can be characterized by a new  $Z_2 \times Z_2$  topological invariant defined through non-Abelian Wilson loops. We develop a tight-binding model for the mono- and bilayer of WTe<sub>2</sub> based on Wannier functions from *ab-initio* calculations and extend our findings to the iso-structural compounds MoTe<sub>2</sub> and ZrI<sub>2</sub>.

## Thursday, March 17, 2016 11:15AM - 2:15PM – Session S30 DMP: Theory of Ferroic Systems 329 - Steve Johnson, ETHZ

**11:15AM S30.00001 New design strategy for realizing multiferroic materials**, DANILO PUGGIONI, Department of Materials Science and Engineering, Northwestern University, Evanston, IL60208, USA, GIANLUCA GIOVANNETTI, MASSIMO CAPONE, CNR-IOM-Democritos National Simulation Centre and International School for Advanced Studies (SISSA), Via Bonomea 265, I-34136, Trieste, Italy, JAMES RONDINELLI, Department of Materials Science and Engineering, Northwestern University, Evanston, IL60208, USA — Ferroelectricity is a property that only insulating materials can exhibit. For this reason, nearly all searches for new multiferroic compounds, those simultaneously exhibiting ferroelectric and magnetic order, have focused on *insulating* magnetic oxides. Here, we propose a different approach: Start from a *conducting* oxide with broken inversion symmetry and search for routes to induce long-range magnetic order [1]. Using density-functional and dynamical mean-field theories, we investigate the electronic properties of the polar metallic oxide LiOsO<sub>3</sub>. We show that a multiferroic state can be engineered by enclosing LiOsO<sub>3</sub> between an insulating material, LiNbO<sub>3</sub>. We predict that the 1/1 superlattice of LiOsO<sub>3</sub> and LiNbO<sub>3</sub> exhibits strong coupling between magnetic and ferroelectric degrees of freedom with a ferroelectric polarization of 41.2  $\mu\text{Ccm}^{-2}$ , Curie temperature of 927 K, and Néel temperature of 379 K. Our results show that one can start with polar metallic oxides to make multiferroics.

**11:27AM S30.00002 Crystal structure and electronic properties of bulk and thin-film brownmillerite oxides**, JOSHUA YOUNG, Drexel University, JAMES RONDINELLI, Northwestern University — The equilibrium structure and functional properties exhibited by brownmillerite oxides (general formula  $A_2B_2O_5$ ), a family of perovskite-derived structures with alternating layers of  $BO_6$  octahedra and  $BO_4$  tetrahedra arising from ordered arrangements of oxygen vacancies, is dependent on a variety of competing crystal-chemistry factors. Using first principles electronic structure calculations, we investigate two antiferromagnetic brownmillerite ferrites, Sr<sub>2</sub>Fe<sub>2</sub>O<sub>5</sub> and Ca<sub>2</sub>Fe<sub>2</sub>O<sub>5</sub>, and find that the stability of the equilibrium ground state is governed by complex interactions among several structural descriptors, including ionic size, distortions of nominally regular oxygen octahedral, and in-plane and out-of-plane separation of tetrahedral chains. Furthermore, we find that these same effects control the preferred oxygen vacancy orientation under epitaxial strain, a tunable parameter which also strongly influences the magnitude of the electronic band gap via an asymmetric-vacancy alignment dependent response. Finally, we show that A-site cation ordering in these materials can lift inversion symmetry, providing a potential new route to room temperature multiferroics.

**11:39AM S30.00003 Unveiling hidden ferrimagnetism and giant magnetoelectricity in polar magnet Fe<sub>2</sub>Mo<sub>3</sub>O<sub>8</sub>**, YAZHONG WANG, GHEORGHE L. PASCUT, BIN GAO, RCEM, Rutgers Univ, TREVOR A. TYSON, New Jersey Institute of Technology, KRISTJAN HAULE, VALERY KIRYUKHIN, SANG-WOOK CHEONG, RCEM, Rutgers Univ, RUTGERS CENTER FOR EMERGENT MATERIALS TEAM, DEPARTMENT OF PHYSICS, NEW JERSEY INSTITUTE OF TECHNOLOGY COLLABORATION — Polar magnets, belonging to the polar crystallographic symmetry groups and containing magnetic ions, can exhibit non-trivial magnetoelectric (ME) effects below magnetic ordering temperatures due to the broken time reversal and space inversion symmetries. Mono-domain polar single crystals can often be grown, and eliminate the need for any poling procedures to reveal the possible ME response. Here, we report a giant ME effect in a polar magnet Fe<sub>2</sub>Mo<sub>3</sub>O<sub>8</sub> at temperature as high as 60 K. Polarization jumps of 0.3  $\mu\text{C}/\text{cm}^2$  and repeated mutual control of ferroelectric and magnetic moments with differential ME coefficients on the order of 10<sup>4</sup> ps/m are achieved. The sign of the ME coefficients can be switched by changing the direction of the applied “bias” magnetic field. Importantly, no electric or magnetic poling is needed, as necessary for applications. Using first principles calculations, we show that exchange striction is the leading mechanism responsible for the observed ME effect.

**11:51AM S30.00004 Theory of colossal magnetoelectric response near spin-flop transition in Ni<sub>3</sub>TeO<sub>6</sub>**<sup>1</sup>, SERGEY ARTYUKHIN, Italian Institute of Technology — The manipulation of magnetic ordering with applied electric fields is of pressing interest for new spintronic and information storage applications. Recently, such magnetoelectric control was realized in multiferroics [1]. However, their magnetoelectric switching is often accompanied by significant hysteresis, resulting from a large barrier, separating different ferroic states. Hysteresis prevents robust switching, unless the applied field overcomes a certain value (coercive field). I will discuss the role of a switching barrier on magnetoelectric control, in particular, in a collinear antiferromagnetic and pyroelectric Ni<sub>3</sub>TeO<sub>6</sub> [2,3]. The barrier between two magnetic states in the vicinity of a spinflop transition is almost flat, and thus small changes in external electric/magnetic fields allow to switch the ferroic state through an intermediate state in a continuous manner, resulting in a colossal magnetoelectric response. This colossal magnetoelectric effect resembles the large piezoelectric effect at the morphotropic phase boundary in ferroelectrics. [1] T. Kimura, T. Goto, H. Shintani et al., Nature 426, 5 (2003) [2] Y.-S. Oh, S. Artyukhin J. J. Yang et al., Nature Communications 5, 3201 (2014) [3] J. W. Kim, S. Artyukhin, E. D. Mun et al., Phys. Rev. Lett. 115, 137201 (2015)

<sup>1</sup>NSF-DMREF-1233349, ONR N00014-12-1-1035

**12:27PM S30.00005 Multiferroic behavior at a spin state transition**, VIVIEN ZAPF, SHALINEE CHIKARA, JOHN SINGLETON, National High Magnetic Field Laboratory, Los Alamos National Lab (LANL), SHIZENG LIN, CRISTIAN BATISTA, Theory Division, LANL, BRIAN SCOTT, MPA-11, LANL, NATHAN SMYTHE, Chemistry Division C-IIAC, LANL — Traditionally, multiferroic behavior is studied in materials with coexisting long-range orders, such as ferromagnetism and ferroelectricity. Here we present multiferroic behavior at a spin-state transition (SST). SSTs, for example, the  $S = 1$  to  $S = 2$  transition in Mn<sup>3+</sup> can become cooperative magneto-structural phase transitions due to structural coupling between ions. SSTs are accompanied by change in the orbital occupation and hence, strongly coupled to the lattice and charge degrees of freedom. They are a dominant functionality in metal-organic materials, persisting up to room temperature in some compounds. We demonstrate that a magnetic SST can induce ferroelectricity. We study a Mn-based metal-organic system in which a three-fold degenerate dynamic Jahn-Teller effect at high temperatures vanishes when the temperature is lowered, and the system drops into a lower spin state. Application of a magnetic field restores the high spin Jahn-Teller-active state and allows the Jahn Teller distortions to order cooperatively, creating a dielectric constant change and a net electric polarization. We use high magnetic fields at the NHMFL to study the magnetic and electric behavior of this system across a significant fraction of its T-H phase space, and compare to theoretical modeling.

**12:39PM S30.00006 Electric polarization induced by the inverse DM interactions in canted antiferromagnets**, NOBUO FURUKAWA, Department of Physics, Aoyama Gakuin Univ, SHIN MIYAHARA, Department of Applied Physics, Fukuoka University — We investigate electric polarizations induced by antisymmetric spin pairs  $S_i \times S_j$  on distorted lattices through the inverse Dzyaloshinsky-Moriya (DM) interaction. From an extended Hubbard model, we microscopically derive a generic form of the electric polarization,  $p = \hat{d}(S_i \times S_j)$ , with a tensor  $\hat{d}$ . This includes components of the electric polarization other than those given by the Katsura-Nagaosa-Balatsky formula  $p \propto e_{ij} \times (S_i \times S_j)$ . Our results indicate that various magnetic structures, such as canted antiferromagnetic as well as proper screw spin structures, show multiferroic properties owing to these non-Katsura-Nagaosa-Balatsky components of the coupling. We also discuss possible novel multiferroic behaviours through these couplings in various compounds.

**12:51PM S30.00007 Spin polarized electronic states and spin textures at the surface of oxygen-deficient SrTiO<sub>3</sub>**<sup>1</sup>, HARALD O. JESCHKE, MICHAELA ALTMAYER, Institut für Theoretische Physik, Goethe-Universität Frankfurt, Germany, MARCELO ROZENBERG, MARC GABAY, Laboratoire de Physique des Solides, Université Paris-Sud, France, ROSER VALENTI, Institut für Theoretische Physik, Goethe-Universität Frankfurt, Germany — We investigate the electronic structure and spin texture at the (001) surface of SrTiO<sub>3</sub> in the presence of oxygen vacancies by means of *ab initio* density functional theory (DFT) calculations of slabs. Relativistic non-magnetic DFT calculations exhibit Rashba-like spin winding with a characteristic energy scale  $\sim 10$  meV. However, when surface magnetism on the Ti ions is included, bands become spin-split with an energy difference  $\sim 100$  meV at the  $\Gamma$  point. This energy scale is comparable to the observations in SARPES experiments performed on the two-dimensional electronic states confined near the (001) surface of SrTiO<sub>3</sub>. We find the spin polarized state to be the ground state of the system, and while magnetism tends to suppress the effects of the relativistic Rashba interaction, signatures of it are still clearly visible in terms of complex spin textures.

**1:03PM S30.00008 Electronic structure studies on competing phases of Aurivillius Bi<sub>4</sub>Ti<sub>3</sub>O<sub>12</sub> using first-principles calculations**, FU-CHANG SUN, University of Connecticut, Department of Physics, SANJEEV NAYAK, University of Connecticut, Department of Materials Science & Engineering, DEEPAM MAURYA, SHASHANK PRIYA, Virginia Tech, Bio-inspired Materials and Devices Laboratory (BMDL), Center for Energy Harvesting Materials and Systems (CEHMS), S. PAMIR ALPAY, University of Connecticut, Department of Materials Science & Engineering — The low temperature ferroelectric to high temperature paraelectric phase transition in bismuth titanate (Bi<sub>4</sub>Ti<sub>3</sub>O<sub>12</sub>) has been experimentally observed at Curie temperature ( $T_C$ ) around 675 °C. The first-principles calculations using density functional theory as implemented in the Vienna *ab initio* simulation package (VASP) with generalized gradient approximation (GGA) for the exchange-correlation interaction are performed to investigate this monoclinic (*b1a1*) to tetragonal (*I4/mmm*) crystal structural transition. We further, provide discussion of the band structure and the Ti-O orbital hybridization, in addition to the frequency dependent dielectric and optical properties of Bi<sub>4</sub>Ti<sub>3</sub>O<sub>12</sub> due to the potential applications in the electronic devices.

**1:15PM S30.00009 ABSTRACT WITHDRAWN —**

**1:27PM S30.00010 Microscopic description of oxide perovskites and automated high-throughput analysis of their energy landscape**, GIOVANNI PIZZI, ANDREA CEPELLOTTI, Ecole Polytechnique Federale de Lausanne, Switzerland, BORIS KOZINSKY, Research and Technology Center, Robert Bosch LLC, Cambridge (MA), NICOLA MARZARI, Ecole Polytechnique Federale de Lausanne, Switzerland — Even if ferroelectric materials like BaTiO<sub>3</sub> or KNbO<sub>3</sub> have been used for decades in a broad range of technological applications, there is still significant debate in the literature concerning their microscopic behavior. For instance, many perovskite materials display a high-temperature cubic phase with zero net polarization, but its microscopic nature is though still unclear, with some materials displaying a very complex energy landscape with multiple local minima. In order to investigate and clarify the microscopic nature of oxide perovskites, we perform a study on a set of about 50 representative ABO<sub>3</sub> systems. We use spacegroup techniques to systematically analyze all possible local displacement patterns that are compatible with a net paraelectric phase, but can provide local non-zero ferroelectric moments. The energetics and the stability of these patterns is then assessed by combining the spacegroup analysis with DFT calculations. All calculations are managed and analyzed using our high-throughput platform AiiDA (www.aiida.net) [1]. Using this technique, we are able to describe the different classes of microscopic models underlying the perovskite systems. [1] G. Pizzi et al., Comp. Mat. Sci 111, 218-230 (2016).

**1:39PM S30.00011 Temperature-dependent phase transition of ferroelectric perovskites: A Wang-Landau-DFT approach<sup>1</sup>**, SIMUCK YUK, YING WAI LI, MARKUS EISENBACH, VALENTINO COOPER, Materials Science and Technology Division, Oak Ridge National Laboratory, Oak Ridge, TN 37831, USA — Since the discovery of ferroelectricity in perovskite oxides, considerable efforts have been devoted to understanding their phase transition behaviors in terms of temperature, pressure, and composition. Such materials have regularly been used in transducer and actuator applications. As our first step to make accurate predictions of the crystal phases of more complex oxides such as  $\text{Pb}(\text{Zr}_x\text{Ti}_{1-x})\text{O}_3$ , we have used the Wang-Landau (WL) algorithm and density functional theory (DFT) to examine the temperature-dependent phase transition of  $\text{PbTiO}_3$ ,  $\text{BaTiO}_3$ , and  $\text{KNbO}_3$ . DFT was employed to evaluate the energetics of important crystal-structure candidates, which were later used as the input for WL algorithm. In addition, we examine how the choice of exchange-correlation functionals affects our predictions of the relevant phase transition temperatures.

**1:51PM S30.00012 First Principle Studies of Electromechanical Properties in Mn-Doped  $\text{BaTiO}_3$ <sup>1</sup>**, HIROYUKI TAKENAKA, Carnegie Institution for Science, Washington, DC, USA, R.E. COHEN, Carnegie Institution of Washington, Washington, DC, US, Department für Geo-und Umweltwissenschaften, Ludwig-Maximilians-Universität, Munich, Germany — We are performing density functional calculations to elucidate the electromechanical properties for Mn-doped  $\text{BaTiO}_3$  with an oxygen vacancy, applying electric field perpendicular to polarization directions. We find that local dipole switching and lattice changes take place at 3MV/m. Spontaneous polarization along x is 0.251 C/m<sup>2</sup> and c/a ratio changes from 1.021 to 1.000. This indicates that coercive field of Mn-doped  $\text{BaTiO}_3$  increases as were experimentally reported since our results for pure  $\text{BaTiO}_3$  exhibit onset of the switching and changes at 0.8 MV/m. We report our computational dielectric constant and strain as a function of electric field for Mn-doped  $\text{BaTiO}_3$ .

<sup>1</sup>This work is supported by ONR and the ERC Advanced Grant ToMCaT.

**2:03PM S30.00013 Towards an understanding of antiferroelectricity in  $\text{PbZrO}_3$  from first principles**, BRIAN M. ABBETT, School of Applied and Engineering Physics, Cornell University, KARIN M. RABE, Department of Physics and Astronomy, Rutgers University, CRAIG J. FENNIE, School of Applied and Engineering Physics, Cornell University — For decades,  $\text{PbZrO}_3$  has been referred to as the prototypical antiferroelectric. According to a recent analysis, an essential requirement for antiferroelectricity is that there is a polar phase almost degenerate with the nonpolar ground state. Indeed, as previously reported, first-principles calculations show that the polar  $R3c$  structure of  $\text{PbZrO}_3$  is only 1 meV per formula unit higher in energy than the nonpolar ground state  $P6mm$  structure. Here, we explore the question of how these two structures, which seem to be only distantly related, can be so close in energy. Using first-principles methods we investigate the energy landscape of  $\text{PbZrO}_3$ . We introduce a simple structural model that both describes the relevant, low-energy, structural motifs and captures the gross energy landscape relating to both structures. We use this model (and test with direct first-principles calculations) to explore a possible switching path between the non-polar ground state and the metastable polar structure. Our results provide insight into why  $\text{PbZrO}_3$  is antiferroelectric, which may prove useful in identifying new antiferroelectric materials.

**Session S31 DCP GSOFT: Ice Nucleation, Amorphous Ices and the Role of Interfaces** 331 -

Nicolas Giovambattista

**11:15AM S31.00001 The Many Faces of Ice and Nonlinear Interferometry.**, MARY JANE SHULTZ, Tufts University — Ice is likely the most ubiquitous solid in the Universe, yet even here on Earth its surface contains many mysteries. At atmospheric pressure, the stable form of ice is hexagonal ice; known as  $I_h$ . This contribution will present data about (i) equilibrium growth at the ice-water interface, (ii) procedures to generate any targeted ice face, and (iii) vibrational spectra of the ice-air interface. Contrary to common belief, the stable ice-water interfaces does not consist of the basal face; rather it consists of pyramidal or prism faces. Growth results from a balance between the molecular density and the top half-bilayer configuration. Arguments reminiscent of Pauling's residual entropy of ice generate the configurational contribution. Prism faces are favored due to greater entropy. Ice grows cryptomorphologically: the macroscopic sample does not reveal the crystalline axes. Locating the crystal axes as well as generating authentic faces for fundamental studies use a combination of the birefringence of ice and etch profiles. Surface vibrational spectroscopy supports an ice model consisting of extended, cooperative motion and beyond-bonding-partner determination of hydrogen bond strength. The surface vibrational spectrum is probed with the nonlinear spectroscopy sum frequency generation (SFG). Currently, nonlinearity limits use of SFG to diagnose interactions. This limitation can be circumvented by measuring the full, complex spectrum. We will report initial results from a newly invented nonlinear interferometer that reveals the full complex spectrum.

**11:51AM S31.00002 Direct Calculation of the Rate of Homogeneous Ice Nucleation for a Molecular Model of Water**, AMIR HAJI-AKBARI, PABLO DEBENEDETTI, Department of Chemical and Biological Engineering, Princeton University — Ice formation is ubiquitous in nature, with important consequences in many systems and environments. However, its intrinsic kinetics and mechanism are difficult to discern with experiments. Molecular simulations of ice nucleation are also challenging due to sluggish structural relaxation and the large nucleation barriers, and direct calculations of homogeneous nucleation rates have only been achieved[1-2] for mW, a monoatomic coarse-grained model of water. For the more realistic molecular models, only indirect estimates have been obtained by assuming the validity of classical nucleation theory[3]. Here, we use a coarse-grained variant of a path sampling approach known as forward-flux sampling to perform the first direct calculation of the homogeneous nucleation rate for TIP4P/Ice, which is the most accurate water model for studying ice polymorphs. By using a novel topological order parameter, we are able to identify a freezing mechanism that involves a competition between cubic and hexagonal ice polymorphs[4]. In this competition, cubic ice wins as its growth leads to more compact crystallites[4]. [1] Li, et al., PCCP, 13, 19807 (2011) [2] Haji-Akbari, et al., PCCP, 16, 25916 (2014) [3] Sanz et al., JACS 135, 15008 (2013) [4] Haji-Akbari, Debenedetti, PNAS, 112, 10582 (2015)

**12:03PM S31.00003 Scratching the surface of ice: Interfacial phase transitions and their kinetic implications.**, DAVID LIMMER, Princeton University — The surface structure of ice maintains a high degree of disorder down to surprisingly low temperatures. This is due to a number of underlying interfacial phase transitions that are associated with incremental changes in broken symmetry relative to the bulk crystal. In this talk I summarize recent work attempting to establish the nature and locations of these different phase transitions as well as how they depend on external conditions and nonequilibrium driving. The implications of this surface disorder is discussed in the context of simple kinetic processes that occur at these interfaces. Recent experimental work on the roughening transition is highlighted.

**12:39PM S31.00004 Exploring the coupling between surface crystallinity and surface hydrophilicity in heterogeneous ice nucleation**, YUANFEI BI, RAFFAELA CABRIOLU, TIANSHU LI, the George Washington University — Heterogeneous ice nucleation has significant influence in a variety of fields ranging from global climate change to intracellular freezing. Although its prevalence can be explained quantitatively by the classical nucleation theory [1], there is a lack of molecular level understanding of the key factors governing ice nucleation at the interface between water and ice nucleator. Here, by employing advanced molecular simulation, we show [2] that heterogeneous ice nucleation on graphitic surface is controlled by the coupling of surface crystallinity and surface hydrophilicity. Molecular level analysis shows that the crystalline graphitic surface with an appropriate hydrophilicity templates ice basal plane forming in the contact layer, thus significantly enhances its ice nucleation efficiency. Remarkably, the templating effect is found to transit from within the first contact layer of water to the second as the hydrophilicity increases, yielding an oscillating distinction between the crystalline and amorphous graphitic surfaces in their ice nucleation efficiencies. Our study sheds new light on the long-standing question of what constitutes a good ice nucleator. 1 R. Cabriolu and T. Li, *Physical Review E* 91, 052402 (2015). 2 Y. Bi, R. Cabriolu, and T. Li, arXiv:1510.01371 (2015).

**12:51PM S31.00005 Two Dimensional Ice crystals intercalated between graphene and mica**, PANTELIS BAMPOULIS, MARTIN H. SIEKMAN, E. STEFAN KOOIJ, DETLEF LOHSE, HAROLD J.W. ZANDVLIET, BENÉ POELSEMA, University of Twente, MESA+ INSTITUTE FOR NANOTECHNOLOGY TEAM — The physics and chemistry of the interfacial contact between water and solid surfaces are of the highest fundamental and practical interest in environmental sciences, many biological systems and corrosion effects. Water intercalated between graphene and mica has recently received much interest, even amplified by intriguing intercalation effects and by the evolution of fractals. These confined water layers are argued to be ice-like at room temperature. Due to its good thermal isolation from the environment, as a result of poor perpendicular heat transport through both mica and graphene, this system is uniquely suited for studying the consequences of heat transport, due to latent heat effects, during growth and melting of 2D ice crystals. The enigmatic growth of ice crystals poses a longstanding fundamental problem and its solution is possibly hidden in influences of heat and particle transport. Indeed, we find that heat and particle transport play a crucial role in the growth of ice crystals under high-temperature and high supersaturation conditions.

**1:03PM S31.00006 2D ice from first principles: structures and phase transitions**, JI CHEN, Thomas Young Centre, University College London, London Centre for nanotechnology, GEORG SCHUSTERITSCH, CHRIS J. PICKARD, Thomas Young Centre, University College London, University of Cambridge, CHRISTOPH G. SALZMANN, University College London, ANGELOS MICHAELIDES, Thomas Young Centre, University College London, London Centre for nanotechnology — Despite relevance to disparate areas such as cloud microphysics and tribology, major gaps in the understanding of the structures and phase transitions of low-dimensional water ice remain. Here we report a first principles study of confined 2D ice as a function of pressure. We find that at ambient pressure hexagonal and pentagonal monolayer structures are the two lowest enthalpy phases identified. Upon mild compression the pentagonal structure becomes the most stable and persists up to ca. 2 GPa at which point square and rhombic phases are stable. The square phase agrees with recent experimental observations of square ice confined within graphene sheets. We also find a double layer AA stacked square ice phase, which clarifies the difference between experimental observations and earlier force field simulations. This work provides a fresh perspective on 2D confined ice, highlighting the sensitivity of the structures observed to both the confining pressure and width.

**1:15PM S31.00007 Using nanoscale amorphous solid water films to create and study deeply supercooled liquid water at interfaces**, BRUCE KAY, Pacific Northwest National Laboratory — Molecular beam vapor deposition of water on cryogenic substrates is known to produce amorphous solid films. When heated above their glass transition these films transform into deeply supercooled liquid water. These nanoscale liquid films can be used to study kinetic processes such as diffusion, isotope exchange, crystallization, and solvent mediated reactions in unprecedented detail. This talk will highlight our recent advances in this area. My colleagues Yuntao Xu, Chunqing Yuan, Collin Dibble, R. Scott Smith, Nick Petrik, and Greg Kimmel made important contributions to this work. This work was supported by the U.S. Department of Energy (DOE), Office of Science, Office of Basic Energy Sciences, Division of Chemical Sciences, Geosciences, and Biosciences. The research was performed using EMSL, a national scientific user facility sponsored by DOE's Office of Biological and Environmental Research and located at Pacific Northwest National Laboratory, which is operated by Battelle, operated for the U.S. DOE under Contract DE-AC05-76RL01830.

**1:51PM S31.00008 Local Structure in *Ab Initio* Liquid Water: Signatures of Amorphous Phases<sup>1</sup>**, BISWAJIT SANTRA, Princeton University, Princeton, USA, ROBERT A. DISTASIO, JR., Cornell University, Ithaca, USA, FAUSTO MARTELLI, ROBERTO CAR, Princeton University, Princeton, USA — Within the framework of density functional theory, the inclusion of exact exchange and non-local van der Waals/dispersion interactions is crucial for predicting a microscopic structure of ambient liquid water that quantitatively agrees with experiment [1]. In this work, we have used the local structure index (LSI) order parameter to analyze the local structure in such highly accurate *ab initio* liquid water. At ambient conditions, the LSI probability distribution,  $P(I)$ , was unimodal with most water molecules characterized by more disordered high-density-like local environments. With thermal excitations removed, the resultant bimodal  $P(I)$  in the inherent potential energy surface (IPES) exhibited a 3:1 ratio between high- and low-density-like molecules, with the latter forming small connected clusters amid the predominant population. By considering the spatial correlations and hydrogen bond network topologies among water molecules with the same LSI identities, we demonstrate that the signatures of the experimentally observed low- and high-density amorphous phases of ice are present in the IPES of ambient liquid water [2]. **Session S32 DCP: Chemical Physics of Extreme Environments I** 332 - Arthur Suits, University of Missouri

**11:15AM S32.00001 Reaction Product Identification in Extreme Chemical Environments by Broadband Rotational Spectroscopy<sup>1</sup>**, BROOKS PATE, University of Virginia — Molecular rotational spectroscopy has several advantages for detection of reaction intermediates and products under extreme laboratory conditions. Rotational spectroscopy has high sensitivity to the molecular structure and provides high spectral resolution in low pressure environments. Furthermore, quantum chemistry provides accurate estimates of the spectroscopic parameters. As a result, rotational spectroscopy can identify molecular species in complex reaction mixtures without the need for chromatographic separation and without the need for a previously recorded "library spectrum" of the molecule. The application of chirped pulse Fourier transform rotational spectroscopy methods for the identification of molecules of astrochemical interest formed in pulsed discharge sources will be described including recent advances for high-throughput mm-wave spectroscopy. The set of reaction products created in the experiment can provide insight into the reaction mechanism. Reactions involving the CN radical will be discussed. These reactions can be barrierless making them candidates for interstellar gas reactions. The possibility that interstellar cyanomethanimine is produced by gas phase radical-neutral reactions instead of surface chemistry on grain-supported ices will be discussed using recent spatially resolved chemical images in Sagittarius B2 observed with the Jansky Very Large Array.

**11:51AM S32.00002 Observation of *K*-dependent Reaction Rates in Pulsed Uniform Supersonic Flows by Chirped-Pulse Microwave Spectroscopy**, BERNADETTE BRODERICK, NUWANDI ARIYASINGHA, ARTHUR SUITS, University of Missouri, UNIVERSITY OF MISSOURI TEAM — Chirped-pulse Fourier-transform microwave spectroscopy was used to interrogate the reaction of Cl atoms with propyne in a pulsed uniform supersonic flow. The technique, termed "CPUF", utilizes broad-band microwave spectroscopy to extract structural information with MHz resolution and near universal detection, in conjunction with a Laval flow system, which offers thermalized conditions at low temperatures and high number densities. Previous studies have exploited this approach to obtain multichannel product branching fractions in a number of polyatomic systems, with isomer and often vibrational level specificity. This report highlights an additional capability of the CUF technique: here, the state-specific reactant depletion is directly monitored on a microsecond timescale. In doing so, a clear dependence on the rotational quantum number *K* in the rate of the reaction between Cl atoms and propyne is revealed. Future prospects for the technique will be discussed.

**12:03PM S32.00003 Rotational Spectroscopic Studies and Observational Searches for HO<sub>3</sub>**, SUSANNA WIDICUS WEAVER<sup>1</sup>, Emory University — Interstellar chemistry is largely driven by reactions of unstable molecules that serve as reaction intermediates in terrestrial chemistry. One such class of compounds are weakly-bound clusters. These clusters could form in interstellar environments through radiative association reactions, but their identification and characterization in interstellar environments is limited by a lack of rotational spectral information. One such species is HO<sub>3</sub>, which could be formed in the interstellar medium from O<sub>2</sub> and OH. HO<sub>3</sub> has been studied extensively in the infrared, and there are a few microwave spectral studies that have also been reported. However, no millimeter or submillimeter spectral information is available to guide astronomical observations. In this talk, we will present the laboratory characterization of *trans*-HO<sub>3</sub> and *trans*-DO<sub>3</sub> from 70 to 450 GHz using our newly developed fast sweeping technique. The molecular constants have been significantly refined, and additional higher order centrifugal distortion constants have been determined. We will also present an initial observational search for HO<sub>3</sub> in 32 star forming regions. Although no HO<sub>3</sub> lines have been detected thus far, strict upper limits can be placed on the HO<sub>3</sub> column density in these sources based on this analysis.

**12:39PM S32.00004 The Extreme Chemical Environments Associated with Dying Stars**, LUCY ZIURYS, University of Arizona — Mass loss from dying stars is the main avenue by which material enters the interstellar medium, and eventually forms solar systems and planets. When stars consume all the hydrogen burning in their core, they start to burn helium, first in their centers, and then in a surrounding shell. During these phases, the so-called "giant branches," large instabilities are created, and stars begin to shed their outer atmospheres, producing so-called circumstellar envelopes. Molecules form readily in these envelopes, in part by LTE chemistry at the base of the stellar photosphere, and also by radical reactions in the outer regions. Eventually most stars shed almost all their mass, creating "planetary nebulae," which consist of a hot, ultraviolet-emitting white dwarf surrounded by the remnant stellar material. The environs in such nebulae are not conducive to chemical synthesis; yet molecular gas exists. The ejecta from these nebulae then flows into the interstellar medium, becoming the starting material for diffuse clouds, which subsequently collapse into dense clouds and then stars. This molecular "life cycle" is repeated many times in the course of the evolution of our Galaxy. We have been investigating the interstellar molecular life cycle, in particular the chemical environments of circumstellar shells and planetary nebulae, through both observational and laboratory studies. Using the facilities of the Arizona Radio Observatory (ARO), we have conducted broad-band spectral-line surveys to characterize the contrasting chemical and physical properties of carbon (IRC+10216) vs. oxygen-rich envelopes (VY CMa and NML Cyg). The carbon-rich types are clearly more complex in terms of numbers of chemical compounds, but the O-rich variety appear to have more energetic, shocked material. We have also been conducting surveys of polyatomic molecules towards planetary nebulae. Species such as HCN, HCO<sup>+</sup>, HNC, CCH, and H<sub>2</sub>CO appear to be common constituents of these objects, and their abundances do not appear to vary with age. These results contradict the predictions of all chemical models. We have also been using millimeter-wave and Fourier transform microwave methods to measure rotational spectra of potential new interstellar molecules to complete the chemical inventories. The current results of these studies will be presented.

**1:15PM S32.00005 Complex Mixture Analysis Using Rotational Spectroscopy**, MICHAEL MCCARTHY, Harvard-Smithsonian Center for Astrophysics — Owing to its very high intrinsic resolution, exceeding ppm levels in supersonic jet sources, rotational spectroscopy is a powerful analytical tool to analyze complex mixtures that consist of both familiar and exotic molecules. We present here an experimental method to rapidly sort rotational lines in broadband spectra and assign them to individual chemical compounds in the cm-band. This method combines a chirped-pulse FT microwave (CP-FTMW) spectrometer with follow-up analysis using an automated cavity FTMW spectrometer with double resonance (DR) capabilities. The CP-FTMW spectrum acts as a filter, identifying only those regions of frequency space that contain molecular signal, and discarding the vast majority of frequency space that is devoid of molecular information. With superior sensitivity and resolution per unit time, a cavity spectrometer is then used for follow-up assays on these bright spectral lines, to group transitions which share common characteristics, such as elemental composition, etc. These groups can be further partitioned into smaller sub-groups by exhaustive DR experiments whereby only those rotational lines that share a common energy level from the same molecule are linked together. From these series of measurements and assays, rotational transitions of multiple, individual chemical compounds can be empirically sorted and identified, without the need for any theoretical guidance or input. Significant automation greatly enhances the overall efficiency, enabling rapid, exhaustive testing with little oversight. Examples illustrating the power of this methodology for rapid analysis of broadband spectra will be presented.

**1:51PM S32.00006 Stretching molecules under extreme tensile strain: density functional theory versus multireference methods.**, GARY KEDZIORA, Engility Corp., STEPHEN BARR, RAJIV BERRY, Air Force Research Lab., Materials and Manufacturing Directorate, JAMES MOLLER, Miami University, Department of Mechanical and Manufacturing Engineering, TIMOTHY BREITZMAN, Air Force Research Lab., Materials and Manufacturing Directorate — A more refined understanding of how molecules behave under extreme tensile strain is desirable for modeling fracture initiation in polymers and other mecho-chemical studies. We investigated several quantum mechanical methods for use in multiscale models of highly strained polymers where bond breaking occurs. A small set of molecules and a protocol for stretching them were used as model test systems. The results from these tests using several functionals were compared with complete active space self-consistent field results. These test systems provide unique challenges for quantum mechanical models. Quantum mechanics is required for accurate bond breaking prediction because the results are dependent on the conformation and secondary electronic structure effects such as hyperconjugation. GGA methods with unrestricted solutions to the Kohn-Sham equations provide adequate results for our purposes even though there are some minor flaws based on the spin symmetry breaking.

**2:03PM S32.00007 Mixed quantum/semiclassical studies of condensed-phase dynamics and spectroscopy**<sup>1</sup>, JEFFREY A CINA, PHILIP A KOVAC, Department of Chemistry & Biochemistry, Oregon Center for Optical, Molecular, and Quantum Science — We report on theoretical and computational studies of molecular-level chemical dynamics and their time-resolved spectroscopic signatures for small molecules embedded in low-temperature crystalline-host environments. Our calculations are based on a mixed quantum mechanical/semiclassical theory, referred to as the variational fixed vibrational basis/Gaussian bath theory (v-FVB/GB), in which certain optically addressed coordinates driven to large-amplitude motion by laser pulses are treated fully quantum mechanically and a larger number of others executing small-amplitude motion are treated semiclassically. Model systems under investigation incorporate a dihalogen molecule isolated in a symmetrical cluster of rare-gas atoms, with the outer layer of host atoms bound together in a harmonic net that preserves the initial equilibrium structure, but emulates an extended medium by preventing dynamical reconstruction and host-atom evaporation.

Session S33 DPOLY: Ion Containing Polymer Membranes 336 - Phil Griffin, University of Pennsylvania

**11:15AM S33.00001 Proton conducting, high modulus polymer electrolyte membranes by polymerization-induced microphase separation**, SUJAY CHOPADE, MARC HILLMYER, TIMOTHY LODGE, Univ of Minn - Minneapolis — Robust solid-state polymer electrolyte membranes (PEMs) are vital for designing next-generation lithium-ion batteries and high-temperature fuel cells. However, the performance of diblock polymer electrolytes is generally limited by poor mechanical stability and network defects in the conducting pathways. We present the *in-situ* preparation of robust cross-linked PEMs via polymerization-induced microphase separation, and incorporation of protic ionic liquid (IL) into one of the microphase separated domains. The facile design strategy involves a delicate balance between the controlled growth of polystyrene from a poly(ethylene oxide) macro-chain transfer agent (PEO-CTA) and simultaneous chemical cross-linking by divinylbenzene in the presence of IL. Small angle X-ray scattering and transmission electron microscopy confirmed the formation of a disordered structure with bicontinuous morphology and a characteristic domain size of order 20 nm. The long-range continuity of the PEO/protic IL conducting nanochannels and cross-linked polystyrene domains imparts high thermal and mechanical stability to the PEMs, with elastic modulus approaching 10 MPa and a high ionic conductivity of 15 mS/cm at 180 C.

**11:27AM S33.00002 The role of tortuosity on ion conduction in block copolymer electrolyte thin films<sup>1</sup>**, YU KAMBE, University of Chicago, CHRISTOPHER G. ARGES, PAUL F. NEALEY, University of Chicago / Argonne National Laboratory — This talk discusses the role of grain tortuosity on ion conductivity in block copolymer electrolyte (BCE) thin films. In particular, we studied lamellae forming BCEs with both domains oriented perpendicular to the substrate surface and connected directly from one electrode to another – i.e., tortuosity of one. The BCE is composed of ion-conducting, poly(2-vinyl n-methylpyridinium) blocks and non-ionic polystyrene blocks. Prior to creating the BCE, the pristine block copolymer, poly(styrene-*b*-2-vinyl pyridine), was directly self-assembled (DSA) on topographical or chemical patterns via graphoepitaxy and chemoepitaxy. A chemical vapor infiltration reaction modified the P2VP block into positively charged, fixed quaternary ammonium groups paired with mobile counteranions. The graphoepitaxy process utilized topographical interdigitated gold nanoelectrodes (100s of nanometers spacing between electrodes) created via e-beam lithography. Alternatively, chemical patterns had gold electrodes incorporated into them with 10s to 100s of microns spacing using conventional optical lithography. The interdigitated gold electrodes enabled in-plane ion conductivity measurements of the DSA BCEs to study the role of grain tortuosity on ion conductivity.

**11:39AM S33.00003 Building non-tortuous ion-conduction pathways using self-assembled block copolymers**, ONNURI KIM, MOON JEONG PARK, Pohang Univ of Sci & Tech — Ion-containing polymers with self-assembled morphologies are becoming important ingredients of a wide range of electrochemical devices such as lithium-ion batteries, fuel cells and electroactive actuators. Although several studies have reported the relationship between morphologies and ion transport properties of such polymers, the most of quantitative analysis have been limited to two-dimensional morphologies as they occupy a large window of the phase diagrams. In present study, we investigated the effects of morphology on the ion transport efficiency with a focus on three-dimensional symmetry. A range of three-dimensional self-assembled morphologies, i.e., ill-defined cubic, orthorhombic network (O<sup>70</sup>), and face-centered cubic phases (fcc) were achieved for a single sulfonated block copolymer upon the addition of non-stoichiometric ionic liquids. The type of three-dimensional lattice was found out to play a crucial role in determining the ion transport properties of composite membranes, where the most efficient ion-conduction was demonstrated for fcc phases with lowest tortuosity of 1 over orthorhombic networks phases (tortuosity:1.5). This intriguing result suggests a new avenue to designing polymer electrolytes with improved transport properties.

**11:51AM S33.00004 Nanostructured anion conducting block copolymer electrolyte thin films<sup>1</sup>**, CHRISTOPHER ARGES, YU KAMBE, PAUL NEALEY, University of Chicago/Argonne National Laboratory — Lamellae forming block copolymer electrolyte (BCE) thin-films with perpendicular aligned orientation were registered with high fidelity over large areas via a self-assembly process followed by a novel chemical vapor infiltration reaction (CVIR) technique. In this scheme, poly(styrene-*b*-2-vinyl pyridine) (PS<sub>6</sub>P2VP) block copolymers were self-assembled with perpendicular orientations on neutral chemical brushes using solvent vapor annealing. The ionic groups were selectively introduced into the P2VP block via a Menshutkin reaction that converted the nitrogen in the pyridine to n-methylpyridinium - anion carrier groups. FTIR-ATR and XPS tools confirmed the formation of the aforementioned ionic moieties post CVIR process and structure imaging tools (e.g., SEM and AFM imaging, GI-SAXS and RSOXs) established that incorporation of the ionic groups did not alter the self-assembled nanostructured films nor did subsequent ion-exchange processes. Electrochemical impedance spectroscopy determined the in-plane ion conductivity of different counteranions in the BCE thin films and alteration to the symmetry of the block copolymer film substantially improved (or hindered) BCE ion conductivity if the P2VP block's volume fraction was slightly greater than (or less than) 0.5.

**12:03PM S33.00005 Surface Structure of Thin Films of Multifunctional Ionizable Copolymers<sup>1</sup>**, ANURADHI WICKRAMASINGHE, DVORA PERAHIA, Clemson University — Phase segregation results in a rich variety of structures in co-polymers where interfacial forces often dominate the structure of thin films. Introduction of ionizable segments often drives the formation of compounded structures with multiple blocks residing at the interfaces. Here we probe thin films, 40-50nm, of an A-B-C-B-A co-polymer where C is a randomly sulfonated polystyrene with sulfonation fractions of 0, 26 and 52 mole %, B is poly (ethylene-*r*-propylene), and A is poly (t-butyl styrene) as the sulfonation level and temperature are varied using Neutron Reflectivity AFM, and surface tension measurements. As cast films form layers with both hydrophobic blocks dominating the solid and air interfaces and the ionizable block segregating to the center. Following annealing at 170°C, above T<sub>g</sub> of styrene sulfonate, the films coarsen, with surface aggregation dominating the structure, though interfacial regions remain dominated by the hydrophobic segments. We show that in contrast to non-ionic co-polymers, formation of micelles dominated the structure of these ionic structured films.

**12:15PM S33.00006 Effects of repeated wet/dry cycling on the structure and performance of sulfonated pentablock copolymer membranes.**, PHUC TRUONG, GILA STEIN, university of houston — Sulfonated block copolymers have shown potential as membranes for water purification. However, the performance of these materials under cyclic wet/dry conditions is not well understood. We measured the membrane structure, mechanical properties, and water vapor transport rates in a sulfonated pentablock copolymer as a function of the number of wet/dry cycles. The polymer is synthesized with an ABCBA block sequence, where A is poly(t-butyl styrene), B is poly(hydrogenated isoprene), and C is poly(styrene sulfonate). The ion exchange capacity is 2 meq, and membranes were prepared by coating from a solution. Using small angle X-ray scattering, we find the structure in as-prepared membranes resembles disordered micelles, and the characteristic length scale swells slightly with each wet/dry cycle. This lattice swelling is likely constrained by the glassy end-blocks. We also detect a lower yield point and less overall tensile strength with repeated cycling. Water vapor transport rates vary with the number of wet/dry cycle, however no specific trend was observed.

**12:27PM S33.00007 Influence of Substrate on PFSA Thin-Film Morphology** , PETER DUDENAS, UC Berkeley, AHMET KUSOGLU, SINGANALLUR VENKATAKRISHNAN, ALEXANDER HEXEMER, ADAM WEBER, Lawrence Berkeley Natl Lab — Perfluorosulfonic-acid (PFSA) ionomers are the most commonly used electrolyte for polymer-electrolyte fuel cells (PEFCs) due to their high conductivity and good electrochemical and thermo-mechanical stability. A PFSA's chemical structure is comprised of a polytetrafluoroethylene (PTFE) backbone that provides mechanical and chemical stability, and randomly placed tethered perfluoroether side chains terminated with sulfonic-acid groups, which impart its remarkable proton-conduction capabilities. Controlled by substrate/film interactions, long-range structural order in PFSAs change when confined to thin films (<200 nm), as does its transport and mechanical properties. The nature of change is substrate dependent, where stronger interactions create a more dramatic change in properties. In this talk, grazing-incidence c-Ray scattering (GIXS) is used to demonstrate induced structural order on metallic substrates, which is not present on other substrates like silicon and carbon. The higher degree of ordering is correlated with measured changes in mechanical properties for the thin films. Scattering data is also modeled using the recently released program high-performance GISAXS (HipGISAXS), to estimate the size and distribution of the ordered domains. -/a

**12:39PM S33.00008 Structure and Properties of a Semi-crystalline Cationic Polymer for Anion Exchange Membranes** , FREDERICK BEYER, SAMUEL PRICE, ALICE SAVAGE, XIAOMING REN, US Army Research Laboratory, INSANE MEMBRANES COLLABORATION — Nafion has long been studied in order to understand its combination of good mechanical properties, chemical resistance, and excellent charge transport characteristics. In the past decade, uncertainty regarding the morphological behavior of Nafion has largely been resolved, allowing researchers to mimic and improve on the structure of this material. In this presentation, work to incorporate key characteristics of Nafion into a model cation-containing polymer will be described. In these new materials, semi-crystalline atactic poly(norbornene) is used to introduce good mechanical properties to anion-exchange membranes, analogous to the PTFE crystallites in Nafion. The ether linkages between the charged species and backbone are also utilized to place the cationic species (trimethylamine) in our materials into a mechanically soft environment. The resulting polymer shows some characteristics that are similar to those of Nafion. In this presentation, the synthesis, alkaline stability, mechanical properties, morphological behavior and charge transport properties will all be described.

**12:51PM S33.00009 Exploring the Parameters Controlling the Crystallinity-Conductivity Correlation of PFSA Ionomers** , AHMET KUSOGLU, SHOUWEN SHI, ADAM WEBER, Lawrence Berkeley Natl Lab — Perfluorosulfonic-acid (PFSA) ionomers are the most commonly used solid-electrolyte in electrochemical energy devices because of their remarkable conductivity and chemical/mechanical stability, with the latter imparted by their semi-crystalline fluorocarbon backbone. PFSAs owe this unique combination of transport/stability functionalities to their phase-separated morphology of conductive hydrophilic ionic domains and the non-conductive hydrophobic backbone, which are connected via pendant chains. Thus, phase-separation is governed by fractions of backbone and ionic groups, which is controlled by the equivalent weight (EW). Therefore, EW, along with the pendant chain chemistry, directly impact the conductive vs non-conductive regions, and consequently the interrelation between transport and stability. Driven by the need to achieve higher conductivities without disrupting the crystallinity, various pendant-chain chemistries have been developed. In this talk, we will report the results of a systematic investigation on hydration, conductivity, mechanical properties and crystallinity of various types and EWs of PFSA ionomers to (i) develop a structure/property map, and (ii) identify the key parameters controlling morphology and properties. It will be discussed how the pendant-chain and backbone lengths affect the conductivity and crystallinity, respectively. Lastly, the data set will be analyzed to explore universal structure/property relationships for PFSAs.

**1:03PM S33.00010 Water's Role in the Relaxation of Polyelectrolyte Complexes and Multilayers** , JODIE LUTKENHAUS, YANPU ZHANG, DARIYA REID, Texas AM University, HANNE ANTILA, EROL YILDIRIM, RAN ZHANG, MARIA SAMMALKORPI, Aalto University — In the last decade, evidence for an intriguing glass-transition-like phase transition has emerged in hydrated polyelectrolyte complex precipitates and polyelectrolyte multilayers. Although the transition is weak, it stimulates large-scale macroscopic phenomena such as multilayer shrinking, swelling, and rearrangement. To date, there is not a clear consensus on what causes this transition, although a growing body of evidence indicates that salt and water are key parameters. Recent simulations of hydrated polyelectrolyte complexes show that water molecules form a stabilizing hydrogen-bonded network and that this network is disrupted by dehydration of the polyanion at the thermal transition, leading to segmental relaxation of polymer chains. If true, this would explain the transition's dependence on water and extrinsic compensation as well as its glass transition-like character. This talk will focus upon water's role in the transition, in which a strong dependence on hydration is observed. Quartz crystal microbalance with dissipation (QCM-D) and modulated differential scanning calorimetry (MDSC) are used to track the transition in polyelectrolyte complexes as a function of hydration.

**1:15PM S33.00011 Probing the mechanism of non-linear growth of polyelectrolyte multilayers** , VICTOR SELIN, Department of Materials Science & Engineering, Texas AM University, College Station, Texas 77843, USA, JOHN ANKNER, Spallation Neutron Source, Oak Ridge National Laboratory, Oak Ridge, Tennessee 37831, USA, SVETLANA A. SUKHISHVILI, Department of Materials Science & Engineering, Texas AM University, College Station, Texas 77843, USA — We report a study of the non-linear growth of electrostatically assembled polyelectrolyte multilayer films (PEM). PEM films were assembled by the layer-by-layer (LbL) technique using poly(methacrylic acid) as a polyanion and quaternized poly-2-(dimethylamino)ethyl methacrylate as a polycation. During film build-up, the thickness evolution as well as water uptake of PEM films were measured by in situ ellipsometry, whereas neutron reflectometry was used to probe the evolution of film internal structure as a function of deposition time. First, we found that during non-linear growth, films remain in a highly swollen hydrogel-like state, but the swelling ratio demonstrated an odd/even effect, with much larger hydration of the PEM when the terminal layer was the polycation. Second, while polycation chains were able to diffuse into the bulk of the film with a diffusion constant several orders of magnitude lower than in their free, unbound state, polyanion invasion was limited to the film surface. The amounts of the polycation and the polyanion adsorbed per deposition cycle were also drastically different. We quantify chemical composition and water content in the film, and correlate these data with the depth polyelectrolyte chains penetrate within the film during PEM construction.

**1:27PM S33.00012 Effect of Aggregation on the Mechanical Properties of Ionomers from MD Simulations<sup>1</sup>** , JANANI SAMPATH, LISA M. HALL, The Ohio State University-Columbus — Ionomers are polymers with a small fraction of charged monomers; these bound ions, along with free counterions, tend to aggregate together strongly in the absence of solvent. Ionic aggregates can act like temporary cross-links, giving rise to interesting mechanical properties. We perform coarse-grained molecular dynamics simulations of ionomers with various spacings of charges along the chain, representing experimental precisely spaced, neutralized poly(ethylene-co-acrylic acid) materials. We calculate aggregate morphology, dynamics, and scattering profiles and study the systems during uniaxial tensile strain to understand how aggregate structure changes under deformation and affects mechanical properties. Anisotropic structure factors (parallel and perpendicular to the direction of pull) and visualization shows that the aggregates align, in qualitative agreement with experimental findings. Stress-strain curves at different strain rates are also obtained. A modification of the model to account for unneutralized acid groups by adjusting their Lennard-Jones interaction strengths with each other and with ionic groups will also be discussed.

**1:39PM S33.00013 Structure and ionic conductivity of block copolymer electrolytes over a wide salt concentration range**, MAHATI CHINTAPALLI, THAO LE, UC Berkeley, NAVEEN VENKATESAN, UC Santa Barbara, JACOB THELEN, ADRIANA ROJAS, NITASH BALSARA, UC Berkeley — Block copolymer electrolytes are promising materials for safe, long-lasting lithium batteries because of their favorable mechanical and ion transport properties. The morphology, phase behavior, and ionic conductivity of a block copolymer electrolyte, SEO mixed with LiTFSI was studied over a wide, previously unexplored salt concentration range using small angle X-ray scattering, differential scanning calorimetry and ac impedance spectroscopy, respectively. SEO exhibits a maximum in ionic conductivity at twice the salt concentration that PEO, the homopolymer analog of the ion-containing block, does. This finding is contrary to prior studies that examined a more limited range of salt concentrations. In SEO, the phase behavior of the PEO block and LiTFSI closely resembles the phase behavior of homopolymer PEO and LiTFSI. The grain size of the block copolymer morphology was found to decrease with increasing salt concentration, and the ionic conductivity of SEO correlates with decreasing grain size. Structural effects impact the ionic conductivity-salt concentration relationship in block copolymer electrolytes. SEO: polystyrene-*block*-poly(ethylene oxide); also PS-PEO LiTFSI: lithium bis(trifluoromethanesulfonyl imide)

**1:51PM S33.00014 Role of Acid Functionality and Placement on Morphological Evolution and Strengthening of Acid Copolymers**, LURI ROBERT MIDDLETON, ERIC SCHWARTZ, KAREN WINEY, University of Pennsylvania — Functional polymers with specific interactions produce hierarchical morphologies that directly impact mechanical properties. We recently reported that the formation of acid-rich layered morphologies in precise poly(ethylene-co-acrylic acid) copolymers improves tensile strength. We now explore the generality of this phenomenon through variations in pendant acid chemistries, acid content and precision in placement of acid groups in polyethylene-based copolymers. In situ X-ray scattering measurements during tensile deformation reveal that the precision in acid group placement is critical to forming well-defined layered morphologies. This phenomenon was observed in both semi-crystalline and amorphous precise acid copolymers with varied acid chemistries (acrylic, geminal acrylic and phosphonic acids). Compositionally identical polymers but with pseudo random acid placement do not form layered morphologies. Acid chemistry and acid content influence morphological evolution predominately through modification of the copolymer Tg and crystallinity. Our results indicate that hierarchical layered structures, commensurate with improved mechanical properties, form in the presence of uniformity in chemical structure and sufficient chain mobility to strongly align during deformation.

**2:03PM S33.00015 States of Salt Water in Polyampholyte Hydrogel Networks at Ice Forming Temperatures**, HYUN-JOONG CHUNG, XINDA LI, JANET A.W. ELLIOTT, Univ of Alberta — The behavior of water in polymers, including ice formation, is of increasing interest. For example, one can achieve improved longevity of water-borne polymeric coatings and aqueous electrolytes that operate at low temperature by understanding the polymer-water interaction. Water molecules that are bound to hydrophilic polymer backbones are known to be non-freezable at extremely low temperatures such as -100C, whereas non-bound water is still freezable at higher temperatures. Polyampholyte, which contains both cationic and anionic groups in its backbone, is an interesting class of anti-fouling coating material with a hygroscopic nature and self-healing ability. In real operational condition, for example in maritime petroleum production in the arctic climate, multiple species of salt ions can complicate the ice formation, but their effect has not been exhaustively studied. Using a random copolymer of sodium p-styrenesulphonate (NaSS) and 3-(methacryloylamino)propyl-trimethylammonium chloride as a model system to study the phase behavior of NaCl salt in the hydrogel, this work presents (i) intriguing mechanical and electrical properties of polyelectrolytes at low temperature (<-20C), (ii) differential scanning calorimetry studies on the effects of salt concentration, polymer chain density, degree of polymerization, and (iii) effect of dialysis on microstructure and phase water behavior in the polyampholyte hydrogel.

**11:15AM S34.00001 Point-to-set correlations and rugged landscapes**, SHO YAJIDA, Duke University, LUDOVIC BERTHIER, Université de Montpellier, PATRICK CHARBONNEAU, Duke University, GILLES TARJUS, Université Pierre et Marie Curie — Upon approaching the glass transition a liquid gets sluggish without obvious structural changes. The glassy slowdown is instead attributed to an increasing roughness in the underlying free-energy landscape. Cavity point-to-set (PTS) correlations are real-space tools for characterizing the evolution of this rugged landscape, but their measurement is a serious computational challenge. Here, we first describe how advanced Monte Carlo techniques can be used to dramatically enhance sampling in cavities, extending the range over which PTS correlations can be obtained. By suitably generalizing the notion of PTS correlations to capture any type of growing order in liquids, be it local or amorphous, we then establish a criterion for distinguishing a dynamical slowdown due to critical ordering from one due to glassiness. These methodological advances shed a new light on the interplay between structure and dynamics in model glass formers, and tie in with recent field-theoretic results about the nature of jumps between metastable minima in rough landscapes.

**11:27AM S34.00002 Evidence for a second-order phase transition to a low-entropy glass**, C. PATRICK ROYALL, FRANCESCO TURCI, University of Bristol, THOMAS SPECK, Johannes Gutenberg-Universität Mainz — The physics underlying the glass transition is a major outstanding. Central to its solution is whether there is some kind of thermodynamic transition to an ideal glass, a disordered state with extremely low entropy, or whether in principle a liquid may be supercooled to arbitrary low temperature. Among the challenges that lie in tackling the glass transition are the immense timescales involved. Computer simulation, which might otherwise be able to pick up hints of a thermodynamic transition is limited by the small time-window over which a liquid can be equilibrated. Here we address this challenge using trajectory sampling in a system undergoing a first order nonequilibrium phase transition to a glassy state rich in low-energy geometric motifs. Extrapolation to equilibrium indicates that the transition would occur at a similar temperature at which the ideal glass transition is expected from extrapolation of dynamic and thermodynamic measurements. We further reweight nonequilibrium data to equilibrium leading to configurations representative of extremely low temperature, which indicate a transition to a low energy state at the ideal glass transition temperature. We thus interpret the ideal glass transition as the lower critical endpoint of this nonequilibrium transition.

**11:39AM S34.00003 Softness Correlations Across Length Scales<sup>1</sup>**, ROBERT IVANCIC, University Of Pennsylvania, AMIT SHAVIT, Thomson Reuters, JENNIFER RIESER, SAMUEL SCHOENHOLZ, University Of Pennsylvania, EKIN CUBUK, Harvard, DOUGLAS DURIAN, ANDREA LIU, ROBERT RIGGLEMAN, University Of Pennsylvania — In disordered systems, it is believed that mechanical failure begins with localized particle rearrangements. Recently, a machine learning method has been introduced to identify how likely a particle is to rearrange given its local structural environment, quantified by *softness*. We calculate the softness of particles in simulations of atomic Lennard-Jones mixtures, molecular Lennard-Jones oligomers, colloidal systems and granular systems. In each case, we find that the length scale characterizing spatial correlations of softness is approximately a particle diameter. These results provide a rationale for why localized rearrangements—whose size is presumably set by the scale of softness correlations—might occur in disordered systems across many length scales.

**11:51AM S34.00004 Onset of cooperative dynamics in equilibrium glass-forming metallic liquids**<sup>1</sup>, ABHISHEK JAISWAL, YANG ZHANG, Univ of Illinois - Urbana — Onset of cooperative dynamics has been observed in the metastable regime of many molecular liquids, colloids, and granular materials approaching their respective glass or jamming transition points. It is also considered to play a significant role in the emergence of slow dynamics. However, the nature of such dynamical cooperativity remains elusive in multicomponent metallic liquids characterized by complex many-body interactions and high mixing entropy. Herein, we report indications of the onset of cooperative dynamics in an equilibrium glass-forming metallic liquid (ZrCuNiAl). This is revealed by deviation of the experimentally measured mean diffusion coefficient from its high temperature Arrhenius behavior below  $T_o \approx 1300$  K, i.e., a crossover from uncorrelated dynamics above  $T_o$  to landscape-influenced correlated dynamics below  $T_o$ . The onset/crossover in this system is observed at approximately twice of its calorimetric glass transition temperature ( $T_g \approx 697$  K) and in the stable liquid phase, unlike many molecular liquids. Furthermore, we show the presence of such a dynamical onset phenomenon in ten other glass-forming metallic liquids, universally occurring at approximately twice of their  $T_g$  and in their liquid phases.

**12:03PM S34.00005 Differences in dynamic heterogeneity in strong and fragile glass formers**<sup>1</sup>, HANNAH STALEY, ELIJAH FLENNER, GRZEGORZ SZAMEL, Colorado State University — We study dynamic heterogeneity in a model strong glass former. We examine the spatial extent  $\xi_4^a(t)$  and the strength  $\chi_4^a(t)$  of the heterogeneity of the dynamics at two length scales  $a$ . One length scale corresponds to the nearest neighbor separation and the other length scale corresponds to the length scale of the tetrahedral network. We find that the dynamic correlation length  $\xi_4^a$  grows much slower with increasing relaxation time at both length scales than for model fragile glass formers. We also find that the dynamically correlated regions are more ramified for the strong glass former than for model fragile glass formers. However, we do find that Stokes-Einstein violation indicates a change in the character of the dynamic heterogeneities for the strong glass former and the fragile glass formers.

**12:15PM S34.00006 Correlating structural and dynamic fragility in glass-forming liquids**<sup>1</sup>, DMITRY VOYLOV, Univ of Tennessee, Knoxville, PHILIP GRIFFIN, University of Pennsylvania, BRANDON MERCADO, Yale University, JONG KEUM, Oak Ridge National Laboratory, VLADIMIR NOVIKOV, ALEXEI SOKOLOV, Univ of Tennessee, Knoxville — The glass transition was attracting wide interest over the last several decades, but still remains the topic of intensive research and discussions. One of the most intriguing and well-known observations is a drastic change of dynamic properties with only slight variations of structure upon cooling down to the glass transition temperature  $T_g$ . This has led many to believe that the changes of dynamics during approach to  $T_g$  have no structural signatures which would be significant and common to different types of glass-forming liquids. Here we demonstrate analysis of temperature dependence of the main diffraction peak in a static structure factor of various glass-formers. We show that the relative changes of its width with temperature correlates with fragility of these materials. This observation was analyzed using Adam-Gibbs approach establishing a connection between the structural and dynamical properties of glass-forming materials.

**12:27PM S34.00007 Aging and random-field magnetism in ferromagnet/antiferromagnet bilayers.**<sup>1</sup>, TIANYU MA, RYAN FREEMAN, XIANG CHENG, STEFAN BOETTCHER, SERGEI URAZHDIN, Emory University — Exchange interaction at the interface between a ferromagnet (F) and an antiferromagnet (AF) results in a random effective exchange field acting on both F and AF [1], which can produce complex equilibrium and dynamical states. We utilized anisotropic magnetoresistance to look for signatures of such states in epitaxial Py=Permalloy/Fe50Mn50 and polycrystalline CoO/Py bilayers. For thin AF layers, both systems exhibit slow cooperative aging indicative of a complex glassy state [2]. Aging follows the same small power-law or logarithmic dependence and is observed over a wide range of temperatures and fields, suggesting a universal aging mechanism. Glassy relaxation is not observed at any temperature for AF thickness above 3.5nm. We argue that these observations are inconsistent with the usual “granular” and “domain-state” models of F/AF systems. We discuss the implications of our results for the random field magnetism, and the relationship between the dimensionality and the topological properties of magnetic systems.

**12:39PM S34.00008 Aging in the two-dimensional random-field systems**<sup>1</sup>, XIANG CHENG, TIANYU MA, SERGEI URAZHDIN, STEFAN BOETTCHER, Department of Physics, Emory University — Random fields introduced into the classical Ising and Heisenberg spin models can roughen the energy landscape, leading to complex nonequilibrium dynamics. The effects of random fields on magnetism have been previously studied in the context of dilute antiferromagnets (AF), impure substrates, and magnetic alloys [1]. We utilized random-field spin models to simulate the observed magnetic aging in thin-film ferromagnet/antiferromagnet (F/AF) bilayers. Our experiments show extremely slow cooperative relaxation over a wide range of temperatures and magnetic fields [2]. In our simulations, the experimental system is coarse-grained into a random field Ising model on a 2D square lattice. Monte Carlo simulations indicate that aging processes may be associated with the glassy evolution of the magnetic domain walls, due to the pinning by the random fields. The scaling of the simulated aging agrees well with experiments. Both are consistent with either a small power-law or logarithmic dependence on time. We further discuss the topological effects on aging due to the dimensional crossover from the Ising to the Heisenberg regime.

**12:51PM S34.00009 Qualitative change in structural dynamics of some glass-forming systems**<sup>1</sup>, VLADIMIR NOVIKOV, ALEXEI SOKOLOV, Univ of Tennessee, Knoxville — Analysis of temperature dependence of structural relaxation time  $\tau(T)$  in supercooled liquids revealed a qualitatively distinct feature - a sharp, cusp-like maximum in the second derivative of  $\log \tau_\alpha(T)$  at some  $T_{max}$ . It suggests that the super-Arrhenius temperature dependence of  $\tau_\alpha(T)$  in glass-forming liquids eventually crosses over to an Arrhenius behavior at  $T < T_{max}$ , and there is no divergence of  $\tau_\alpha(T)$  at non-zero  $T$ .  $T_{max}$  can be above or below  $T_g$ , depending on sensitivity of  $\tau(T)$  to change in liquid's density quantified by the exponent  $\gamma$  in the scaling  $\tau_\alpha(T) \sim \exp(A/T\rho^{-\gamma})$ . These results might turn the discussion of the glass transition to the new avenue – the origin of the limiting activation energy for structural relaxation at low  $T$ .

**1:03PM S34.00010 Percolation Thresholds in Angular Grain media: Drude Directed Infiltration**, DONALD PRIOUR, Youngstown State University — Pores in many realistic systems are not well delineated channels, but are void spaces among grains impermeable to charge or fluid flow which comprise the medium. Sparse grain concentrations lead to permeable systems, while concentrations in excess of a critical density block bulk fluid flow. We calculate percolation thresholds in porous materials made up of randomly placed (and oriented) disks, tetrahedrons, and cubes. To determine if randomly generated finite system samples are permeable, we deploy virtual tracer particles which are scattered (e.g. specularly) by collisions with impenetrable angular grains. We hasten the rate of exploration (which would otherwise scale as  $n_{\text{coll}}^{1/2}$  where  $n_{\text{coll}}$  is the number of collisions with grains if the tracers followed linear trajectories) by considering the tracer particles to be charged in conjunction with a randomly directed uniform electric field. As in the Drude treatment, where a succession of many scattering events leads to a constant drift velocity, tracer displacements on average grow linearly in  $n_{\text{coll}}$ . By averaging over many disorder realizations for a variety of systems sizes, we calculate the percolation threshold and critical exponent which characterize the phase transition.

**1:15PM S34.00011 Influence of Hydrogen Bonding on the Kinetic Stability of Vapor Deposited Triazine Glasses**, AUDREY LAVENTURE, University of Montreal; University of Wisconsin-Madison, ANKIT GUJRAL, University of Wisconsin-Madison, OLIVIER LEBEL, Royal Military College of Canada, CHRISTIAN PELLERIN, University of Montreal, MARK D. EDIGER, University of Wisconsin-Madison — Physical vapor deposition (PVD) can produce glasses with enhanced kinetic stability, high density and anisotropy. However, the influence of hydrogen bonding on these properties has not been fully explored. We vapor deposit a series of triazine derivatives containing functional groups with different H-bonding capability, i.e. NHMe (H-bond donor), OMe (H-bond acceptor) and Et (none) using a wide range of substrate temperatures, from 0.60 to 1.05T<sub>g</sub>. PVD glasses of the NHMe derivative have inferior kinetic stability compared to its OMe and Et analogues. This behavior can be rationalized by the higher average number of bonded NH per molecule found in PVD glasses of the NHMe derivative, as quantified by infrared spectroscopy (IR). Despite this difference in H-bonding, IR and wide angle X-ray scattering reveal that all three compounds show a tendency to orient parallel to the substrate at low substrate temperatures. Our results support the hypothesis that strong intermolecular interactions, such as H-bonds, can hinder mobility of the molecules at the interface and thus limit their possibility to sample the potential energy landscape to produce stable glasses.

**1:27PM S34.00012 Thermal properties of composite materials: a complex systems approximation**<sup>1</sup>, J. L. CARRILLO, BEATRIZ BONILLA, J. J. REYES, Instituto de Física BUAP, VICTOR DOSSETTI, CIDS- BUAP — We propose an effective media approximation to describe the thermal diffusivity of composite samples made of polyester resin and magnetite inclusions. By means of photoacoustic spectroscopy, the thermal diffusivity of the samples were experimentally measured. The volume fraction of the inclusions was systematically varied in order to study the changes in the effective thermal diffusivity of the composites. For some samples, a static magnetic field was applied during the polymerization process, resulting in anisotropic inclusion distributions. Our results show a significant difference in the thermal properties of the anisotropic samples, compared to the isotropic randomly distributed. We correlate some measures of the complexity of the inclusion structure with the observed thermal response through a multifractal analysis. In this way, we are able to describe, and at some extent predict, the behavior of the thermal diffusivity in terms of the lacunarity and other measures of the complexity of these samples [1]. [1] F. **1:39PM S34.00013 Preparing anisotropic glasses from structural analogs of liquid crystal formers by physical vapor deposition**, JARITZA GOMEZ, MARK EDIGER, University of Wisconsin - Madison — Physical vapor deposition (PVD) can be used to tune molecular orientation in glasses by depositing at substrate temperatures ( $T_{\text{substrates}}$ ) just below the glass transition temperature ( $T_g$ ). Glasses of a smectic A liquid crystal (LC) former, itraconazole, deposited at a  $T_{\text{substrate}} = T_g$  have been shown to inherit the structure of the equilibrium smectic liquid and orient nearly perpendicular to the substrate. Here we report the deposition of glasses prepared from molecules that are structural analogs to known LC formers: posaconazole and a functionalized perylenemonoimide (PMI), analogs to itraconazole and a previously reported columnar LC, respectively. Spectroscopic ellipsometry and infrared spectroscopy are used to characterize average molecular orientation in the as-deposited glasses. Surprisingly, we find that molecular orientation in glasses of posaconazole deposited at different  $T_{\text{substrates}}$  does not follow the previously observed trends for linear molecules without LC states, but more closely follows itraconazole. In addition, we find that glasses deposited at  $T_g$  are not isotropic, even though liquid-cooled glasses do not show preferential molecular orientation. Similarly, glasses from a functionalized PMI, structural analog to a known columnar LC, show molecular orientation at  $T_{\text{substrate}} = T_g$ . These results may provide insights into the mechanism by which physical vapor deposition can produce glasses with tunable molecular orientation.

**1:51PM S34.00014 Fragility of Ionic Liquids Measured by Flash Differential Scanning Calorimetry**, RAN TAO, NIST - Natl Inst of Stds & Tech, ESHAN GURUNG, EDWARD L. QUITEVIS, SINDEE L. SIMON, Texas Tech University — Ionic liquids are a class of materials that possess attractive properties. They generally have low rates of crystallization due to their bulky and asymmetrical ion structure, and are often considered as good glass-forming materials. In this work, a series of imidazolium-based ionic liquids with varying functionalities from aliphatic to aromatic groups and a fixed anion are characterized using fast scanning differential scanning calorimetry. The limiting fictive temperature  $T_f^*$ , which is equivalent to the glass transition temperature  $T_g$ , is measured on heating as a function of cooling rate using Flash differential scanning calorimetry. Different calculation methods are employed and compared for the determination of  $T_f^*$ . The dynamic fragility is obtained for the series of ionic liquids, and using this data along with a compilation of data from the literature reveals the relationship between molecular structure and fragility for ionic liquids.

**2:03PM S34.00015 Generating tunable structures in glassy materials: Smectic-like layering in glasses of a liquid crystal system prepared by vapor deposition**, ANKIT GUJRAL, JARITZA GOMEZ, JING JIANG, CHENGBIN HUANG, University of Wisconsin-Madison, KATHRYN O'HARA, University of California Santa Barbara, MICHAEL TONEY, Stanford Synchrotron Radiation Lightsource, MICHAEL CHABINYC, University of California Santa Barbara, LIAN YU, MARK EDIGER, University of Wisconsin-Madison — Anisotropic packing, particularly in highly ordered liquid crystalline configurations, has been shown to be useful in organic electronic and optoelectronic applications. In this work, vapor deposited glasses of a model smectic liquid crystal-forming molecule, itraconazole, are investigated. The films are characterized using x-ray scattering, FTIR and spectroscopic ellipsometry, and are found to exhibit unprecedented structural and optical anisotropy for a macroscopically homogeneous solid. A smectic-like layered structure is observed in the glasses that are prepared by depositing the glass at a substrate temperature during deposition ( $T_{\text{sub}}$ ) maintained below the glass transition temperature,  $T_g$ , of the molecule. The layer spacing, and the associated average tilt angle of the molecules, is found to be tunable as a function of  $T_{\text{sub}}$ . The layer spacing reduces by 16% as  $T_{\text{sub}}$  is lowered. These features are retained in the films when heated to at least  $T_g$  of the molecule.

**11:15AM S35.00001 Fluid flows created by swimming bacteria drive self-organization in confined suspensions**, ENKELEIDA LUSHI, Brown University, HUGO WIOLAND, Institut Jacques Monod, Paris 7 Diderot, RAYMOND GOLDSTEIN, DAMTP, University of Cambridge — Concentrated suspensions of micro-swimmers can display intricate self-organized spatiotemporal patterns on scales larger than those of the individual motile units. The collective dynamics of swimming microorganisms exhibits a complex interplay with the surrounding fluid: the motile cells stir the fluid, which in turn can reorient and advect them. This feedback loop can result in long-range interactions between the cells. We present a computational model that takes into account these cell-fluid interactions and cell-cell forces and that predicts counterintuitive cellular order driven by long-range flows. The predictions are confirmed by new experiments with *Bacillus Subtilis* bacteria. Simulations and experiments show that if the micro-swimmers are confined inside thin cylindrical chambers the suspension self-organizes into a stable swirling vortex. If the micro-swimmers are confined in thin racetracks, a persistent unidirectional stream can emerge. Both these phenomena emerge as a result of the complex interplay between the swimmers, the specific confining boundaries and the fluid flow.

**11:27AM S35.00002 Fluid flow in monolayers: Cells under pressure**, KYLE SCHULZE, STEVEN ZEHNDER, GREG SAWYER, THOMAS ANGELINI, University of Florida — Number density fluctuations are intimately tied to collective behavior in particulate soft matter and active matter systems, including tissue cell monolayers. In cell monolayers, there is no free space between cells, so density fluctuations must involve either out of plane motion, or cell volume fluctuations. Recent work has shown that cells fluctuate in volume to accommodate collective density fluctuations, and that fluid moves between cells in this process. However, measurements of the resistance to this flow with controlled applied pressures have never been performed. Here we apply pressure to local regions in cell monolayers with an indentation instrument mounted on an inverted microscope. While simultaneously measuring contact area, indentation depth, and applied force as a function of time we determine a compression modulus and a permeability of cells. We find that cells are highly permeable, and that cytoskeleton-generated stresses are large enough to drive fluid from cell to cell as they spontaneously fluctuate in volume.

**11:39AM S35.00003 Hydrodynamic interactions and their role on the dynamics of bacterial predators.**<sup>1</sup>, HOSSEIN JASHNSAZ, Physics Department, IUPUI, Indianapolis, IN 46202, MOHAMMED AL JUBOORI, Biomedical Engineering, IUPUI, Indianapolis, IN 46202, COREY WEISTUCH, Department of Applied Mathematics and Statistics, Stony Brook University, Stony Brook, NY 11794, TYLER NGUYEN, Stark Neurosciences Research Institute, IUSM, Indianapolis, IN 46202, NICK MILLER, Biomedical Engineering, IUPUI, Indianapolis, IN 46202, VIKTORIA MEYERHOFF, Mechanical Engineering, IUPUI, Indianapolis, IN 46202, KYLE PROCTOR, BRYAN MCCOY, Biological Chemistry, IUPUI, Indianapolis, IN 46202, STEPHANIE PERKINS, GREGORY ANDERSON, Biology Department, IUPUI, Indianapolis, IN 46202, STEVE PRESSE, Physics Department, IUPUI, Indianapolis, IN 46202 — We consider the effects of hydrodynamics on the behavior of bacterial predators searching for bacterial prey. Experimentally, we find that bacterial predators respond to external flow fields in addition to responding to their own self-generated flow fields neighboring surfaces and finite boundaries. We will discuss the implications of this finding on bacterial hunting strategies.

**11:51AM S35.00004 Non-homogeneous flow profiles in sheared bacterial suspensions**, DEVRANJAN SAMANTA<sup>1</sup>, XIANG CHENG<sup>2</sup>, Univ of Minn - Minneapolis — Bacterial suspensions under shear exhibit interesting rheological behaviors including the remarkable superfluidic state with vanishing viscosity at low shear rates. Theoretical studies have shown that such superfluidic state is linked with non-homogeneous shear flows, which are induced by coupling between nematic order of active fluids and hydrodynamics of shear flows. However, although bulk rheology of bacterial suspensions has been experimentally studied, shear profiles within bacterial suspensions have not been explored so far. Here, we experimentally investigate the flow behaviors of *E. coli* suspensions under planar oscillatory shear. Using confocal microscopy and PIV, we measure velocity profiles across gap between two shear plates. We find that with increasing shear rates, high-concentration bacterial suspensions exhibit an array of non-homogeneous flow behaviors like yield-stress flows and shear banding. We show that these non-homogeneous flows are due to collective motion of bacterial suspensions. The phase diagram of sheared bacterial suspensions is systematically mapped as functions of shear rates and bacterial concentrations. Our experiments provide new insights into rheology of bacterial suspensions and shed light on shear induced dynamics of active fluids.

**12:03PM S35.00005 Discontinuous fluidization transition in dense suspensions of actively deforming particles**, ELSÉN TJHUNG, Univ of Cambridge, LUDOVIC BERTHIER, CNRS, Université Montpellier — Collective dynamics of self-propelled particles at high density have been shown to display a glass-like transition with a critical slowing down of 2 to 4 orders of magnitude. In this talk, we propose a new mechanism of injecting energy or activity via volume fluctuations. We show that the behaviour of actively deforming particles is strikingly different from that of self-propelled particles. In particular, we find a discontinuous non-equilibrium phase transition from a flowing state to an arrested state. Our minimal model might also explain the collective dynamics in epithelial tissues. In particular, without needing self-propulsion or cell-cell adhesion, volume fluctuations of individual cells alone might be sufficient to give rise to an active fluidization and collective dynamics in densely packed tissues.

**12:15PM S35.00006 Superfluid-like dynamics in active vortex fluids**, JONASZ SLOMKA, JORN DUNKEL, Massachusetts Inst of Tech-MIT — Active biological fluids exhibit rich non-equilibrium dynamics and share striking similarities with quantum fluids, from vortex formation and magnetic ordering to superfluid-like behavior. Building on universality ideas, we have recently proposed a generalization of the Navier–Stokes equations that captures qualitatively the active bulk flow structures observed in bacterial suspensions. Here, we present new numerical simulations that explicitly account for boundary and shear effects. The theory successfully reproduces recent experimental observations of bacterial suspensions, including a superfluid-like regime of nearly vanishing shear viscosity. Our simulations further predict a geometry-induced ‘quantization’ of viscosity and the existence of excited states capable of performing mechanical work. It is plausible that these results generalize to a broad class of fluids that are subject to an active scale selection mechanism.

**12:27PM S35.00007 Swarming in viscous fluids: three-dimensional patterns in swimmer- and force-induced flows**<sup>1</sup>, YAO-LI CHUANG, MARIA R. D'ORSOGNA, Dept. of Mathematics, CSUN & Dept. of Biomathematics, UCLA, TOM CHOU, Dept. of Biomathematics UCLA & Dept. of Mathematics, UCLA — Mathematical models of self-propelled interacting particles have reproduced various fascinating “swarming” patterns observed in natural and artificial systems. The formulation of such models usually ignores the influence of the surrounding medium in which the particles swarm. Here we develop from first principles a three-dimensional theory of swarming particles in a viscous fluid environment and investigate how the hydrodynamic coupling among the particles may affect their collective behavior. Specifically, we examine the hydrodynamic coupling among self-propelled particles interacting through “social” or “mechanical” forces. We discover that new patterns arise as a consequence of different interactions and self-propulsion mechanisms. Examples include flocks with prolate or oblate shapes, intermittent mills, recirculating peloton-like structures, and jet-like fluid flows that kinetically destabilize mill-like structures. Our results reveal possible mechanisms for three-dimensional swarms to kinetically control their collective behaviors in fluids.

<sup>1</sup>Supported by NSF DMS 1021818 & 1021850, ARO W1911NF-14-1-0472, ARO MURI W1911NF-11-10332

### 12:39PM S35.00008 Numerical study of the hydrodynamic interactions in an *E. coli* suspension

XINLIANG XU, LIPENG LAI, Beijing Computational Science Research Center, YI PENG, XIANG CHENG, Department of Chemical Engineering and Materials Science, University of Minnesota — The active suspension of *E. coli* displays many interesting non-equilibrium phenomena, e.g. “swarming” at high bacteria concentrations, and viscosity change under simple shear. To understand the microscopic mechanism underlying these phenomena requires detailed knowledge about the hydrodynamics within the suspension. Here we numerically study in detail the hydrodynamic interactions between a bacterium and an ellipsoid tracer at small separations, where the tracer can no longer be treated as a point-like particle that creates no disturbance to local flow field. We observed a significant drop in bacterium swimming velocity, in agreement with previous experimental study.

### 12:51PM S35.00009 Anomalous diffusion of an ellipsoid in quasi-2D active fluids<sup>1</sup>, YI PENG, OU

YANG, CHAO TANG, XIANG CHENG, Department of Chemical Engineering and Materials Science, University of Minnesota — Enhanced diffusion of a tracer particle is a unique feature in active fluids. Here, we studied the diffusion of an ellipsoid in a free-standing film of *E. coli*. Particle diffusion is linearly enhanced at low bacterial concentrations, whereas a non-linear enhancement is observed at high bacterial concentrations due to the giant fluctuation. More importantly, we uncover an anomalous coupling between the translational and rotational degrees of freedom that is strictly prohibited in the classical Brownian diffusion. Combining experiments with theoretical modeling, we show that such an anomaly arises from the stretching flow induced by the force dipole of swimming bacteria. Our work illustrates a novel universal feature of active matter and transforms the understanding of fundamental transport processes in microbiological systems.

### 1:03PM S35.00010 Non-monotonic size-dependent particle diffusion in active fluids<sup>1</sup>, ALISON

PATTESON, Univ of Pennsylvania, ARVIND GOPINATH, University of California, Merced, PAULO ARRATIA, University of Pennsylvania — We experimentally investigate the effect of particle size on the motion of passive polystyrene spheres in suspensions of *Escherichia coli*. Using particles covering a range of sizes from 0.6 to 39 microns, we probe particle dynamics at both short and long time scales. In all cases, the particles exhibit super-diffusive ballistic behavior at short times before eventually transitioning to diffusive behavior. Surprisingly, the long-time hydrodynamic effective diffusivity exhibits a peak in particle size; an anomalous response that is fundamentally different from classical thermal diffusion. Consistent with recent theory, we find that the active contribution to particle diffusion is controlled by a dimensionless parameter, the Peclet number. We propose a minimal model that allows us to predict the requirements for a peak in the diffusivity as well as the magnitude of the peak as a function of particle size and bacterial concentration. Our results have broad implications on characterizing active fluids using concepts drawn from classical thermodynamics.

<sup>1</sup>NSF-DMR-1104705 and NSF-CBET-1437482

### 1:15PM S35.00011 Hydrodynamics of spinning bacteria at a surface, RACHEL BENNETT, Univ of Pennsylvania,

RAMIN GOLESTANIAN, University of Oxford — Bacteria tethered to a surface by their flagellum show a variety of different spinning behaviors, including different angles made with the surface and rotation velocities. We have developed a hydrodynamic model to show that the different behaviors arise from several factors including the degree of flagellar constraint, the shape of the bacterium, the flexibility of the flagellar hook and the motor torque. Our minimal model produces the wide variety of behaviors observed in experiments and successfully predicts the detachment angle for bacteria with three different body curvatures.

### 1:27PM S35.00012 Mobile wedges in an active turbulent bath, ANDREAS KAISER, ANDREY SOKOLOV, Argonne

Natl Lab, HARTMUT LOWEN, Heinrich-Heine Universität Düsseldorf, IGOR S. ARONSON, Argonne Natl Lab — The motion of micro-wedges in a turbulent bacterial bath is explored using computer simulations with explicit modeling of the bacteria and experiments. We demonstrate that collective turbulentlike motion in a bacterial bath can power and steer the directed transport of mesoscopic carriers through the suspension. We will show that both polar ordering and swirl shielding inside the wedge yield an optimal transport velocity. Finally, we show the behavior of several wedges exposed to a bacterial bath.

### 1:39PM S35.00013 Entrainment dominates the interaction of microalgae with micron-sized objects, RAPHAEL JEANNERET, VASILY KANTSLER, MARCO POLIN, University of Warwick —

Swimming microorganisms usually navigate through fluids containing a variety of microparticles, with which they inevitably interact with important biological and ecological implications. Regarding the prokaryotic realm, it has been shown that the colloidal dynamics within bacterial suspensions is well described by a persistent random walk. As to the other major class of microorganisms, the eukaryotes, much less is known. By directly tracking polystyrene colloids in baths of the model puller-type alga *Chlamydomonas reinhardtii*, a pioneering work [1] has shown that they still behave diffusively asymptotically with diffusivities linearly increasing with the concentration. The values reported as well as the distribution of displacements having exponential tails are well explained theoretically when considering the hydrodynamic far-field contribution of the algae. However nothing has yet been described regarding the short range interactions that inevitably exist. In this work we show, by means of 3 different experiments, that the coarse-grained dynamics of the colloids is in fact dominated by very rare but large jumps due to entrainment by the algae leading to a total effective diffusion an order of magnitude higher than previously reported. [1] Leptos et al, PRL 103, 198103 (2009).

Session S36 GSOF: Soft Matter at Interfaces: Wetting and Thin Films 339 - Justin Burton, Emory University

### 11:15AM S36.00001 Quantifying stick-slip contact line motion of evaporating sessile droplets,

CLAY WOOD, JUSTIN PYE, JUSTIN BURTON, Department of Physics, Emory University — Sessile droplet evaporation often involves an apparent stick-slip motion of pinning and de-pinning of the drop's edge. The small forces and complex hydrodynamics at the contact line make this phenomena difficult to quantify, although easily observable. We have characterized the stick-slip motion on gold and glass surfaces with the use of a quartz crystal microbalance (QCM). We observe changes in both the resonant frequency and dissipation during droplet evaporation. Depositing a droplet onto this oscillating surface greatly decreases the frequency while the dissipation increases. Evaporation occurs in two stages; when the droplet's contact line is pinned to the surface, its contact angle decreases. Then, at a critical angle, the contact line is pulled over pinning points and continues to evaporate with a receding contact area. These stick-slip events appear in our data as a sharp increase in frequency, followed by a sharp decrease; simultaneously, the dissipation displays a single sharp peak. QCMs pre-cleaned in an oxygen plasma environment exhibited a significantly reduced occurrence and magnitude of these features. We interpret these features and quantify the forces involved in the stick-slip motion using a dynamic model of the QCM with additional surface forces at the contact line.

### **11:27AM S36.00002 High-precision measurements of molecular slip at a solid/liquid interface**

, JUSTIN PYE, CLAY WOOD, JUSTIN BURTON, Department of Physics, Emory University — As fluidic devices get smaller and measurements become more precise and stringent, the need to fully understand the dynamics at interfaces becomes more important. It is now clear that slip near an interface is common at the nanoscale in Newtonian liquids. In simple systems, there is a general trend to larger slip lengths for non-wetting liquid/solid combinations, but many conflicting measurements and interpretations remain. We have developed a novel differential technique using a quartz crystal microbalance (QCM) to measure slip lengths on various substrates. A drop of one liquid is grown on the QCM in the presence of a second, ambient liquid. By choosing the two liquids such that their bulk effects on the QCM frequency and dissipation are identical in the presence of no-slip, we are able to isolate anomalous boundary effects due to interfacial slip. Our data for water on gold (in undecane) are consistent with a slip length of 5nm (for water). A glass surface, wetted by both gold and undecane has also shown strongly anomalous results for the water-undecane pair. In addition to investigating other liquid pairs, future work will include extending this technique to surfaces with independently controllable chemistry and roughness, both of which are known to strongly affect interfacial hydrodynamics.

### **11:39AM S36.00003 Asymmetric and speed-dependent contact angle hysteresis and relaxation of a suddenly stopped moving contact line<sup>1</sup>**

, DONGSHI GUAN, YONG JIAN WANG, Hong Kong University of Science and Technology, ELISABETH CHARLAIX, Université Grenoble Alpes , PENG ER TONG, Hong Kong University of Science and Technology — We report direct atomic-force-microscope measurements of capillary force hysteresis and relaxation of a circular moving contact line (CL) formed on a long micron-sized hydrophobic fiber intersecting a water-air interface. The measured capillary force hysteresis and CL relaxation show a strong asymmetric speed dependence in the advancing and receding directions. A unified model based on force-assisted barrier-crossing is utilized to find the underlying energy barrier  $E_b$  and size  $\lambda$  associated with the defects on the fiber surface. The experiment demonstrates that the pinning (relaxation) and depinning dynamics of the CL can be described by a common microscopic frame-work, and the advancing and receding CLs are influenced by two different sets of relatively wetting and non-wetting defects on the fiber surface.

<sup>1</sup>Work supported in part by the Research Grants Council of Hong Kong SAR.

### **11:51AM S36.00004 Visualizing the shape of soft solid and fluid contacts between two surfaces**

, JONATHAN PHAM, FRANK SCHELLENBERGER, MICHAEL KAPPL, DORIS VOLLMER, HANS-JÜRGEN BUTT, Max Planck Institute for Polymer Research — The soft contact between two surfaces is fundamentally interesting for soft materials and fluid mechanics and relevant for friction and wear. The deformation of soft solid interfaces has received much interest because it interestingly reveals similarities to fluid wetting. We present an experimental route towards visualizing the three-dimensional contact geometry of either liquid-solid (i.e., oil and glass) or solid-solid (i.e., elastomer and glass) interfaces using a home-built combination of confocal microscopy and atomic force microscopy. We monitor the shape of a fluid capillary bridge and the depth of indentation in 3D while simultaneously measuring the force. In agreement with theoretical predictions, the height of the capillary bridge depends on the interfacial tensions. By using a slowly evaporating solvent, we quantify the temporal evolution of the capillary bridge and visualized the influence of pinning points on its shape. The position dependence of the advancing and receding contact angle along the three-phase contact line, particle-liquid-air, is resolved. Extending our system, we explore the contact deformation of soft solids where elasticity, in addition to surface tension, becomes an important factor.

**12:03PM S36.00005 Imbibition kinetics of spherical aggregates** , PASCAL HBRAUD, IPCMS/CNRS, DIDIER LOOTENS, SIKA, ALBAN DEBACKER, IPCMS/CNRS — The imbibition kinetics of a millimeter-sized aggregate of 300 nm diameter colloidal particles by a wetting pure solvent is studied. Three successive regimes are observed : in the first one, the imbibition proceeds by compressing the air inside the aggregate. Then, the solvent stops when the pressure of the compressed air is equal to the Laplace pressure at the meniscus of the wetting solvent in the porous aggregate. The interface is pinned and the aggregate slowly degases, up to a point where the pressure of the entrapped air stops decreasing and is controlled by the Laplace pressure of small bubbles. Depending on the curvature of the bubble, the system may then be in an unstable state. The imbibition then starts again, but with an inner pressure in equilibrium with these bubbles. This last stage leads to the complete infiltration of the aggregate.

**12:15PM S36.00006 Tracking single particles motion in shaken wet powder clusters** , JENNIFER WENZL, National Superconducting Cyclotron Laboratory, MSU, GUENTER K. AUERNHAMMER, LAURENT GILSON, Max-Planck Institute for Polymer Research, Mainz — In many industrial branches wet granulate powders, where the particles are connected via an additional binding liquid, are widely used. Ample investigated were model systems, where the binding liquid is homogeneously distributed, i.e. building a connecting capillary network. In contrast wet granulate model systems with an inhomogeneous liquid distribution have been rarely in focus of research. In this work a model system for wet powders was developed, which is suitable for 3D imaging with confocal microscopy. Fluorescent silica particles were immersed in a mixture of two immiscible liquids, one continuous and one binding liquid. In detail a wet powder cluster, where the binding liquid formed droplets was studied in 3D. During applying a mechanical load the motion of the powder particles and the binding liquid droplets was followed. Deformation of the binding liquid droplets led to an increase of its surface area and energy. When the droplet relaxed to an energetically more favored shape upon further cluster deformation, the sudden release of the stored surface energy led to complex powder particle and droplet motions. The model system illustrated the complex dynamics upon shaking, and showed that the binding liquid dominated the cluster dynamics on a local scale.

**12:27PM S36.00007 Force vs. extension of colloidal membranes<sup>1</sup>** , LEROY JIA, ROBERT PELCOVITS, THOMAS POWERS, Brown University, MARK ZAKHARY, ZVONIMIR DOGIC, Brandeis University — In experiments, disk-shaped colloidal membranes composed of long rod-like viruses will take on a twisted ribbon shape under the application of a diametric stretching force. We use an effective model valid for membranes with small twist penetration to study this phase transition and calculate the force necessary to stretch the membrane to a given extension. The model predicts that for small deformations, the force is linear with spring constant depending on the effective edge bending stiffness of the membrane, while for large extensions, the force is found to saturate to a constant value. Surprisingly, the force is not a monotonic function of the extension. Finally, we use simple numerical calculations to find a power law that accurately describes the critical stretch at which the membrane starts to twist, which may be used to estimate the value of unknown parameters by comparison with experimental data.

<sup>1</sup>We are grateful for support from the Brandeis Center for Bioinspired Soft Materials, NSFMRSEC, DMR-1420382.

### **12:39PM S36.00008 Thermal-mechanical behavior of self-assembled nanoparticle membranes**

, YIFAN WANG, SEAN MCBRIDE, University of Chicago, XIAO-MIN LIN, Argonne National Laboratory, HEINRICH JÄGER, University of Chicago — Monolayers composed of colloidal nanoparticles with a thickness of less than ten nanometers have remarkable mechanical strength and can suspend over micron-sized holes to form free-standing membranes. However, previous measurements on mechanical properties of these monolayers were typically carried out at room temperature. Here, we report the first systematic experimental study of the stiffness of free-standing nanoparticle membranes as a function of temperature. At room temperature and below, these membranes exhibit reversible changes in stiffness, which increases with temperature. At higher temperatures irreversible membrane relaxation was found. This work provides a better understanding of the sub-nanometer scale ligand interactions in self-assembled nanoparticle membranes, and opens up opportunities for using these membranes as thermal-mechanical devices.

**12:51PM S36.00009 Direct observation of critical adsorption on colloidal particles**, HONGYU GUO, ZHIYUAN WANG, C. E. BERTRAND, NIST - Natl Inst of Stds & Tech, PAUL DOUGLAS GODFRIN, University of Delaware, YUN LIU, NIST - Natl Inst of Stds & Tech — We report our direct measurements of critical adsorption on the surface of small spherical silica particles suspended in a binary mixture of lutidine and water, using small-angle neutron scattering (SANS). The surface concentration profile and excess adsorption are studied as functions of temperature, lutidine concentrations, and surface curvature. The profile shape agree with scaling laws. The adsorption associated with the profile shape is found to increase monotonically with increasing lutidine concentration and to decrease with increasing temperature. These observations are important to understand colloidal aggregation behaviors close to the critical point of a binary solvent.

**1:03PM S36.00010 Obtaining self-similar scalings in focusing flows**, JOSHUA DIJKSMAN, Wageningen University, SHOMEK MUKHOPADHYAY, Yale University, CAMERON GAEBLER, Harvey Mudd College, THOMAS WITELSKI, ROBERT BEHRINGER, Duke University — The surface structure of converging thin fluid films displays self-similar behavior, as was shown in the work by Diez et al [Q. Appl. Math 210, 155, 1990]. Extracting the related similarity scaling exponents from either numerical or experimental data is non-trivial. Here we provide two such methods. We apply them to experimental and numerical data on converging fluid films driven by both surface tension and gravitational forcing. In the limit of pure gravitational driving, we recover Diez' semi-analytic result, but our methods also allow us to explore the entire regime of mixed capillary and gravitational driving, up to entirely surface tension driven flows. We find scaling forms of smoothly varying exponents up to surprisingly small Bond numbers. Our experimental results are in reasonable agreement with our numerical simulations, which confirm theoretically obtained relations between the scaling exponents.

**1:15PM S36.00011 Visualizing Nanoscopic Topography and Patterns in Freely Standing Thin Films**, VIVEK SHARMA, YIRAN ZHANG, SUBINUR YILIXIATI, Chemical Engineering, University of Illinois at Chicago — Thin liquid films containing micelles, nanoparticles, polyelectrolyte-surfactant complexes and smectic liquid crystals undergo thinning in a discontinuous, step-wise fashion. The discontinuous jumps in thickness are often characterized by quantifying changes in the intensity of reflected monochromatic light, modulated by thin film interference from a region of interest. Stratifying thin films exhibit a mosaic pattern in reflected white light microscopy, attributed to the coexistence of domains with various thicknesses, separated by steps. Using Interferometry Digital Imaging Optical Microscopy (IDIOM) protocols developed in the course of this study, we spatially resolve for the first time, the landscape of stratifying freely standing thin films. We distinguish nanoscopic rims, mesas and craters, and follow their emergence and growth. In particular, for thin films containing micelles of sodium dodecyl sulfate (SDS), these topological features involve discontinuous, thickness transitions with concentration-dependent steps of 5-25 nm. These non-flat features result from oscillatory, periodic, supramolecular structural forces that arise in confined fluids, and arise due to complex coupling of hydrodynamic and thermodynamic effects at the nanoscale.

**1:27PM S36.00012 Out-of-contact elastohydrodynamic deformation due to lubrication forces.**<sup>1</sup>, YUMO WANG, CHARLES DHONG, JOELLE FRECHETTE, Johns Hopkins University — We characterize the spatiotemporal deformation of an elastic film during the radial drainage of fluid from a narrowing gap. Elastic deformation of the film takes the form of a dimple and prevents full contact to be reached. With thinner elastic film the stress becomes increasingly supported by the underlying rigid substrate, the dimple formation is suppressed, which allows the surfaces to reach full contact. We highlight the lag due to viscoelasticity on the surface profiles, and that for a given fluid film thickness deformation leads to stronger hydrodynamic forces than for rigid surfaces.

**1:39PM S36.00013 Approaching a flat boundary with a block copolymer coated emulsion drop: late stage drainage dynamics.**, DAMITH ROZAIRO, ANDREW CROLL, North Dakota State Univ — Understanding the dynamics of the formation and drainage of the thin fluid film that becomes trapped by a deformable droplet as it approaches another object is crucial to the advancement of many industrial and biomedical applications. Adding amphiphilic diblock copolymers, which are becoming more commonly used in drug delivery and oil recovery, only add to the complexity. Despite their increased use, little is known about how long polymer chains fill an emulsion drops interface or how the molecules influence hydrodynamic processes. We study the drainage dynamics of a thin water film trapped between mica and a diblock copolymer saturated oil droplet. Specifically, we examine several different polystyrene-b-poly(ethylene oxide) (PS-PEO) molecules self-assembled at a toluene-water interface using laser scanning confocal microscopy. Our experiments reveal that the molecular details of the polymer chains deeply influence the drainage times, indicating that they are not acting as a simple surfactant. The presence of the chains creates a much slower dynamic as fluid is forced to drain through an effective polymer brush, the brush itself determined by chain packing at the interface. We present a simple model which accounts for the basic physics of the interface.

**1:51PM S36.00014 Soft Levelling: Capillary Relaxation of a Thin Liquid Film on an Elastic Substrate**, MARCO RIVETTI, CHRISTINE LINNE, Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany, THOMAS SALEZ, MAXENCE ARUTKIN, ELIE RAPHAEL, UMR 7083 Gulliver, ESPCI and CNRS, PSL Research University, Paris, France, OLIVER BAEUMCHEN, Max Planck Institute for Dynamics and Self-Organization, Goettingen, Germany — A thin liquid film with non-zero curvature at its free surface spontaneously relaxes towards a flat configuration. The flow of this liquid film is driven by Laplace pressure gradients and it is resisted by viscosity. In the last few years the dynamics of this system has been studied experimentally, numerically and analytically. Inspired by recent progresses on the wetting behaviour of liquid droplets on soft substrates, we here consider the relaxation of a thin viscous film supported by an elastic foundation. We present experiments involving thin polystyrene films on polydimethylsiloxane substrates, where the dynamics of the liquid-air interface is monitored using an atomic force microscope. In this system, Laplace pressure gradients not only drive the flow but they also induce elastic deformations on the substrate. These deformations affect the flow and the shape of the liquid-air interface itself, giving rise to an original example of elasto-capillary interaction that is not mediated by the presence of a contact line. We show that the width of the profile scales with the time to the power 1/6, rather than 1/4 which has been observed on rigid substrates. A theoretical model that describes the coupled evolution of the elastic-liquid and liquid-air interfaces is also presented.

**2:03PM S36.00015 Slowing of Dynamics of Hydration Water Depends on Length Scale of Measurement**, JONATHAN NICKELS, Oak Ridge National Laboratory, JOHN ATKINSON, University of Guelph, SOULEYMANE DIALLO, STEFANIA PERTICAROLI, JOHN KATSARAS, Oak Ridge National Laboratory, JOHN DUTCHER, University of Guelph — The dynamics of hydration water associated with biomolecules is often slower than in bulk. We have used quasielastic neutron scattering (QENS) to study the dynamics of hydration water associated with soft colloidal, monodisperse phytylglycogen nanoparticles. The large water content of the phytylglycogen nanoparticles makes this an ideal system for investigations of hydration water in hydrophilic environments. We find that the hydration water translation is sub-diffusive, occurring, on average,  $\sim 5.8$  times slower than that of bulk water. Significantly, these data demonstrate a clear  $q$ -dependence in the measured retardation factor, implying a corresponding length scale dependence. This observation may help to reconcile the often-conflicting range of hydration water retardation factors reported in the literature using different experimental techniques.

**Session S37 GSOF: Liquid Crystals, Membranes, Micelles and Vesicles** 340 - L J Martinez-Miranda, University of Maryland, College Park

**11:15AM S37.00001 Tetratic, triatic and nematic liquid crystals on a complex plane<sup>1</sup>**, OKSANA MANYUHINA, MARK BOWICK, Syracuse University — Liquid crystals are elastic materials able to resolve geometric and topological frustration by creating disclinations, discontinuities in their continuous orientation field. The strength and the nature of disclinations depend on the symmetry of elements forming liquid crystal phase. Several examples of confined nematic (director field), triatic (Y-field) and tetratic (cross-field) liquid crystals will be considered to show that their ground state contains topological defects. Next, we analyze shape variation of the boundary, enclosing different defect textures. We argue that topological defects can capture essential features of macroscopic shape and relate it to microscopic order, providing a natural way to connect different length scales and to account for large deformations in soft and biological systems.

<sup>1</sup>Soft Matter Program of Syracuse University

**11:27AM S37.00002 Nano-electromechanical Rotation of Graphene and Giant Enhancement in Dielectric Anisotropy in a Liquid Crystal**, RAJRATAN BASU, DANIEL KINNAMON, ALFRED GARVEY, US Naval Academy — A nematic liquid crystal (LC) is doped with dilute concentrations of pristine monolayer graphene flakes (GP), and the LC+GP hybrids are found to exhibit a dramatic increase in the dielectric anisotropy. Electric field-dependent conductance studies reveal that the graphene flakes follow the nematic director that mechanically rotates on increasing an applied electric field. Further studies show that the  $\pi-\pi$  electron stacking, between the graphene's honeycomb structure and the LC's benzene rings, stabilizes *pseudo-nematic domains* that collectively amplify the dielectric anisotropy by improving the orientational order parameter in the nematic phase. These anisotropic domains interact with the external electric field, resulting in a *nonzero* dielectric anisotropy in the isotropic phase as well. The enhancement in dielectric anisotropy, due to the LC – graphene coupling, is found to have subsequent positive impacts on the LC's orientational threshold field and elasticity that allows the nematic director to respond quicker on switching the electric field off.

**11:39AM S37.00003 Smectic Liquid Crystal-Nanoparticle arrangement observed with X-ray Scattering<sup>1</sup>**, LUZ J MARTINEZ-MIRANDA, University of Maryland, College Park, MD, PATRICIO ROMERO-HASLER, ARIEL MENESES-FRANCO, EDUARDO A. SOTO-BUSTAMANTE, Universidad de Chile, Santiago, Chile — We observed the alignment of two different monomeric liquid crystals combined with TiO<sub>2</sub> in a concentration of 0.3 wt of TiO<sub>2</sub>. The liquid crystals are M6R8 and I6R8. These two monomeric compounds have a crystal-SmC-SmA-isotropic phase progression. The two monomeric compounds differ in the final group at the end of one of the carbon chains. The nanoparticle ties itself to the monomers through hydrogen bonding. The difference in the final group determines where the nanoparticle attaches to the liquid crystal molecule. This difference in the way it attaches can be observed using X-ray scattering. The way the nanoparticle attaches has consequences in the current-voltage curve obtained [1]. Under the influence of an electric field, the M6R8 polymerizes. We observe by X-ray scattering that the nanoparticles migrate and the scan is very similar to the scan of the I6R8 monomer with the nanoparticle. In addition the nanoparticle is ordered along one direction and does not seem as ordered in the direction perpendicular to this direction. [1] A. Meneses-Franco, J. Mater. Chem. C, 2015, 3, 8566.

**11:51AM S37.00004 Organized composites of Carbon Nanotubes and Lyotropic Liquid Crystals at very low Surfactant Concentration**, GIUSY SCALIA, University of Luxembourg, Physics & Materials Science Research Unit, HYERAN JO, Seoul National University, Graduate School of Convergence Science & Technology, JI HYUN PARK, JAN LAGERWALL, University of Luxembourg, Physics & Materials Science Research Unit — The difficulties in dispersing and organizing carbon nanotubes (CNTs) can be efficiently tackled using surfactant-based lyotropic liquid crystals, combining high nanotube loading with long-range order. A problem with surfactants is, however, that their residues negatively affect CNT device performance. Here we show aligned CNT-lyotropic composites at reduced surfactant concentration. By combining cat- and anionic surfactants a lyotropic nematic phase forms at just 8% surfactant concentration, and CNTs can be well dispersed and aligned in it [1]. The CNTs themselves were first dispersed below the Krafft temperature of the surfactant used for their stabilization, minimizing also its concentration [2]. The composites exhibit very interesting properties with strong sensitivity to the surfactant ratios. They were investigated by Polarized Optical Microscopy and Polarized Raman spectroscopy, and also the electrical properties were studied. [1] G. Scalia, C. J. von Buehler, C. Haegeler, S. Roth, F. Giesselmann, J. P. F. Lagerwall. Soft Matter, 4, 570, 2008. [2] S. Dölle, B.-D. Lechner, J. H. Park, S. Schymura, J. P. F. Lagerwall and G. Scalia, Angewandte Chemie, 51, 13, 3254, 2012

**12:03PM S37.00005 Effects of graphene on in-plane electro-optic switching for a nematic liquid crystal**, DANIEL KINNAMON, NICOLE SKAGGS, ALFRED GARVEY, RAJRATAN BASU, US Naval Academy — A small quantity of graphene flakes was doped in a nematic liquid crystal (LC), and the in-plane electro-optic switching was found to be significantly faster in the LC+graphene hybrid than that of the pure LC. Additional studies revealed that the presence of graphene reduced the rotational viscosity and the twist elastic constant of the LC, allowing the nematic director to respond faster on switching the electric field on.

**12:15PM S37.00006 Flow of anisotropic and isotropic objects in quasi-twodimensional fluids<sup>1</sup>**, RALF STANNARIUS, ALEXEY EREMIN, SARAH DÖLLE, KIRSTEN HARTH, CHRISTOPH KLOPP, Otto von Guericke University, Magdeburg — We study the motion of microscopic objects in very thin freely suspended smectic liquid-crystal films. The aspect ratios of these films are of the order of  $1:10^6$ . Hydrodynamic motion is restricted to the film plane. Thus such films represent quasi-twodimensional fluids. Not only do they provide the opportunity to test theoretical models on mobilities in thin membranes, they also allow access to viscosity parameters of in-plane isotropic (smectic A) and anisotropic (smectic C) fluids. Combinations of these environments with isotropic and anisotropic geometries of inclusions provide rich information about interactions of rotational and translational particle motions, the anchoring-induced and flow-induced alignments of the embedding fluid, and interactions of particles via flow and director fields. Thermal diffusion in horizontal films as well as controlled effective gravity in tilted films are explored.

### **12:39PM S37.00008 Field-driven dynamics of microcapillaries filled with nematic liquid crystal<sup>1</sup>**

, FRED FU, POUYA KHAYATZADEH, NASSER M ABUKHDEIR, University of Waterloo — Polymer-dispersed liquid crystal (PDLC) composites have long been a focus of study for their unique electro-optical properties and the feasibility of manufacturing them on a large scale, resulting in applications such as switchable windows. LC domains within PDLCs are typically spheroidal, as opposed to rectangular in LCD technology, and thus exhibit substantially different behaviour in the presence of an external field. In this work, continuum simulations were performed in order to capture the complex formation and electric field-driven switching dynamics of approximations of PDLC domains. A simplified elliptic cylinder (microcapillary) geometry is used and the effects of varying aspect ratio, surface anchoring, and external field strength were studied using the Landau-de Gennes model. The observed nematic formation and reorientation dynamics were found to be governed by the presence and motion of defects within the domain. Aspect ratio was found to strongly influence domain texture by providing regions of high curvature to which defects are attracted. Simulations also predict the presence of a geometry-controlled transition from nematic order enhanced by an external field (low aspect ratio) to nematic order frustrated by an external field (high aspect ratio).

<sup>1</sup>This work was made possible by the Natural Sciences and Engineering Research Council of Canada and Compute Ontario.

### **12:51PM S37.00009 Structural organization of liquid crystals at liquid crystal-air interface: Synchrotron X-ray reflectivity and computational simulations**

, MONIRO SADAT, HADI RAMEZANI-DAKHEL, IME, UChicago, WEI BU, CARS, UChicago, EMRE SEVGEN, IME, UChicago, ZHU LIANG, CEM EROL, Dept. Phys., UIC, NADER TAHERI QAZVINI, MOHAMMAD RAHIMI, IME, UChicago, BINHUA LIN, CARS, UChicago, BENOIT ROUX, Dept. Biochem. Molecular Biol., UChicago, MARK SCHLOSSMAN, Dept. Phys., UIC, JUAN J. DE PABLO, IME, UChicago — Numerous applications of liquid crystals (LC) rely on control of molecular orientation at an interface. However, little is known about the precise molecular structure of such interfaces. In this work, we have performed synchrotron X-ray reflectivity measurements accompanied by an advanced theoretical and computational analysis to study the structural organization of liquid crystals at the air-liquid crystal interface. The X-ray reflectivity was measured from two nematic (5CB) and smectic (8CB) liquid crystals at several temperatures, in the nematic phase and above the nematic-isotropic transition. Our computational simulations and X-ray reflectivity results indicate that in the case of 8CB nematic phase, incipient bulk smectic fluctuations are pinned at the interface to form temperature-dependent multilayers at the interface. Such layers can extend far from the interface. However, the interface of 5CB in the nematic phase exhibits a relatively small number of layers. These measurements will be extended to the study of the LC-aqueous electrolyte interfaces to understand the effects of electrostatic interactions and external stimuli on the interfacial anchoring energy and LC orientational ordering.

### **1:03PM S37.00010 Gold nanoparticle encapsulation into a mixed lipid nanodisk: molecular dynamics simulations**

, HARI SHARMA, ZILU WANG, ELENA DORMIDONTOVA, Department of Physics and Institute of Materials Science, University of Connecticut, Storrs, CT — There is a growing interest in applications of nanoparticles in biomedicine. For practical applications of gold nanoparticles it is often desirable to encapsulate them into lipid nanocarriers. To this end it is important to understand gold-lipid interactions at the molecular level. We have performed coarse grained molecular dynamics simulations using a MARTINI force field of a lipid nanodisk composed of long and short tail lipids, DPPC and DHPC mixed in the ratio of 3:1 and studied its interaction with small gold nanoparticles (AuNP) functionalized with hydrophobic alkane tethers. We found that the inhomogeneous distribution of lipids in the nanodisk affects the outcome the AuNP-nanodisk interaction. The ordered arrangement of long chain lipids forming the interior region of the nanodisk are found to be less accessible for AuNP penetration compared to the rim of the nanodisk, where more mobile short lipids are located. Once encapsulated into a nanodisk, AuNP's have tendency to aggregate, especially if temperature is not too low. The results of computer modeling will be compared to experiment and the implications of our findings for experimental design of lipid nanocarriers for AuNP delivery will be discussed.

### **1:15PM S37.00011 Nanoscale Membrane Curvature detected by Polarized Localization Microscopy**

, CHRISTOPHER KELLY, ABIR MAAROUF, XINXIN WOODWARD, Wayne State University — Nanoscale membrane curvature is a necessary component of countless cellular processes. Here we present Polarized Localization Microscopy (PLM), a super-resolution optical imaging technique that enables the detection of nanoscale membrane curvature with order-of-magnitude improvements over comparable optical techniques. PLM combines the advantages of polarized total internal reflection fluorescence microscopy and fluorescence localization microscopy to reveal single-fluorophore locations and orientations without reducing localization precision by point spread function manipulation. PLM resolved nanoscale membrane curvature of a supported lipid bilayer draped over polystyrene nanoparticles on a glass coverslip, thus creating a model membrane with coexisting flat and curved regions and membrane radii of curvature as small as 20 nm. Further, PLM provides single-molecule trajectories and the aggregation of curvature-inducing proteins with super-resolution to reveal the correlated effects of membrane curvature, dynamics, and molecular sorting. For example, cholera toxin subunit B has been observed to induce nanoscale membrane budding and concentrate at the bud neck. PLM reveals a previously hidden and critical information of membrane topology.

### **1:27PM S37.00012 Membrane Domain Formation on Nanostructured Scaffolds**

, FANGJIE LIU, BERNADETA SRIJANTO, Oak Ridge National Laboratory — The spatial organization of lipids and proteins in biological membranes seems to have a functional role in the life of a cell. Separation of the lipids into distinct domains of greater order and anchoring to the cytoskeleton are two main mechanisms for organizing the membrane in cells. We propose a novel model membrane consisting of a lipid bilayer suspended over a nanostructured scaffold consisting of arrays of fabricated nanopillars. Unlike traditional model membranes, our model will have well-defined lateral structure and distributed substrate attachments that will emulate the connections of cellular membranes to the underlying cytoskeleton. Membranes will be characterized using neutron reflectometry, atomic force microscopy and fluorescence to verify a suspended, planar geometry with restricted diffusion at suspension points, and free diffusion in between. This architecture will allow the controlled study of lipid domain reorganization, viral infection and signal transduction that depend on the lateral structure of the membrane.

### **1:39PM S37.00013 Structure and dynamics of a hydrated phospholipid bilayer in the presence of a silica substrate<sup>1</sup>**

, MATTHEW MCCUNE, IOAN KOSZTIN, University of Missouri — We study the structure and dynamics of a hydrated diiristoyl-phosphatidylcholine (DMPC) lipid bilayer supported on a silica substrate using all-atom molecular dynamics (MD) simulation. A similar MD simulation of a freestanding DMPC bilayer is used as a reference to determine changes to both lipid and hydration water properties due to the introduction of the substrate. Long time (0.1 microsecond) MD trajectories were used to investigate the effect of the substrate on the structure and dynamics of the lipid bilayer by determining (i) the spatial distribution of water molecules and selected lipid atoms; (ii) the out of plane fluctuations of the lipid molecules; (iii) the dipole moment orientation of hydration waters; and (iv) the lateral mean-square-displacement of both lipid and water molecules. The obtained results suggest that (i) at equilibrium the space between the substrate and lipid bilayer is filled by only hydration water; (ii) the presence of the substrate has no major influence on the structure of hydration water layers and on the out-of-plane fluctuations of the lipids; and (iii) the silica substrate alters considerably the lateral diffusion of the lipids in the closest bilayer leaflet and the hydration waters between the substrate and DMPC membrane. The reported results appear to be consistent with previous MD and neutron scattering studies.

**1:51PM S37.00014 Insight into cholesterol transport in different lipid environments: a simulation study**, KLAS KARIS, URSULA PEREZ-SALAS, FATEMEH KHALILI-ARAGHI, Univ of Illinois - Chicago — With molecular dynamics simulations employing the MARTINI coarse grained force field, we investigate the difference in the dynamic behavior of cholesterol, linked to the absorption and desorption of cholesterol in two phospholipid environments consisting of either an uncharged, zwitterionic lipid (POPC) or the charged counterpart (POPS). The work is motivated by results from recent neutron scattering experiments measuring the transfer rate of inter-membrane cholesterol transfer, revealing that cholesterol inter-membrane transport is significantly slower in lipid membranes composed of charged lipids, than in membranes composed of uncharged lipids. By systematically investigating dynamical and equilibrium parameters such as the free energy of desorption, lateral diffusion, tilt angle distribution, structural parameters and estimated absorption rates, we map the key differences in interaction of the two lipid species with cholesterol. Results point towards a shift in cholesterol absorption rates for POPS compared to POPC.

**2:03PM S37.00015 Phase separation in artificial vesicles driven by light and curvature**, MELISSA RINALDIN, WIM POMP, THOMAS SCHMIDT, LUCA GIOMI, DANIELA KRAFT, Leiden University, PHYSICS OF LIFE PROCESSES TEAM, SOFT AND BIO MECHANICS COLLABORATION, SELF-ASSEMBLY IN SOFT MATTER SYSTEMS COLLABORATION — The role of phase-demixing in living cells, leading to the lipid-raft hypothesis, has been extensively studied. Lipid domains of higher lipid chain order are proposed to regulate protein spatial organization. Giant Unilamellar Vesicles provide an artificial model to study phase separation. So far temperature was used to initiate the process. Here we introduce a new methodology based on the induction of phase separation by light. To this aim, the composition of the lipid membrane is varied by photo-oxidation of lipids. The control of the process gained by using light allowed us to observe vesicle shape fluctuations during phase-demixing. The presence of fluctuations near the critical mixing point resembles features of a critical process. We quantitatively analyze these fluctuations using a 2d elastic model, from which we can estimate the material parameters such as bending rigidity and surface tension, demonstrating the non-equilibrium critical behaviour. Finally, I will describe recent attempts toward tuning the membrane composition by controlling the vesicle curvature.

Session S38 DPOLY DBIO: Mechanics of Biopolymers: Networks and Assemblies 341 - Louis Foucard, UCLA

**11:15AM S38.00001 Rheology and nonlinear mechanics of transiently cross linked semiflexible networks: Bundling, ripping, healing, and mechnomemory**, ALEX LEVINE, UCLA — Transiently cross linked networks of semiflexible filaments make up the principal structural component of the cell the cytoskeleton. This intracellular network, along with molecular motors, forms the basis for cellular control of morphology and force generation. In this talk, I report on investigations of the effect of transiently bound cross linkers on the structure and mechanics of semiflexible networks. Specifically, I address the role of Casimir or fluctuation-induced interactions between cross linkers in the formation of filament bundles. I report on the linear viscoelasticity of transiently cross-linked networks of bundles. Finally, I discuss the nonlinear mechanical response of such networks, where applied stress induces a persistent structural rearrangement of the network that can dramatically alter its nonlinear response to stresses subsequently applied.

**11:51AM S38.00002 A coarse-grained model of microtubule self-assembly**, CHOLA REGMI, SHENGFENG CHENG, Virginia Polytechnic Institute and State University — Microtubules play critical roles in cell structures and functions. They also serve as a model system to stimulate the next-generation smart, dynamic materials. A deep understanding of their self-assembly process and biomechanical properties will not only help elucidate how microtubules perform biological functions, but also lead to exciting insight on how microtubule dynamics can be altered or even controlled for specific purposes such as suppressing the division of cancer cells. Combining all-atom molecular dynamics (MD) simulations and the essential dynamics coarse-graining method, we construct a coarse-grained (CG) model of the tubulin protein, which is the building block of microtubules. In the CG model a tubulin dimer is represented as an elastic network of CG sites, the locations of which are determined by examining the protein dynamics of the tubulin and identifying the essential dynamic domains. Atomistic MD modeling is employed to directly compute the tubulin bond energies in the surface lattice of a microtubule, which are used to parameterize the interactions between CG building blocks. The CG model is then used to study the self-assembly pathways, kinetics, dynamics, and nanomechanics of microtubules.

**12:03PM S38.00003 Molecular Simulations of Actomyosin Network Self-Assembly and Remodeling<sup>1</sup>**, JAMES KOMIANOS, Univ of Maryland-College Park, KONSTANTIN POPOV, Univ of North Carolina-Chapel Hill, GAREGIN PAPOIAN, Univ of Maryland-College Park, PAPOIAN LAB TEAM — Actomyosin networks are an integral part of the cytoskeleton of eukaryotic cells and play an essential role in determining cellular shape and movement. Actomyosin network growth and remodeling in vivo is based on a large number of chemical and mechanical processes, which are mutually coupled and spatially and temporally resolved. To investigate the fundamental principles behind the self-organization of these networks, we have developed a detailed mechanochemical, stochastic model of actin filament growth dynamics, at a single-molecule resolution, where the nonlinear mechanical rigidity of filaments and their corresponding deformations under internally and externally generated forces are taken into account. Our work sheds light on the interplay between the chemical and mechanical processes governing the cytoskeletal dynamics, and also highlights the importance of diffusional and active transport phenomena. Our simulations reveal how different actomyosin micro-architectures emerge in response to varying the network composition.

<sup>1</sup>Support from NSF Grant CHE-1363081.

**12:15PM S38.00004 Active mechanics in living oocytes reveal molecular-scale force kinetics**, WYLIE AHMED, Institut Curie, ETIENNE FODOR, Université Paris Diderot, MARIA ALMONACID, Collège de France, MATTHIAS BUSSONNIER, Institut Curie, MARIE-HELENE VERLHAC, Collège de France, NIR GOV, Weizmann Institute of Science, PAOLO VISCO, FREDERIC VAN WIJLAND, Université Paris Diderot, TIMO BETZ, University of Muenster — Unlike traditional materials, living cells actively generate forces at the molecular scale that change their structure and mechanical properties. This nonequilibrium activity is essential for cellular function, and drives processes such as cell division. Single molecule studies have uncovered the detailed force kinetics of isolated motor proteins in-vitro, however their behavior in-vivo has been elusive due to the complex environment inside the cell. Here, we quantify active forces and intracellular mechanics in living oocytes using in-vivo optical trapping and laser interferometry of endogenous vesicles. We integrate an experimental and theoretical framework to connect mesoscopic measurements of nonequilibrium properties to the underlying molecular-scale force kinetics. Our results show that force generation by myosin-V drives the cytoplasmic-skeleton out-of-equilibrium (at frequencies below 300 Hz) and actively softens the environment. In vivo myosin-V activity generates a force of  $F \sim 0.4$  pN, with a power-stroke of length  $\Delta x \sim 20$  nm and duration  $\tau \sim 300$   $\mu$ s, that drives vesicle motion at  $v_v \sim 320$  nm/s. This framework is widely applicable to characterize living cells and other soft active materials.

**12:27PM S38.00005 Biopolymer mechanics across the force regimes**, OMAR SALEH, Materials Department and BMSE Program, UCSB — The elastic response of a single polymer can explain certain material properties, including the thickness of polymer brushes and the mechanics of gels; in turn, these material properties have a variety of biological applications, such as to the brush-like pericellular matrix surrounding certain cells. More fundamentally, the force-extension relation of a polymer can be predicted theoretically, making it possible to probe the structure of a polymer by measuring its elastic response. This works in a manner similar to scattering: just as scattering at a wave vector  $q$  gives information on structure at a length scale  $1/q$ , the elastic response under applied tension  $f$  gives information on structure at a length scale of  $kT/f$ . Thus, in exact analogy to low-angle scattering, low-force elastic measurements are needed to probe the interesting long-range structure of polymers. I will discuss the basic physics of low-force elasticity, and present our experiments on various polymers, including nucleic acids and polysaccharides, that validate the power of low-force elastic measurements.

**1:03PM S38.00006 Investigating collagen self-assembly with optical tweezers microrheology**, NANCY FORDE, Department of Physics, Simon Fraser University, MARJAN SHAYEGAN<sup>1</sup>, Department of Chemistry, Simon Fraser University, TUBA ALTINDAL, Department of Physics, Simon Fraser University — Collagen is the fundamental structural protein in vertebrates. Assembled from individual triple-helical proteins to make strong fibres, collagen is a beautiful example of a hierarchical self-assembling system. Using optical tweezers to perform microrheology measurements, we explore the dynamics of interactions between collagens responsible for their self-assembly and examine the development of heterogeneous mechanics during assembly into fibrillar gels. Telopeptides, short non-helical regions that flank the triple helix, have long been known to facilitate fibril self-assembly. We find that their removal not only slows down fibril nucleation but also results in a significant frequency-dependent reduction in the elastic modulus of collagens in solution. We interpret these results in terms of a model in which telopeptides facilitate transient intermolecular interactions, which enhance network connectivity in solution and lead to more rapid assembly in fibril-forming conditions.

<sup>1</sup>Current address: Department of Physics, McGill University

**1:15PM S38.00007 Nonlinear microrheology and molecular imaging to map microscale deformations of entangled DNA networks**, TSAI-CHIN WU, RAE ANDERSON, University of San Diego — We use active microrheology coupled to single-molecule fluorescence imaging to elucidate the microscale dynamics of entangled DNA. DNA naturally exists in a wide range of lengths and topologies, and is often confined in cell nuclei, forming highly concentrated and entangled biopolymer networks. Thus, DNA is the model polymer for understanding entangled polymer dynamics as well as the crowded environment of cells. These networks display complex viscoelastic properties that are not well understood, especially at the molecular-level and in response to nonlinear perturbations. Specifically, how microscopic stresses and strains propagate through entangled networks, and what molecular deformations lead to the network stress responses are unknown. To answer these important questions, we optically drive a microsphere through entangled DNA, perturbing the system far from equilibrium, while measuring the resistive force the DNA exerts on the bead during and after bead motion. We simultaneously image single fluorescent-labeled DNA molecules throughout the network to directly link the microscale stress response to molecular deformations. We characterize the deformation of the network from the molecular-level to the mesoscale, and map the stress propagation throughout the network. We further study the impact of DNA length (11 – 115 kbp) and topology (linear vs ring DNA) on deformation and propagation dynamics, exploring key nonlinear features such as tube dilation and power-law relaxation.

**1:27PM S38.00008 Dual-feedback microrheology in cytoskeletal networks**, NATSUKI HONDA, KENJI NISHIZAWA, TAKAYUKI ARIGA, DAISUKE MIZUNO, Kyushu Univ — Cytoskeletons are critical for understanding cell behaviors since they generate forces together with molecular motors and supply mechanical integrity to cells. Since response of cytoskeletons to motor-generated forces is highly nonlinear, cell behaviors intricately depend on activities and mechanics of cytoskeletons. Investigating local response of cytoskeletons to forces generated by molecular motors, which optical trap can imitatively reproduce, is therefore essential. Here, we performed this by developing a novel optical-trap-based microrheology implemented with dual-feedback control. With the slow feedback of piezo-stage, probes under drift, caused by the traction force applied by the optical trap, were stably tracked. By the rapid feedback of trapping laser, artifacts in probes motion, that had been caused by strong optical trap potential, were completely removed. We observed that fluctuations of probes embedded in various cytoskeletons were significantly reduced when subjected to forces. Under the assumption that the fluctuation-dissipation theorem is satisfied, our results indicate the stress stiffening of cytoskeletons, that became now possible to be studied in micro-scales and in a frequency range appropriate for cell behaviors.

**1:39PM S38.00009 Coupled actin-lamin biopolymer networks and protecting DNA**, TAO ZHANG, Chemical Engineering Department, University of Pittsburgh, D. ZEB ROCKLIN, XIAOMING MAO, University of Michigan, Department of Physics, J. M. SCHWARZ, Department of Physics, Syracuse University — The mechanical properties of cells are largely determined by networks of semiflexible biopolymers forming the cytoskeleton. Similarly, the mechanical properties of cell *nuclei* are also largely determined by networks of semiflexible biopolymers forming the *nuclear* cytoskeleton. In particular, a network of filamentous lamin sits just inside the inner nuclear membrane to presumably protect the heart of the cell nucleus—the DNA. It has been demonstrated over the past decade that the actin cytoskeletal biopolymer network and the lamin biopolymer network are coupled via a sequence of proteins bridging the outer and inner nuclear membranes, known as the LINC complex. We, therefore, probe the consequences of such a coupling in a model biopolymer network system via numerical simulations to understand the resulting deformations in the lamin network in response to perturbations in the actin cytoskeletal network. We find, for example, that the force transmission across the coupled system can depend sensitively on the concentration of LINC complexes. Such study could have implications for mechanical mechanisms of the regulation of transcription since DNA couples to lamin via lamin-binding domains so that deformations in the lamin network may result in deformations in the DNA.

**1:51PM S38.00010 The Effect of Crosslinking on the Microscale Stress Response and Molecular Deformations in Actin Networks**, BEKELE GURMESSA, ROBERT FITZPATRICK, JONATHON VALDIVIA, RAE M. R. ANDERSON, Univ of San Diego — Actin, the most abundant protein in eukaryotic cells, is a semi-flexible biopolymer in the cytoskeleton that plays a crucial structural and mechanical role in cell stability, motion and replication, as well as muscle contraction. Most of these mechanically driven structural changes in cells stem from the complex viscoelastic nature of entangled actin networks and the presence of a myriad of proteins that cross-link actin filaments. Despite their importance, the mechanical response of actin networks is not yet well understood, particularly at the molecular level. Here, we use optical trapping - coupled with fluorescence microscopy - to characterize the microscale stress response and induced filament deformations in entangled and cross-linked actin networks subject to localized mechanical perturbations. In particular, we actively drive a microsphere 10 microns through an entangled or cross-linked actin network at a constant speed and measure the resistive force that the deformed actin filaments exert on the bead during and following strain. We simultaneously visualize and track individual sparsely-labeled actin filaments to directly link force response to molecular deformations, and map the propagation of the initially localized perturbation field throughout the rest of the network (~100  $\mu$ m). By varying the concentration of actin and cross-linkers we directly determine the role of crosslinking and entanglements on the length and time scales of stress propagation, molecular deformation and relaxation mechanisms in actin networks.

**2:03PM S38.00011 Mechanically tunable actin networks using programmable DNA based cross-linkers** , JOERG SCHNAUSS, University of Leipzig & Fraunhofer Institute for Cell Therapy and Immunology IZI, JESSICA LORENZ, Fraunhofer Institute for Cell Therapy and Immunology IZI, CARSTEN SCHULDT, University of Leipzig & Fraunhofer Institute for Cell Therapy and Immunology IZI, JOSEF KAES, University of Leipzig, DAVID SMITH, Fraunhofer Institute for Cell Therapy and Immunology IZI — Cells employ multiple cross-linkers with very different properties. Studies of the entire phase space, however, were infeasible since they were restricted to naturally occurring cross-linkers. These components cannot be controllably varied and differ in many parameters. We resolve this limitation by forming artificial actin cross-linkers, which can be controllably varied. The basic building block is DNA enabling a well-defined length variation. DNA can be attached to actin binding peptides with known binding affinities. We used bulk rheology to investigate mechanical properties of these networks. We were able to reproduce mechanical features of actin networks cross-linked by fascin by using a short version of our artificial complex with a high binding affinity. Additionally, we were able to resemble findings for the cross-linker alpha-actinin by employing a long cross-linker with a low binding affinity. Between these natural limits we investigated three different cross-linker lengths each with two different binding affinities. With these controlled variations we are able to precisely screen the phase space of cross-linked actin networks by changing only one specific parameter and not the entire set of properties as in the case of naturally occurring cross-linking complexes.

**Session S39 DBIO DPOLY GSNP: Physics of Genome Organization: from DNA to Chromatin**

II 342 - Leonid Mirny, MIT

**11:15AM S39.00001 Inferring the locations of DNA bound proteins from Hi-C data** , PAU FARRE, ELDON EMBERLY, Simon Fraser University — Eukaryotic DNA can be found in either a tightly packed state (heterochromatin) or an open conformation (euchromatin). Certain proteins that bind to the DNA are responsible for setting up these two types of states. They interact with each other, and generate spatially separated compartments in the DNA through the formation of loops. In this talk I will present a combination of analytic and simulation results for the effects of protein-protein interactions on the large-scale 3D structure of chromatin. Using these findings we have developed a maximum-likelihood method for inferring the distribution of DNA bound factors that can help refine and make new predictions for the locations of proteins responsible of structuring the chromosome.

**11:27AM S39.00002 Coalescence Model for Crumpled Globules Formed in Polymer Collapse** , GUY BUNIN, MEHRAN KARDAR, Massachusetts Inst of Tech-MIT — The rapid collapse of a polymer, due to external forces or changes in solvent, yields a long-lived "crumpled globule." The conjectured fractal structure shaped by hierarchical collapse dynamics has proved difficult to establish, even with large simulations. To unravel this puzzle, we study a coarse-grained model of in-falling spherical blobs that coalesce upon contact. Distances between pairs of monomers are assigned upon their initial coalescence, and do not "equilibrate" subsequently. Surprisingly, the model reproduces quantitatively the dependence of distance on segment length, suggesting that the slow approach to scaling is related to the wide distribution of blob sizes.

**11:39AM S39.00003 Probing nuclear dynamics and architecture using single-walled carbon nanotubes** , YOON JUNG, JUNANG LI, NIKTA FAKHRI, Department of Physics, Massachusetts Institute of Technology — Chromatin is a multiscale dynamic architecture that acts as a template for many biochemical processes such as transcription and DNA replication. Recent developments such as Hi-C technology enable an identification of chromatin interactions across an entire genome. However, a single cell dynamic view of chromatin organization is far from understood. We discuss a new live cell imaging technique to probe the dynamics of the nucleus at a single cell level using single-walled carbon nanotubes (SWNTs). SWNTs are non-perturbing rigid rods (diameter of 1 nm and length of roughly 100 nm) that fluoresce in the near infrared region. Due to their high aspect ratio, they can diffuse in tight spaces and report on the architecture and dynamics of the nucleoplasm. We develop 3D imaging and tracking of SWNTs in the volume of the nucleus using double helix point spread function microscopy (DH-PSF) and discuss the capabilities of the DH-PSF for inferring the 3D orientation of nanotubes based on vectorial diffraction theory.

**11:51AM S39.00004 Fractionation of Exosomes and DNA using Size-Based Separation at the Nanoscale** , BENJAMIN WUNSCH, JOSHUA SMITH, IBM Research Labs, CHAO WANG, Arizona State University, STACEY GIFFORD, MARKUS BRINK, ROBERT BRUCE, GUSTAVO SOLOVITZKY, IBM Research Labs, ROBERT AUSTIN, Princeton University, YANN ASTIER, IBM Research Labs — Exosomes, a key target of liquid biopsies, are nano-vesicles found in nearly all biological fluids. Exosomes are secreted by eukaryotic and prokaryotic cells alike, and contain information about their originating cells, including surface proteins, cytoplasmic proteins, and nucleic acids. One challenge in studying exosome morphology is the difficulty of sorting exosomes by size and surface markers. Common separation techniques for exosomes include ultracentrifugation and ultrafiltration, for preparation of large volume samples, but these techniques often show contamination and significant heterogeneity between preparations. To date, deterministic lateral displacement (DLD) pillar arrays in silicon have proven an efficient technology to sort, separate, and enrich micron-scale particles including human parasites, eukaryotic cells, blood cells, and circulating tumor cells in blood; however, the DLD technology has never been translated to the true nanoscale, where it could function on bio-colloids such as exosomes. We have fabricated nanoscale DLD (nanoDLD) arrays capable of rapidly sorting colloids down to 20 nm in continuous flow, and demonstrated size sorting of individual exosome vesicles and dsDNA polymers, opening the potential for on-chip biomolecule separation and diagnosis.

**12:03PM S39.00005 The impact of non-uniform capsid charge density on virus assembly<sup>1</sup>** , SIYU LI, GONCA ERDEMCI-TANDOĞAN, University of California,riverside, JEF WAGNER, Lawrence University, ROYA ZANDI, University of California,riverside — Many spherical viruses efficiently encapsulate their genome into shells (capsids) with icosahedral symmetry. Under many circumstances, this process is spontaneous and is primarily driven by the electrostatic interaction between positively charged capsid proteins and negatively charged genome. Through the free energy minimization of a generic potential, we calculate the optimal encapsulated genome length. In this talk, I will present our results due to a non-uniform charge distribution on the shell and its impact on the optimal size of encapsulated genome.

<sup>1</sup>This work was supported by the National Science Foundation through Grant No. DMR-13-10687.

**12:15PM S39.00006 Single molecule fluorescence studies of transition paths in DNA hairpin folding** , KATHERINE TRUEX, HOI SUNG CHUNG, JOHN LOUIS, WILLIAM EATON, National Institutes of Health — DNA hairpins are the simplest structures for investigating fundamental aspects of nucleic acid folding mechanisms. For two-state hairpins, all of the mechanistic information on how the hairpin folds is contained in the transition path (TP), the rare event in single molecule trajectories when the free energy barrier between folded and unfolded states is actually crossed. The only previous experimental study of TPs in nucleic acids used optical tweezer measurements and Szabo's analytical theory for diffusive barrier crossing to reconstruct the free energy surface for an indirect determination of average TP times (Neupane *et al.* *PRL* 2012). We used confocal single molecule FRET and maximum likelihood analysis of photon trajectories to determine an upper bound of 2.5  $\mu$ s for the average TP time of a DNA hairpin (Truex *et al.*, *PRL* 2015), compared to the value of 4  $\mu$ s predicted by Neupane *et al.*, providing an important test of energy landscape theory. Current experiments are aimed at eventually characterizing structural changes during TPs, which will provide a very demanding test of mechanisms predicted by both theoretical models and simulations.

**12:27PM S39.00007 The Molecular Atlas Project** , JESSE SILVERBERG, PENG YIN, Wyss Institute for Biologically Inspired Engineering, Harvard University — The promise of super-resolution microscopy is a technology to discover new biological mechanisms that occur at smaller length scales than previously observable. However, with higher-resolution, we generally lose the larger spatial context of the image itself. The *Molecular Atlas Project* (MAP) directly asks how these competing interests between super-resolution imaging and broader spatially contextualized information can be reconciled. MAP enables us to acquire, visualize, explore, and annotate proteomic image data representing 7 orders of magnitude in length ranging from molecular (nm) to tissue (cm) scales. This multi-scale understanding is made possible by combining multiplexed DNA-PAINT, a DNA nanotechnology approach to super-resolution imaging, with “big-data” strategies for information management and image visualization. With these innovations combined, MAP enables us to explore cell-specific heterogeneity in ductal carcinoma for every cell in a cm-sized tissue section, analyze organoid growth for advances in high-throughput tissue-on-a-chip technology, and examine individual synapses for connectome mapping over extremely wide areas. Ultimately, MAP is a fundamentally new way to interact with multiscale biophysical data.

**12:39PM S39.00008 simulation of the DNA force-extension curve** , GREGORY SHINABERRY, IVAN MIKHAYLOV, ALEXANDER BALAEFF, University of Central Florida — A molecular dynamics simulation study of the force-extension curve of double-stranded DNA is presented. Extended simulations of the DNA at multiple points along the force-extension curve are conducted with DNA end-to-end length constrained at each point. The calculated force-extension curve qualitatively reproduces the experimental one. The DNA conformational ensemble at each extension shows that the famous plateau of the force-extension curve results from B-DNA melting, whereas the formation of the earlier-predicted novel DNA conformation called ‘zip-DNA’ takes place at extensions past the plateau. An extensive analysis of the DNA conformational ensemble in terms of base configuration, backbone configuration, solvent interaction energy, etc., is conducted in order to elucidate the physical origin of DNA elasticity and the main interactions responsible for the shape of the force-extension curve.

**12:51PM S39.00009 Characterization of the full base pairing probability distribution in RNA secondary structure folding<sup>1</sup>** , WILLIAM BAEZ, Ohio State University, KAY WIESE, CNRS-LPTENS, RALF BUNDSCHUH, Ohio State University — Below the denaturation temperature of RNA, its secondary structures can exist in one of two phases: a strongly disordered, low-temperature glass phase and a weakly disordered, high-temperature molten phase. The probability of two bases pairing in these phases have been shown to scale with the distance between the two bases as  $-3/2$  and  $-4/3$  in the molten and glass phases, respectively. In this study, we characterize the full probability distributions of pair binding both near and far from the critical point rather than just the behavior of their means studied before. We anticipate that this approach allows one to more closely probe the nature of the phase transition and better measure the system's critical exponents close to and at its critical point.

<sup>1</sup>This material is based upon work supported by the National Science Foundation under Grants No. DMR-01105458 and DMR-01410172.

**1:03PM S39.00010 Gene dosage imbalance during DNA replication controls bacterial cell-fate decision<sup>1</sup>** , OLEG IGOSHIN, Rice University — Genes encoding proteins in a common regulatory network are frequently located close to one another on the chromosome to facilitate co-regulation or couple gene expression to growth rate. Contrasting with these observations, here we demonstrate a functional role for the arrangement of *Bacillus subtilis* sporulation network genes on opposite sides of the chromosome. We show that the arrangement of two sporulation network genes, one located close to the origin, the other close to the terminus leads to a transient gene dosage imbalance during chromosome replication. This imbalance is detected by the sporulation network to produce cell-cycle coordinated pulses of the sporulation master regulator Spo0A~P. This pulsed response allows cells to decide between sporulation and continued vegetative growth during each cell-cycle spent in starvation. Furthermore, changes in DNA replication and cell-cycle parameters with decreased growth rate in starvation conditions enable cells to indirectly detect starvation without the need for evaluating specific metabolites. The simplicity of the uncovered coordination mechanism and starvation sensing suggests that it may be widely applicable in a variety of gene regulatory and stress-response settings.

<sup>1</sup>This work is supported by National Science Foundation grants MCB-1244135, EAGER-1450867, MCB-1244423, NIH NIGMS grant R01 GM088428 and HHMI International Student Fellowship.

**1:39PM S39.00011 Torque-induced buckling behavior in stretched intertwined DNAs<sup>1</sup>** , SUMITABHA BRAHMACHARI, JOHN F. MARKO, Northwestern Univ — Two intertwined DNA molecules (a DNA ‘braid’) is a common occurrence in the cell and is a relevant substrate for the study of topoisomerase and recombination enzymes. Single molecule experiments have observed the signature of a buckling transition in braids under tensile and torsional stress. We present a free energy model for braided DNA to investigate the mechanical properties of these structures. Our model is based on the semi-flexible polymer model for double helix DNA and is in quantitative accord with the experiments. We identify coexistence of a force-extended state with a plectonemically buckled state, which is reminiscent of single supercoiled DNA behavior. However, the absence of an intrinsic twist modulus in braided DNA results in unique mechanical properties such as non-linear torque in the extended state. At the buckling transition, we predict a jump in the braid extension due to the plectoneme end loop which acts as a nucleation barrier. We investigate the effect of salt concentration on the mechanical response of braids, e.g. we find that buckling starts at a lower linking number for lower salt concentration, the opposite of what is seen for single supercoiled DNAs. Also, concentrations less than 20 mM monovalent salt favor formation of multiple plectoneme domains.

**1:51PM S39.00012 Sequence Heterogeneity Accelerates Protein Search for Targets on DNA<sup>1</sup>** , ALEXEY SHVETS, ANATOLY KOLOMEISKY, Rice Univ — The process of protein search for specific binding sites on DNA is fundamentally important since it marks the beginning of all major biological processes. We present a theoretical investigation that probes the role of DNA sequence symmetry, heterogeneity and chemical composition in the protein search dynamics. Using a discrete-state stochastic approach with a first-passage events analysis, which takes into account the most relevant physical-chemical processes, a full analytical description of the search dynamics is obtained. It is found that, contrary to existing views, the protein search is generally faster on DNA with more heterogeneous sequences. In addition, the search dynamics might be affected by the chemical composition near the target site. The physical origins of these phenomena are discussed. Our results suggest that biological processes might be effectively regulated by modifying chemical composition, symmetry and heterogeneity of a genome.

**2:03PM S39.00013 SA1 and TRF1 synergistically bind to telomeric DNA and promote DNA-DNA pairing**, HONG WANG, JIANGGUO LIN, PRESTON COUNTRYMAN, HAI PAN, North Carolina State University, PARMINDER KAUR TEAM, ROBERT RIEHN TEAM, PATRICIA OPRESKO TEAM, JANE TAO TEAM, SUSAN SMITH TEAM — Impaired telomere cohesion leads to increased aneuploidy and early onset of tumorigenesis. Cohesion is thought to occur through the entrapment of two DNA strands within tripartite cohesin ring(s), along with a fourth subunit (SA1/SA2). Surprisingly, cohesion rings are not essential for telomere cohesion, which instead requires SA1 and shelterin proteins including TRF1. However, neither this unique cohesion mechanism at telomeres or DNA-binding properties of SA1 is understood. Here, using single-molecule fluorescence imaging of quantum dot-labeled proteins on DNA we discover that while SA1 diffuses across multiple telomeric and non-telomeric regions, the diffusion mediated through its N-terminal domain is slower at telomeric regions. However, addition of TRF1 traps SA1 within telomeric regions, which form longer DNA-DNA pairing tracts than with TRF1 alone, as revealed by atomic force microscopy. Together, these experimental results and coarse-grained molecular dynamics simulations suggest that TRF1 and SA1 synergistically interact with DNA to support telomere cohesion without cohesin rings.

**11:15AM S40.00001 First-Passage Statistics of Extreme Values**, ELI BEN-NAIM, Los Alamos National Laboratory — Theoretical concepts from nonequilibrium statistical physics such as scaling and correlations are used to analyze first-passage processes involving extreme values. The focus of this talk is statistics of the running maxima, defined as the largest variable in a sequence of random variables. In particular, the running maxima of multiple independent sequences of stochastic variables are compared. The probability that these maxima remain perfectly ordered decays algebraically with the number of random variables, and the decay exponent characterizing this decay is nontrivial. Exact solutions for the scaling exponents will be discussed for uncorrelated variables as well as Brownian trajectories which are correlated. Relevance of such statistical measures for analysis of empirical data will be discussed as well.

**11:51AM S40.00002 Emergence of universal statistics from conserved topological features of underlying network dynamics**, SRIVIDYA IYER-BISWAS, Department of Physics, Purdue University — In this talk I will discuss how universal statistics emerge from conserved topological features of underlying network dynamics. I will indicate how dynamical phase transitions between different network structures also encode universal signatures. I will connect these results with our single-cell experiments on *C. crescentus* cells.

**12:03PM S40.00003 Anomalous Dimension in a Two-Species Reaction-Diffusion Model**, JOSHUA HELLERICK, BENJAMIN VOLLMAYR-LEE, Bucknell University — We consider particles ( $A$ ) diffusing in the presence of traps ( $B$ ), which themselves are diffusing and reacting, i.e. the two-species reaction diffusion model  $A + B \rightarrow B$  and  $B + B \rightarrow (0, B)$ . We introduce a simulation technique that provides the full probability distribution of particles for a given realization of the trap dynamics. Previous renormalization group analysis predicted that the density of  $A$  particles decays as  $a t^{-\theta}$  where  $\theta$  is a nontrivial, universal exponent for  $d < 2$ . We compare our results with these predictions, and also demonstrate the scaling of the correlation functions. We discover an anomalous dimension in the particle-particle correlation function, described by  $G_{AA}(0) \sim t^\phi$ , and we report our measurements for this new exponent.

**12:15PM S40.00004 Non-equilibrium steady states of stochastic processes with intermittent resetting**, STEPHAN EULE, Max-Planck-Institute, JAKOB METZGER, Rockefeller University — Stochastic processes that are randomly reset to an initial condition serve as a showcase to analytically investigate non-equilibrium steady states. Here we study such processes for which the time between the resets is random and drawn from a generic waiting time distribution. We obtain the general solution for the stationary state and quantify the temporal relaxation of the process in terms of its moments. Our results are applied to analyze the efficiency of constrained random search processes. For a fixed mean reset time, we show that the search efficiency can be optimized by adapting the shape of the waiting time distribution.

**12:27PM S40.00005 Persistent Probability Currents in Non-equilibrium Steady States<sup>1</sup>**, ROYCE ZIA, Iowa State and Virginia Tech, ANDREW MELLOR, MAURO MÖBILIA, University of Leeds, BAYLOR FOX-KEMPER, Brown University, JEFFREY WEISS, University of Colorado at Boulder — For many interesting phenomena in nature, from all life forms to the global climate, the fundamental hypothesis of equilibrium statistical mechanics does not apply. Instead, they are perhaps better characterized by non-equilibrium steady states, evolving with dynamical rules which violate detailed balance. In particular, such dynamics leads to the existence of non-trivial, persistent probability currents - a principal characteristic of non-equilibrium steady states. In turn, they give rise to the notion of 'probability angular momentum'. Observable manifestations of such abstract concepts will be illustrated in two distinct contexts: a heterogeneous nonlinear voter model and our ocean heat content.

**12:39PM S40.00006 From randomly accelerated particles to Lévy walks: non-ergodic behavior and aging**, GUENTER RADONS, TONY ALBERS, Tech Univ Chemnitz, INSTITUTE OF PHYSICS, COMPLEX SYSTEMS AND NONLINEAR DYNAMICS TEAM — For randomly accelerated particles we detected, and were able to analyze in detail (PRL 113, 184101 (2014)), the phenomenon of weak-ergodicity breaking (WEB), i.e. the inequivalence of ensemble- and time-averaged mean-squared displacements (MSD). These results, including their aging time dependence, are relevant for anomalous chaotic diffusion in Hamiltonian systems, for passive tracer transport in turbulent flows, and many other systems showing momentum diffusion. There are, however, several related models, such as the integrated random excursion model, or, space-time correlated Lévy walks and flights, with similar statistical behavior. We compare the WEB related properties of these models and find surprising differences although, for equivalent parameters, all of them are supposed to lead to the same ensemble-averaged MSD. Our findings are relevant for distinguishing possible models for the anomalous diffusion occurring in experimental situations.

**12:51PM S40.00007 Disordered confinement and anomalous diffusion<sup>1</sup>**, GERALD LAPEYRE, IDAEA-CSIC / ICFO — We discuss the effect of disordered confinement on anomalous diffusion. We treat confinement in conjunction with ordinary diffusion and with anomalous diffusions associated with aging and with correlated displacements. In particular, we compute the altered anomalous exponents. Finally, we relate these results to previous work and show that they shed light on the nature of diffusion on percolation clusters.

**1:03PM S40.00008 Non-equilibrium dynamics of the complex Ginzburg-Landau equation<sup>1</sup>**, WEIGANG LIU, UWE TAUBER, Virginia Tech — The complex Ginzburg-Landau equation combines the quantum many-particle nonlinear Schrödinger equation with the time-dependent Ginzburg-Landau equation or model A relaxational dynamics. It arises in quite diverse contexts that include spontaneous pattern formation out of equilibrium, chemical oscillations, multi-mode lasers, thermal convection in binary fluids, cyclic population dynamics, and driven-dissipative Bose-Einstein condensates. Indeed, the complex Ginzburg-Landau equation exhibits a remarkably rich phase diagram with intriguing dynamics. We employ detailed numerical studies as well as analytical tools such as the perturbative renormalization group and the spherical model limit to study the non-equilibrium coarsening and critical aging scaling for the complex Ginzburg-Landau equation following quenches from an initial disordered configuration to either one of the ordered phases or the critical point.

**1:15PM S40.00009 Multiscale phenomena and crossover in fluctuations in non-equilibrium systems**, A. SURJALAL SHARMA, VENKAT ANURAG SETTY, University of Maryland — Fluctuations in multiscale phenomena in natural systems, e. g., Earth's magnetosphere, exhibit crossover behavior in the scaling exponents. These exponents represent the nature of correlation in the system and the crossover shows the presence of more than one type of correlation. An accurate characterization of the crossover behavior is thus needed for a better understanding of the inherent correlations in the system. A multi-step process is developed for accurate computation of the crossover behavior. First the detrended fluctuation analysis is used to remove the trends in the data and the scaling exponents are computed. The crossover point is then computed by a Hyperbolic regression technique, with no prior assumptions. The time series data of the magnetic field variations in the Earth's magnetosphere is analyzed with these techniques and yields a crossover behavior with a time scale of ~ 4 hrs. A Langevin model of the magnetospheric dynamics yields an excellent fit to the crossover in the scaling exponents and thus provide a model of the non-equilibrium system.

**1:27PM S40.00010 Ligand binding kinetics in surface plasmon resonance devices: A Monte Carlo simulation analysis**, JACOB CARROLL, UWE TAUBER, Virginia Tech — Surface plasmon resonance (SPR) chips are widely used to measure association and dissociation rates for the binding kinetics between two species of chemicals, e.g., cell receptors and ligands. It is commonly assumed that ligands are spatially well mixed in the SPR region, and hence a mean-field rate equation description is appropriate. This approximation however ignores the spatial fluctuations as well as temporal correlations induced by multiple local rebinding events, which become prominent for slow diffusion rates. We report detailed Monte Carlo simulations of ligand binding kinetics in an SPR cell subject to laminar flow. We extract the binding and dissociation rates by means of the techniques frequently employed in experimental analysis that are motivated by the mean-field approximation. We find major discrepancies in a wide parameter regime between the thus extracted rates and the input simulation values. These results underscore the crucial quantitative importance of spatio-temporal correlations in binary reaction kinetics in SPR cell geometries.

**1:39PM S40.00011 Thermodynamic and Information Entropy in Electroconvection**, JOHN CRESSMAN, George Mason University, MARCUS DAUM, George Institute of Technology, DAVID PATRICK, George Mason University, RORY CERBUS, WALTER GOLDBURG, University of Pittsburgh — Transitions in driven systems often produce wild fluctuations that can be both detrimental and beneficial. Our fundamental understanding of these transients is inadequate to permit optimal interactions with systems ranging from biology, to energy generation, to finance. Here we report on experiments performed in electroconvecting liquid crystals where we abruptly change the electrical forcing across the sample from a state below defect turbulence into a state of defect turbulence. We simultaneously measure the electrical power flow through the liquid crystal as well as image the structure in the sample. These measurements enable us to simultaneously track the evolution of the thermodynamic and information entropies. Our experiments demonstrate that there are strong correlations between the fluctuations in these two entropic measures however they are not exact. We will discuss these discrepancies as well as the relevance of large transient fluctuations in non-equilibrium transitions in general.

**1:51PM S40.00012 Low dissipation in non-equilibrium control: sampling the ensemble of efficient protocols.**, GRANT ROTSKOFF, Univ of California - Berkeley, TODD GINGRICH, Massachusetts Institute of Technology, GAVIN CROOKS, Lawrence Berkeley National Laboratory, PHILLIP GEISSLER, Univ of California - Berkeley — Designing schemes to efficiently control fluctuating, non-equilibrium systems is problem of fundamental importance and tremendous practical interest. A number of optimization techniques have proven fruitful in the pursuit of optimal control, but these approaches focus on the singular goal of finding the exact, optimal protocol. Here, we investigate the diversity of protocols that achieve low dissipation with a Monte Carlo path sampling algorithm. Akin to Boltzmann weighting configurations in Metropolis Monte Carlo, each protocol is exponentially biased by its mean dissipation. We show that the ensemble of low dissipation protocols can be sampled exactly in the Gaussian limit and that the method continues to robustly generate low dissipation protocols, even as the external control drives the system far from equilibrium.

**2:03PM S40.00013 Geometry of dissipative evolution equations**, CELIA REINA, University of Pennsylvania — The modeling of continuum dissipative evolution equations remains a challenge and is primarily based on phenomenological constitutive relations. In this talk we present some connections between the geometry of dissipative gradient flows, the principle of maximum entropy production, large deviation principles for stochastically augmented evolution equations and fluctuation-dissipation relations.

**11:15AM S41.00001 Dynamics and mechanism of ultrafast water-protein interactions**, DONGPING ZHONG<sup>1</sup>, Ohio State Univ - Columbus — Protein hydration is essential to protein stability, flexibility, dynamics and function. We have used a tryptophan scan with femtosecond spectroscopy to probe global surface water dynamics and characterize the coupled interactions of water and proteins. With extensive temperature-dependent studies, we found that water plays the dominant role to drive relaxation on the picosecond time scales. By measuring both water and protein relaxations, it shows that hydration water drives local protein fluctuations, a clear beta-relaxation, and such results are significant for the understanding of protein dynamics and functions.

<sup>1</sup>This is an invited speaker.

**11:51AM S41.00002 Effect of protein crystal hydration on side chain conformational heterogeneity**, HAKAN ATAKISI, DAVID MOREAU, JESSE HOPKINS, ROBERT THORNE, Cornell University, ROBERT THORNE'S GROUP TEAM — The structure of protein crystals is determined in part by water-mediated interactions involving both protein surface-ordered (hydration) and bulk water, and so is sensitive to the relative humidity of the environment. Monoclinic lysozyme provides a remarkable model for studying structural changes induced by dehydration, as it maintains excellent order for relative humidities (r.h.) down to 5%, corresponding to solvent content of 9% by volume, much smaller than the 88% (22% by volume) at which lysozyme loses its enzymatic activity. Although the main chain conformation does not change significantly, the effect of dehydration on side chain conformations has not been systematically studied. High resolution (1.1 to 1.7 Å) structural data sets for monoclinic lysozyme at r.h. between 99% and 11% have been analyzed to identify major and minor side chain conformers at each humidity, and to map out how the side chain conformational ensemble evolves with hydration. Modest dehydration produces comparable overall effects to cooling to  $T=100$  K, but with conformational changes largely confined to solvent-exposed residues. The largest side chain conformation changes occur at humidities that deplete water within the first two hydration shells.

**12:03PM S41.00003 Determination of Protein Surface Hydration by Systematic Charge Mutations.**, JIN YANG, Department of Physics, The Ohio State University, MENGHUI JIA, State Key Laboratory of Precision Spectroscopy, East China Normal University, YANGZHONG QIN, Department of Physics, The Ohio State University, DIHAO WANG, Program of Biochemistry, The Ohio State University, HAIFENG PAN, State Key Laboratory of Precision Spectroscopy, East China Normal University, LIJUAN WANG, Department of Physics, The Ohio State University, JIANHUA XU, State Key Laboratory of Precision Spectroscopy, East China Normal University, DONGPING ZHONG, Department of Physics, Department of Chemistry and Biochemistry, and Programs of Biophysics, Chemical Physics and Biochemistry, The Ohio State University, DONGPING ZHONG COLLABORATION, JIANHUA XU COLLABORATION — Protein surface hydration is critical to its structural stability, flexibility, dynamics and function. Recent observations of surface solvation on picosecond time scales have evoked debate on the origin of such relatively slow motions, from hydration water or protein charged sidechains, especially with molecular dynamics simulations. Here, we used a unique nuclease with a single tryptophan as a local probe and systematically mutated neighboring three charged residues to differentiate the contributions from hydration water and charged sidechains. By mutations of alternative one and two and all three charged residues, we observed slight increases in the total tryptophan Stokes shifts with less neighboring charged residue(s) and found insensitivity of charged sidechains to the relaxation patterns. The dynamics is correlated with hydration water relaxation with the slowest time in a dense charged environment and the fastest time at a hydrophobic site. On such picosecond time scales, the protein surface motion is restricted. The total Stokes shifts are dominantly from hydration water relaxation and the slow dynamics is from water-driven relaxation, coupled with local protein fluctuations.

**12:15PM S41.00004 Biomolecular solvation study of proteins in liquid water by a wide range gigahertz-to-terahertz spectroscopy**, ALI CHARKHESHT, DEEPU GEORGE, VINH NGUYEN, Virginia Tech — Solvent dynamics within biomolecular solvation layers play a major role in enzyme activity, but obtaining an accurate and quantitative picture of solvent activity around proteins is challenging. Due to the strong absorption of water in the gigahertz-to-terahertz frequencies, it is challenging to study properties of the solvent dynamics as well as conformational changes protein in water. We have developed a highly sensitive dielectric gigahertz-to-terahertz frequency-domain spectroscopy system for probing the collective dynamics of proteins and solvent. Using this technique, we investigate the complex dielectric response of bovine serum albumin and lysozyme proteins in aqueous environment on a wide frequency range from 0.1 GHz up to 2 THz. We explore the conformation flexibility of proteins and compare the hydration dynamics around proteins to understand the effects of surface-mediated solvent dynamics, relationships among different measures of interfacial solvent dynamics, and protein-mediated solvent dynamics.

**12:27PM S41.00005 Structure and conformation of peptides at air/aqueous interface and their impact on interfacial water structure.**, KAILASH CHANDRA JENA<sup>1</sup>, Assistant Professor, DEEPAK TOMAR<sup>2</sup>, Research Scholar — Process of protein folding is very essential for the proper functioning of the protein molecules at membrane surface and other organelles. Understanding the process of protein folding at various biological relevant aqueous interfaces are very important to understand various complicated chemical and physical processes relevant to chemistry, physics, and medicine. The building blocks of proteins molecules are amino acids and the chemistry of each amino acid is very different; as a consequence their sequence plays an important role for various conformations upon adsorption for the protein molecules. In the present study, we have investigated the interfacial structure and conformation of two amino acids (L-Proline and L-Tyrosine) and peptide molecules formed from these two amino acids (L-Tyr-Pro). We have used sum frequency generation (SFG) vibrational spectroscopy to probe the air/aqueous interface. We have studied the impact of adsorption of the amino acids and the peptide molecules on the interfacial water structure by slowly varying concentration and ionic strength of the solutions. Our preliminary result shows a huge impact of the adsorption process of peptide molecules on the hydrogen bonding environment of interfacial structure of water.

**12:39PM S41.00006 Roles of urea and TMAO on the interaction between extended non-polar peptides**, ZHAOQIAN SU<sup>1</sup>, CRISTIANO DIAS<sup>2</sup>, New Jersey Inst of Tech — Urea and trimethylamine n-oxide (TMAO) are small molecules known to destabilize and stabilize, respectively, the structure of proteins when added to aqueous solution. To unravel the molecular mechanisms of these cosolvents on protein structure we perform explicit all-atom molecular dynamics simulations of extended poly-alanine and polyleucine dimers. We use an umbrella sampling protocol to compute the potential of mean force (PMF) of dimers at different concentrations of urea and TMAO. We find that the large non-polar side chain of leucine is affected by urea whereas backbone atoms and alanine's side chain are not. Urea is found to occupy positions between leucine's side chains that are not accessible to water. This accounts for extra Lennard-Jones bonds between urea and side chains that favors the unfolded state. These bonds compete with urea-solvent interactions that favor the folded state. The sum of these two energetic terms provide the enthalpic driving force for unfolding. We show here that this enthalpy correlate with the potential of mean force of poly-leucine dimers. Moreover, the framework developed here is general and may be used to provide insights into effects of other small molecules on protein interactions. The effect of the TMAO will be in the presentation.

**12:51PM S41.00007 Theory Of Salt Effects On Protein Solubility**<sup>1</sup>, YUBA DAHAL, JEREMY SCHMIT, Kansas State Univ — Salt is one of the major factors that effects protein solubility. Often, at low salt concentration regime, protein solubility increases with the salt concentration (salting in) whereas at high salt concentration regime, solubility decreases with the increase in salt concentration (salting out). There are no quantitative theories to explain salting in and salting out. We have developed a model to describe the salting in and salting out. Our model accounts for the electrostatic Coulomb energy, salt entropy and non-electrostatic interaction between proteins. We analytically solve the linearized Poisson Boltzmann equation modelling the protein charge by a first order multipole expansion. In our model, protein charges are modulated by the anion binding. Consideration of only the zeroth order term in protein charge doesn't help to describe salting in phenomenon because of the repulsive interaction. To capture the salting in behaviour, it requires an attractive electrostatic interaction in low salt regime. Our work shows that at low salt concentration, dipole interaction is the cause for salting in and at high salt concentration a salt-dependent depletion interaction dominates and gives the salting out. Our theoretical result is consistent with the experimental result for Chymosin protein

### 1:03PM S41.00008 Computational and Experimental Study of Neuroglobin and Mutants<sup>1</sup>

LAUREN NELSON, Wake Forest University Department of Physics, SAMUEL CHO, Wake Forest University Departments of Physics and Computer Science, DANIEL KIM-SHAPRIO, Wake Forest University Department of Physics —

Neuroglobin (Ngb) is a hexacoordinated heme protein that is closely related to hemoglobin and myoglobin and normally found in the brain and nervous systems. It is involved in cellular oxygen homeostasis and reversibly binds to oxygen with a higher binding affinity than hemoglobin. To protect the brain tissue from hypoxic or ischemic conditions, Ngb increases oxygen availability. We have previously shown that a mutant form of Ngb reduces nitrite to nitric oxide 50x faster than myoglobin and 500x faster than hemoglobin. It also tightly binds to carbon monoxide (CO) with an association rate that is 500x faster than hemoglobin. To analyze the structure of neuroglobin and the characteristics causing these phenomena, we performed 3 sets of 1 microsecond molecular dynamic (MD) simulations of wild-type oxidized and reduced human Ngb and their C46A, C55A, H64L, and H64Q mutants. We also directly compare our MD simulations with time-resolved absorption spectroscopy. These studies will help identify treatments for diseases involving low nitric oxide availability and carbon monoxide poisoning.

### 1:15PM S41.00009 Analysis of Cavity Volumes in Proteins Using Percolation Theory , SHERIDAN GREEN, The University of North Carolina at Chapel Hill, DONALD JACOBS, JENNY FARMER, The University of North Carolina at Charlotte —

Molecular packing is studied in a diverse set of globular proteins in their native state ranging in size from 34 to 839 residues. An new algorithm has been developed that builds upon the classic Hoshen-Kopelman algorithm for site percolation combined with a local connection criterion that classifies empty space within a protein as a cavity when large enough to hold a spherical shaped probe of radius, R, otherwise a microvoid. Although microvoid cannot fit an object (e.g. molecule or ion) that is the size of the probe or larger, total microvoid volume is a major contribution to protein volume. Importantly, the cavity and microvoid classification depends on probe radius. As probe size decreases, less microvoid forms in favor of more cavities. As probe size is varied from large to small, many disconnected cavities merge to form a percolating path. For fixed probe size, microvoid, cavity and solvent accessible boundary volume properties reflect conformational fluctuations. These results are visualized on three-dimensional structures. Analysis of the cluster statistics within the framework of percolation theory suggests interconversion between microvoid and cavity pathways regulate the dynamics of solvent penetration during partial unfolding events important to protein function.

### 1:27PM S41.00010 Characterization of DNA-protein interactions using high-throughput sequencing data from pulldown experiments<sup>1</sup> , BLYTHE MORELAND, Ohio State Univ - Columbus, KENJI OMAN, Fred Hutchinson Cancer Research Center, JOHN CURFMAN, PEARLLY YAN, RALF BUNDSCHUH, Ohio State Univ - Columbus —

Methyl-binding domain (MBD) protein pulldown experiments have been a valuable tool in measuring the levels of methylated CpG dinucleotides. Due to the frequent use of this technique, high-throughput sequencing data sets are available that allow a detailed quantitative characterization of the underlying interaction between methylated DNA and MBD proteins. Analyzing such data sets, we first found that two such proteins cannot bind closer to each other than 2 bp, consistent with structural models of the DNA-protein interaction. Second, the large amount of sequencing data allowed us to find rather weak but nevertheless clearly statistically significant sequence preferences for several bases around the required CpG. These results demonstrate that pulldown sequencing is a high-precision tool in characterizing DNA-protein interactions.

### 1:39PM S41.00011 Molecular stripping in the $NF\kappa B/I\kappa B/DNA$ genetic regulatory network ,

DAVIT POTOYAN, PETER WOLYNES, Rice University — Genetic switches based on the  $NF\kappa B/I\kappa B/DNA$  system are master regulators of an array of cellular responses. Recent kinetic experiments have shown that  $I\kappa B$  can actively remove  $NF\kappa B$  bound to its genetic sites via a process called "molecular stripping". This allows the  $NF\kappa B/I\kappa B/DNA$  switch to function under kinetic control rather than the thermodynamic control contemplated in the traditional models of gene switches. Using molecular dynamics simulations of coarse grained predictive energy landscape models for the constituent proteins by themselves and interacting with the DNA we explore the functional motions of the transcription factor  $NF\kappa B$  and its various binary and ternary complexes with DNA and the inhibitor  $I\kappa B$ . These studies show that the function of the  $NF\kappa B/I\kappa B/DNA$  genetic switch is realized via an allosteric mechanism. Molecular stripping occurs through the activation of a domain twist mode by the binding of  $I\kappa B$  which occurs through conformational selection. Free energy calculations for DNA binding show that the binding of  $I\kappa B$  not only results in a significant decrease of the affinity of the transcription factor for the DNA but also kinetically speeds DNA release. Projections of the

### 1:51PM S41.00012 Modeling Adsorption Kinetics (Bio-remediation of Heavy Metal Contaminated Water).<sup>1</sup> , CHRIS MCCARTHY, BMCC CUNY —

My talk will focus on modeling the kinetics of the adsorption and filtering process using differential equations, stochastic methods, and recursive functions. The models have been developed in support of our interdisciplinary lab group which is conducting research into bio-remediation of heavy metal contaminated water via filtration through biomass such as spent tea leaves. The spent tea leaves are available in large quantities as a result of the industrial production of tea beverages. The heavy metals bond with the surfaces of the tea leaves (adsorption).

### 11:15AM S42.00001 Polydots, Soft Nanoparticles, at Membrane Interfaces , SIDATH WIJESINGHE,

DVORA PERAHIA, Clemson University, CHRISTOPH JUNGHANS, Los Alamos National Laboratory, GARY GREEST, Sandia National Laboratories — Luminescent polymers confined into long lived nano-configurations form dynamic nanoparticles (NPs) or polydots with a potential for new bio imaging markers and targeted drug delivery vehicles. A key step in the use of any NP for therapeutic applications is their translocation across membranes. Here we report the results of all-atom molecular dynamics simulation of a polydot that consists of carboxylate decorated dinonyl poly para phenylene ethynylene, at the interface with a 1,2-dipalmitoyl-sn-glycero-3-phosphocholine (DPPC) bilayer. The polydot size and surface charge are controlled by varying the polymer molecular weight and degree of carboxylation. The polydot structure and its effect on the membrane structure are probed. We find that the polydot remains stable as it transcends the membrane where the initial curvature of the membrane is strongly affected as polydot inserted, but it relaxes with time. The larger the polydots are the less dynamic the DPPC molecules become. Further we find that neutral-surface polydots reside in the center of the bilayer, while increasing the polydot surface charge, the polydot migrates towards the hydrophilic leaflet of the bilayer.

**11:27AM S42.00002 Surface-Engineered Graphene Quantum Dots for Shape Control of Block Copolymer Particles**, HYUNSEUNG YANG, KANG HEE KU, JAE MAN SHIN, JUNHYUK LEE, CHAN HO PARK, HAN-HEE CHO, KAIST, SE GYU JANG, KIST, BUMJOON KIM, KAIST, KIST COLLABORATION — Surface-engineered, 10 nm-sized graphene quantum dots (GQDs) are shown to be efficient surfactants for producing poly(styrene-*b*-4-vinylpyridine) (PS-*b*-P4VP) particles that feature tunable shapes and internal morphologies. The surface properties of GQDs were modified by grafting different alkyl ligands, such as hexylamine and oleylamine, to generate the surfactant behavior of the GQDs. In stark contrast to the behavior of the unmodified GQDs, hexylamine-grafted GQDs and oleylamine-grafted GQD surfactants were selectively positioned on the PS and P4VP domains, respectively, at the surface of the particles. This positioning effectively tuned the interfacial interaction between two different PS/P4VP domains of the particles and the surrounding water during emulsification and induced a dramatic morphological transition to an unconventional convex lens-shaped particles. Precise and systematic control of interfacial activity of GQD surfactants was also demonstrated by varying the density of the alkyl ligands on the GQDs. The excellent surface tunability of 10 nm-sized GQDs combined with their significant optical and electrical properties highlight their importance as surfactants for producing colloidal particles with novel functions.

**11:39AM S42.00003 Self-Assembled Soft Porous Particles with Tailored Nano-Porosity.**, KANG HEE KU, JAEMAN SHIN, KAIST, DANIEL KLINGER, U.C. Santa Barbara, RYAN C. HAYWARD, University of Massachusetts, SE GYU JANG, KIST, CRAIG J. HAWKER, U.C. Santa Barbara, BUMJOON J. KIM, KAIST — A series of porous block copolymer (BCP) particles with controlled porosity and nanostructure was fabricated by tuning interfacial hydrodynamics of toluene-in-water emulsion droplets. A synergistic adsorption of polystyrene-*b*-poly(4-vinylpyridine) (PS-*b*-P4VP) BCPs and sodium dodecyl sulfate (SDS) to the surface of emulsion particle induced a dramatic decrease in the interfacial tension and generated the interfacial instability at the particle surface, thus producing different types of particles including closed pore particles, open pore particles, capsules and micelles. In particular, the SDS concentration and the P4VP volume fraction of PS-*b*-P4VP were key parameters in determining the degree of interfacial instability of the emulsion, producing porous particles with tunable pore sizes ranging from 10 to 500 nm. These porous particles could be used as pH responsive carriers, which were demonstrated by combining and releasing of different colored dyes to particles at desired pH conditions.

**11:51AM S42.00004 Particle-Directed Assembly of Semiflexible Polymer Chains**, MICHAEL MCGOVERN, KEVIN DORFMAN, DAVID MORSE, University of Minnesota — We use molecular dynamics simulations to investigate several models of semiflexible polymers that exhibit an attractive interaction with spherical particles. The organization of semiflexible polymer chains through attractive interactions with spherical particles occurs in several important processes in nature, such as the winding of DNA around histones and counter-ion condensation of charged polymers. The process is also of technological interest in the packaging of DNA for delivery to cells. In this presentation, we will present data on both the phase behavior and the kinetics of self-assembly as a function of the stiffness of the polymers, the attractive potential between the monomers and the particles, and the relative size of the monomers and particles. Our simulations suggest a transition between globular and rod-like aggregates that changes from a gradual to a sudden transition depending on particle size, and that rod formation is a slow, nucleation dependent process.

**12:03PM S42.00005 Structure and Entanglement Factors on Dynamics of Polymer Grafted Magnetic Nanoparticles**, SIQI LIU, Stevens Institute of Technology, ERKAN SENSES, NCNR NIST, YANG JIAO, Air Force Research Laboratory, SURESH NARAYANAN, Argonne National Laboratory, PINAR AKCORA, Stevens Institute of Technology — Magnetic nanoparticles functionalized with long polymer chains at low graft density are interesting systems to study structure-dynamic relationships in polymer nanocomposites since they are shown to aggregate into strings in both solution and melts, and also into spheres and branched aggregates in the presence of free polymer chains. This work investigates the structure, free volume and entanglement effects in composites of polystyrene grafted iron oxide nanoparticles by measuring particle dynamics with x-ray photon correlation spectroscopy technique. Particles of highly ordered strings and aggregated systems follow heterogeneous dynamics commonly observed in jammed soft glassy systems and other nanocomposites. On the other hand, particle dynamics becomes diffusive in branched structures which could be caused by the less penetration of long matrix chains into the brushes. These results show that particle dynamics is dictated through the strong interactions of low graft density chains with the host polymer.

**12:15PM S42.00006 Selective Permeability of Uranyl Peroxide Nanocages to Different Alkali Ions: Influences from Surface Pores and Hydration Shells<sup>1</sup>**, YUNYI GAO, Univ of Akron, JENNIFER SZYMANOWSKI, PETER BURNS, University of Notre Dame, TIANBO LIU, Univ of Akron — The precise guidance to different ions across the biological channels is essential for many biological processes. An artificial nanopore system will facilitate the study of ion transport mechanism through nanosized channels and offer new views for designing nanodevices. Here we reveal that a 2.5-nm-size, fullerene-shaped molecular cluster  $\text{Li}_{48+m}\text{K}_{12}(\text{OH})_m[\text{UO}_2(\text{O}_2)(\text{OH})]_{60-(\text{H}_2\text{O})_n}$  ( $m \approx 20$  and  $n \approx 310$ ) ( $\text{U}_{60}$ ) shows selective permeability to different alkali ions. The sub-nanometer pores on the water-ligand-rich surface of  $\text{U}_{60}$  are able to block  $\text{Rb}^+$  and  $\text{Cs}^+$  ions from passing through, while allow  $\text{Na}^+$  and  $\text{K}^+$  ions, which possess larger hydrated sizes, to enter the interior space of  $\text{U}_{60}$ . An interestingly high entropy gain during the binding process between  $\text{U}_{60}$  and alkali ions suggest that the hydration shells of  $\text{Na}^+/\text{K}^+$  and  $\text{U}_{60}$  are damaged during the interaction. The ion selectivity of  $\text{U}_{60}$  is greatly influenced by both the morphologies of surface nanopores and the dynamics of the hydration shells.

**12:27PM S42.00007 Understanding of DNA directed nanoparticle superlattices in bulk and thin film**, BYEONGDU LEE, Argonne National Laboratory — Over the years, there have been significant advances in assembling nanoparticles with DNA into superlattices. Since the first reports on DNA directed FCC and BCC superlattices consisting of single type of spherical nanoparticles,[1,2] building blocks for the DNA-nanoparticle superlattices have been extended from a spherical gold nanoparticle to various types of other particles including quantum dots, magnetic, hollow, or polyhedral particles.[3,4] Not only single component, but superlattices of binary[5] and ternary components[6] have also been synthesized. Although still many details are unclear, now there is a general consensus about thermodynamics of this type of assembly, which led us to fabricate thin films of DNA directed nanoparticle superlattices on substrate for applications such as optical materials.[7] Since the structures are formed in aqueous condition, small angle x-ray scattering (SAXS) that does not disturb the system has been a critical tool to determine structural and thermodynamic characteristics of the assemblies. Thus, we have also been improving SAXS instrumentations and computational methods to calculate scattering profiles for the nanoparticle superlattices.[8] In this talk, we will summarize our works with a focus on some structural details of these superlattices and DNA and understanding about the role of DNA in the crystallization processes in bulk and thin film. 1. **1:03PM S42.00008 Modeling of water-borne coating: stress relaxation of suspensions of colloids linked by telechelic HEUR polymers.**<sup>1</sup> , SHIHU WANG, RONALD G. LARSON, Univ of Michigan - Ann Arbor — In water-borne coatings, the rheology of colloidal suspensions is modified by the presence of rheological modifiers, such as Hydrophobic Ethoxylated Urethane (HEUR) polymers. HEUR is a telechelic polymer with two hydrophobic tails (hydrophobes) and a long hydrophilic interblock consisting of poly(ethylene oxide), and its thickening effect is largely determined by the self-association of hydrophobes as well as their adsorption onto latex particles. Here we describe a model that simulates the complex interactions among latex particles due to the formation of bridges or superbridges via model HEURs. We calculate the stress relaxation of the system and identify different relaxation modes. We explore the relaxation time at different latex volume fractions, HEUR concentrations and energies of association between hydrophobes and latex particles, and discuss its relationship with the bridge or latex cluster formation. These results provide important insights for HEUR adsorption and water-borne coating rheology.

**1:15PM S42.00009 Anisotropic Packing of DNA-Mediated Colloidal Self-Assembly** , THI VO, Chemical Engineering, Columbia University, FANG LU, YUGANG ZHANG, OLEG GANG, Center for Functional Nanomaterials, Brookhaven National Lab, SANAT KUMAR, Chemical Engineering, Columbia University — The self-assembly of DNA-grafted nanoparticles has garnered considerable interest in recent years. However, many efforts focused on the usage of spherical nanoparticles, which limits us to the formation of only a handful of crystal lattices. Recent advances in the synthesis of non-spherical particles have directed attention towards the usage of these anisotropic particles for self-assembly. Here we combine experiments and theory on a series of DNA-grafted nanocubes. Our studies indicate that anisotropy not only directs where DNA linkers graft onto the particle but also affects how they pack and orient within a lattice, giving rise to both a preferential attachment effect and orientation-directed self-assembly. These results emphasize anisotropic self-assembly as a powerful new tool that allows for precise and directed control of nanoparticle self-assembly.

**1:27PM S42.00010 Giant soft-memory in liquid crystal-nanocomposites** , RAVINDRA KEMPAIAH, YIJING LIU, ZHIHONG NIE, University of Maryland, College Park, RAJRATAN BASU, US Naval Academy — Here, we report a novel way of introducing giant, non-volatile soft-memory in a nanocomposite comprising of amphiphilic polymer functionalized barium titanate ( $\text{BaTiO}_3$ ) nanoparticles and *isotropic* phase of 5CB liquid crystal. Doping of pure ferroelectric NPs in isotropic phase of 5CB creates nanoscopic domains of highly ordered regions as 5CB molecules arrange themselves around the NPs and we call these regions, *pseudonematic domains*. Here, mesogens can *electromechanically* rotate the  $\text{BaTiO}_3$  NPs within the domain, along the direction of applied electric field. These domains are spatially and thermodynamically locked-in and retain their directional orientation and net polarization even after the applied electric field is switched off. We call this net remnant polarization or hysteresis, '*soft memory*'. When NPs are functionalized with amphiphilic block copolymers, self-assembly of mesogens occurs at the interface of polymer tethers and nanoparticles via combination of non-covalent coupling and  $\pi$ - $\pi$  stacking interaction and this results in multi-fold enhancement in the volume of pseudonematic domains and subsequent increase in the soft memory. This work provides new insight into understanding the interaction of nanoparticles, polymers and liquid crystal and potentially lead to the creation of nanoelectromechanical (NEMS) storage device using functionalized nanoparticles.

**1:39PM S42.00011 Temperature Effects on Soft Polymeric Nanoparticles: Molecular Dynamics Study**<sup>1</sup> , SABINA MASKEY, Clemson University, GARY S. GRETT, Sandia National Laboratory, DVORA PERAHIA, Clemson University — Luminescent polymers collapsed into soft nanoparticles or polydots have emerged as the potential candidates for biomedical applications such as drug delivery and biosensing. Here, using fully atomistic molecular dynamics simulation, the temperatures effects on the stability, internal structure and dynamics of polydots formed by substituted and bare dialkyl *para* phenylene ethynylenes (PPEs) will be discussed. We find that with increasing temperature from 300 K to 600K both substituted and bare PPE polydots expand but do not fully unfold and remain in their confined state. As observed visually and by measurement of structure factor  $S(q)$ , the overall shape of the both type of polydots changes from spherical to elongated with the increase in temperature. These effects are more pronounced for bare PPE polydots which show that interdigitation of side chains in substituted PPE polydots enhances stability. In addition, the side chains are more dynamic than the backbone..

**1:51PM S42.00012 Spectroscopic Investigations on PVDF-MWCNTs Nanocomposites.** , OSCAR GUERRERO, SAMANTHA RAMIREZ, ROBERT JONES, BRIAN YUST, JAMES HINTHORNE, MIRCEA CHIPARA, Univ of Texas Rio Grande Valley — Nanocomposites have been obtained by dispersing Multi Walled Carbon Nanotubes (MWCNTs) within polyvinylidene fluoride. Various samples loaded by 0 to 20 % wt. MWCNTs have been obtained by melt mixing using a Haake RheoMixer, with two counter rotating screws. The effect of the nanofiller concentration on the glass, melting, and crystallization temperatures, as determined from Differential Scanning Calorimetry measurements, is reported. Small shifts towards higher temperatures as the loading with MWCNTs was increased have been noticed. A detailed analysis on the effect of MWCNTs on the degree of crystallinity of PVDF is reported. Raman data obtained by using a Renishaw InVia spectrometer have been used to estimate the stress transfer. Additional information was obtained by FTIR and Wide Angle X-Ray Scattering. The nature of the crystalline phases was determined for each sample. Thermogravimetric data showed a small increase of the thermal stability of the polymeric matrix upon the loading with MWCNTs.

**2:03PM S42.00013 Investigation of Molecular Interactions between AFM-Tip and Thiol Films**<sup>1</sup> , AHMED TOUHAMI, JUSTIN MOORE, University of Texas Rio Grande Valley, T. RANDALL LEE, University of Houston — Among various self-assembly processes, the formation of a self-assembled monolayer (SAM) is one of the most elegant ways for making an organic film with specific surface properties. Recently, much effort has been devoted in using AFM-based single-molecule force spectroscopy (SMFS) to understanding the formation of alkanethiol SAMs on gold surfaces. Investigating the factors that affect the AFM tip-SAMs interactions is necessary to clarify the controversial results of these studies. Here, we investigated the interactions between bare AFM-tips and several SAMs thiols-gold surfaces under controlled humidity conditions. Our results demonstrate that the Tip-SAM interactions can be used to precisely determine the length of the thiol chains, the adhesion force between thiols head groups and the AFM tip, and the strength of the thiol-gold contact. Our findings on the dynamics and the structure of the SAMs of alkanethiols on gold are useful for detail understanding of the thermodynamics, kinetics and mechanisms of SAM technology assembly.

## 11:15AM S43.00001 Quantifying Stability in Complex Networks: From Linear to Basin Stability

JÜRGEN KURTHS, Humboldt University — The human brain, power grids, arrays of coupled lasers and the Amazon rainforest are all characterized by multistability. The likelihood that these systems will remain in the most desirable of their many stable states depends on their stability against significant perturbations, particularly in a state space populated by undesirable states. Here we claim that the traditional linearization-based approach to stability is in several cases too local to adequately assess how stable a state is. Instead, we quantify it in terms of basin stability, a new measure related to the volume of the basin of attraction. Basin stability is non-local, nonlinear and easily applicable, even to high-dimensional systems. It provides a long-sought-after explanation for the surprisingly regular topologies of neural networks and power grids, which have eluded theoretical description based solely on linear stability. Specifically, we employ a component-wise version of basin stability, a nonlinear inspection scheme, to investigate how a grid's degree of stability is influenced by certain patterns in the wiring topology. Various statistics from our ensemble simulations all support one main finding: The widespread and cheapest of all connection schemes, namely dead ends and dead trees, strongly diminish stability. For the Northern European power system we demonstrate that the inverse is also true: 'Healing' dead ends by addition of transmission lines substantially enhances stability. This indicates a crucial smart-design principle for tomorrow's sustainable power grids: add just a few more lines to avoid dead ends. Further, we analyse the particular function of certain network motifs to promote the stability of the system. Here we uncover the impact of so-called detour motifs on the appearance of nodes with a poor stability score and discuss the implications for power grid design. Moreover, it will be shown that basin stability enables uncovering the mechanism for explosive synchronization and understanding of evolving networks.

## 11:51AM S43.00002 Control of State Transitions in Complex and Biophysical Networks<sup>1</sup>

ADILSON MOTTER, DANIEL WELLS, WILLIAM KATH, Northwestern University — Noise is a fundamental part of intracellular processes. While the response of biological systems to noise has been studied extensively, there has been limited understanding of how to exploit it to induce a desired cell state. Here I will present a scalable, quantitative method based on the Freidlin-Wentzell action to predict and control noise-induced switching between different states in genetic networks that, conveniently, can also control transitions between stable states in the absence of noise. I will discuss applications of this methodology to predict control interventions that can induce lineage changes and to identify new candidate strategies for cancer therapy. This framework offers a systems approach to identifying the key factors for rationally manipulating network dynamics, and should also find use in controlling other classes of complex networks exhibiting multi-stability. Reference: D. K. Wells, W. L. Kath, and A. E. Motter, *Phys. Rev. X* 5, 031036 (2015).

## 12:03PM S43.00003 Landscape Construction in Dynamical Systems

YING TANG, RUOSHI YUAN, GAOWEI WANG, PING AO, Shanghai Jiao Tong Univ — The idea of landscape has been recently applied to study various of biological problems. We demonstrate that a dynamical structure built into nonlinear dynamical systems allows us to construct such a global optimization landscape, which serves as the Lyapunov function for the ordinary differential equation. We find exact constructions on the landscape for a class of dynamical systems, including a van der Pol type oscillator, competitive Lotka-Volterra systems, and a chaotic system. The landscape constructed provides a new angle for understanding and modelling biological network dynamics.

## 12:15PM S43.00004 Cell fate reprogramming by control of intracellular network dynamics<sup>1</sup>

JORGE G. T. ZANUDO, REKA ALBERT, The Pennsylvania State University — Identifying control strategies for biological networks is paramount for practical applications that involve reprogramming a cell's fate, such as disease therapeutics and stem cell reprogramming. Although the topic of controlling the dynamics of a system has a long history in control theory, most of this work is not directly applicable to intracellular networks. Here we present a network control method that integrates the structural and functional information available for intracellular networks to predict control targets. Formulated in a logical dynamic scheme, our control method takes advantage of certain function-dependent network components and their relation to steady states in order to identify control targets, which are guaranteed to drive any initial state to the target state with 100% effectiveness and need to be applied only transiently for the system to reach and stay in the desired state. We illustrate our method's potential to find intervention targets for cancer treatment and cell differentiation by applying it to a leukemia signaling network and to the network controlling the differentiation of T cells. We find that the predicted control targets are effective in a broad dynamic framework. Moreover, several of the predicted interventions are supported by experiments.

## 12:27PM S43.00005 Predictive Control of Large Complex Networks

ALEKSANDAR HABER, ADILSON E. MOTTER, Northwestern University — Networks of coupled dynamical subsystems are increasingly used to represent complex natural and engineered systems. While recent technological developments give us improved means to actively control the dynamics of individual subsystems in various domains, network control remains a challenging problem due to difficulties imposed by intrinsic nonlinearities, control constraints, and the large-scale nature of the systems. In this talk, we will present a model predictive control approach that is effective while accounting for these realistic properties of complex networks. Our method can systematically identify control interventions that steer the trajectory to a desired state, even in the presence of strong nonlinearities and constraints. Numerical tests show that the method is applicable to a variety of networks, ranging from power grids to chemical reaction systems.

## 12:39PM S43.00006 Reconstructing Directed Networks From Noisy Dynamics<sup>1</sup>

HIU CHING TAM, EMILY SC CHING, Department of Physics, The Chinese University of Hong Kong — Complex systems can be fruitfully studied as networks of many elementary units, known as nodes, interacting with one another with the interactions being the links between the nodes. The overall behavior of the systems depends crucially on the network structure depicting how the nodes are linked with each other. It is usually possible to measure the dynamics of the individual nodes but difficult, if not impossible, to directly measure the interactions or links between the nodes. For most systems of interest, the links are directional in that one node affects the dynamics of the other but not vice versa. Moreover, the strength of interaction can vary for different links. Reconstructing directed and weighted networks from dynamics is one of the biggest challenges in network research. We have studied directed and weighted networks modelled by noisy dynamical systems with nonlinear dynamics and developed a method that reconstructs the links and their directions using only the dynamics of the nodes as input. Our method is motivated by a mathematical result derived for dynamical systems that approach a fixed point in the noise-free limit. We show that our method gives good reconstruction results for several directed and weighted networks with different nonlinear dynamics.

**12:51PM S43.00007 Hamiltonian-Based Model to Describe the Nonlinear Physics of Cascading Failures in Power-Grid Networks**, YANG YANG, ADILSON MOTTER, Department of Physics and Astronomy, Northwestern University — A local disturbance to the state of a power-grid system can trigger a protective response that disables some grid components, which leads to further responses, and may finally result in large-scale failures. In this talk, I will introduce a Hamiltonian-like model of cascading failures in power grids. This model includes the state variables of generators, which are determined by the nonlinear swing equations and power-flow equations, as well as the on/off status of the network components. This framework allows us to view a cascading failure in the power grid as a phase-space transition from a fixed point with high energy to a fixed point with lower energy. Using real power-grid networks, I will demonstrate that possible cascade outcomes can be predicted by analyzing the stability of the system's equilibria. This work adds an important new dimension to the current understanding of cascading failures.

**1:03PM S43.00008 Cascading Failures in Flow-Driven Networks Induced by Multiple Initiators**<sup>1</sup>, ALAA MOUSSAWI, NOEMI DERZSY, XIN LIN, BOLESŁAW SZYMANSKI, GYORGY KORNISS, Rensselaer Polytechnic Institute — Flow-driven networks are particularly prone to cascading failures. These failures are non self-averaging and this makes them very difficult to predict or subdue [1, 2]. Previous work has suggested that uniformly increasing edge or node capacities may lead to larger failures [1]. This suggests that some nodes/edges may act as fuses and mitigate cascading failures. We investigate this idea, and analyze how properties of the initiators of the cascade influence its outcome. We also discuss how stochastic node capacity allocation can be utilized to mitigate cascades induced by multiple initiators. We demonstrate the efficacy of these strategies on random geometric graphs (RGG) and the UCTE European electrical power transmission network, with capacities allocated in a fashion similar to the industry standard. [1] A. Asztalos, S. Sreenivasan, B.K. Szymanski, and G. Korniss, "Cascading Failures in Spatially-Embedded Random Networks", PLOS ONE 9(1): e84563 (2014). **1:15PM S43.00009 Cascading processes on multiplex networks: Impact of weak layers**, KYU-MIN LEE, KWANG-IL GOH, Korea University — Many real-world complex systems such as biological and socio-technological systems consist of manifold layers in multiplex networks. The multiple network layers give rise to the nonlinear effect for the emergent dynamics of systems. Especially, the weak layers plays the significant role in nonlinearity of multiplex networks, which can be neglected in single-layer network framework overlaying all layers. Here we present a simple model of cascades on multiplex networks of heterogeneous layers. The model is simulated on the multiplex network of international trades. We found that the multiplex model produces more catastrophic cascading failures which were the result of collective behaviors from coupling layers rather than the simple summation effect. Therefore risks can be systematically underestimated in simply overlaid network system because the impact of weak layers is overlooked. Our simple theoretical model would have some implications to investigate and design optimal real-world complex systems.

**1:27PM S43.00010 Long-term Failure Prediction based on an ARP Model of Global Risk Network**<sup>1</sup>, XIN LIN, ALAA MOUSSAWI, BOLESŁAW SZYMANSKI, GYORGY KORNISS, Rensselaer Polytechnic Institute — Risks that threaten modern societies form an intricately interconnected network. Hence, it is important to understand how risk materializations in distinct domains influence each other. In the paper <sup>2</sup>, we study the global risks network defined by World Economic Forum experts in the form of Stochastic Block Model. We model risks as Alternating Renewal Processes with variable intensities driven by hidden values of exogenous and endogenous failure probabilities. Based on the expert assessments and historical status of each risk, we use Maximum Likelihood Evaluation to find the optimal model parameters and demonstrate that the model considering network effects significantly outperforms the others. In the talk, we discuss how the model can be used to provide quantitative means for measuring interdependencies and materialization of risks in the network. We also present recent results of long-term predictions in the form of predicated distributions of materializations over various time periods. Finally we show how the simulation of ARPs enables us to probe limits of the predictability of the system parameters from historical data and ability to recover hidden variable.

**1:39PM S43.00011 Hybrid dynamics in delay-coupled swarms with “mothership” networks**<sup>1</sup>, JASON HINDES, IRA SCHWARTZ, U.S. Naval Research Laboratory — Swarming behavior continues to be a subject of immense interest because of its centrality in many naturally occurring systems in biology and physics. Moreover, the development of autonomous mobile agents that can mimic the behavior of swarms and can be engineered to perform complex tasks without constant intervention is a very active field of practical research. Here we examine the effects on delay-coupled swarm pattern formation from the inclusion of a small fraction of highly connected nodes, “motherships”, in the swarm interaction network. We find a variety of new behaviors and bifurcations, including new hybrid motions of previously analyzed patterns. Both numerical and analytic techniques are used to classify the dynamics and construct the phase diagram. The implications for swarm control and robustness from topological heterogeneity are also discussed.

**11:15AM S44.00001 A universal scheme for indirect quantum control**<sup>1</sup>, DAVID LAYDEN, University of Waterloo (Department of Applied Mathematics), Institute for Quantum Computing, EDUARDO MARTIN-MARTINEZ, ACHIM KEMPF, University of Waterloo (Department of Applied Mathematics), Institute for Quantum Computing, Perimeter Institute for Theoretical Physics — The goal of indirect quantum control is to coherently steer a quantum system solely by acting on a quantum actuator to which it is coupled. This approach to quantum control is convenient in many physical settings, as it allows one to avoid direct addressing of the system—and any associated difficulties—altogether. While it is known in principle that control of the actuator typically yields universal control of the system, the practical details of how such indirect control can be achieved are less clear. This deficiency has led to a number of implementation- and model-specific indirect control schemes, in lieu of a general recipe applicable to any physical setting. Here, we present such a recipe, in the form of an open-loop control scheme which implements arbitrary unitary operations on the system by exploiting open dynamics in the actuator.

<sup>1</sup>arXiv:1506.06749

## 11:27AM S44.00002 Symmetry-protected topologically ordered states for universal quantum computation<sup>1</sup>

HENDRIK POULSEN NAUTRUP, Department of Physics and Astronomy, Stony Brook University, TZU-CHIEH WEI, C. N. Yang Institute for Theoretical Physics, Stony Brook University — Measurement-based quantum computation (MBQC) is a model for quantum information processing utilizing only local measurements on suitably entangled resource states for the implementation of quantum gates. A complete characterization for universal resource states is still missing. It has been shown that symmetry-protected topological order (SPTO) in one dimension can be exploited for the protection of certain quantum gates in MBQC. Here we investigate whether any 2D nontrivial SPTO states can serve as resource for MBQC. In particular, we show that the nontrivial SPTO ground state of the CZX model on the square lattice by Chen et al. [Phys. Rev. B **84**, 235141 (2011)] can be reduced to a 2D cluster state by local measurement, hence a universal resource state. Such ground states have been generalized to qudits with symmetry action described by three cocycles of a finite group  $G$  of order  $d$  and shown to exhibit nontrivial SPTO. We also extend these to arbitrary lattices and show that the generalized two-dimensional plaquette states on arbitrary lattices exhibit nontrivial SPTO in terms of symmetry fractionalization and that they are universal resource states for quantum computation. SPTO states therefore can provide a new playground for measurement-based quantum computation.

## 11:39AM S44.00003 Two-dimensional quantum walk under artificial magnetic field

ISKENDER YALCINKAYA, ZAFER GEDIK, Sabanci University — We introduce the Peierls substitution to a two-dimensional discrete-time quantum walk on a square lattice to examine the spreading dynamics and the coin-position entanglement in the presence of an artificial gauge field [1]. We use the ratio of the magnetic flux through the unit cell to the flux quantum as a control parameter. For a given flux ratio, we obtain faster spreading for a small number of steps and the walker tends to be highly localized around the origin. Moreover, the spreading of the walk can be suppressed and decreased within a limited time interval for specific rational values of flux ratio. When the flux ratio is an irrational number, even for a large number of steps, the spreading exhibit diffusive behavior rather than the well-known ballistic one as in the classical random walk and there is a significant probability of finding the walker at the origin. We also analyze the coin-position entanglement and show that the asymptotic behavior vanishes when the flux ratio is different from zero and the coin-position entanglement become nearly maximal in a periodic manner in a long time range.

## 11:51AM S44.00004 Quantum Ultra-Walks: Walks on a Line with Spatial Disorder<sup>1</sup>

STEFAN BOETTCHER<sup>2</sup>, STEFAN FALKNER<sup>3</sup>, Physics Department, Emory University — We discuss the model of a heterogeneous discrete-time walk on a line with spatial disorder in the form of a set of ultrametric barriers. Simulations show that such a quantum ultra-walk spreads with a walk exponent  $d_w$  that ranges from ballistic ( $d_w = 1$ ) to complete confinement ( $d_w = \infty$ ) for increasing separation  $1 \leq 1/\epsilon < \infty$  in barrier heights. We develop a formalism by which the classical random walk as well as the quantum walk can be treated in parallel using a coined walk with internal degrees of freedom. For the random walk, this amounts to a 2<sup>nd</sup>-order Markov process with a stochastic coin, better known as an (anti-)persistent walk. The exact analysis, based on the real-space renormalization group (RG), reproduces the results of the well-known model<sup>4</sup> of “ultradiffusion,”  $d_w = 1 - \log_2 \epsilon$  for  $0 < \epsilon \leq 1/2$ . However, while the evaluation of the RG fixed-points proceeds virtually identical, for the corresponding quantum walk with a unitary coin<sup>5</sup> it fails to reproduce the numerical results. A new way to analyze the RG is indicated.

## 12:03PM S44.00005 Quantum walks outside of boolean domain as a gate for one, two, or three qubits.

THOMAS CAVIN, DMITRY SOLENOV, Department of Physics, Saint Louis University, St. Louis, MO 63103 — Quantum computing needs entangling quantum gates to perform computation and error correction. We will discuss a novel way to implement quantum gates, such as CNOT, using quantum walks that are directed through a network of states outside of the boolean domain. In such implementations it is important to investigate walks on networks of different connectivities. Specifically, we will discuss solutions to non-symmetric linear chain networks and demonstrate how solutions to more complex networks that have branching, such as cubes, can be expressed in terms of linear chain solutions. We then show examples of implementing single qubit and two-qubit entangling gates.

## 12:15PM S44.00006 Duality quantum computer and the efficient quantum simulations

SHIJIE WEI, GUILU LONG, Tsinghua Univ, TSINGHUA NATIONAL LABORATORY FOR INFORMATION SCIENCE AND TECHNOLOGY COLLABORATION, COLLABORATIVE INNOVATION CENTER OF QUANTUM MATTER COLLABORATION — Duality quantum computer is a new kind of quantum computer which is able to perform an arbitrary sum of unitaries, and therefore a general quantum operator. This gives more computational power than a normal quantum computer. All linear bounded operators can be realized in a duality quantum computer, and unitary operators are just the extreme points of the set of generalized quantum gates. Duality quantum computer can provide flexibility and clear physical picture in designing quantum algorithms, serving as a useful bridge between quantum and classical algorithms. In this report, we will firstly briefly review the theory of duality quantum computer. Then we will introduce the application of duality quantum computer in Hamiltonian simulation. We will show that duality quantum computer can simulate quantum systems more efficiently than ordinary quantum computer by providing descriptions of the recent efficient quantum simulation algorithms.

## 12:27PM S44.00007 Optimized probabilistic quantum processors: A unified geometric approach

JANOS BERGOU, CUNY Hunter College, EMILIO BAGAN, Fisica Teorica: Informacio i Fenomens Quanticos, Universitat Autonoma de Barcelona, EDGAR FELDMAN, Department of Mathematics, Graduate Center of the City University of New York — Using probabilistic [1] and deterministic quantum cloning [2], and quantum state separation [3] as illustrative examples we develop a complete geometric solution for finding their optimal success probabilities. The method is related to the approach that we introduced earlier for the unambiguous discrimination of more than two states [4]. In some cases the method delivers analytical results, in others it leads to intuitive and straightforward numerical solutions. We also present implementations of the schemes based on linear optics employing few-photon interferometry. [1] V. Yerkhin, A. Shehu, E. Feldman, E. Bagan, and J. Bergou, Probabilistically perfect cloning, submitted to PRL (2015). [2] V. Yerkhin, A. Shehu, E. Bagan, E. Feldman, and J. Bergou, Approximate probabilistic cloning, in preparation. [3] V. Yerkhin, A. Shehu, E. Feldman, E. Bagan, and J. Bergou, A geometric approach to state separation, submitted to NJP (2015). [4] J. Bergou, U. Futschik, and E. Feldman, Optimal unambiguous discrimination of pure quantum states, Phys. Rev. Lett. **108**, 250502 (2012).

**12:39PM S44.00008 Three step implementation of any unitary matrix with complete graph of  $n$  qubits**, AMARA KATABARWA, MICHAEL GELLER, Univ of Georgia — The use of programmable array of superconducting qubits for general purpose quantum computation has been recently proposed, and applications to amplitude amplification, phase estimation and simulation of realistic molecular collisions. This Single Excitation Subspace (SES) approach does not require error correction and is practical now. We show that any element in the unitary group  $U(n)$  can be generated in three steps, for any  $n$ . This allows for implementation of highly complex operations in constant time.

**12:51PM S44.00009 Recursive linear optical networks for realizing quantum algorithms<sup>1</sup>**, GELO NOEL TABIA, Univ of Tartu — Linear optics has played a leading role in the development of practical quantum technologies. In recent years, advances in integrated quantum photonics have significantly improved the functionality and scalability of linear optical devices [1]. In this talk, I present recursive schemes for implementing quantum Fourier transforms and inversion about the mean in Grover's algorithm with photonic integrated circuits [2]. By recursive, I mean that two copies of a  $d$ -dimensional unitary operation is used to build the corresponding unitary operation on  $2d$  modes. The linear optical networks operate on path-encoded qudits and realize  $d$ -dimensional unitary operations using  $O(d^2)$  elements. To demonstrate that the recursive circuits are viable in practice, I conducted simulations of proof-of-principle experiments using a fabrication model of realistic errors in silicon-based photonic integrated devices. The results indicate high-fidelity performance in the circuits for 2-qubit and 3-qubit quantum Fourier transforms, and for quantum search on 4-item and 8-item databases. Ref: [1] G. D. Marshall, et al., Opt. Express 17, 12546 (2009); [2] G. N. M. Tabia, arXiv:1509.04246 (2015).

**1:03PM S44.00010 Controlling Quantum Transport with a Programmable Nanophotonic Processor**, NICHOLAS HARRIS, GREGORY STEINBRECHER, JACOB MOWER, YOAV LIHINI, MIHIKA PRABHU, Massachusetts Institute of Technology, TOM BAEHR-JONES, MICHAEL HOCHBERG, Coriant Advanced Technology, SETH LLOYD, DIRK ENGLUND, Massachusetts Institute of Technology — Recent experimental and theoretical work has revealed emergent, counter-intuitive quantum transport effects in a range of physical media including solid-state and biological systems. Photonic integrated circuits are promising platforms for studying such effects. A central goal in for photonic quantum transport simulators has been the ability to rapidly control all parameters of the transport problem. Here, we present a large-scale programmable nanophotonic processor composed of 56 Mach-Zehnder interferometers that enables control over modal couplings and differential phases between modes—enabling observations of Anderson localization, environment-assisted quantum transport, ballistic transport, and a number of intermediate quantum transport regimes. Rapid programmability enables tens of thousands of realizations of disordered and noisy systems. In addition, low loss makes this nanophotonic processor a promising platform for many-boson quantum simulation experiments.

If possible schedule directly before Universal Linear Optics: A Testbed for Optical Quantum Logic, author Chris Sparrow.

**1:15PM S44.00011 Universal Linear Optics: An implementation of Boson Sampling on a Fully Reconfigurable Circuit**, CHRISTOPHER HARROLD, JACQUES CAROLAN, CHRIS SPARROW<sup>1</sup>, NICHOLAS J. RUSSELL, JOSHUA W. SILVERSTONE, GRAHAM D. MARSHALL, MARK G. THOMPSON, JONATHAN C.F. MATTHEWS, JEREMY L. O'BRIEN, ANTHONY LAING, University of Bristol, ENRIQUE MARTIN-LOPEZ, Nokia Technologies, Cambridge, PETER J. SHADBOLT, Imperial College London, NOBUYUKI MATSUDA, NTT Basic Research Laboratories, NTT Corporation, MANABU OGUMA, MIKITAKA ITOH, TOSHIKAZU HASHIMOTO, NTT Device Technology Laboratories, NTT Corporation — Linear optics has paved the way for fundamental tests in quantum mechanics and has gone on to enable a broad range of quantum information processing applications for quantum technologies. We demonstrate an integrated photonics processor that is universal for linear optics. The device is a silica-on-silicon planar waveguide circuit (PLC) comprising a cascade of 15 Mach Zehnder interferometers, with 30 directional couplers and 30 tunable thermo-optic phase shifters which are electrically interfaced for the arbitrary setting of a phase. We input ensembles of up to six photons, and monitor the output with a 12-single-photon detector system. The calibrated device is capable of implementing any linear optical protocol. This enables the implementation of new quantum information processing tasks in seconds, which would have previously taken months to realise. We demonstrate 100 instances of the boson sampling problem with verification tests, and six-dimensional complex Hadamards.

**1:27PM S44.00012 Universal Linear Optics: A Testbed for Optical Quantum Logic**, CHRIS SPARROW, Centre for Quantum Photonics, University of Bristol, UK and Department of Physics, Imperial College London, UK, JACQUES CAROLAN, CHRISTOPHER HARROLD, NICHOLAS RUSSELL, GRAHAM MARSHALL, JOSHUA SILVERSTONE, MARK THOMPSON, JONATHAN MATTHEWS, JEREMY O'BRIEN, ANTHONY LAING, Centre for Quantum Photonics, University of Bristol, UK, ENRIQUE MARTIN-LOPEZ, Nokia Technologies, Cambridge, UK, PETER SHADBOLT, Department of Physics, Imperial College London, UK, NOBUYUKI MATSUDA, NTT Basic Research Laboratories, NTT Corporation, Japan, MANABU OGUMA, MIKITAKA ITOH, TOSHIKAZU HASHIMOTO, NTT Device Technology Laboratories, NTT Corporation, Japan — Linear optics is a promising platform for scalable quantum information processing. We demonstrate a single reprogrammable optical circuit that is sufficient to implement all possible linear optical protocols up to the size of the circuit [Carolan et al., Science, 349, (2015)]. The system is an ideal testbed for rapidly prototyping new linear optical quantum gates, and testing known protocols in experimentally realistic scenarios. We use the device to perform a series of postselected and heralded quantum logic gates including a new scheme for heralded bell state generation, a key primitive in measurement-based linear optical quantum computation. We propose and demonstrate techniques for efficiently and accurately characterising and verifying these gates operation. The ability to rapidly reprogram linear optical devices promises to replace a multitude of existing and future prototype systems, pointing the way to applications across quantum technologies.

**1:39PM S44.00013 Entanglement Dynamics in Heisenberg spin systems coupled to a dissipative environment**, GEHAD SADIEK, Department of Applied Physics, University of Sharjah, Sharjah 27272, UAE, SAMAHER ALMALKI, Department of Physics, King Saud University, Riyadh 11451, Saudi Arabia — Heisenberg Spin chains and lattices have been intensively used to represent many of the physical systems that are considered as promising candidates for quantum computing and quantum information processing. The main obstacle toward realizing the ultimate goals in these fields is decoherence caused by the surrounding dissipative and thermal environments. We are studying spin relaxation and entanglement dynamics in one and two-dimensional XYZ Heisenberg spin systems under coupling with a dissipative Lindblad environment at finite temperature. We investigate the effect of the anisotropy of the coupling between the spins on the asymptotic steady state of the system and the spin relaxation rates at different temperatures of the environment. We demonstrate the role played by the initial system setup on the entanglement and spin dynamics and steady state properties. Also we examine the effect of the long range interaction between the spins on the asymptotic behavior of the system.

**1:51PM S44.00014 Geometrical, response, and gap properties of Lindbladians**, VICTOR V. ALBERT, Yale University, BARRY BRADLYN, Princeton University, MARTIN FRAAS, University of Munich, LIANG JIANG, Yale University — We study Lindbladians admitting multi-dimensional steady-state subspaces (SSS) which can be used to store, protect, and process quantum information. We derive an analytical formula for the left eigenmatrices of such Lindbladians corresponding to purely imaginary eigenvalues. This formula resolves how Lindbladian evolution affects perturbative response and geometrical features of the SSS and allows us to generalize recent work to all types of SSS. We show that Hamiltonian and certain jump operator perturbations induce, to first order, exclusively unitary evolution on the SSS. Similarly, the holonomy (generalization of geometric phase) induced on the SSS after adiabatic traversal of a closed path in parameter space is unitary. We derive a new Riemannian metric tensor in parameter space induced by one type of SSS, generalizing the Fubini-Study metric to Lindbladians possessing one or more mixed steady states. We derive a Kubo formula governing linear response of the SSS to Hamiltonian perturbations. Finally, we show that the energy scale governing leakage out of the SSS is different from the conventional Lindbladian dissipative gap.

**11:15AM S45.00001 Quantum Rabi Model in Quantum Technologies**, JULEN PEDERNALES, URTZI LAS HERAS, LUCAS LAMATA, University of the Basque Country, Spain, ENRIQUE SOLANO, University of the Basque Country and IKERBASQUE, Spain — We will discuss how to simulate a wide range of regimes of the Quantum Rabi Model (QRM) in quantum platforms as trapped ions and circuit QED. Directly accessible regimes of the QRM correspond to a very narrow set of values of the ratio between the coupling strength and the characteristic frequencies of the system, typically in the strong coupling regime or in the perturbative zone of the ultrastrong coupling regime. However, with analog and digital quantum simulation techniques we can access the most elusive regimes of the QRM. Recent theoretical developments have disclosed a plethora of physical phenomena appearing at these previously unexplored regimes of the QRM, making its experimental implementation timely and of high interest.

**11:27AM S45.00002 What can we learn from the dynamics of entanglement and quantum discord in the Tavis-Cummings model?**<sup>1</sup>, JULIANA RESTREPO, Universidad Antonio Nario, BORIS A. RODRIGUEZ, Universidad de Antioquia — We revisit the problem of the dynamics of quantum correlations in the exact Tavis-Cummings model. We show that many of the dynamical features of quantum discord attributed to dissipation are already present in the exact framework and are due to the well known non-linearities in the model and to the choice of initial conditions. Through a comprehensive analysis, supported by explicit analytical calculations, we find that the dynamics of entanglement and quantum discord are far from being trivial or intuitive. In this context, we find states that are indistinguishable from the point of view of entanglement and distinguishable from the point of view of quantum discord, states where the two quantifiers give opposite information and states where they give roughly the same information about correlations at a certain time. Depending on the initial conditions, this model exhibits a fascinating range of phenomena that can be used for experimental purposes such as: Robust states against change of manifold or dissipation, tunable entanglement states and states with a counterintuitive sudden birth as the number of photons increase. We furthermore propose an experiment called quantum discord gates where discord is zero or non-zero depending on the number of photons.

**11:39AM S45.00003 ABSTRACT WITHDRAWN —**

**11:51AM S45.00004 Robust quantum state transfer with suppressed parametric noise**, MENGZHEN ZHANG, CHANGLING ZOU, LIANG JIANG, Yale University — For opto-electro-mechanical transducers, there are undesirable parametric processes that introduce parametric noise, which will limit the fidelity of the transferred quantum state<sup>1</sup>. To overcome this imperfection, we propose a quantum state transfer scheme with squeezed input states and measurement dependent compensation to eliminate the parametric noise from the quantum state transfer. Besides parametric noise, we also investigate the sensitivity of our scheme to thermal noise, signal frequency detuning and imperfect impedance matching, and show a good quantum state fidelity and applicability to quantum state transfer.

**12:03PM S45.00005 High efficiency in Mode Selective Frequency Conversion for Optical Quantum Information Processing**, NICOLAS QUESADA, Universite de Sherbrooke, J.E. SIPE, University of Toronto — Mode selective Frequency conversion (FC) is an enabling process in many quantum information protocols<sup>1</sup>. Recently, it has been observed that upconversion efficiencies in single-photon, mode-selective FC are limited to around 80%<sup>2</sup>. In this contribution we show that these limits can be understood as time ordering corrections (TOCs) that modify the joint conversion amplitude of the process<sup>3</sup>. Furthermore we show, using a simple scaling argument, that recently proposed cascaded FC protocols<sup>4</sup> that overcome the aforementioned limitations act as “attenuators” of the TOCs. This observation allows us to argue that very similar cascaded architectures can be used to attenuate TOCs in photon generation via spontaneous parametric down-conversion<sup>5</sup>. Finally, by using the Magnus expansion, we argue that the TOCs, which are usually considered detrimental for FC efficiency, can also be used to increase the efficiency of conversion in partially mode selective FC.

**12:15PM S45.00006 Maximal adaptive-decision speedups in quantum-state readout<sup>1</sup>**, BENJAMIN D'ANJOU, LOUTFI KURET, LILIAN CHILDRESS, WILLIAM A. COISH, McGill University — The average time  $T$  required for high-fidelity readout of quantum states can be significantly reduced via a real-time adaptive decision rule. An adaptive decision rule stops the readout as soon as a desired level of confidence has been achieved, as opposed to setting a fixed readout time  $t_f$ . The performance of the adaptive decision is characterized by the “adaptive-decision speedup”,  $t_f/T$ . In this work, we reformulate this readout problem in terms of the first-passage time of a particle undergoing stochastic motion. This formalism allows us to theoretically establish the maximum achievable adaptive-decision speedups for several physical two-state readout implementations. We show that for two common readout schemes (the Gaussian latching readout and a readout relying on state-dependent decay), the speedup is bounded by 4 and 2, respectively, in the limit of high single-shot readout fidelity. We experimentally study the achievable speedup in a real-world scenario by applying the adaptive decision rule to a readout of the nitrogen-vacancy-center (NV-center) charge state. We find a speedup of  $\approx 2$  with our experimental parameters. Our results should lead to immediate improvements in nano-scale magnetometry based on spin-to-charge conversion of the NV-center spin.

<sup>1</sup>We acknowledge support from NSERC, INTRIQ, CIFAR and the Walter C. Sumner Foundation.

**12:27PM S45.00007 Negatively-charged NV-center in SiC: Electronic structure properties**, PRATIBHA DEV, Dept. of Physics and Astronomy, Howard University, Washington, D.C., SOPHIA ECONOMOU, Dept. of Physics, Virginia Tech, Blacksburg, Virginia — Deep defects with high-spin states in semiconductors are promising candidates as solid-state systems for quantum computing applications. The charged NV-center in diamond is the best-known and most-studied defect center, and has proven to be a good proof-of-principle structure for demonstrating the use of such defects in quantum technologies. Increasingly, however, there is an interest in exploring deep defects in alternative semiconductors such as SiC. This is due to the challenges posed by diamond as host material for defects, as well as the attractive properties of SiC. In this density functional theory work, we study the spin-1 structure of the negatively charged NV-center in two polytypes: 3C-SiC and 4H-SiC. The calculated zero phonon line for the excited state of the defect is in telecom range (0.90eV), making it a very good candidate for quantum technologies. This work provides basic ingredients required to understand the physics of this color center at a quantitative and qualitative level. We also design quantum information applications, such as a spin-photon interface and multi-photon entanglement.

**12:39PM S45.00008 Optical patterning of trapped charge in nitrogen-doped diamond<sup>1</sup>**, SIDDHARTH DHOMKAR, HARISHANKAR JAYAKUMAR, DANIELA PAGLIERO, ABDELGHANI LARAOU, REMUS ALBU, City College of New York-CUNY, NEIL MANSON, MARCUS DOHERTY, Australian National University, JACOB HENSHAW, CARLOS MERILES, City College of New York-CUNY, Graduate Center-CUNY — The nitrogen-vacancy (NV) center in diamond is emerging as a promising platform for solid-state quantum information processing and nanoscale metrology. Of interest in these applications is the manipulation of the NV charge state, which can be attained by optical illumination. Here we use two-color optical microscopy to investigate the dynamics of NV photo-ionization, charge diffusion, and trapping in type-1b diamond. We combine fixed-point laser excitation and scanning fluorescence imaging to locally alter the concentration of negatively charged NVs and to subsequently probe the corresponding redistribution of charge. We uncover the formation of various spatial patterns of trapped charge, which we semi-quantitatively reproduce via a model of the interplay between photo-excited carriers and atomic defects in the diamond lattice. Further, by using the NV as a local probe, we map the relative fraction of positively charged nitrogen upon localized optical excitation. These observations may prove important to various technologies, including the transport of quantum information between remote NVs and the development of three-dimensional, charge-based memories.

<sup>1</sup>We acknowledge support from the National Science Foundation through grant NSF-1314205

**12:51PM S45.00009 Towards High Density 3-D Memory in Diamond<sup>1</sup>**, JACOB HENSHAW, City College of New York- CUNY, Graduate Center-CUNY, SIDDHARTH DHOMKAR, City College of New York- CUNY, CARLOS MERILES, City College of New York- CUNY, Graduate Center-CUNY, HARISHANKAR JAYAKUMAR, City College of New York- CUNY — The nitrogen-vacancy (NV) center in diamond is presently the focus of widespread attention for applications ranging from quantum information processing to nanoscale metrology. Of great utility is the ability to optically initialize the NV charge state, which has an immediate impact on the center's light emission properties. Here, we use two-color microscopy in NV-rich, type-1b diamond to demonstrate fluorescence-encoded long-term storage of classical information. As a proof of principle, we write, reset, and rewrite various patterns with 2-D binary bit density comparable to present DVD-ROM technology. The strong fluorescence signal originating from the diffraction-limited bit volume allows us to transition from binary to multi-valued encoding, which translates into a significant storage capacity boost. Finally, we show that our technique preserves information written on different planes of the diamond crystal and thus serves as a platform for three-dimensional storage. Substantial enhancement in the bit density could be achieved with the aid of super resolution microscopy techniques already employed to discriminate between NVs with sub-diffraction, nanometer accuracy, a regime where the storage capacity could exceed  $10^{17}$  bytes/cm<sup>3</sup>

<sup>1</sup>We acknowledge support from the National Science Foundation through grant NSF-1314205

**1:03PM S45.00010 Quantum memory enhanced nuclear magnetic resonance of nanometer-scale samples with a single spin in diamond**, NABEEL ASLAM, MATTHIAS PFENDER, SEBASTIAN ZAISER, FELIPE FAVARO DE OLIVEIRA, S. ALI MOMENZADEH, ANDREJ DENISENKO, 3rd Physics Institute, University of Stuttgart, JUNICHI ISOYA, Research Center for Knowledge Communities, University of Tsukuba, PHILIPP NEUMANN, JOERG WRACHTRUP, 3rd Physics Institute, University of Stuttgart — Recently nuclear magnetic resonance (NMR) of nanoscale samples at ambient conditions has been achieved with nitrogen-vacancy (NV) centers in diamond. So far the spectral resolution in the NV NMR experiments was limited by the sensor's coherence time, which in turn prohibited revealing the chemical composition and dynamics of the system under investigation. By entangling the NV electron spin sensor with a long-lived memory spin qubit we increase the spectral resolution of NMR measurement sequences for the detection of external nuclear spins. Applying the latter sensor-memory-couple it is particularly easy to track diffusion processes, to identify the molecules under study and to deduce the actual NV center depth inside the diamond. We performed nanoscale NMR on several liquid and solid samples exhibiting unique NMR response. Our method paves the way for nanoscale identification of molecule and protein structures and dynamics of conformational changes.

**1:15PM S45.00011 Single molecule spin resonance spectroscopy and imaging by diamond-sensor**, JIANGFENG DU, University of Science and Technology of China — Single-molecule magnetic resonance spectroscopy and imaging is one of the ultimate goals in magnetic resonance and will have great applications in a broad range of scientific areas, from life science to physics and chemistry. The spin of a single nitrogen vacancy (NV) center in diamond is a highly sensitive magnetic-field sensor, which has been proposed for detection of single molecules or nanoscale targets. We and co-workers have successfully obtained the first single-protein spin resonance spectroscopy under ambient conditions [1], high-resolution vector microwave imaging [2], and realized atomic-scale structure analysis of single nuclear-spin clusters in diamond [3]. Moreover, we have tried to improve the quantum control technique and succeed to achieve fault-tolerant universal quantum gates [4]. As the last part, I will briefly introduce our most recently work on single protein imaging in situ in cell. References: [1] Fazhan Shi, et al., Science, 347, 1135 (2015) [2] Pengfei Wang, et al., Nature Commu., 6, 6631 (2015) [3] Fazhan Shi, et al., Nature Physics, 10, 21 (2014) [4] Xing Rong, et al., Nature Commu., In press (2015)

**1:27PM S45.00012 Beating the Shot-Noise Limit with Partially-Distinguishable Photons**, PATRICK M. BIRCHALL, JAVIER SABINES-CHESTERKING, JEREMY L. OBRIEN, HUGO CABLE, JONATHAN C. F. MATTHEWS C. F. MATTHEWS, Centre for Quantum Photonics, University of Bristol — Quantum metrology promises high-precision measurements beyond the capability of any classical techniques. This has the potential to be an integral part of investigative techniques, utilised across all areas of science and technology. However, all sensors must be able to operate despite imperfections to be of practical use. Proposals for photonic quantum sensors typically exploit quantum interference between photons which are perfectly indistinguishable, but achieving this indistinguishability can be a major technical challenge in practice, in particular with immature but promising approaches to photon sources. Here we show that highly indistinguishable photons are not required for quantum-enhanced measurements, nor do partially distinguishable photons have to be engineered to mitigate the effects of distinguishability. We conduct an experiment to verify the utility of two- and four-photon states containing partially distinguishable particles by performing quantum-enhanced measurements with low-visibility quantum interference. This demonstrates that sources producing spectrally-mixed single photons can be readily applied in quantum metrology systems.

**1:39PM S45.00013 How zero light intensity can exert a nonzero force on a charged particle**, JUSTIN DRESSEL, JEFF TOLLAKESEN, Chapman University, YAKIR AHARONOV, Chapman University, Tel Aviv University — A classical electromagnetic field is deterministic and fully specified by a single temporal boundary condition. In contrast, a quantum electromagnetic field is irreducibly stochastic, such that only its average corresponds to a classical field for large ensembles of measurements. Such a field-average may be further refined by a second temporal boundary condition, which can expose fundamentally different classical fields in the same classical averaging limit. To demonstrate this, we consider an ensemble of coherent laser pulses that interact with identically prepared test charges before being collected at an intensity meter. Isolating only the pulses with zero collected intensity reveals a nonzero average classical force on the charge from those pulses. The charge is affected with no light collected.

**1:51PM S45.00014 Sub-Cycle Quantum Optics: Direct Access to Electric Field Vacuum Fluctuations.**, DENIS SELETSKIY, CLAUDIUS RIEK, ANDREY MOSKALENKO, JAN SCHMIDT, PHILIPP KRAUSPE, SEBASTIAN ECKART, STEFAN EGGERT, GUIDO BURKARD, ALFRED LEITENSTORFER, University of Konstanz — Vacuum fluctuations are fundamental to a variety of physical aspects ranging from spontaneous photon emission via the Casimir force all the way to cosmology. Study and manipulation of the ground state of the radiation field is a central subject in quantum optics. In common approaches, such as for example homodyne detection, the information is averaged over multiple cycles of light and amplification to finite intensity is mandatory. Usually, ultrashort pulses are applied for quantum measurements within a slowly-varying envelope approximation. We demonstrate direct detection of the vacuum fluctuations of the local electric field amplitude in free space. Broadband electro-optic sampling with sub-6 femtosecond gate pulses enables quantum-statistic readout [1]. Distinction from the detector shot noise is achieved by modification of the sampled space-time volume. Measuring with a bandwidth matching the 70 THz center frequency maximizes the vacuum amplitude since the ground-state energy approaches half a photon per optical cycle. Our findings open up a new avenue to quantum analysis and manipulation of light working in the time domain and with sub-cycle access to the electric field quadrature.

Session S47 DCP GSOF: Chemical Physics of Surfaces, Interfaces and Colloids 312 - Jeff Owrutsky, Naval Research Laboratory

**11:15AM S47.00001 Effects of Oxide Surface on the Detonation Initiation of Energetic Materials from First Principles**, FENG GONG WANG, ROMAN TSYSHEVSKY, MAIJA KUKLJA, Department of Materials Science and Engineering, University of Maryland, College Park, MD 20742, USA, UMD TEAM — Organic-inorganic interface provides both intrigues and opportunities for designing systems possessing properties and functionalities inaccessible by individual component. The electronic, catalytic, and defect properties of inorganic surfaces can affect the adsorption, chemical reaction, and photo-responsive properties of organic molecules. In particular, the presence of a particular oxide additive prompts the energy absorption for detonation initiation. Here, we choose the highly catalytic oxide  $\text{TiO}_2$  and explosive trinitrotoluene (TNT) as prototypical examples to explore the role of oxide surface on the detonation initiation of explosives from first principles. We show that the TNT- $\text{TiO}_2$  (110) interface induces optical transitions between  $\text{TiO}_2$  and TNT, shifting the light absorption edge to lower energy. This helps to control the detonation initiation by laser light with a modest optical energy. In addition, the presence of surface oxygen vacancies leads to electron transfer from surface to molecule, facilitating the decomposition of TNT. Our results not only provide guidelines for designing a controllable oxide-explosive formulation that can be initiated by available lasers, but also help to understand interfaces with target properties and functionalities.

**11:27AM S47.00002 Effect of surface morphology on kinetic compensation effect**, NAYELI ZUNIGA-HANSEN, Louisiana State University, LEONARDO E. SILBERT, Southern Illinois University Carbondale — The existence of the kinetic compensation effect, observed in many fields of science, continues to be debated and believed to be a mathematical artifact. Recently, we performed a computational study of the thermal desorption of interacting adsorbates from an energetically homogeneous surface and we observed that the kinetic compensation effect indeed occurs to varying degrees depending on interaction strength. However, other factors which may lead to a kinetic compensation effect have yet to be explored. In the present work, using kinetic Monte Carlo simulations, we study the effects of substrate topology on thermal desorption. We focus on differences between ordered and disordered surfaces at a fixed site coordination number. The rates of desorption depend on surface configuration due to the inherent differences in the local environments of adsorbing sites. While the compensation effect persists for the disordered substrate, it is more strongly influenced by variations in the preexponential factor rather than the activation energy which dominates in the ordered lattice. We expect our results to provide a deeper insight into the microscopic events that originate compensation effects in our system of study but also in other fields where these effects have been reported.

**11:39AM S47.00003 Thermodynamics of catalytic nanoparticle morphology**, MICHAEL ZWOLAK, RENU SHARMA, PIN ANN LIN, Center for Nanoscale Science and Technology, National Institute of Standards and Technology — Metallic nanoparticles are an important class of industrial catalysts. The variability of their properties and the environment in which they act, from their chemical nature & surface modification to their dispersion and support, allows their performance to be optimized for many chemical processes useful in, e.g., energy applications and other areas. Their large surface area to volume ratio, as well as varying sizes and faceting, in particular, makes them an efficient source for catalytically active sites. These characteristics of nanoparticles – i.e., their morphology – can often display intriguing behavior as a catalytic process progresses. We develop a thermodynamic model of nanoparticle morphology, one that captures the competition of surface energy with other interactions, to predict structural changes during catalytic processes. Comparing the model to environmental transmission electron microscope images of nickel nanoparticles during carbon nanotube (and other product) growth demonstrates that nickel deformation in response to the nanotube growth is due to a favorable interaction with carbon. Moreover, this deformation is halted due to insufficient volume of the particles. We will discuss the factors that influence morphology and also how the model can be used to extract interaction strengths from experimental observations.

**11:51AM S47.00004 Support- dependent evolution of oxidation state and nanoassembly formation of subnanometer copper clusters under carbon dioxide conversion conditions**, AVIK HALDER, BING YANG, KARTHIKA L. KOLIPAKA, MICHAEL PELLIN, SOENKE SEIFERT, STEFAN VAJDA, Argonne National Laboratory, MATERIALS SCIENCE DIVISION TEAM — Size- and support- dependence of the properties of copper clusters have been investigated during carbon dioxide conversion with hydrogen at high reactant concentrations and atmospheric pressure. The model catalyst systems were prepared by depositing size-selected  $\text{Cu}_n$  clusters ( $n = 3, 4, 12$  and  $20$ ) on various amorphous metal oxide ( $\text{Al}_2\text{O}_3$ ,  $\text{ZnO}$ , and  $\text{ZrO}_2$ ), and carbon-based (UNCD = ultrananocrystalline diamond) supports. During the temperature ramp, the evolution of the chemical state and size of the particles were characterized by *in situ* grazing incidence X-ray absorption near edge structure (GIXANES), and grazing incidence small angle X-ray scattering (GISAXS) respectively. Under reaction conditions the initially oxidized Cu clusters reduced at various temperatures depending on cluster size and support. Clusters supported on  $\text{ZnO}$  and UNCD were found to be sinter-resistant under reactive gases at elevated temperatures and atmospheric pressures, whereas on  $\text{ZrO}_2$  support the clusters formed stable aggregates. Clusters on  $\text{Al}_2\text{O}_3$  support demonstrated unique properties, where a formation of a nanostructure was observed during heating, which then disintegrated during the cool down. Under applied conditions,  $\text{Cu}_4$  clusters on  $\text{Al}_2\text{O}_3$  were found to be the most efficient in methanol formation.

**12:03PM S47.00005 Molecular Imprinting of Silica Nanoparticle Surfaces via Reversible Addition-Fragmentation Polymerization for Optical Biosensing Applications<sup>1</sup>**, ZEHRA OLUZ, TOBB UET Materials Science and Nanotechnology Engineering, SANA NAYAB, Lahore College for Women University Department of Chemistry, TALYA TUGANA KURSUN, TUNCER CAYKARA, Gazi University Department of Chemistry, BASIT YAMEEN, Harvard Medical School Laboratory of Nanomedicine and Biomaterials, HATICE DURAN, TOBB UET Materials Science and Nanotechnology Engineering — Azo initiator modified surface of silica nanoparticles were coated via reversible addition-fragmentation polymerization (RAFT) of methacrylic acid and ethylene glycol dimethacrylate using 2-phenylprop 2-yl dithobenzoate as chain transfer agent. Using L-phenylalanine anilide as template during polymerization led molecularly imprinted nanoparticles. RAFT polymerization offers an efficient control of grafting process, while molecularly imprinted polymers shows enhanced capacity as sensor. L-phenylalanine anilide imprinted silica particles were characterized by X-Ray photoelectron spectroscopy (XPS), atomic force microscopy (AFM). Performances of the particles were followed by surface plasmon resonance spectroscopy (SPR) after coating the final product on gold deposited glass substrate against four different analogous of analyte molecules: D-phenylalanine anilide, L-tyrosine, L-tryptophan and L-phenylalanine. Characterizations indicated that silica particles coated with polymer layer do contain binding sites for L-phenylalanine anilide, and are highly selective for the molecule of interest.

**12:15PM S47.00006 Sum Frequency Generation at the  $\text{Al}_2\text{O}_3$ - $\text{H}_2\text{O}$  Interface: An Effective Bond Polarizability Model<sup>1</sup>**, MARK DELLOSTRITTO, Physics Dept., Pennsylvania State University, JAMES KUBICKI, Dept. of Geological Sciences, University of Texas at El Paso, JORGE SOFO, Physics Dept., Pennsylvania State University — Sum Frequency Generation (SFG) is a powerful tool for extracting the vibrational spectrum of an interface as it is a second-order optical process and therefore prohibited in centrosymmetric bulk media. When calculating the spectrum, it is often desirable to write the response as a sum over components of the system, such as atoms or molecules. This can pose a number of challenges however, as the response depends upon the total polarizability, which is in general not an additive quantity. We employ a Thole-type model to assign polarizabilities to the bonds of a system, which allows us to treat the contribution of molecules and surface groups to the spectrum. Local field effects are then taken into account using modified Ewald sums. Following the time-dependent approach of Morita, we are able to produce the SFG spectrum at an interface from molecular dynamics simulations ranging in size and detail from small ab-initio to large classical simulations. We tested our method on ab-initio simulations of the  $\text{Al}_2\text{O}_3$ (0001)- $\text{H}_2\text{O}$  interface as  $\text{Al}_2\text{O}_3$  has a low dissolution rate, a well-known surface structure, and thoroughly studied surface-water interactions. We were able to successfully reproduce the experimental spectrum and decompose it in terms of molecular motions and local correlations.

**12:27PM S47.00007 Electrokinetic Stabilization of Thin Surfactant Films**, SOUMYADIP SETT, RAKESH SAHU, ALEXANDER YARIN, University of Illinois at Chicago — Ionic surfactant solutions were used to study gravitational drainage from thin vertical planar films supported on a frame with the upper and lower parts being electrodes. The imposed electric field resulted in the following physical phenomena: (i) surface charge redistribution, (ii) electroosmotic flow in the diffuse layer, and (iii) pressure build-up near the electrode to which the electroosmotic flow is directed. The interplay of these phenomena stabilized the film drainage irrespectively of polarity. Similar effects were observed with foams.

**12:39PM S47.00008 Tuning surface reactivity by finite size effects: role of orbital symmetry in the *d*-band model<sup>1</sup>**, PAUL SNIJDERS, XIANGSHI YIN, VALENTINO COOPER, Oak Ridge National Laboratory, HANNO WEITERING, University of Tennessee, Knoxville — Catalytic activity depends sensitively on the strength of the interactions between reactant molecules and catalyst surface: too weak and the catalyst cannot capture enough molecules to react; too strong and the reaction products do not desorb, blocking further reactions. The ability to control the binding strength of molecules to metal surfaces is thus fundamental to the design of efficient and selective catalysts. Catalyst design often relies on increasing the interaction strength on relatively non-reactive materials by introducing active sites. Here, we present a complementary approach: we exploit finite size effects in the electronic structure of ultrathin Pd(111) films grown on Ru(0001) to tune their reactivity by changing the film thickness one atom layer at a time. While bulk Pd(111) is reactive toward oxygen, we find that Pd films thinner than 6 atom layers are surprisingly inert to oxidation. This observation can be explained with the *d*-band model only when it is applied to the orbitals directly involved in the bonding. The insight into orbital specific contributions to surface reactivity could be useful in the design of catalysts.

**12:51PM S47.00009 Nonequilibrium thermodynamics of an interface**, THIERRY SAVIN, University of Cambridge, MARCO SCHWEIZER, HANS CHRISTIAN ÖTTINGER, ETH Zurich — Interfacial thermodynamics has deep ramifications in understanding the boundary conditions of transport theories. We present a formulation of local equilibrium for interfaces that extends the thermodynamics of the “dividing surface,” as introduced by Gibbs, to nonequilibrium settings such as evaporation or condensation. By identifying the precise position of the dividing surface in the interfacial region with a gauge degree of freedom, we exploit gauge-invariance requirements to consistently define the intensive variables for the interface. The model is verified under stringent conditions by employing high-precision nonequilibrium molecular dynamics simulations of a coexisting vapor-liquid Lennard-Jones fluid. We conclude that the interfacial temperature is determined using the surface tension as a “thermometer,” and can be significantly different from the temperatures of the adjacent phases.

**1:03PM S47.00010 CO<sub>2</sub> Adsorption on ZIF-8**, ALDO MIGONE, BRICE RUSSELL, Southern Illinois University Carbondale — We present the results of an adsorption isotherm study of CO<sub>2</sub> on the metal-organic framework ZIF-8. This material undergoes a structural transition (“gate-opening”) as a function of increasing pressure and sorbent loading for sorbates. Gate-opening manifests itself in the isotherm data as a quasi-vertical substep, corresponding to an increase in the amount that can adsorb in the ZIF-8. We measured ten CO<sub>2</sub> isotherms from 133 K to 227 K. In this range, we did not find in any of the isotherms the characteristic substep indicative of the gate-opening. It is possible that the temperature range over which this transition would manifest in the data simply has not been explored in our measurements. The adsorption isotherm data was used to determine the isosteric heat of adsorption of CO<sub>2</sub> on this sorbent as a function of sorbent loading. We have studied the adsorption kinetics for this system, i.e., how the equilibration times for adsorption change as a function of sorbent loading. Trends in the isosteric heat, and kinetics of adsorption data will be discussed.

**1:15PM S47.00011 Low frequency ionic conduction across liquid interfaces.**, FRANCISCO J SOLIS, Arizona State University, GUILLERMO IVAN GUERRERO, Universidad Autnoma de San Luis Potos, MONICA OLVERA DE LA CRUZ, Northwestern University — Ionic conduction in liquid media is a central component of many recently proposed technologies. As in the case of solid state systems, the presence of heterogeneous media gives rise to interesting nonlinear phenomena. We present simulations and theoretical analysis of the low frequency ionic conduction in a two-liquid system. In the case analyzed, the conduction is driven by an electric field perpendicular to the liquid-liquid interface. We show that the dielectric contrast between the liquids produces non-linear effects in the effective conductivity of the system and discuss the effects of the ion solubility in the media.

**1:27PM S47.00012 Protonation of octadecylamine Langmuir monolayer by adsorption of halide counterions**, WOONGMO SUNG, ZAURE AVAZBAEVA, JONGGWAN LEE, DOSEOK KIM, Sogang University — Langmuir monolayer consisting of octadecylamine (C<sub>18</sub>H<sub>37</sub>NH<sub>2</sub>, ODA) was investigated by heterodyne vibrational sum-frequency generation (HD-VSFG) spectroscopy in conjunction with surface pressure-area ( $\pi$ -A) isotherm, and the result was compared with that from cationic-lipid (DPTAP) Langmuir monolayer. In case of ODA monolayer on pure water, both SF intensity of water OH band and the surface pressure were significantly smaller than those of the DPTAP monolayer implying that only small portion of the amine groups (-NH<sub>3</sub><sup>+</sup>) is protonated in the monolayer. In the presence of sodium halides (NaCl and NaI) in the subphase water, it was found that the sign of Im $\chi^{(2)}$  of water OH band remained the same as that of the ODA monolayer on pure water, but there was a substantial increase in the SF amplitude. From this, we propose that surface excess of the halide counterions (Cl<sup>-</sup> and I<sup>-</sup>) makes the solution condition near the ODA monolayer/water interface more acidic so that ODA molecules in the monolayer are more positively charged, which works to align the water dipoles at the interface.

**1:39PM S47.00013 Single Molecule Mechanochemistry<sup>1</sup>**, SHAOWEI LI, Dept. of Chemistry, University of California, YANXING ZHANG, Dept. of Physics and Astronomy, University of California, WILSON HO, Dept. of Chemistry, University of California, RUQIAN WU, Dept. of Physics and Astronomy, University of California, RUQIAN WU, YANXING ZHANG TEAM, WILSON HO, SHAOWEI LI TEAM — Mechanical forces can be used to trigger chemical reactions through bending and stretching of chemical bonds. Using the reciprocating movement of the tip of a scanning tunneling microscope (STM), mechanical energy can be provided to a single molecule sandwiched between the tip and substrate. When the mechanical pulse center was moved to the outer ring feature of a CO molecule, the reaction rate was significantly increased compared with bare Cu surface and over Au atoms. First, DFT calculations show that the presence of CO makes the Cu cavity more attractive toward H<sub>2</sub>. Second, H<sub>2</sub> prefers the horizontal adsorption geometry in the Cu-Cu and Au-Cu cavities and no hybridization occurs between the antibonding states of H<sub>2</sub> and states of Cu atoms. While H<sub>2</sub> loses electrons from its bonding state in all three cavities, the filling of its anti-bonding state only occurs in the CO-Cu cavity. Both make the CO-Cu cavity much more effectively to chop the H<sub>2</sub> molecule.

**1:51PM S47.00014 Charge-patterning phase transition on a surface lattice of titratable sites adjacent to an electrolyte solution<sup>1</sup>**, JOEL SHORE, GEORGE THURSTON, Rochester Institute of Technology — We discuss a model for a charge-patterning phase transition on a two-dimensional square lattice of titratable sites, here regarded as protonation sites, placed on a square lattice in a dielectric medium just below the planar interface between this medium and an aqueous salt solution. Within Debye-Huckel theory, the analytical form of the electrostatic repulsion between protonated sites exhibits an approximate inverse cubic power-law decrease beyond short distances. The problem can thus be mapped onto the two-dimensional antiferromagnetic Ising model with this longer-range interaction, which we study with Monte Carlo simulations. As we increase pH, the occupation probability of a site decreases from 1 at low pH to 0 at high pH. For sufficiently-strong interaction strengths, a phase transition occurs as the occupation probability of 1/2 is approached: the charges arrange themselves into a checkerboard pattern. This ordered phase persists over a range of pH until a transition occurs back to a disordered state. This state is the analogue of the Neel state in the antiferromagnetic Ising spin model. More complicated ordered phases are expected for sufficiently strong interactions (with occupation probabilities of 1/4 and 3/4) and if the lattice is triangular rather than square.

**2:03PM S47.00015 Understanding the electronic band structure of Pt-alloys for surface reactivity**, JONGKEUN JUNG, Seoul Natl Univ, BEOMYOUNG KIM, Lawrence Berkeley National Laboratory, JI SOOK HONG, TAE WON JIN, JI HOON SHIM, Postech, SLAVOMIR NEMSAK, BESSY II, JONATHAN D. DENLINGER, Lawrence Berkeley National Laboratory, ARITA MASASHI, SHIMADA KENYA, Hiroshima Synchrotron Radiation Center, CHANGYOUNG KIM, Seoul Natl Univ, BONGJIN SIMON MUN, GIST — In polymer exchange membrane fuel cell (PEMFC), the oxygen reduction reaction (ORR) at cathode side has been continuously investigated due to its critical importance in performance of fuel cell. So far, even with best industrial catalyst made with Pt, the performance of ORR is too far below from the commercial purpose. In 2007, Stamenkovic et al. showed that Pt alloys with 3-*d*-transition metal exhibited significantly improved ORR performance and pointed out the altered electronic structure of surface as the major contributing factor for enhanced ORR. Since 1990, with the advance of DFT calculation, the trend of surface chemical reactivity is explained with the analysis of *d*-band structures, known as *d*-band model. While *d*-band provides valid insight on surface chemical reactivity based on the valence band DOS, the relation between surface work function and DOS has not been well understood. The element-specific local electronic band structure of Pt alloys are identified by ARPES measurement, and the correlation between surface work function and local charge density is investigated.

**11:15AM S48.00001 Hybrid-free Josephson Parametric Converter<sup>1</sup>**, N.E. FRATTINI, A. NARLA, K.M. SLIWA, S. SHANKAR, M. HATRIDGE, M.H. DEVORET, Department of Applied Physics, Yale University — A necessary component for any quantum computation architecture is the ability to perform efficient quantum operations. In the microwave regime of superconducting qubits, these quantum-limited operations can be realized with a non-degenerate Josephson junction based three-wave mixer, the Josephson Parametric Converter (JPC). Currently, the quantum signal of interest must pass through a lossy 180 degree hybrid to be presented as a differential drive to the JPC. This hybrid therefore places a limit on the quantum efficiency of the system and also increases the device footprint. We present a new design for the JPC eliminating the need for any external hybrid. We also show that this design has nominally identical performance to the conventional JPC.

<sup>1</sup>Work supported by ARO, AFOSR and YINQE

**11:27AM S48.00002 Simplifying the circuit of Josephson parametric converters**, BALEEGH ABDO, MARKUS BRINK, JOSE CHAVEZ-GARCIA, GEORGE KEEFE, IBM- Research Center — Josephson parametric converters (JPCs) are quantum-limited three-wave mixing devices that can play various important roles in quantum information processing in the microwave domain, including amplification of quantum signals, transduction of quantum information, remote entanglement of qubits, nonreciprocal amplification, and circulation of signals [1-4]. However, the input-output and biasing circuit of a state-of-the-art JPC consists of bulky components, i.e. two commercial off-chip broadband 180-degree hybrids, four phase-matched short coax cables, and one superconducting magnetic coil. Such bulky hardware significantly hinders the integration of JPCs in scalable quantum computing architectures. In my talk, I will present ideas on how to simplify the JPC circuit and show preliminary experimental results. [1] B. Abdo et al., PRB 87, 014508. [2] M. Silveri et al., arxiv:1507.00732. [3] B. Abdo et al., PRL 112, 167701. [4] K. Sliwa et al., arxiv:1503.00209.

**11:39AM S48.00003 Phase-sensitive, through-amplification with a double-pumped JPC.<sup>1</sup>**, K.M. SLIWA, M. HATRIDGE, N.E. FRATTINI, A. NARLA, S. SHANKAR, M.H. DEVORET, Department of Applied Physics, Yale University — The Josephson Parametric Converter (JPC) is now routinely used as a quantum-limited signal processing device for superconducting qubit experiments. The JPC consists of two modes, the signal and the idler, that are coupled by a ring of Josephson junctions that implements a non-degenerate, three-wave mixing process. This device is conventionally operated as either a phase-preserving parametric amplifier, or a coherent frequency converter, by pumping it at the sum or difference of the signal and idler frequencies, respectively. Here we present a novel double-pumping scheme based on theory by Metelmann and Clerk where a coherent conversion process and a gain process are simultaneously imposed between the signal and idler modes. The interference of these two processes results in a phase-sensitive amplifier with only forward gain, and which breaks the traditional gain-bandwidth limit of parametric amplification. We present results on phase-sensitive amplification with increased bandwidth, and on noise performance and dynamic range that are comparable to the traditional mode of operation.

<sup>1</sup>Work supported by ARO, AFOSR, NSF and YINQE

**11:51AM S48.00004 Traveling-Wave Parametric Amplifier Based on a Chain of Coupled Asymmetric SQUIDs<sup>1</sup>**, MATTHEW BELL, ANA SAMOLOV, University of Massachusetts Boston — A traveling-wave parametric amplifier (TWPA) composed of a transmission line made up of a chain of coupled asymmetric superconducting quantum interference devices (SQUIDs) is proposed. The unique nature of this transmission line is that its nonlinearity can be tuned with an external magnetic flux and can even change sign. This feature of the transmission line can be used to perform phase matching in a degenerate four-wave mixing process which can be utilized for the parametric amplification of a weak signal in the presence of a strong pump. Numerical simulations of the TWPA design show that, with tuning, phase matching can be achieved and an exponential gain as a function of the transmission-line length can be realized. The flexibility of the proposed design can realize: compact TWPAs with fewer than 211 unit cells, signal gains greater than 20 dB, 3-dB bandwidth greater than 5.4 GHz, and saturation powers up to -98 dBm. This amplifier design is well suited for the multiplexed readout of quantum circuits or astronomical detectors in a compact configuration which can foster on-chip implementations. Phys. Rev. Applied 4, 024014 (2015).

**12:03PM S48.00005 Strong field dynamics and quantum noise in Josephson traveling wave parametric amplifiers (JTWPAs)**, KEVIN O'BRIEN, NSF Nano-scale Science and Engineering Center, UC Berkeley, CHRIS MACKLIN, Quantum Nanoelectronics Laboratory, UC Berkeley, YUAN WANG, NSF Nano-scale Science and Engineering Center, UC Berkeley, IRFAN SIDDIQI, Quantum Nanoelectronics Laboratory, UC Berkeley, XIANG ZHANG, NSF Nano-scale Science and Engineering Center, UC Berkeley — Josephson traveling wave parametric amplifiers (JTWPAs) with resonant phase matching have demonstrated high gain over a broad bandwidth with near quantum-limited noise performance. Several amplifier non-idealities were observed in experiments, including a rapid drop in gain at a certain pump power and a near, but non-unity intrinsic quantum efficiency. To understand these non-idealities, we solve the full nonlinear wave equation for the JTWPA for a sinusoidal drive, finding higher harmonic generation and observing a blow-up at an input pump current below the junction critical current. We find analytic traveling wave solutions in the form of snoidal waves which propagate without distortion. A snoidal drive scheme may increase the drive power at which the blow-up occurs. The quantum noise properties of JTWPAs are critically important for their role as low noise amplifiers. We calculate the noise figure and find that coupling to higher order sidebands imposes an upper limit for the quantum efficiency, in good agreement with empirical results. We further show that this limit can be increased by modest changes to the phase matching of the pump and the dispersion relation.

**12:15PM S48.00006 Broadband Josephson parametric amplifiers: Beyond the standard gain-bandwidth product**, TANAY ROY, SUMAN KUNDU, MADHAVI CHAND, A. M. VADIRAJ, A. RANADIVE, N. NEHRA, MEGHAN P. PATANKAR, Tata Institute of Fundamental Research, Mumbai 400005, J. AUMENTADO, National Institute of Standards and Technology, Boulder, Colorado 80305, A. A. CLERK, McGill University, 3600 rue University, Montreal, Quebec H3A 2T8, Canada, R. VIJAY, Tata Institute of Fundamental Research, Mumbai 400005 — Recent development of multiplexed qubit measurement schemes demand broadband quantum-limited amplifiers to enable high fidelity readout with minimal resources. We present a simple technique to enhance the bandwidth of a resonator based Josephson Parametric Amplifier (JPA) beyond the standard gain-bandwidth product. This is achieved by introducing a positive linear slope in the imaginary component of the input impedance seen by the JPA using a  $\lambda/2$  transformer. Our theoretical model predicts an extremely flat gain profile with a bandwidth enhancement proportional to the square root of the amplitude gain. Experimentally, we achieved a nearly flat 20 dB gain profile over a 640 MHz band, with a mean 1-dB compression point of -110 dBm along with nearly quantum-limited noise performance. The results are in excellent agreement with our theoretical model. We will then discuss strategies to further enhance the performance in terms of bandwidth and dynamic range of the JPA. Finally, we will consider the applicability of our technique to different parametric pumping methods and other parametric amplifier designs as well.

**12:27PM S48.00007 Microwave design optimization for broadband Josephson parametric amplifiers** , MATTHEW REAGOR, EYOB SETE, DANE THOMPSON, Rigetti Quantum Computing, ARPIT RANADIVE, R. VIJAY, Tata Institute of Fundamental Research, Mumbai, CHAD RIGETTI, Rigetti Quantum Computing — Broadband Josephson parametric amplifiers are crucial components of a scalable superconducting quantum computing architecture. Recently, the bandwidth of a resonator-based Josephson parametric amplifier was significantly enhanced by introducing a controlled reactance in the signal chain. The design was based on a  $\lambda/2$  section fabricated on an RF circuit board. We present the design of an on-chip version that will improve robustness and minimize performance variability from one device to another. Further, we will discuss microwave design optimization for flux pumping mechanism to minimize cross-talk between different input-output ports of the device. Finally, we will discuss design goals for further improvement of amplifier performance.

**12:39PM S48.00008 High dynamic range Josephson parametric amplifiers** , NICOLAS ROCH, CNRS and Universite Grenoble Alpes, Institut Neel, 38042 Grenoble, France, KATER W. MURCH, Department of Physics, Washington University, St. Louis, Missouri 63130, USA, RAJAMANI VIJAY, Tata Institute of Fundamental Research, Mumbai 400005, India — Josephson parametric amplifiers (JPAs) have become the technology of choice to amplify small amplitude microwave signals since they show noise performances close to the quantum limit of amplification. An important challenge that faces this technology is the low dynamic range of current devices, which limits the number of measurements that can be performed concurrently and the rate of information acquisition for single measurements. We have fabricated and tested novel parametric amplifiers based on arrays of up to 100 SQUIDS. The amplifiers produce gain in excess of 20 dB over a large bandwidth and match the dynamic range achieved with traveling wave devices. Compared to the latter devices they are fabricated in a single lithography step and we will show that their bandwidth performance can be further extended using a recently developed impedance matching technique.

**12:51PM S48.00009 Microwave response and photon emission of a voltage biased Josephson junction** , SALHA JEBARI, ALEXANDER GRIMM, DIBYENDU HAZRA, MAX HOFHEINZ, CEA Grenoble — The readout of superconducting qubits requires amplifiers combining noise close to the quantum limit, high gain, large bandwidth, and sufficient dynamic range. Josephson parametric amplifiers using Josephson junctions in the 0-voltage state, driven by a large microwave signals, begin to perform sufficiently well in all 4 of these aspects to be of practical use, but remain difficult to optimize and use. Recent experiments with superconducting circuits consisting of a DC voltage-biased Josephson junction in series with a resonator, showed that a tunneling Cooper pair can emit one or several photons with a total energy of 2e times the applied voltage. We present microwave reflection measurements on this device indicating that amplification is possible with a simple DC voltage-biased Josephson junction. We compare these measurements with the noise power emitted by the junction and show that, for low Josephson energy, transmission and noise emission can be explained within the framework of P(E) theory of inelastic Cooper pair tunneling. Combined with a theoretical model, our results indicate that voltage-biased Josephson junctions might be useful for amplification near the quantum limit, offering simpler design and a different trade-off between gain, bandwidth and dynamic range.

**1:03PM S48.00010 Estimation of the projection error of a qubit readout by quantum Zeno effect** , KOSUKE KAKUYANAGI, YUICHIRO MATSUZAKI, HAYATO NAKANO, NTT Basic Research Laboratories, KOUICHI SEMBA, National Institute of Information and Communications Technology, SHIRO SAITO, NTT Basic Research Laboratories — In a quantum system, frequent projection operations can suppress a specific kind of time evolutions that show quadratic behavior in a time domain. This phenomenon is known as quantum Zeno effect (QZE). Normally, projection operations freeze the qubit state so that the qubit remains in the initially prepared state such as a ground state or an excited state. However, if a projection error occurs, qubit state is flipped. In this case, frequent projection operations do not keep qubit state. This means that, by investigating the efficiency of the QZE, we can in principle estimate the projection error rate of the qubit readout system. A Josephson bifurcation amplifier (JBA) readout method provides us a way to perform fast and low back-action superconducting qubit readout. We fabricate a sample that has a JBA resonator coupled to the superconducting flux qubit. By using this sample, we demonstrated QZE by applying multiple readout pulses during Rabi oscillations. Because of the multiple readout pulses, Rabi oscillation was suppressed and the qubit was kept in its initial state. From the holding time of the state via the QZE, we concluded that the projection error of the JBA readout is less than 2%.

**1:15PM S48.00011 Single-shot Readout of a Superconducting Qubit using a Josephson Parametric Oscillator<sup>1</sup>** , PHILIP KRANTZ, ANDREAS BENGTTSSON, MICHAEL SIMOEN, Chalmers, SIMON GUSTAVSSON, MIT, VITALY SHUMEIKO, Chalmers, W. D. OLIVER, MIT, MIT Lincoln Laboratory, C. M. WILSON, Waterloo, PER DELSING, JONAS BYLANDER, Chalmers — We propose and demonstrate a new read-out technique for a superconducting qubit by dispersively coupling it to a Josephson parametric oscillator. We employ a tunable quarter-wavelength superconducting resonator and modulate its resonant frequency at twice its value with an amplitude surpassing the threshold for parametric instability. We map the qubit states onto two distinct states of classical parametric oscillation: one oscillating state, with  $185 \pm \sum 15$  photons in the resonator, and one with zero oscillation amplitude. This high contrast obviates a following quantum-limited amplifier. We demonstrate proof-of-principle, single-shot readout performance, and present an error budget indicating that this method can surpass the fidelity threshold required for quantum computing.

<sup>1</sup>Support came from the Wallenberg foundation, the European Research Council (ERC), the Royal Swedish Academy of Science (KVA), the European project ScaleQIT, STINT, and Marie Curie CIG.

**1:27PM S48.00012 SLUG Microwave Amplifier as a Nonreciprocal Gain Element for Scalable Qubit Readout** , TED THORBECK, EDWARD LEONARD, SHAOJIANG ZHU, ROBERT MCDERMOTT, University of Wisconsin - Madison — Josephson parametric amplifiers for superconducting qubits require several stages of cryogenic isolation to protect the qubit from strong microwave pump tones and downstream noise. But isolators and circulators are large, expensive and magnetic, so they are an obstacle to scaling up a superconducting quantum computer. In contrast, the SLUG (Superconducting Low-inductance Undulatory Galvanometer) is a high gain, broadband, low noise microwave amplifier that provides built-in reverse isolation. Here, we describe the dependence of the SLUG reverse isolation on signal frequency and device operating point. We show that the reverse isolation of the SLUG can be as large as or larger than that of a bulk commercial isolator. Finally, we discuss the use of the SLUG to read out a transmon qubit without isolators or circulators.

**1:39PM S48.00013 Noise Characteristics of the Josephson Amplifiers by Stochastic Calculus<sup>1</sup>** , WENSHUO LIU, ROBERT MCDERMOTT, MAXIM VAVILOV, University of Wisconsin, Madison — We present theoretical studies of the noise performance of non-reciprocal gain elements based on Josephson junctions including the SQUID and the SLUG. We develop a perturbative approach by means of stochastic calculus which combines both analytical and numerical methods, and calculate the noise characteristics of the amplifiers in the thermal regime. We show that noise in the amplifiers originates mainly from the diffusive behavior of phase slips. This new method could help with the optimization of Josephson amplifiers for high-fidelity multiplexed qubit readout.

**1:51PM S48.00014 Qubit Readout with the Josephson Photomultiplier** , IVAN PECHENEZHSKIY, GUILHEM RIBEILL, University of Wisconsin, Madison, M. HUTCHINGS, CALEB HOWINGTON, Syracuse University, MAXIM VAVILOV, University of Wisconsin, Madison, FRANK WILHELM, Saarland University, B.L.T. PLOURDE, Syracuse University, ROBERT MCDERMOTT, University of Wisconsin, Madison — The realization of a large-scale fault-tolerant quantum processor will require scalable high-fidelity readout of multiqubit parity operators. Here we describe development of a scalable qubit measurement approach based on microwave photon counting. The measurement protocol involves mapping the qubit state to photon occupation of bright and dark cavity pointer states, followed by photodetection using the Josephson photomultiplier (JPM). We discuss use of the qubit as a calibrated source of photons to measure JPM quantum efficiency, and we describe global optimization of the measurement protocol. Finally, we discuss prospects for interfacing the JPM output to single flux quantum circuits to allow low-latency classical postprocessing of the qubit measurement result.

**2:03PM S48.00015 Multi-qubit measurements with a Josephson Photomultiplier<sup>1</sup>** , CALEB HOWINGTON, M HUTCHINGS, Syracuse University, GUILHEM RIBEILL, IVAN PECHENEZHSKIY, MAXIM G. VAVILOV, University of Wisconsin, FRANK K. WILHELM, Saarland University, R. MCDERMOTT, University of Wisconsin, BLT PLOURDE, Syracuse University — The ability to measure multi-qubit parity is critical for the realization of a fault-tolerant quantum information processor. For a system of transmon qubits coupled to a superconducting cavity, a threshold photon detector can provide an efficient path towards the digital readout of qubit parity after the parity information is mapped onto the cavity photon occupation. We will describe progress towards the implementation of such a scheme for measuring the parity of two transmon qubits. On-chip flux bias lines allow us to tune the dispersive cavity shifts related to the state of the two qubits and an appropriately shaped pulse driven to the cavity results in a bright state for one parity but not the other. A Josephson Photomultiplier then serves as a phase-insensitive digital detector of the microwave photons that leak out of the cavity. Future improvements and various technical difficulties will be discussed.

**11:15AM S50.00001 P-wave contacts for two dimensional quantum gas** , YICAI ZHANG, The University of Hong Kong, ZHENHUA YU, Institute for Advanced Study, Tsinghua University, SHIZHONG ZHANG, The University of Hong Kong — The s-wave contact has played an important role in our understanding of the strongly interacting Fermi gases. Recently, theoretical and experimental work has shown that two similar contacts exist for a p-wave interacting Fermi gas in three-dimensions. In this work, we extend the considerations to two dimensional spineless Fermi gas and derive exact results regarding the energy, momentum distributions and in particular, shifts of monopole frequency in a harmonic trap. Asymptotic formula for the frequency shift is given at high temperature via virial expansion and this can be checked by future experiments.

**11:27AM S50.00002 Multi-Branch Spin Chain Models for Strongly interacting Spinor Fermi and Bose gases in One-Dimension** , LI YANG, HAN PU, Rice Univ — By mapping a 1D spinor Fermi or Bose gases wavefunction to a direct product of a spinless fermion wavefunction and a spin chain wavefunction, we obtain a spin-charge coupling Hamiltonian which is a multi-branch spin chain model. The charge part of this model are p-wave  $\vec{\sigma}\delta(x)\vec{\sigma}$  interactions. The spin part of this model are spin parity projection operators. Previously obtained spin chain models (Nature Commun. 5, 5300. Phys. Rev. A 90, 013611. Phys. Rev. A 91, 043634.) are first order perturbation of this multi-branch spin chain model. With this model, for particles in a harmonic trap in strongly interacting regime, we study breathing mode frequencies and the system's response to a spin dependent magnetic gradient and quench dynamics. We also studied the properties of the system with large particle numbers under local density approximation. The resulted spin chain models are studied by exact numerical methods such as Matrix Product States. Other than harmonic trap we also considered traps with  $\delta(x)$  impurity, which can not be approximated by local density approximation.

**11:39AM S50.00003 ABSTRACT WITHDRAWN —**

**11:51AM S50.00004 Efimov correlations in strongly interacting Bose gases** , JOHANNES HOFMANN, University of Cambridge, MARCUS BARTH, Technische Universitaet Muenchen — A series of recent hallmark experiments have demonstrated that Bose gases can be created in the strongly interacting unitary limit in the non-degenerate high-temperature regime. These systems display the three-body Efimov effect, which poses a theoretical challenge to compute observables including these relevant three-body correlations. In this talk, I shall present our results for the virial coefficients, the contact parameters, and the momentum distribution of a strongly interacting three-dimensional Bose gas obtained by means of a virial expansion up to third order in the fugacity, which takes into account three-body correlations exactly. Our results characterize the non-degenerate regime of the interacting Bose gas, where the thermal wavelength is smaller than the interparticle spacing but the scattering length may be arbitrarily large. In addition, we provide a calculation of the momentum distribution at unitarity, which displays a universal high-momentum tail with a log-periodic momentum dependence - a direct signature of Efimov physics. In particular, we provide a quantitative description of the momentum distribution at high momentum as measured by the JILA group [Makotyn et al., Nat. Phys. 10, 116 (2014)]. Our results allow the spectroscopy of Efimov states at unitarity.

**12:03PM S50.00005 Competing order parameters in Fermi systems with engineered band dispersion** , CHIEN-TE WU, RUFUS BOYACK, BRANDON ANDERSON, K LEVIN, James Franck Institute — We explore a variety of competing phases in 2D and 3D Fermi gases in the presence of novel dispersion relations resulting from a shaken optical lattice. We incorporate spin imbalance along with attractive interactions. In 3D, at the mean field level we present phase diagrams reflecting the stability of alternative order parameters in the pairing (including LOFF) and charge density wave channels. We perform analogous studies in 2D, where we focus on the competition between different paired phases. Important in this regard is that our 2D studies [1] are consistent with the Mermin-Wagner theorem, so that, while there is competition, conventional superfluidity cannot occur. [1] C.-T. Wu, B. M. Anderson, R. Boyack, and K. Levin, arXiv:1509.00857 (to be published in Phys. Rev. Lett.)

**12:15PM S50.00006 Spectral function and dark continuum of the resonant Fermi Polaron<sup>1</sup>** , OLGA GOULKO, UMass Amherst, ANDREY MISHCHENKO, RIKEN Center for Emergent Matter Science (CEMS), NIKOLAY PROKOFEV, BORIS SVISTUNOV, UMass Amherst — The Fermi polaron is an impurity interacting with a sea of fermions. It is an exemplary system to study impurity problems, strongly imbalanced Fermi gases and quasiparticles. Experiments probe its spectral function, which is directly linked to many physical properties. We present the first numerical results for the polaron spectral function with controlled error bars, obtained from first principles with diagrammatic Monte Carlo and analytic continuation. The spectral function exhibits a narrow ground state peak and another broad peak at positive energy, which are separated by a region of extremely low spectral weight. This "dark continuum" surprisingly starts to emerge in the absence of a small parameter, around  $k_F a \sim 1$ , and quickly broadens into a gap-like structure deeper on the BEC side. We confirm that the dark continuum is indeed physical and not an artefact of approximate calculations and establish a controlled upper bound on its integrated weight.

**12:27PM S50.00007 Finite Temperature Response of a 2D Dipolar Bose Gas at Different Dipolar Tilt Angles<sup>1</sup>**, PENGTAO SHEN, KHANDKER QUADER, Kent State University — We calculate finite temperature (T) response of a 2D Bose gas, subject to dipolar interaction, within the random phase approximation (RPA). We evaluate the appropriate 2D finite-T pair bubble diagram needed in RPA, and explore ranges of density and temperature for various dipolar tilt angles. We find the system to exhibit a collapse transition and a finite momentum instability, signaling a density wave or striped phase. We construct phase diagrams depicting these instabilities and resulting phases, including a normal Bose gas phase. We also consider the finite-T response of a quasi-2D dipolar Bose gas. We discuss how our results may apply to ultracold dense Bose gas of polar molecules, such as <sup>41</sup>K<sup>87</sup>Rb, that has been realized experimentally.

**12:39PM S50.00008 Strengthening Supersolids with Disorder in the Extended Bose-Hubbard Model**, FEI LIN, Washington and Lee University, THOMAS MAIER, Oak Ridge National Lab, VITO SCAROLA, Virginia Tech — The extended Bose-Hubbard model captures the essential properties of a wide variety of physical systems including ultracold atoms and molecules in optical lattices, Josephson junction arrays, and narrow band superconductors. It exhibits a rich phase diagram including a supersolid phase where a lattice solid coexists with a superfluid. We use quantum Monte Carlo to map out the phase diagram of the extended Bose-Hubbard model on the simple cubic lattice where the supersolid is expected. We find that the supersolid is very delicate because unexpected phase separated states compete with the supersolid. We add disorder to the extended Bose-Hubbard model and find that the supersolid phase is enhanced by disorder as phase separation is suppressed. Our results establish optimal regimes for observing supersolids and therefore have important implications for their observation.

**12:51PM S50.00009 *p*-wave superfluid shells for trapped fermions with population imbalance<sup>1</sup>**, AMMAR KIRMANI, KHANDKER QUADER, MAXIM DZERO, Kent State University — We present the phase diagram for a *p*-wave fermionic superfluid with imbalanced populations in a potential trap. We find shells of various superfluid phases, whose realization is determined by the parameters of a trap. In order to compute the resulting phase diagram, we use weak-coupling BCS theory together with the local density approximation in which the effect of the trapping potential is accounted for by a spatially inhomogeneous chemical potential. We compare our phase diagram with the one found for the trapped population imbalanced *s*-wave fermionic superfluid [Lin, Yi & Duan, Phys. Rev. A 74, 031604R (2006)], and also point out key differences with results for the population imbalanced *p*-wave case in the absence of a trap [Liao, Popescu & Quader, Phys. Rev. B 88, 134507 (2013)].

**1:03PM S50.00010 Quantum Criticality of the Two-dimensional Bose Gas with the Lifshitz dispersion**, CONGJUN WU, JIANDA WU, UC San Diego — Bosonic systems with the synthetic spin-orbit coupling and Zeeman field can be tuned into a quantum Lifshitz point exhibiting the  $q^4$ -dispersion. They are fundamentally different from the conventional ones with the  $q^2$ -dispersion, and are also connected to quantum frustrated magnets. We set up a generic quantum  $\phi^4$ -theory at the Lifshitz point and investigate quantum critical behaviors at both zero and finite temperatures following the perturbative renormalization group method. Controlled by different fixed points, various physical quantities exhibit significantly different scalings from those of the conventional bosonic systems, exhibiting rich quantum critical physics in different interaction and temperature ranges.

**1:15PM S50.00011 Equation of state of ultracold fermions in the 2D BEC-BCS crossover**, IGOR BOETTCHER, Department of Physics, Simon Fraser University, Burnaby, British Columbia V5A 1S6, Canada, LUCA BAYHA, DHRUV KEDAR, PUNEET MURTHY, MATHIAS NEIDIG, MARTIN RIES, ANDRE WENZ, GERHARD ZUERN, SELIM JOCHIM, Physikalisches Institut, Heidelberg University, D-69120 Heidelberg, Germany, TILMAN ENSS, Institute for Theoretical Physics, Heidelberg University, D-69120 Heidelberg, Germany — We report the experimental measurement of the equation of state of a two-dimensional Fermi gas with attractive *s*-wave interactions throughout the crossover from a weakly coupled Fermi gas to a Bose gas of tightly bound dimers as the interaction strength is varied. We demonstrate that interactions lead to a renormalization of the density of the Fermi gas by several orders of magnitude. We compare our data near the ground state and at finite temperature to predictions for both fermions and bosons from Quantum Monte Carlo simulations and Luttinger-Ward theory. Our results serve as input for investigations of close-to-equilibrium dynamics and transport in the two-dimensional system.

**1:27PM S50.00012 Fluctuation theory of Rashba Fermi gases: Gaussian and beyond<sup>1</sup>**, VIJAY B. SHENOY, Indian Institute of Science Bangalore, JAYANTHA P. VYASANAKERE, Tumkur University — Fermi gases with generalized Rashba spin orbit coupling induced by a synthetic gauge field have the potential of realizing many interesting states such as rashbon condensates and topological phases. Here we address the key open problem of the fluctuation theory of such systems and demonstrate that beyond-Gaussian effects are *essential* to capture finite temperature physics of such systems. We obtain their phase diagram by constructing an approximate non-Gaussian theory. We conclusively establish that spin-orbit coupling can enhance the exponentially small transition temperature ( $T_c$ ) of a weakly attracting superfluid to the order of Fermi temperature, paving a pathway towards high  $T_c$  superfluids.

**1:39PM S50.00013 Superfluidity and BCS-BEC crossover of ultracold atomic Fermi gases in mixed dimensions<sup>1</sup>**, LEIFENG ZHANG, QIJIN CHEN, Zhejiang University — Atomic Fermi gases have been under active investigation in the past decade. Here we study the superfluid and pairing phenomena of a two-component ultracold atomic Fermi gas in the presence of mixed dimensionality, in which one component is confined on a 1D optical lattice whereas the other is free in the 3D continuum. We assume a short-range pairing interaction and determine the superfluid transition temperature  $T_c$  and the phase diagram for the entire BCS-BEC crossover, using a pairing fluctuation theory which includes self-consistently the contributions of finite momentum pairs. We find that, as the lattice depth increases and the lattice spacing decreases, the behavior of  $T_c$  becomes very similar to that of a population imbalance Fermi gas in a simple 3D continuum. There is no superfluidity even at  $T = 0$  below certain threshold of pairing strength in the BCS regime. Nonmonotonic  $T_c$  behavior and intermediate temperature superfluidity emerge, and for deep enough lattice, the  $T_c$  curve will split into two parts. Implications for experiment will be discussed. References: 1. Q.J. Chen, Ioan Kosztin, B. Janko, and K. Levin, Phys. Rev. B 59, 7083 (1999). 2. Chih-Chun Chien, Qijin Chen, Yan He, and K. **1:51PM S50.00014 Bose polarons in the strongly interacting regime.**<sup>1</sup>, MING-GUANG HU, MICHAEL VAN DE GRAAFF, DHRUV KEDAR, ERIC CORNELL, DEBORAH JIN, JILA, NIST and CU-Boulder — Impurities immersed in and interacting with a Bose-Einstein condensate (BEC) are predicted to form quasiparticle excitations called Bose polarons. I will present experimental evidence of Bose polarons in cold atoms obtained using radio-frequency spectroscopy to measure the excitation spectrum of fermionic <sup>40</sup>K impurities interacting with a BEC of <sup>87</sup>Rb atoms. We use an interspecies Feshbach resonance to tune the interactions between the impurities and the bosons, and we take data in the strongly interacting regime.

<sup>1</sup>This work is supported by NSF, NASA and NIST

**2:03PM S50.00015 Self consistent theories of superfluid density and collective modes in BCS-BEC**, RUFUS BOYACK, BRANDON ANDERSON, CHIEN-TE WU, KATHRYN LEVIN, James Franck Inst — Establishing fully self consistent and sum rule compatible response functions in strongly correlated Fermi superfluids has been a historically challenging subject. In this talk, we present recent progress pertaining to response functions in many-body Fermi systems. We note that even in strict BCS theory, the textbook derivation of density and current response functions in the gradient expansion breaks certain conservation laws such as the compressibility sum rule. To include additional contributions that preserve all expected conservation laws, we show how to exploit Ward identities within two different t-matrix schemes. In this way we address the density-density response (including collective modes) and the superfluid density. Finally, we characterize approximations made in the literature where some consistency requirements have been dropped.

**11:15AM S51.00001 Magneto-Inter-Subband Oscillations in GaAs quantum wells with three populated subbands placed in tilted magnetic fields.**<sup>1</sup>, WILLIAM MAYER, JESSE KANTER, SERGEY VITKALOV, City College of New York, CUNY Graduate Center, ALEXEY BYKOV, Institute of Semiconductor Physics, Novosibirsk, Russia — The effect of tilted magnetic fields on magnetotransport is studied in GaAs quantum wells with three populated subbands. In perpendicular fields magneto-intersubband oscillations (MISO) are observed. These oscillations obey the relation  $\Delta_{ij} = (E_i - E_j) = k\omega_c$ , where  $E_i$  is the energy of the bottom of  $i$ -th subband and  $k$  is an integer. MISO are periodic in the inverse magnetic field and show three frequencies  $f_{ij} \sim \Delta_{ij}$ . Due to  $E_{1,2} \ll E_3$  two MISO oscillate at high frequencies (HF) demonstrating a beat pattern with the beat frequency  $f_b = (f_{13} - f_{23})/2 \sim \Delta_{12}$ . With increasing tilt angle at small magnetic fields,  $\omega_c < \Delta_{12}$ , the periodicity of HF-MISO changes indicating a change in the subband gap  $\Delta_{12}$ . The dependence of  $\Delta_{12}$  on the parallel magnetic field is found to be in a good agreement with existing theory. At larger parallel magnetic fields and  $\omega_c > \Delta_{12}$ , the high frequency beating disappears leaving only HF-MISO with single frequency  $f = (f_{13} + f_{23})/2$ . It indicates a magnetic breakdown between the lower two subbands. Investigations of the 2D electron system in the regime of the magnetic breakdown are presented.

**11:27AM S51.00002 Blockade in a silicon double quantum dot via the valley degree of freedom**, JUSTIN PERRON<sup>1</sup>, Cal State Univ - San Marcos, MICHAEL J. GULLANS<sup>2</sup>, JACOB M. TAYLOR<sup>3</sup>, Joint Quantum Institute, National Institute of Standards and Technology, Gaithersburg, Maryland, 20899, M. D. STEWART, JR., NEIL M. ZIMMERMAN, National Institute of Standards and Technology, Gaithersburg, Maryland 20899, USA — Measuring electrical transport through double quantum dots (DQDs) is a useful way of illuminating several aspects of the states of the carriers. We show transport measurements through a silicon DQD formed in a mesa etched nanowire. Comparing the data at positive and negative bias voltage we observe a size asymmetry in the region of allowed current typically associated with Pauli spin blockade (PSB). However, the qualitative features of the asymmetry in our data, including i) lack of odd/even filling, ii) same polarity of asymmetry across many bias triangles, iii) lack of systematic dependence on magnetic field, and iv) a dependence on gate voltages, are all in disagreement with the predictions of PSB. In contrast, we have developed a model based on the selective filling of valley states in the DQD and the conservation of the valley degree of freedom during tunneling that predicts all of the qualitative features in our data.

**11:39AM S51.00003 Negative Differential Conductance from Space Charge Limited Currents in Semiconductors**, ANDREW BROOKS, XIAO GUANG ZHANG, University of Florida — Applying the theory of space charge limited currents (SCLC), we show that negative differential conductance can arise from doubly occupied traps that are nearly degenerate with the bottom of the conduction band. Using degenerate state perturbation theory, the Coulomb energy of the doubly occupied traps is shown to depend on the hybridization with the conduction band states. Initially, when carriers are injected into the solid, traps begin to fill while the conduction band states stay relatively empty and thus accessible to trapped electrons via hopping. Trap and conduction states continue to be filled as current is increased, and the energy of trapped electrons begins to rise. A critical current is reached whereupon a further increase in current leads to a reduction of filled traps (i.e. a reduction of space charge in the solid), and thus a corresponding decrease in voltage. This trend in the current-voltage characteristic curves persists until the bottom of the conduction band has been filled, then voltage rises with current.

**11:51AM S51.00004 Vertical electronic transport in van de waals heterostructures**, ZHENHUA QIAO, University of Science and Technology of China, ZHENHUA QIAO'S GROUP TEAM — In this work, we will introduce the theoretical investigation of the vertical electronic transport in various heterostructures by using both tight-binding method and first-principles calculations. Counterintuitively, we find that the maximum electronic transport is achieved at very limited scattering regions but not at large overlapped catering regions. Based on this finding, we design a special setup to measure the tunneling effect in rotated bilayer systems.

**12:03PM S51.00005 First principles lattice thermal conductivity of  $\text{Li}_2\text{Se}$ ,  $\text{Li}_2\text{Te}$  and alloys: phase space guidelines for thermal transport**<sup>1</sup>, LUCAS LINDSAY, SAIKAT MUKHOPADHYAY, DAVID PARKER, Oak Ridge National Laboratory — The lattice thermal conductivities ( $k$ ) of  $\text{Li}_2\text{Se}$ ,  $\text{Li}_2\text{Te}$  and alloys are examined using a first-principles Peierls-Boltzmann transport methodology. The dominant resistance to heat-carrying acoustic phonons in  $\text{Li}_2\text{Se}$  and  $\text{Li}_2\text{Te}$  comes from the interactions of these modes with two optic phonons, a.o scattering. In typical cubic and hexagonal materials (*e.g.*, Si, GaAs, AlN) a.o scattering does not play a considerable role in determining  $k$ , as it requires significant bandwidth and dispersion of the optic phonon branches, both present in  $\text{Li}_2\text{Se}$  and  $\text{Li}_2\text{Te}$ . We discuss how these properties and other features of the phonon dispersion (*e.g.*, bunching of the acoustic branches and an acoustic-optic frequency gap) combine to determine the overall conductivity of a material. Thus, microscopic scattering phase space arguments are generalized to give a more comprehensive view of intrinsic thermal transport in crystalline solids. We note that these general considerations are important for the discovery and design of new ‘high $k$ ’ and ‘low  $k$ ’ materials for thermal management applications.

**12:15PM S51.00006 Thermal Conductivity Accumulation Function of Silicon-Germanium Alloy from Thermorefectance and First-Principles**, KEVIN PARRISH, JUSTIN FREEDMAN, KEITH REGNER, ANKIT JAIN, JONATHAN MALEN, ALAN MCGAUGHEY, Carnegie Mellon Univ — Phonons are the dominant heat carriers in semiconductors. Alloying changes their properties by introducing mass disorder and altering the bonding environment. In this study, we determine the thermal conductivity accumulation functions of silicon-germanium alloys using broadband frequency-domain thermorefectance experiments. The accumulation function describes the cumulative mean free path-dependent contributions to thermal conductivity and provides a measure for determining how alloying alters thermal conductivity compared to pure semiconductors. The experimental results are compared to calculations based in density functional theory, lattice dynamics, the virtual crystal approximation, and the Boltzmann transport equation. In both thermorefectance and lattice dynamics we find alloying increases the proportional accumulation of long MFP phonons.

**12:27PM S51.00007 Study of Thermal properties of  $\text{VO}_2$  and multilayer  $\text{VO}_2$  thin films for application in Thermal Switches.**, GAOHUA ZHU, Toyota Research Institute of North America — Ultrafast nature of the phase transition near room temperature in  $\text{VO}_2$  makes it attractive material for applications in electronics and optical devices however utilization of corresponding drastic change in thermo-physical properties are rarely reported. In this study we investigate thermal and electronic properties of  $\text{VO}_2$  thin films on various substrates across the transition temperature to seek possibility of utilizing  $\text{VO}_2$  based thermal switches for applications in thermal devices. In addition, the interfacial heat transfer in  $\text{VO}_2$ /metal multilayer thin film is mediated by phonons at low temperature, and when temperature is elevated beyond phase transition temperature, the interface thermal conductance is mediated mainly by both phonons and electrons.  $\text{VO}_2$ -multilayers approach is studied to utilize the switching interface thermal conductance in order to obtain higher thermal conductivity switch ratio than what can be achieved in intrinsic  $\text{VO}_2$ . Thermal conductivities and interface thermal conductance of  $\text{VO}_2$  and  $\text{VO}_2$  multilayer thin films are measured using the time-domain thermorefectance (TDTR) method. We will discuss interplay of phononic and electronic component to thermal conductivity in the light of Wiedemann–Franz law across the metal to insulator state of  $\text{VO}_2$  films.

**12:39PM S51.00008 Efros-Shklovskii variable range hopping conductivity without Coulomb gap**, TIANRAN CHEN, Department of Physics, West Chester University of Pennsylvania, BRIAN SKINNER, Center for Excitonics, Massachusetts Institute of Technology — In doped semiconductors and Coulomb glasses, in the limit of weak coupling, the electron conductivity primarily proceeds by phonon-assisted tunneling or hopping between different sites through the insulating gaps that separate them. Electron conduction can occur both through nearest-neighbor hopping and through cotunneling of electrons between distant sites via a chain of intermediate virtual states. In the presence of some disorder, the latter mechanism dominates at low temperatures, where the length of the hops grows to optimize the conductivity. This transport mechanism was introduced by Mott, and is called variable range hopping. When the Coulomb interaction between localized electrons is taken into account, it can be shown that at a sufficiently low temperature, variable range hopping conductivity obeys the Efros-Shklovskii (ES) law, which has been observed in a number of amorphous semiconductors and granular metal systems at low temperatures. ES conductivity has been long understood as the result of a soft, Coulomb gap at the Fermi level. However, such a theory overlooks the presence of spatial correlations between site energies and their possible effects on electrical conductivity. In this talk, we show both analytically and numerically that in systems where spatial correlations must be taken into account, ES conductivity may persist far outside the Coulomb gap, in contrast to conventional transport theory for doped semiconductors and Coulomb glasses where ES conductivity only occurs within the Coulomb gap.

**12:51PM S51.00009 Maximum non-saturating magnetoresistance in  $\text{MoTe}_2$** , MAHMOUD ABDEL-HAFIEZ, ZHEHAO GU, XIAO-JIA CHEN, Center for High Pressure Science and Technology Advanced Research, Shanghai, 201203, China, CENTER FOR HIGH PRESSURE SCIENCE AND TECHNOLOGY ADVANCED RESEARCH, SHANGHAI, 201203, CHINA TEAM — The search for exotic materials with a linear magnetoresistance (MR) is one of the most challenging tasks of the condensed matter community and materials science. Here, we investigated the magnetoresistance behavior of high-quality single crystals  $\text{MoTe}_2$ . A large linear non-saturating MR in a magnetic field of 60 T, was observed with a maximum at a temperature of  $T = 45$  K. The detailed field and temperature dependencies will be presented. Our results not only provide a general scaling approach for the anisotropic MR but also are crucial for correctly understanding the mechanism of the linear MR, including the origin of the remarkable “turn-on” behavior in the resistance versus temperature curve.

**1:03PM S51.00010 Negative thermal expansion above a quantum phase transition**, SAHAN HAN-DUNKANDA, ERIN CURRY, JASON HANCOCK, Univ of Connecticut - Storrs — Strong, thermally persistent, isotropic negative thermal expansion (NTE) is unusual and has been observed in only a handful of materials. Scandium trifluoride ( $\text{ScF}_3$ ) features large isotropic thermal expansion persistent over a 1000K range of temperature. More interestingly, no structural phase transition has been reported above 0.4K and it retains the simple cubic structure up to its high melting point of 1800K, which is unusual compared with other transition metal trifluorides. Here, we present a combined inelastic x-ray scattering (IXS) and x-ray diffraction study of  $\text{ScF}_3$ , which reveals some exciting features of this material. The low-energy ( $\sim 1$  meV) vibrational modes corresponding to M and R points of simple cubic Brillouin zone could explain NTE in  $\text{ScF}_3$ , and we find that the low temperature IXS data show a central peak which is especially strong at these points. In addition, the whole M-R branch undergoes unusual softening at low temperature. We determine that this mode softens nearly to zero energy as the temperature approaches to 0K. These signature portend an approach to a quantum phase transition of this insulating, nonmagnetic simple cubic perovskite material  $\text{ScF}_3$ . The central peak, soft mode and thermal expansion could all be consequences of this incipient transition. The connections we have established in the phenomenology of  $\text{ScF}_3$  may be present in other perovskites as well as other materials that display strong NTE

**1:15PM S51.00011 First Principles Study of structural characteristics and phase change mechanism of Ge-Sb-Te based materials**, HANJIN PARK, CHEOL-WOON KIM, HYUNG-JUNE LEE, HOSIN SONG, YOUNG-KYUN KWON, Department of Physics and Research Institute for Basic Sciences, Kyung Hee University, Seoul, 130-701, Korea — Using *ab initio* density functional theory, we investigate the structural properties and their phase transition mechanism of the crystalline and amorphous phases of Ge-Sb-Te (GST) based phase change materials, which would be utilized for phase change random access memory. Among various stoichiometries of GST, we focus on compositions along the  $(\text{GeTe})_n(\text{Sb}_2\text{Te}_3)_m$  pseudo-binary line, denoted simply by  $(n, m)$  with integer  $n$  and  $m$ . We explore various GST materials corresponding  $(n, m)$  sets including (1,0), (0,1), (1,1), (2,1) and (1,2) by modeling their both phases. Especially, their amorphous phases can be constructed based on experimental data available or molecular dynamics (MD) simulations performing melt-quench processes. To understand the phase transition mechanism, we evaluate their coordination numbers, radial distribution functions, and angle distribution functions, which enables us to identify the characteristic local geometry representing each phase. We further investigate the thermal properties of various phases by evaluating their phonon densities of states obtained by Fourier-transforming the velocity autocorrelation functions calculated directly from our MD simulation.

**1:27PM S51.00012 Nonlinear THz absorption and cyclotron resonance in InSb.**<sup>1</sup>, KATE HEFFERNAN, SHUKAI YU, DIYAR TALBAYEV, Tulane University — The emergence of coherent high-field terahertz (THz) sources in the past decade has allowed the exploration of nonlinear light-matter interaction at THz frequencies. Nonlinear THz response of free electrons in semiconductors has received a great deal of attention. Such nonlinear phenomena as saturable absorption and self-phase modulation have been reported. InSb is a narrow-gap (bandgap 0.17 eV) semiconductor with a very low electron effective mass and high electron mobility. Previous high-field THz work on InSb reported the observation of ultrafast electron cascades via impact ionization. We study the transmission of an intense THz electric field pulse by an InSb wafer at different incident THz amplitudes and 10 K temperature. Contrary to previous reports, we observe an increased transmission at higher THz field. Our observation appears similar to the saturable THz absorption reported in other semiconductors. Along with the increased absorption, we observe a strong modulation of the THz phase at high incident fields, most likely due to the self-phase modulation of the THz pulse. We also study the dependence of the cyclotron resonance on the incident THz field amplitude. The cyclotron resonance exhibits a lower strength and frequency at the higher incident THz field.

**1:39PM S51.00013 Bound excitons at nitrogen and bismuth isoelectronic impurities**, THERESA CHRISTIAN, Univ of Colorado - Boulder, KIRSTIN ALBERI, DANIEL BEATON, BRIAN FLUEGEL, ANGELO MASCARENHAS, National Renewable Energy Lab — When nitrogen and bismuth dopants are simultaneously incorporated into a host lattice such as gallium arsenide (GaAs) or gallium phosphide (GaP), each dopant species contributes to the evolution of the electronic structure. Bound excitons in these systems luminescence from localized states whose distinctive radiative signatures provide invaluable clues into the nature of impurity clustering and inter-impurity interactions within the host lattice. Spectroscopic studies of these states will be presented for a series of samples grown by molecular beam epitaxy. Research was supported by the U. S. Department of Energy, Basic Energy Sciences, Materials Sciences and Engineering Division under contract DE-AC36-08GO28308 and by the Department of Energy Office of Science Graduate Fellowship Program (DOE SCGF), made possible in part by the American Recovery and Reinvestment Act of 2009, administered by ORISE-ORAU under contract no. DE-AC05-06OR23100.

**1:51PM S51.00014 Electron-Phonon Renormalization of Electronic Band Structures of C Allotropes and BN Polymorphs**<sup>1</sup>, ROXANNE M. TUTCHTON, CHRISTOPHER MARCHBANKS, ZHIGANG WU, The Colorado School of Mines — The effect of lattice vibration on electronic band structures has been mostly neglected in first-principles calculations because the electron-phonon (e-ph) renormalization of quasi-particle energies is often small ( $< 100$  meV). However, in certain materials, such as diamond, the electron-phonon coupling reduces the band gap by nearly 0.5 eV, which is comparable to the many-body corrections of the electronic band structures calculated using the density functional theory (DFT). In this work, we compared two implementations of the Allen-Heine-Cardona theory in the EPW code and the ABINIT package respectively. Our computations of Si and diamond demonstrate that the ABINIT implementation converges much faster. Using this method, the e-ph renormalizations of electronic structures of three C allotropes (diamond, graphite, graphene) and four BN polymorphs (zincblende, wurtzite, mono-layer, and layered-hexagonal) were calculated. Our results suggest that (1) all of the zero-point renormalizations of band gaps in these materials, except for graphene, are larger than 100 meV, and (2) there are large variations in e-ph renormalization of band gaps due to differences in crystal structure.

**2:03PM S51.00015 Non-adiabatic effects on the optical response of driven systems**, BENJAMIN M. FREGOSO, MICHAEL KOLODRUBETZ, JOEL MOORE, Univ of California - Berkeley — Periodically driven systems have received renewed interest due to their capacity to engineer non-trivial effective Hamiltonians. A characteristic of such systems is how they respond to weak periodicity-breaking drive, as for example when a laser is pulsed instead of continuous wave. We develop semi-classical equations of motion of a wave packet in the presence of electric and magnetic fields which are turned on non-adiabatically. We then show the emergence of significant corrections to electronic collective excitations and optical responses of topological insulator surface states, Weyl metals and semiconductor mono-chalcogenides.

**Session S52 DAMOP: Photonic Topological Materials** Hilton Baltimore Holiday Ballroom 3 - Xiaopeng Li, Joint Quantum Institute, University of Maryland

**11:15AM S52.00001 The Science and Applications of Photonic Topological Insulators: From Robust Delay Lines to Non-Reciprocal Metawaveguides<sup>1</sup>** , GENNADY SHVETS, The University of Texas at Austin — Electromagnetic (EM) waves propagating through an inhomogeneous medium inevitably scatter whenever the medium's electromagnetic properties change on the scale of a single wavelength. This fundamental phenomenon constrains how optical structures are designed and interfaced with each other. Our theoretical work indicates [1] that electromagnetic structures collectively known as photonic topological insulators (PTIs) can be employed to overcome this fundamental limitation, thereby paving the way to ultra-compact photonic structures that no longer have to be wavelength-scale smooth. Here I present the first experimental demonstration of a photonic structure that supports topologically protected surface electromagnetic waves (TPSWs) that are counterparts to the edge states between two quantum spin-Hall topological insulators in condensed matter. Unlike conventional guided EM waves that do not benefit from topological protection, TPSWs are shown to experience reflections-free time delays when detoured around sharply-curved paths, thus offering a unique paradigm for wave buffers and delay lines. I will also discuss how the photonic analogs of the quantum Hall and valley-Hall topological insulators can be realized and interfaced with each other. [1] T. Ma et. al., "Guiding Electromagnetic Waves around Sharp Corners: Topologically Protected Photonic Transport in Metawaveguides", Phys. Rev. Lett. 114, 127401 (2015).

**11:51AM S52.00002 Disordered Interactions and Fractional Quantum Hall States** , WADE DEGOT-TARDI, MOHAMMAD HAFEZI, Joint Quantum Institute, University of Maryland — The possibility that topological ordered states may be realized in photonic systems has recently attracted a great deal of attention. Given the rich phenomenology of the fractional quantum Hall effect, the bosonic Laughlin states have been of particular focus in this context. These states are known to arise in strongly nonlinear photonic lattices with artificial gauge fields, where nonlinearities associated with the resonators mimic on-site interactions. These effective interaction strengths are not universal and are subject to spatial disorder. We present a detailed study of the stability of these states and what implications they have for experiments.

**12:03PM S52.00003 Topological photonic crystal with ideal Weyl points** , LUYANG WANG, SHAO-KAI JIAN, HONG YAO, Institute for Advanced Study, Tsinghua University — Weyl points in three-dimensional photonic crystals behave as monopoles of Berry flux in momentum space. Here, based on symmetry analysis, we show that a minimal number of symmetry-related Weyl points can be realized in time-reversal invariant photonic crystals. We propose to realize these "ideal" Weyl points in modified double-gyroid photonic crystals, which is confirmed by our first-principle photonic band-structure calculations. Photonic crystals with ideal Weyl points are qualitatively advantageous in applications such as angular and frequency selectivity, broadband invisibility cloaking, and broadband 3D-imaging.

**12:15PM S52.00004 Topological photonics: an observation of Landau levels for optical photons<sup>1</sup>** , NATHAN SCHINE, Univ of Chicago, ALBERT RYOU, ARIEL SOMMER, JONATHAN SIMON, University of Chicago — Creating photonic materials with nontrivial topological characteristics has seen burgeoning interest in recent years; however, a major route to topology, a magnetic field for continuum photons, has remained elusive. We present the first experimental realization of a bulk magnetic field for optical photons. By using a non-planar ring resonator, we induce an image rotation on each round trip through the resonator. This results in a Coriolis/Lorentz force and a centrifugal anticonfining force, the latter of which is cancelled by mirror curvature. Spatial- and energy- resolved spectroscopy tracks photonic eigenstates as residual trapping is reduced, and we observe photonic Landau levels as the eigenstates become degenerate. We will discuss the conical geometry of the resulting manifold for photon dynamics and present a measurement of the local density of states that is consistent with Landau levels on a cone. While our work already demonstrates an integer quantum Hall material composed of photons, we have ensured compatibility with strong photon-photon interactions, which will allow quantum optical studies of entanglement and correlation in manybody systems including fractional quantum Hall fluids.

**12:27PM S52.00005 Topological crystalline insulators in photonic systems<sup>1</sup>** , JIANXIAO ZHANG, MIKAEL RECHTSMAN, CHAO-XING LIU, Pennsylvania State Univ — Topological crystalline insulators are a class of materials with a bulk energy gap and edge or surface modes, which are protected by crystalline symmetry, at their boundaries. They have been realized in electronic systems: in particular, in SnTe. In this work, we propose a mechanism to realize photonic boundary states topologically protected by crystalline symmetry. We map this one-dimensional system to a two-dimensional lattice model with opposite magnetic fields, as well as opposite Chern numbers, in its even and odd mirror parity subspaces, thus corresponding to a topological mirror insulator. Furthermore, we test how sensitive and robust edge modes depend on their mirror parity by performing time dependent evolution simulation of edge modes in a photonic setting with realistic experimental parameters.

**12:39PM S52.00006 Braiding light quanta<sup>1</sup>** , THOMAS IADECOLA, THOMAS SCHUSTER, CLAUDIO CHAMON, Boston University — The possibility that anyons — quantum particles other than fermions or bosons — can emerge in condensed matter systems has motivated generations of physicists. In addition to being of fundamental scientific importance, so-called non-Abelian anyons are particularly sought-after for potential applications to quantum computing. However, experimental evidence of anyons in electronic systems remains inconclusive. We propose to demonstrate non-Abelian braiding by injecting coherent states of light into topological guided modes in specially-fabricated photonic waveguide arrays. These modes are photonic analogues of topological zero modes in electronic systems. Light traveling inside spatially well-separated topological guided modes can be braided, leading to the accumulation of non-Abelian phases. We propose an optical interference experiment to probe this non-Abelian braiding directly.

<sup>1</sup>T.I. is supported by a National Science Foundation Graduate Research Fellowship under grant no. DGE-1247312.

**12:51PM S52.00007 Topological Photonics for Continuous Media<sup>1</sup>** , MARIO SILVEIRINHA, University of Coimbra — Photonic crystals have revolutionized light-based technologies during the last three decades. Notably, it was recently discovered that the light propagation in photonic crystals may depend on some topological characteristics determined by the manner how the light states are mutually entangled. The usual topological classification of photonic crystals explores the fact that these structures are periodic. The periodicity is essential to ensure that the underlying wave vector space is a closed surface with no boundary. In this talk, we prove that it is possible to calculate Chern invariants for a wide class of continuous bianisotropic electromagnetic media with no intrinsic periodicity. The nontrivial topology of the relevant continuous materials is linked with the emergence of edge states. Moreover, we will demonstrate that continuous photonic media with the time-reversal symmetry can be topologically characterized by a  $\mathbb{Z}_2$  integer. This novel classification extends for the first time the theory of electronic topological insulators to a wide range of photonic platforms, and is expected to have an impact in the design of novel photonic systems that enable a topologically protected transport of optical energy.

**1:03PM S52.00008 From Casimir-Polder Force to Dicke Physics: Interaction between Atoms and a Topological Insulator**, SEBASTIAN FUCHS, STEFAN BUHMANN, University of Freiburg — We apply the theory of macroscopic quantum electrodynamics in dispersing and absorbing media to study the Casimir-Polder force between an atom and a topological insulator [1]. The electromagnetic response of a topological insulator surface leads to a mixing of electric and magnetic fields, breaking the time-reversal symmetry [2, 3]. The coupling of these fields to an atom causes shifts of the atom's eigenenergies and modified decay rates near the surface of the topological insulator. Energy shifts and modified decay rates cannot only be triggered by the presence of a material, but can be caused by other atoms in close proximity as well. The collective dynamics of atoms (Dicke Physics) leads to a superradiant burst [4]. Combining macroscopic QED and Dicke physics opens the door to the investigation of cooperative atom-surface interactions. [1] S. Y. Buhmann, Dispersion Forces II, Springer-Verlag Berlin Heidelberg (2012). [2] S. Y. Buhmann, D. T. Butcher, and S. Scheel, New Journal of Physics 14, 083034 (2012). [3] J. A. Crosse, S. Fuchs, and S. **1:15PM S52.00009 Robust topological states in Parity-time (PT) symmetric photonic lattices<sup>1</sup>**, ANDREW HARTER, YOGESH JOGLEKAR, Indiana University Purdue University Indianapolis (IUPUI) — We consider generalized Aubry-Andre models, which support topological states and are experimentally realizable in integrated waveguide lattices, in the presence of balanced gain and loss. When the gain-loss strength exceeds a threshold set by the nearest neighbor tunneling, the non-Hermitian, PT-symmetric Hamiltonian of this system undergoes PT breaking transition. We investigate the interplay between the PT-breaking transition, tuned by the gain-loss strength, and topological transitions between different states with Chern numbers. We show, due to sub-lattice-localization property of the topological edge states in these models, these edge states remain robust across the PT-breaking transition. We present the consequences of this result for light-propagation in such materials, obtained via both tight-binding model and beam-propagation method.

**1:27PM S52.00010 Exciting Reflectionless, Unidirectional Edge Mode in Bianisotropic Meta-waveguide Using Rotating Dipole Antenna.<sup>1</sup>**, BO XIAO, THOMAS ANTONSEN, EDWARD OTT, STEVEN ANLAGE, Univ of Maryland-College Park, TZUHSUAN MA, GENNADY SHVETS, University of Texas Austin — Electronic chiral edge states in Quantum Hall Effect systems has attracted a lot of attention in recent years because of its unique directionality and robustness against scattering from disorder. Its electromagnetic counterpart can be found in photonic crystals, which is a material with periodic dielectric constant. Here we present the experimental results demonstrating the unidirectional edge mode inside a bi-anisotropic meta-waveguide [1] (BMW) structure. It is a parallel plate waveguide with metal rods placed in a hexagonal lattice. Half of the rods are attached to the top plate while the other half are attached to the bottom plate creating a domain wall. The edge mode is excited by two loop antennas placed perpendicular to each other within one wavelength, generating a rotating magnetic dipole that couples to the left or right-going mode. The transmission measurement are taken along the BMW boundary and shows high transmission only around the edge, thus confirming the presence of an edge mode. We also demonstrated that very high directivity can be achieved when the input amplitude and phase of the two loop antennas are tuned properly. [1] T. Ma, A. B. Khanikaev, S. H. Mousavi, And G. Shvets, Phys. Rev. Lett. 114, 127401 (2015).

**1:39PM S52.00011 Angle-Resolved Mid-Infrared Spectroscopy of Gyroid Photonic Crystals**, EMIL T. KHABIBOULLINE, SIYING PENG, Applied Physics, California Institute of Technology, PHILIP HON, Nanophotonics and Metamaterials Laboratory, Northrop Grumman Aerospace Systems, RUNYU ZHANG, Department of Materials Science and Engineering, UIUC, HONGJIE CHEN, Applied Physics, California Institute of Technology, LUKE A. SWEATLOCK, Nanophotonics and Metamaterials Laboratory, Northrop Grumman Aerospace Systems, PAUL BRAUN, Department of Materials Science and Engineering, UIUC, HARRY A. ATWATER, Applied Physics, California Institute of Technology — Photonic topological insulators form a new class of materials with exciting properties. Theory has indicated that gyroid photonic crystals are photonic topological insulators. In this paper, we experimentally characterize the photonic properties of gyroid photonic crystals at mid-infrared wavelengths, using angle-resolved spectroscopy with coherent light from a quantum cascade laser tuned from  $7.7\ \mu\text{m}$  to  $11.1\ \mu\text{m}$  and focused onto a  $100\ \mu\text{m} \times 100\ \mu\text{m}$  spot. From measurements of reflection and transmission spectra over incidence angles, we construct the band structure of the photonic crystals. In this study, the photonic crystals are single and double gyroid made of amorphous silicon, with unit cell size of  $5\ \mu\text{m}$ , sitting on an intrinsic silicon substrate. Simulations predict band gaps for the single gyroid and Weyl points for the double gyroid. We compare results of angle-resolved spectroscopy experiments with simulations for nanofabricated gyroid structures and discuss the topological features observable in angle-resolved scattering.

**1:51PM S52.00012 Squeezing as a route to photonic analogues of topological superconductors**, MARTIN HOUE, McGill Univ, VITTORIO PEANO, CHRISTIAN BRENDL, FLORIAN MARQUARDT, University of Erlangen-Nrnberg, AASHISH CLERK, McGill Univ — There has been considerable recent interest in studying topological phases of photonic systems. In many cases the resulting system is described by a quadratic particle-conserving Hamiltonian which is directly equivalent to its fermionic counterpart. Here, we consider a class of photonic topological phases where this correspondence fails: photonic systems where particle-number non-conserving terms break time-reversal symmetry [1]. We show that these phases support protected edge modes which facilitate chiral inelastic and elastic transport channels. We also discuss the possibility of quantum amplification using these edge states. Our system could be realized in a variety of systems, including nonlinear photonic crystals, superconducting circuits and optomechanical systems. [1] Vittorio Peano, Martin Houde, Christian Brendel, Florian Marquardt, and Aashish Clerk, arXiv:1508.01383 (2015).

**2:03PM S52.00013 Gyroid photonic crystal with Weyl points: synthesis and mid-infrared photonic characterization**, SIYING PENG, EMIL KHABIBOULLINE, Applied Physics, California Institute of Technology, RUNYU ZHANG, Department of Materials Science and Engineering, UIUC, HONGJIE CHEN, Applied Physics, California Institute of Technology, PHILIP HON, LUKE SWEATLOCK, Nanophotonics and Metamaterials Laboratory, Northrop Grumman Aerospace Systems, PAUL BRAUN, Department of Materials Science and Engineering, UIUC, HARRY ATWATER, Applied Physics, California Institute of Technology — Weyl points are degenerate energy states resulting from crossings of linear bands in 3D momentum space. Unlike their 2D counterparts, Weyl points are bulk degenerate states that are stable to weak perturbation. The topological surface states associated with Weyl points exhibit unidirectional backscattering-immune transport. Double gyroid photonic crystals with a parity-breaking perturbation are predicted to possess Weyl points. We designed and synthesized single and double gyroid mid-IR photonic crystals composed of a-Si. We characterized them by mid-IR spectroscopy. We observed 100% reflection at  $8\ \mu\text{m}$  for single gyroids with unit cell size of  $5\ \mu\text{m}$ , in agreement with the predicted photonic bandgap seen in full-wave EM simulations. As the unit cell size of single gyroids changes to  $6\ \mu\text{m}$ , the observed reflection peak shifted to  $9\ \mu\text{m}$ , also agreeing with simulation. For double gyroids with unit cell size of  $5\ \mu\text{m}$ , we observed a 20% decrease in reflection at  $8\ \mu\text{m}$ , which could be explained by a new pair of states appearing within the bandgap from our simulation of double gyroids. We use angle-resolved mid-IR spectroscopy with a QCL to characterize Weyl points.

**Session S53 GIMS: Keithley Award Session** Hilton Baltimore Holiday Ballroom 4 - Francis Hellman, University of California, Berkeley

**11:15AM S53.00001 Joseph F. Keithley Award For Advances in Measurement Science: Resonant Ultrasound Spectroscopy: An Odyssey in Measurement Science<sup>1</sup>**, ALBERT MIGLIORI, Los Alamos Natl Lab

— Perhaps the speeds of sound, or, equivalently, the elastic moduli are some of the most fundamental attributes of a solid, connecting to fundamental physics, metallurgy, non-destructive testing, and more. Unlike most of the quantities used to characterize condensed matter, the elastic moduli are fourth-rank tensors containing a wealth of detail, directional information, and consistency constraints that provide some of the most revealing probes of solids. We describe here the current state of the art in one method, Resonant Ultrasound Spectroscopy, where the mechanical resonances of a specimen of regular shape (easy to measure) are analyzed (difficult computational problem) to obtain the full elastic tensor. With modern advances in electronics and analysis, fractions of a part per million changes in elastic moduli are detectable providing new and important insight into grand challenges in condensed matter physics.

<sup>1</sup>This work was supported as part of the Materials Science of Actinides, an Energy Frontier Research Center funded by the U.S. Department of Energy, Office of Science, Basic Energy Sciences under Award DE-SC0001089.

**11:51AM S53.00002 Strain coupling and dynamic relaxation dynamics associated with ferroic and multiferroic phase transition**, MICHAEL CARPENTER, Dept. of Earth Sciences, University of Cambridge

— Almost any change that occurs in a crystal structure results in some lattice strain and it is inevitable that this will appear also as a change in elastic properties. It follows that one of the most characteristic features of phase transitions, whether driven by structural, magnetic or electronic effects, will be variations of elastic constants. In addition, transformation microstructures such as ferroelastic twins may be mobile under some conditions of temperature and stress and will give characteristic patterns of acoustic loss when measured by dynamical methods. Thanks substantially to the pioneering work of Dr Albert Migliori in developing the technique of Resonant Ultrasound Spectroscopy (RUS), it has been possible to follow the elastic and anelastic behaviour associated with phase transitions quantitatively as a function of temperature through the interval 2-1600 K. It is also possible to add magnetic and electric fields. The frequency window 0.1-2 MHz and inherently small strains of RUS appear to be particularly sensitive for observing the consequences of strain coupling and microstructure relaxation dynamics. Recent collaborative work carried out using the RUS facilities in Cambridge will be presented, relating to phase transitions in multiferroic perovskites, such as  $\text{PbZr}_{0.53}\text{Ti}_{0.47}\text{O}_3$ - $\text{PbFe}_{0.5}\text{Nb}_{0.5}\text{O}_3$  and  $\text{Sr}_2\text{FeMoO}_6$ , the ferroelectric/improper ferroelastic transition in GeTe, and magnetoelastic behaviour of  $\text{EuTiO}_3$ . A common feature of these is softening of the shear modulus ahead of the transition that is not expected on the basis of linear/quadratic coupling between strain and the driving order parameter (improper ferroelastic). This appears to be due to coupling of acoustic modes with unseen central modes which are related to collective motions of domains with short range order. In some cases the ferroelastic twin walls have a well defined freezing interval (GeTe) whereas anelastic loss and stiffening over a wide temperature interval appears to be diagnostic of a microstructure with heterogeneous strain variations. Elastic softening by 10's of percent is typical of the effect of shear strains in the range 0.005-0.03.

**12:27PM S53.00003 Ultrasonic techniques for measuring physical properties of fluids in harsh environments**, CRISTIAN PANTEA, Los Alamos National Laboratory

— Ultrasonic-based measurement techniques, either in the time domain or in the frequency domain, include a wide range of experimental methods for investigating physical properties of materials. This discussion is specifically focused on ultrasonic methods and instrumentation development for the determination of liquid properties at conditions typically found in subsurface environments (in the U.S., more than 80% of total energy needs are provided by subsurface energy sources). Such sensors require materials that can withstand harsh conditions of high pressure, high temperature and corrosiveness. These include the piezoelectric material, electrically conductive adhesives, sensor housings/enclosures, and the signal carrying cables, to name a few. A complete sensor package was developed for operation at high temperatures and pressures characteristic to geothermal/oil-industry reservoirs. This package is designed to provide real-time, simultaneous measurements of multiple physical parameters, such as temperature, pressure, salinity and sound speed. The basic principle for this sensor's operation is an ultrasonic frequency domain technique, combined with transducer resonance tracking. This multipurpose acoustic sensor can be used at depths of several thousand meters, temperatures up to 250 C, and in a very corrosive environment. In the context of high precision measurement of sound speed, the determination of acoustic nonlinearity of liquids will also be discussed, using two different approaches: (i) the thermodynamic method, in which precise and accurate frequency domain sound speed measurements are performed at high pressure and high temperature, and (ii) a modified finite amplitude method, requiring time domain measurements of the second harmonic at room temperature. Efforts toward the development of an acoustic source of collimated low-frequency (10-150 kHz) beam, with applications in imaging, will also be presented.

**1:03PM S53.00004 Real time studies of Elastic Moduli Pu Aging using Resonant Ultrasound Spectroscopy**, BORIS MAIOROV, Los Alamos National Laboratory

— Elastic moduli are fundamental thermodynamic susceptibilities that connect directly to thermodynamics, electronic structure and give important information about mechanical properties. To determine the time evolution of the elastic properties in  $^{239}\text{Pu}$  and its Ga alloys, is imperative to study its phase stability and self-irradiation damage process. The most-likely sources of these changes include a) ingrowth of radioactive decay products like He and U, b) the introduction of radiation damage, c)  $\delta$ -phase instabilities towards  $\alpha$ -Pu or to  $\text{Pu}_3\text{Ga}$ . The measurement of mechanical resonance frequencies can be made with extreme precision and used to compute the elastic moduli without corrections giving important insight in this problem. Using Resonant Ultrasound Spectroscopy, we measured the time dependence of the mechanical resonance frequencies of fine-grained polycrystalline  $\delta$ -phase  $^{239}\text{Pu}$ , from 300K up to 480K. At room temperature, the shear modulus shows an increase in time (stiffening), but the bulk modulus decreases (softening). These are the first real-time measurements of room temperature aging of the elastic moduli, and the changes are consistent with elastic moduli measurements performed on 44 year old  $\delta$ -Pu. As the temperature is increased, the rate of change increases exponentially, with both moduli becoming stiffer with time. For  $T > 420\text{K}$  an abrupt change in the time dependence is observed indicating that the bulk and shear moduli have opposite rates of change. Our measurements provide a basis for ruling out the decomposition of  $\delta$ -Pu towards  $\alpha$ -Pu or  $\text{Pu}_3\text{Ga}$ , and indicate a complex defect-related scenario from which we are gathering important clues.

**Session S55 DBIO GSNP: Inference in Biophysics** Hilton Baltimore Holiday Ballroom 6 - Steve Presse, Indiana University of Pennsylvania

**11:15AM S55.00001 Genetic networks and the flow of positional information in embryonic development** , WILLIAM BIALEK, Princeton University — When we study a biological system, we make inferences about the underlying mechanisms and dynamics. But biological systems themselves must also solve inference problems, as when our brains draw conclusions about the world given (often quite limited) data from our eyes and ears. My colleagues and I have been exploring both of these inference problems as they play out in the first hours of development in the fruit fly embryo. In this system, the concentrations of particular molecules encode the position of each cell in the embryo, and these concentrations are the outputs of a genetic network. Putting ourselves in the place of the cells, we have been able to read the code, building a dictionary that maps gene expression levels back into estimates of position. If our dictionary really is the one used by the embryo, then mutants should build predictably distorted body plans, and preliminary results show quantitative agreement with these predictions. Independent of their role as carriers of information, we can also analyze the patterns of gene expression to draw inferences about the underlying network. Finally, it is possible that the network architecture and parameters have been chosen to optimize the flow of information, and we see signatures of this optimization. Joint work with CG Callan, JO Dubuis, T Gregor, D Krotov, M Petkova, TR Sokolowski, G Tkacik, AM Walczak, and EF Wieschaus.

**11:51AM S55.00002 Deep Learning, Group representations, and the Information-Bottleneck phase transitions.** , NAFTALI TISHBY, Hebrew University — Deep Neural Networks (DNNs) are analyzed via the theoretical framework of the information bottleneck (IB). We first show that any DNN can be quantified by the mutual information between the layers and the input and output variables. Using this representation we can calculate the optimal information theoretic limits of the DNN and obtain finite sample generalization bounds. The advantage of getting closer to the theoretical limit is quantifiable both by the generalization bound and by the network's simplicity. We argue that both the optimal architecture, number of layers and features/connections at each layer, are related to critical points on the information bottleneck tradeoff line, namely, relevant compression of the input layer with respect to the output layer. The hierarchical representations at the layered network naturally correspond to the structural phase transitions along the information curve. An interesting class of solvable DNN's arise by applying this framework to the case of symmetries in the supervised learning task. The case of translation invariance leads to the familiar convolution neural networks. Other symmetry groups yield different types of bifurcation diagrams and network architectures, which correspond to information contained by irreducible representations of the group. These new insights also suggest new sample complexity bounds, architecture design principles (number and widths of layers), and eventually entirely different deep learning algorithms. Based partly on works with Noga Zaslavsky and Ravid Ziv.

**12:27PM S55.00003 Fock spaces for modeling macromolecular complexes** , JUSTIN KINNEY, Cold Spring Harbor Laboratory — Large macromolecular complexes play a fundamental role in how cells function. Here I describe a Fock space formalism for mathematically modeling these complexes. Specifically, this formalism allows ensembles of complexes to be defined in terms of elementary molecular "building blocks and "assembly rules. Such definitions avoid the massive redundancy inherent in standard representations, in which all possible complexes are manually enumerated. Methods for systematically computing ensembles of complexes from a list of components and interaction rules are described. I also show how this formalism readily accommodates coarse-graining. Finally, I introduce diagrammatic techniques that greatly facilitate the application of this formalism to both equilibrium and non-equilibrium biochemical systems.

**1:03PM S55.00004 Causal inference of signaling networks using single cell data** , KAREN SACHS, Stanford University — No abstract available.

**1:39PM S55.00005 Maximum Entropy and the Inference of Pattern and Dynamics in Ecology** , JOHN HARTE, University of California, Berkeley — Constrained maximization of information entropy yields least biased probability distributions. From physics to economics, from forensics to medicine, this powerful inference method has enriched science. Here I apply this method to ecology, using constraints derived from ratios of ecological state variables, and infer functional forms for the ecological metrics describing patterns in the abundance, distribution, and energetics of species. I show that a static version of the theory describes remarkably well observed patterns in quasi-steady-state ecosystems across a wide range of habitats, spatial scales, and taxonomic groups. A systematic pattern of failure is observed, however, for ecosystems either losing species following disturbance or diversifying in evolutionary time; I show that this problem may be remedied with a stochastic-dynamic extension of the theory.

**T1.00001 GENERAL THEORY/COMPUTATIONAL PHYSICS –**

**T1.00002 Formation of graphene flakes from oxidation of SiC nanoparticle** , PANKAJ RAJAK, KENICHI NAMURA, RAJIV KALIA, AIICHIRO NAKANO, PRIYA VASHISHTA, Univ of Southern California — We have performed the largest (112 million atoms) reactive molecular dynamics simulation using reactive force fields to study the oxidation of a SiC nanoparticle on the full Blue Gene/P machine. The SiC nanoparticle of diameter 100 nm is surrounded by O<sub>2</sub> gas and heated to 2,800 K. Subsequently, we let the SiC nanoparticle oxidize at 2,800K. We observe formation of graphene-like flakes despite the harsh oxidation condition. We find the fractal dimension of the flakes is 1.85. We will discuss the implication of reaction kinetics on the structure and distribution of graphene flakes.

**T1.00003 Bayesian Inference of Effective Classical Spin Hamiltonians from Hartree-Fock Calculation** , HIKARU TAKENAKA, KENJI NAGATA, Graduate School of Frontier Sciences, The University of Tokyo, TAKASHI MIZOKAWA, School of Advanced Science and Engineering, Waseda University, MASATO OKADA, Graduate School of Frontier Sciences, The University of Tokyo — A novel method is described for extracting effective classical spin Hamiltonians from mean-field type electronic structural calculations by means of Bayesian inference[1]. The method is applied to a NiS<sub>2</sub> triangular lattice in NiGa<sub>2</sub>S<sub>4</sub> with a spin disordered ground state. Unrestricted Hartree-Fock calculations for the spin configurations of 16 Ni sites led to the estimation that not only the strongest superexchange interaction between the third nearest neighbor sites but also those between the nearest and the second nearest neighbor sites should be taken into account to extract effective classical spin Hamiltonians for NiGa<sub>2</sub>S<sub>4</sub>. Results obtained from the above calculations with the Boltzmann factor are also shown. It was estimated that the superexchange interaction between the nearest neighbor sites is ferromagnetic, which is consistent with magnetic experiment results. This supports the theory that the competition between the antiferromagnetic third neighbor interaction and the ferromagnetic nearest neighbor interaction may lead to the quantum spin liquid in NiGa<sub>2</sub>S<sub>4</sub>. **T1.00004 Enhancing AFLOW Visualization using Jmol**, JACOB LANASA, ELIZABETH NEW, PATRIK STEFEK, BRIGETTE HONAKER, ROBERT HANSON, St. Olaf College, AFLOW COLLABORATION — The AFLOW library[1,2] is a database of theoretical solid-state structures and calculated properties created using high-throughput *ab initio* calculations. Jmol[3] is a Java-based program capable of visualizing and analyzing complex molecular structures and energy landscapes. In collaboration with the AFLOW consortium, our goal is the enhancement of the AFLOWLIB database through the extension of Jmol's capabilities in the area of materials science. Modifications made to Jmol include the ability to read and visualize AFLOW binary alloy data files, the ability to extract from these files information using Jmol scripting macros that can be utilized in the creation of interactive web-based convex hull graphs, the capability to identify and classify local atomic environments by symmetry, and the ability to search one or more related crystal structures for atomic environments using a novel extension of inorganic polyhedron-based SMILES strings. **T1.00005 Composition-Dependent Phase Concentrations from First Principles: Simulating Combinatorial Libraries of Transition Metal Oxides<sup>1</sup>**, GUO LI, QIMIN YAN, Lawrence Berkeley Natl Lab, LAN ZHOU, PAUL NEWHOUSE, JOHN GREGOIRE, California Institute of Technology, JEFFREY NEATON, Lawrence Berkeley Natl Lab; UC-Berkeley; Kavli Energy NanoSciences Institute at Berkeley — To identify material phases in experimental combinatorial libraries, we develop a theoretical model as a complementary approach to accelerate phase identification. In this approach, samples in a combinatorial library are simulated as mixtures in chemical equilibria. Each of these mixtures contains all the solid-state phases, which can possibly exist in the library. Using the total energies of these phases obtained in first-principle calculations, we calculate the Gibbs free energy changes in the corresponding chemical reactions, and subsequently evaluate the equilibrium concentrations of the phases in every sample according to the law of mass action. Furthermore, to test this approach, we simulate pseudobinary libraries  $M_nV_{1-x}O_y$  and  $Cu_xV_{1-x}O_y$ . Interestingly, we find that the composition-dependent phase concentrations calculated within our approach agree well with the experimental results measured with XRD spectroscopy.

**T1.00007 Introduction to Electromagnetic Fields and Geodesics in a Tokamak**, STEPHEN SHARMA, Univ. of Calif. Berkeley, Univ. of Southern California — Photons mediate electromagnetic radiation such that electric and magnetic particles obey the principle of least action from the applied fields. Elastic and inelastic collisions arise after summation of Lagrangian geodesics. In the case of reacting tritium and deuterium, energy is released in the form of electromagnetic radiation, neutrons, and alpha particles. Within fusion tokamaks, alpha particle energies determine if a self sustaining reaction—or ignition—will proceed. If particle mean free path is confined by electric and magnetic fields, then fusion occurs at higher frequencies. If temperature is increased and particle velocity is increased, then collision frequency increases. Modeling the nucleons as polarizable quark dielectric liquid drops increases differentiation between scattering events and fusion. When the cross section of two reactant liquid drops is coincident, fusion occurs. If cross sections do not overlap sufficiently, Coulomb scattering occurs. One strives for understanding of geometric approaches to solving for reactants' cross sections and fusion collision frequency in order to determine power output per particle and critical density of reactants.

**T1.00008 Global and short-range entanglement properties in excited, many-body localized spin chains**, COLIN WEST, TZU-CHIEH WEI, State Univ of NY- Stony Brook — Many-body localization is a manifestation of the violation of the eigenstate thermalization hypothesis. As one of many characteristic features, eigenstates in a many-body localized regime have been observed to obey an area law in the scaling of the entanglement entropy. Consequently, such states can be efficiently represented by matrix product states (MPS). Here, we use the SIMPS algorithm proposed by Yu, Pekker, and Clark to numerically access these excited states in spin chains with disorder, and study them from the perspective of their global and short range entanglement properties, as well as through other local observables. We compare the behavior across excited states as the strength of disorder varies.

**T1.00009 Atomistic Simulations of High-intensity XFEL Pulses on Diffractive Imaging of Nano-sized Systems<sup>1</sup>**, PHAY HO, CHRISTOPHER KNIGHT, LINDA YOUNG, Argonne National Laboratory, MIKLOS TEGZE, GYULA FAIGEL, Institute for Solid State Physics and Optics of the Wigner Research Centre for Physics — We have developed a large-scale atomistic computational method based on a combined Monte Carlo and Molecular Dynamics (MC/MD) method to simulate XFEL-induced radiation damage dynamics of complex materials. The MD algorithm is used to propagate the trajectories of electrons, ions and atoms forward in time and the quantum nature of interactions with an XFEL pulse is accounted for by a MC method to calculate probabilities of electronic transitions. Our code has good scalability with MPI/OpenMP parallelization, and it has been run on Mira, a petascale system at the Argonne Leadership Computing Facility, with particle number >50 million. Using this code, we have examined the impact of high-intensity 8-keV XFEL pulses on the x-ray diffraction patterns of argon clusters. The obtained patterns show strong pulse parameter dependence, providing evidence of significant lattice rearrangement and diffuse scattering. Real-space electronic reconstruction was performed using phase retrieval methods. We found that the structure of the argon cluster can be recovered with atomic resolution even in the presence of considerable radiation damage.

**T1.00010 Canonical Quantization of Crystal Dislocation and Electron-Dislocation Scattering in an Isotropic Media**, MINGDA LI, MIT, WENPING CUI, Boston College, M. S. DRESSELHAUS, GANG CHEN, MIT, MIT TEAM, BOSTON COLLEGE TEAM — Crystal dislocations govern the plastic mechanical properties of materials but also affect the electrical and optical properties. However, a fundamental and decent quantum-mechanical theory of dislocation remains undiscovered for decades. Here we present an exact and manageable Hamiltonian theory for both edge and screw dislocation line in an isotropic media, where the effective Hamiltonian of a single dislocation line can be written in a harmonic-oscillator-like form, with closed-form quantized 1D phonon-like excitation. Moreover a closed-form, position dependent electron-dislocation coupling strength is obtained, from which we obtained good agreement of relaxation time when comparing with classical results. This Hamiltonian provides a platform to study the effect of dislocation to materials' non-mechanical properties from a fundamental Hamiltonian level.

**T1.00011 Electron binding energies using perturbative delta-SCF method**, SHUSIL BHUSAL, TUNNA BARUAH, RAJENDRA ZOPE, University of Texas at El Paso — The knowledge of fundamental and optical gaps is of significant importance for organic photovoltaics. The electron binding energies estimated from the Kohn-Sham eigenvalues are significantly underestimated. Here, we use our recently outlined perturbative delta-SCF approach to compute the electron binding energies of a number of aromatic organic molecules commonly used in organic photovoltaics. Further, the electron affinities are also computed for the C60, C70 and PCBM. The results show that the perturbative delta-SCF provide adequate description of valence electron binding energies. We also applied the method to compute the core binding energies and the core-valence excited states. While the method can successfully predict the core-valence excited states the results on the core-binding energies are mixed. The strategies for improvement of the core binding energies will be discussed.

**T1.00012 Berry phase oscillations in a one-dimensional Dirac comb**, WILLIAM HODGE, NICHOLAS CASSERA, Stevenson University, MATTHEW RAVE, Western Carolina University — In quantum mechanics, the Berry phase is a geometric phase acquired by a wave function over the course of a cycle, when subjected to adiabatic processes. In general, this phase is due to the geometry of the underlying parameter space and thus depends only on the path taken. In any system described by a periodic potential, the torus topology of the Brillouin zone itself can lead to such a phase. In this work, we numerically calculate the Berry phase for a one-dimensional Dirac comb described by  $N$  distinct wells per unit cell. As expected, the resulting Berry phase exhibits a rich band-dependence. In the case where  $N = 2$ , we find that the Berry phase corresponding to the  $n^{\text{th}}$  energy band oscillates such that  $\gamma_n(x) = A_n \sin(\pi x) \cos[(2n - 1)\pi x]$ , where  $A_n$  is a band-dependent constant and  $0 < x < 1$  is the relative position of the two wells. This expression, obtained using perturbation theory, gives excellent agreement with exact numerical results, even at low energy levels. The Berry phase exhibits a similar behavior for cases where  $N > 2$ .

**T1.00013 Single Electron in Systems of Two and Three Quantum Dots<sup>1</sup>**, IGOR FILIKHIN, BRANISLAV VLAHOVIC, North Carolina Central University — We consider the single electron confinement states in the system of two and three quantum dots (QDs). The InAs/GaAs QDs are modeled as laterally distributed dots, using single sub-band effective mass approach with effective potential simulating the strain effect. Electron localization in double quantum dots (DQDs) and in triple quantum dots (TQDs) is studied over the entire electron energy spectrum by varying the geometry parameters of these QDs arrays. It is shown that a small violation of the DQD shape symmetry drastically affects tunneling. This effect also appears as a numerical instability in calculations of spectral distribution of localized/delocalized electron states for small variations of the input parameters of numerical procedure. The effect of adding a third dot to a DQD is investigated. We show that the presence of a third dot increases the tunneling in the initial DQD. The spectral distribution of localized/delocalized states appears sensitive to the violation of the mirror symmetry of TQDs.

**T1.00014 State of the art for ab initio vs empirical potentials for HeH<sup>+</sup> (2e<sup>-</sup>), BeH<sup>+</sup> (4e<sup>-</sup>), BeH (5e<sup>-</sup>), Li<sub>2</sub> (6e<sup>-</sup>) and BH (6e<sup>-</sup>)**, NIKE DATTANI, Kyoto University — For large internuclear distances, the potential energy between two atoms is known analytically, based on constants that are calculated from atomic *ab initio* rather than molecular *ab initio*. This analytic form can be built into models for molecular potentials that are fitted to spectroscopic data. Such empirical potentials constitute the most accurate molecular potentials known. For HeH<sup>+</sup>, and BeH<sup>+</sup>, the long-range form of the potential is based only on the polarizabilities for He and H respectively, for which we have included up to 4th order QED corrections. For BeH, the best ab initio potential matches all but one observed vibrational spacing to  $\pm 1 \text{ cm}^{-1}$  accuracy, and for Li<sub>2</sub> the discrepancy in the spacings is  $\pm 0.08 \text{ cm}^{-1}$  for all vibrational levels. But experimental methods such as photoassociation require the absolute energies, not spacings, and these are still several in several  $\text{cm}^{-1}$  disagreement. So empirical potentials are still the only reliable way to predict energies for few-electron systems. We also give predictions for various unobserved "halo nucleonic molecules" containing the "halo" isotopes: <sup>6,8</sup>He, <sup>11</sup>Li, <sup>11,14</sup>Be and <sup>8,17,19</sup>B.

**T1.00015 Efficient method of finite-size correction in quantum Monte Carlo calculations**, SAM AZADI, Department of Physics and Tomas Young Centre, University College London, MATTHEW FOULKES, Department of Physics, Imperial College London — We present a simple but efficient method of finite size correction for metallic crystals [1]. Our method is based on an accurate combination of twist averaging boundary condition and density functional theory. We compare our method with several previously introduced schemes. Our quantum Monte Carlo results for lithium and aluminium show the accuracy and practicality of our method. :1] Sam Azadi, and W. M. C. Foulkes, J. Chem. Phys. **143**, 102807 (2015).

**T1.00016 Microscopic Picture of Atomic Dynamics in the Double Perovskite, PrBaCo<sub>2</sub>O<sub>6</sub>**, ELVIS SHOKO, UDO SCHWINGENSCHLOGL, PSE Division, KAUST, Saudi Arabia — We have used a combination of lattice dynamics and *ab initio* molecular dynamics to study atomic dynamics in PrBaCo<sub>2</sub>O<sub>6</sub>, a prototype material for a large class of layered compounds of both fundamental and technological interest. We find clear signatures of the layered structure of this compound on the overall atomic dynamics. In particular, we find that O atom dynamics in the PrO layer is predominantly in-plane (*ab*-plane) in contrast to the predominantly out-of-plane dynamics in the CoO<sub>2</sub> layer. This suggests that the oxide ionic conductivity is dominated by the O atoms in the PrO layer, a finding of interest in solid-oxide fuel cells. Additionally, our results reveal sharp low-energy vibrational modes below 20 meV for both Ba and Pr atoms leading to the intriguing possibility that this material may be engineered for thermoelectric applications.

**T1.00017 Obtaining model parameters for real materials from ab-initio calculations: Heisenberg exchange<sup>1</sup>**, DMITRY KOROTIN, Institute of Metal Physics, Yekaterinburg, VLADIMIR MAZURENKO, Ural Federal University, Yekaterinburg, VLADIMIR ANISIMOV, SERGEY STRELTISOV, Institute of Metal Physics, Yekaterinburg — An approach to compute exchange parameters of the Heisenberg model in plane-wave based methods is presented. This calculation scheme is based on the Green's function method and Wannier function projection technique. It was implemented in the framework of the pseudopotential method and tested on such materials as NiO, FeO, Li<sub>2</sub>MnO<sub>3</sub>, and KCuF<sub>3</sub>. The obtained exchange constants are in a good agreement with both the total energy calculations and experimental estimations for NiO and KCuF<sub>3</sub>. In the case of FeO our calculations explain the pressure dependence of the Néel temperature. Li<sub>2</sub>MnO<sub>3</sub> turns out to be a Slater insulator with antiferromagnetic nearest neighbor exchange defined by the spin splitting. The proposed approach provides a unique way to analyze magnetic interactions, since it allows one to calculate orbital contributions to the total exchange coupling and study the mechanism of the exchange coupling.

## **T1.00018 Devil's staircase in a quantum dimer model on the hexagonal lattice**, THOMAS BARTHEL,

Duke University, Department of Physics, GRÉGOIRE MISGUICH, CEA Saclay, Institut de Physique Théorique, THIAGO M. SCHLITTLER, JULIEN VIDAL, RÉMY MOSSERI, Université Paris 6, LPTMC — Quantum dimer models appear in different contexts when describing dynamics in constrained low-energy manifolds, such as for frustrated Ising models in weak transverse fields. In this talk, I address a particularly interesting case, where a quantum dimer model on the hexagonal lattice, in addition to the standard Rokhsar-Kivelson Hamiltonian, includes a competing potential term, counting dimer-free hexagons. It has a rich zero-temperature phase diagram that comprises a cascade of rapidly changing flux quantum numbers (tilt in the height language). This cascade is partially of fractal nature and the model provides, in particular, a microscopic realization of the “devil's staircase” scenario [E. Fradkin *et al.* Phys. Rev. B **69**, 224415 (2004)]. We have studied the system by means of quantum Monte-Carlo simulations and the results can be explained using perturbation theory, RG, and variational arguments.

References: arXiv:1507.04643, arXiv:1501.02242.

## **T1.00019 Fermionic Quantum Monte Carlo simulations without fixed nodes**, TOBIAS DORNHEIM, TIM

SCHOOF, SIMON GROTH, MICHAEL BONITZ, Kiel university — Recent restricted PIMC (RPIMC) simulations [PRL **110**, 146405 (2013)] of the uniform electron gas (UEG) at finite temperature have turned out to be surprisingly inaccurate [PRL **115**, 130402 (2015)]. Therefore, there exists a high need for alternative approaches which circumvent the fermion sign problem (FSP). In this work, we present two independent approaches which exhibit a complementary behavior. The configuration PIMC (CPIMC) method [Contrib. Plasma Phys. **51**, 687-697 (2011)], which operates in Fock space, excels at high density and allows for cutting edge results at strong degeneracy. In contrast, the permutation blocking PIMC (PB-PIMC) approach [New J. Phys. **17**, 073017 (2015)] is formulated in coordinate space and combines antisymmetric imaginary time propagators (determinants) with a higher order factorization of the density matrix. This leads to a significant reduction of the sign problem and extends the range of applicability of standard PIMC towards higher density and lower temperature [arXiv:1508.03221 (2015)]. Joining these two complementary methods allows us to present accurate thermodynamic results for the uniform electron gas over a broad parameter range and, therefore, to partly avoid the FSP.

## **T1.00020 Modeling of Electromagnetic Phenomenon in Fractional Dimensional Space**, MUHAM-

MAD ZUBAIR, L.K. ANG, Engineering Product Development, Singapore University of Technology and Design, East Coast Campus, 8 Somapah Road, Singapore 487372, Singapore — Fractional dimensional space has emerged as an extremely useful concept in many areas of physics, including electromagnetic (EM) theory. The development made in the area of fractional calculus has made it possible to study the most important physical phenomenon in a generalized  $D$ -dimensional fractional space. It is worthwhile to mention that many natural objects, such as clouds, snowflakes, rough surfaces, cracks, turbulence in fluids, are aptly described by dimensions of fractional order. Therefore, EM wave propagation in such fractal media is best characterized by considering an effective space of non-integer (fractional) dimensions. Here we present the recent developments in the study of differential Maxwell equations in a  $D$ -dimensional fractional space, where  $D$  is a non-integer value. Same examples will be used in order to show the transition to the traditional non-fractional conditions or settings.

## **T1.00021 Optimized simulations of Olami-Feder-Christensen systems using parallel algorithms**<sup>1</sup>, RACHELE DOMINGUEZ, RANCE NECAISE, ERIC MONTAG, Randolph-Macon College — The sequential nature of the Olami-Feder-

Christensen (OFC) model for earthquake simulations limits the benefits of parallel computing approaches because of the frequent communication required between processors. We developed a parallel version of the OFC algorithm for multi-core processors. Our data, even for relatively small system sizes and low numbers of processors, indicates that increasing the number of processors provides significantly faster simulations; producing more efficient results than previous attempts that used network-based Beowulf clusters. Our algorithm optimizes performance by exploiting the multi-core processor architecture, minimizing communication time in contrast to the networked Beowulf-cluster approaches. Our multi-core algorithm is the basis for a new algorithm using GPUs that will drastically increase the number of processors available. Previous studies incorporating realistic structural features of faults into OFC models have revealed spatial and temporal patterns observed in real earthquake systems. The computational advances presented here will allow for studying interacting networks of faults, rather than individual faults, further enhancing our understanding of the relationship between the earth's structure and the triggering process.

## **T1.00022 CHEMICAL PHYSICS —**

### **T1.00023 Ab initio molecular electrostatic potential of hexanuclear Cu, Ag, and Au clusters**<sup>1</sup>

, ALVARO POSADA-AMARILLAS, Dept de Investigacion en Fisica, Universidad de Sonora — DFT calculations of electrostatic potential (ESP) are carried out under the PBE/SDD theory level. Planar initial structures are given as input to perform DFT optimization with the aim of obtaining ground state structures. ESP is thus calculated and results show the existence of both, nucleophilic and electrophilic sites. In each case, the latter are located over the cluster planes while the former are observed in cluster vertices. Binding energy is provided, as well as structural parameters of ground state structures.

<sup>1</sup>CONACyT-Mxico is acknowledged for funding project No. 180424.

## **T1.00024 Hyperpolarized <sup>13</sup>C NMR lifetimes in the liquid-state: relating structures and T1 relaxation times**<sup>1</sup>, CHRISTOPHER PARISH, PETER NIEDBALSKI, University of Texas at Dallas, ZOHREH HASHAMI, LEILA FIDELINO, ZOLTAN KOVACS, Advanced Imaging Research Center, University of Texas Southwestern Medical Center, LLOYD LUMATA, University of Texas at Dallas — Among the various attempts to solve the insensitivity problem in nuclear magnetic resonance (NMR), the physics-based technique dissolution dynamic nuclear polarization (DNP) is probably the most successful method of hyperpolarization or amplifying NMR signals. Using this technique, liquid-state NMR signal enhancements of several thousand-fold are expected for low-gamma nuclei such as carbon-13. The lifetimes of these hyperpolarized <sup>13</sup>C NMR signals are directly related to their <sup>13</sup>C spin-lattice relaxation times T1. Depending upon the <sup>13</sup>C isotopic location, the lifetimes of hyperpolarized <sup>13</sup>C compounds can range from a few seconds to minutes. In this study, we have investigated the hyperpolarized <sup>13</sup>C NMR lifetimes of several <sup>13</sup>C compounds with various chemical structures from glucose, acetate, citric acid, naphthalene to tetramethylallene and their deuterated analogs at 9.4 T and 25 deg C. Our results show that the <sup>13</sup>C T1s of these compounds can range from a few seconds to more than 60 s at this field. Correlations between the chemical structures and T1 relaxation times will be discussed and corresponding implications of these results on <sup>13</sup>C DNP experiments will be revealed.

**T1.00025 Hyperpolarized  $^{89}\text{Y}$  NMR spectroscopic detection of yttrium ion and DOTA macrocyclic ligand complexation: pH dependence and Y-DOTA intermediates<sup>1</sup>**, SARAH FERGUSON, ANDHIKA KISWANDHI, PETER NIEDBALSKI, CHRISTOPHER PARISH, University of Texas at Dallas, ZOLTAN KOVACS, University of Texas Southwestern Medical Center, LLOYD LUMATA, University of Texas at Dallas — Dissolution dynamic nuclear polarization (DNP) is a rapidly emerging physics technique used to enhance the signal strength in nuclear magnetic resonance (NMR) and imaging (MRI) experiments for nuclear spins such as yttrium-89 by >10,000-fold. One of the most common and stable MRI contrast agents used in the clinic is Gd-DOTA. In this work, we have investigated the binding of the yttrium and DOTA ligand as a model for complexation of Gd ion and DOTA ligand. The macrocyclic ligand DOTA is special because its complexation with lanthanide ions such as  $\text{Gd}^{3+}$  or  $\text{Y}^{3+}$  is highly pH dependent. Using this physics technology, we have tracked the complexation kinetics of hyperpolarized Y-triflate and DOTA ligand in real-time and detected the Y-DOTA intermediates. Different kinds of buffers were used (lactate, acetate, citrate, oxalate) and the pseudo-first order complexation kinetic calculations will be discussed.

<sup>1</sup>The authors would like to acknowledge the support by US Dept of Defense award no. W81XWH-14-1-0048 and Robert A. Welch Foundation grant no. AT-1877.

**T1.00026 Temperature dependence of proton NMR relaxation times at earth's magnetic field<sup>1</sup>**, PETER NIEDBALSKI, ANDHIKA KISWANDHI, CHRISTOPHER PARISH, SARAH FERGUSON, EDUARDO CERVANTES, ANISHA OOMEN, ANAGHA KRISHNAN, AAYUSH GOYAL, LLOYD LUMATA, University of Texas at Dallas — The theoretical description of relaxation processes for protons, well established and experimentally verified at conventional nuclear magnetic resonance (NMR) fields, has remained untested at low fields despite significant advances in low field NMR technology. In this study, proton spin-lattice relaxation ( $T_1$ ) times in pure water and water doped with varying concentrations of the paramagnetic agent copper chloride have been measured from 6 to 92°C at earth's magnetic field (1700 Hz). Results show a linear increase of  $T_1$  with temperature for each of the samples studied. Increasing the concentration of the copper chloride greatly reduced  $T_1$  and reduced dependence on temperature. The consistency of the results with theory is an important confirmation of past results, while the ability of an ultra-low field NMR system to do contrast-enhanced magnetic resonance imaging (MRI) is promising for future applicability to low-cost medical imaging and chemical identification.

<sup>1</sup>This work is supported by US Dept of Defense award no. W81XWH-14-1-0048 and the Robert A. Welch Foundation grant no. AT-1877.

**T1.00027 Impact of  $\text{Gd}^{3+}$  doping and glassing solvent deuteration on  $^{13}\text{C}$  DNP at 5 Tesla<sup>1</sup>**, ANDHIKA KISWANDHI, Univ of Texas, Dallas, BIMALA LAMA, AMRIS/NHMFL, Univ of Florida, PETER NIEDBALSKI, MUDREKH GODERYA, Univ of Texas, Dallas, JOANNA LONG, AMRIS/NHMFL, Univ of Florida, LLOYD LUMATA, Univ of Texas, Dallas — Dynamic nuclear polarization (DNP) is a technique which can be used to amplify signals in nuclear magnetic resonance (NMR) and magnetic resonance imaging (MRI) by several thousand-fold. The most commonly available DNP system typically operates at the W-band field or 3.35 T, at which it has been shown that  $^{13}\text{C}$  NMR signal can be enhanced by deuteration and  $\text{Gd}^{3+}$  doping. In this work, we have investigated the applicability of these procedures at 5 T. Our results indicate that the deuteration of the glassing matrix still yields an enhancement of  $^{13}\text{C}$  DNP when 4-oxo-TEMPO free radical is used. The effect is attributed to the lower heat load of the deuterons compared to protons. An addition of a trace amount of  $\text{Gd}^{3+}$  gives a modest enhancement of the signal when trityl OX063 is used, albeit with a less pronounced relative enhancement compared to the results obtained at 3.35 T. The results suggest that the enhancement obtained via  $\text{Gd}^{3+}$  doping may become saturated at higher field. These results will be discussed using a thermodynamic model of DNP.

**T1.00028 STRUCTURAL AND ELEMENTAL ANALYSIS OF DEGRADED SINGLE JUNCTION AMORPHOUS SILICON SOLAR MODULE<sup>1</sup>**, GILBERT OSAYEMWENRE, EDSON MEYER, Fort Hare — Photovoltaic solar modules have different defects and degradation characteristic modes. These degradation modes normally heats up some regions in the PV module. Depending on the degree and size of the localised heat, the localized heat can raise above the temperature limit of the module and cause damage to the structural orientation. The presence of severe defect and degradation correlates with high temperature gradients that usually results in morphological damage especially under outdoor conditions. The present study investigates the effect of defect/degradation on the surface morphology of single junction amorphous silicon modules (a-Si:H) during outdoor deployment. The observed structural damage was analysed using scanning electron microscope (SEM) and energy dispersion X-ray (EDX) to ascertain the elemental composition. Results show huge discrepancies in the chemical composition constitute alone different regions. The presence of high concentration of carbon and oxygen was found in the affected region.

**T1.00029 Enhanced confinement in compositionally heterogeneous alloy quantum dots**, ZUBAER HOSSAIN, University of Delaware — While there is a growing need to increase solar cell efficiencies and reduce the cost per watt, reported efficiencies are still well below the thermodynamic limit of photovoltaic energy conversion. The major factor that affects the efficiency (by more than 40%) is the lack of absorption or thermalization of electrons. To improve absorption, existing approaches, till date, are focused on combining multiple materials in the form of heterostructures. This talk will show the application of a physics-based mechanistic approach to engineer absorption by using alloy quantum dots and exploiting its heterogeneous compositional and deformation fields. Using a multiscale computational framework that combines density functional theory, k.p method and the finite element calculations, the work shows that heterogeneous distribution of composition and strain fields can lead to substantial confinement in alloy quantum dots. Subsequently alloy quantum dots that are much larger (on the order of 50 nm) in size – compared to their single crystalline counterparts (which are on the order of 5 nm) – can still provide significant confinement. The findings uncover new fundamental insights for engineering confinement that are unattainable under conventional homogenization approximations.

**T1.00030 Electric Transport Phenomena of Nanocomposite Organic Polymer Thin Films<sup>1</sup>**, NICHOLAS C. JIRA, ILДАР SABIRIANOV, CAROLINA C. ILIE, SUNY Oswego — We discuss herein the nanocomposite organic thin film diodes for the use of plasmonic solar cells. This experimental work follows the theoretical calculations done for plasmonic solar cells using the MNPBEM toolbox for MatLab. These calculations include dispersion curves and amount of light scattering cross sections for different metallic nanoparticles. This study gives us clear ideas on what to expect from different metals, allowing us to make the best choice on what to use to obtain the best results. One specific technique for light trapping in thin films solar cells utilizes metal nanoparticles on the surface of the semiconductor. The characteristics of the metal, semiconductor interface allows for light to be guided in between them causing it to be scattered, allowing for more chances of absorption. The samples were fabricated using organic thin films made from polymers and metallic nanoparticles, more specifically Poly(1-vinylpyrrolidone-co-2-dimethylaminoethyl methacrylate) copolymer and silver or gold nanoparticles. The two fabrication methods applied include spin coating and Langmuir-Blodgett technique. The transport properties are obtained by analyzing the I-V curves. We will also discuss the resistance, resistivity, conductance, density of charge carriers.

**T1.00031 Optimized growth of gold nanobars for energy responsive applications.** , ERIK HOBBS, ANTHONY JOHNSON, CACIE HART, DAVID SCHAEFER, RAJESWARI KOLAGANI, Department of Physics, Towson University, MARY SAJINI DEVADAS, Department of Chemistry, Towson University — The aim of this research is to create a reliable protocol for the synthesis of plasmonic gold nano bars for energy responsive applications such as light harvesting. The mechanism of growth in these metallic structures is not fully understood. Symmetry breaking by twinning introduces anisotropy in the shape of the nanostructures. This also results in the formation of highly faceted tip geometries that support the propagation of surface plasmon polaritons. Gold nanobars have been synthesized through chemical reduction in the presence of surfactants: cetyltrimethylammonium bromide (CTAB) and polyvinylpyrrolidone (PVP). Synthesis is executed by varying the concentrations of CTAB and PVP, as well as adjusting the growth temperature. The influence of additives such as metal ions will be presented. Resulting plasmonic gold nanobars are viewed using darkfield microscopy and scanning electron microscopy to visualize the nanoparticle product mixture. Atomic force microscopy is employed to measure the length and width of the nanobelts. X-ray diffraction determines the degree of crystallinity in the synthesized gold nanobars.

**T1.00032 Nanostructured SnO<sub>2</sub> current collectors for solar energy conversion devices: relating morphology and conductivity** , BENJAMIN DRINGOLI, Department of Physics, Worcester Polytechnic Institute, L. ZHOU, B. GIRI, H. JOSHI, Department of Mechanical Engineering, Worcester Polytechnic Institute, W. BELLEMAN, Department of Physics, Worcester Polytechnic Institute, P.M. RAO, Department of Mechanical Engineering, Worcester Polytechnic Institute, L.V. TITOVA, Department of Physics, Worcester Polytechnic Institute — Large bandgap (3.8 eV), high bulk conductivity, and a low-lying valence band make nanostructured SnO<sub>2</sub> a promising candidate material for extracting photoexcited electrons from absorbers in solar energy conversion devices. Efficient charge collection requires high surface to volume ratio of a nanostructured SnO<sub>2</sub> network, which comes at a cost of reduced conductivity due to incorporation of defects and grain boundaries, and reduction of electrical connectivity. We use terahertz time-domain spectroscopy (THz-TDS) to measure conductivity in nanoporous SnO<sub>2</sub> films and nanowire arrays with different average lengths and packing densities. THz-TDS allows a non-contact measurement of frequency-resolved conductivity over nanoscale distances. Modeling the THz-TDS data using the the Drude–Smith model, we extract intrinsic properties of SnO<sub>2</sub> as well as the effects of morphology on nanoscale conductivity. We find that the intrinsic carrier mobility of SnO<sub>2</sub> making up a nano-porous film is 100 cm<sup>2</sup>/Vs, while the nanoscale mobility is 25 cm<sup>2</sup>/Vs. Correlating THz conductivity of nanostructured SnO<sub>2</sub> with morphology allows us to establish optimal morphology and growth conditions for achieving highest conductivity while maintaining high surface to volume ratio.

**T1.00033 ABSTRACT WITHDRAWN —**

**T1.00034 Environmental Effects on the Terahertz Surface Plasmons in Epitaxial Graphene** , PAULA FEKETE, Department of Physics and Nuclear Engineering, US Military Academy at West Point, NY, GODFREY GUMBS, Hunter College of the City University of New York, NY, ANDRII IUROV, Center for High Technology Materials, University of New Mexico, Albuquerque, New Mexico, JHAO-YING WU, MING-FA LIN, Department of Physics, National Cheng Kung University, Tainan, Taiwan 701 — We predict the existence of low-frequency nonlocal plasmons at the vacuum-surface interface of a superlattice of  $N$  graphene layers interacting with conducting substrate. We derive a dispersion function that incorporates the polarization function of both the graphene monolayers and the semi-infinite electron liquid at whose surface the electrons scatter specularly. We find a surface plasmon-polariton that is not damped by particle-hole excitations or the bulk modes and which separates below the continuum mini-band of bulk plasmon modes. The surface plasmon frequency of the hybrid structure always lies below a limiting value of the surface plasmon frequency of the conducting substrate. The intensity of this mode depends on the distance of the graphene layers from the conductor's surface, the energy band gap between valence and conduction bands of graphene monolayer and, most importantly, on the number of two-dimensional layers. For a sufficiently large number of layers ( $N > 7$ ) the hybrid structure has no surface plasmon. The existence of two plasmons with different dispersion relations indicates that quasiparticles with different group velocity may coexist for various ranges of wavelengths determined by the number of layers in the superlattice.

**T1.00035 Modeling Wettability and Friction of Water on MoS<sub>2</sub> Surface** , BINQUAN LUAN, RUHONG ZHOU, IBM T J Watson Res Ctr — The molybdenum disulfide (MoS<sub>2</sub>) nanosheet is a promising new two-dimensional (2D) material and has recently been used in biological sensing. While the electronic structure of 2D MoS<sub>2</sub> sheet has been extensively studied, the role of its atomic structure and thus the interfacial interactions with bio-fluids are still elusive. Using Molecular dynamics simulations, we modeled the contact angle of water on the MoS<sub>2</sub> nanosheet and predicted the slip-length of water (that is not measurable in experiment yet). Simulation results suggest that the MoS<sub>2</sub> nanosheet is a hydrophobic and low-friction surface. We expect that our newly developed force fields for depicting surface atoms of MoS<sub>2</sub> will facilitate future research in understanding biomolecule-MoS<sub>2</sub> interactions in MoS<sub>2</sub>-based biosensors.

**T1.00036 Unraveling the microscopic pathway of homogeneous water crystallization at supercooled conditions from direct simulations** , FAUSTO MARTELLI, Department of Chemistry, Princeton University, JEREMY PALMER, Department of Chemical and Biomolecular Engineering, University of Houston, RAKESH SINGH, PABLO DEBENEDETTI, Department of Chemical and Biological Engineering, Princeton University, ROBERTO CAR, Department of Chemistry, Princeton University — By means of unbiased classical molecular dynamics simulations, we identify the microscopic pathways of spontaneous homogeneous crystallization in supercooled ST2 water. By introducing a new order parameter, we are able to monitor formation/disruption of locally ordered regions characterized by small ice clusters with intermediate range order. When two of these regions are close each other, they percolate and form a larger ordered region. The process is slow enough to allow for polymorphic selection in favor of cubic ice (Ic). The formation of an ice nucleus requires percolation of many small clusters so that the transformations at the interface of the nucleus do not involve its core, thus guaranteeing the stability of the nucleus. The growth of the crystalline nucleus is fast and involves direct transformation of interfacial liquid molecules as well as percolation of small Ic/Ih clusters. The growth is too fast to allow conversion of Ih into Ic sites, originating the formation of a stacking fault in the final crystal. We recognize Euclidean structures in the oxygen configuration of the second shell in Ic and Ih clusters. This new point of view allows us to explain the source of the ordered stacking fault geometry.
